MoO_2 (acac)$_2$ catalyses: (a) the oxidation of primary (e.g. cinnamyl alcohol) or secondary alcohols (e.g. 1-phenylpropan-1-ol) to their respective aldehydes or ketones in high yields using sodium percarbonate (see *[15630-89-4]*) as oxidant and Adogen 464 (0.2 equivalents, as phase transfer catalyst see *[72749-59-8]* below) in boiling (6-24 hours) CH_2Cl_2 [Maignien et al. *Synlett* 439 *1996*, DOI: 10.1055/s-1996-5449]; (b) the mild and efficient deprotection of acetals (e.g. benzaldehyde dimethyl acetal, dodecanal dimethyl acetal) in > 70-95% yields using ~10% of catalyst in MeCN under N_2 for ~4 hours [Kantam et al. *Synth Commun* **25** 2529 *1995*, DOI:10.1080/00397919508011796], (c) the oxidation of 3-β-cholesteryl esters to the corresponding 5,6-β-epoxides in the presence of isobutyraldehyde and O_2 in CH_2Cl_2 in yields >75% [Kantam et al. *Synth Commun* **24** 961 *1994*, DOI:10.1080/00397919408020771], and (d) the methoxymethylation of primary, secondary and tertiary alcohols (R-OH) to their corresponding methoxymethyl ethers (R-OCH_2OCH_3) in 75-95% yields using excess of methylal {$CH_2(OMe)_2$ see *[109-87-5]*} in refluxing $CHCl_3$ [Kantam & Santhi *Synlett* 429 *1993*, DOI: 10.1055/s-1993-22483].

(2*S*)-3-exo-(Morpholino)isoborneol [(-)MIB] *[287105-48-0]* **and (2*R*)-3-exo-(morpholino)iso-borneol [(+)MIB] (Nugent's reagent) $C_{14}H_{25}NO_2$, M 239.4, m 60-65º, 65-67º, $[\alpha]_D^{25}$ -6 and +6 (c 1, MeOH).** The (2*R*)-*enantiomer* is prepared from (2*R*)(+)-*cis*-3-exo-(amino)isoborneol (4.53g, 26.8mmol; Chittenden & Cooper *J Chem Soc C* 49 *1970*, DOI: 10.1039/J39700000049) in DMSO (25ml) and Et_3N (10ml), to which is added dropwise, with stirring, a solution of di(2-bromoethyl) ether (8.07g, ~90% pure, 31.3mmol) in DMSO (20ml). After 72 hours the mixture is poured into H_2O (250ml), basified with aqueous M NaOH (60ml), extracted with Et_2O (3 x 100ml), and the extract is evaporated *in vacuo*. The residue is then dissolved in Et_2O, extracted into aqueous M HCl (50ml), basified with aqueous NaOH and re-extracted into Et_2O which is dried ($MgSO_4$), filtered, evaporated *in vacuo*, and the residue is dissolved in hot hexanes (4ml/g crude), filtered and

cooled to -30° to give ***analytically pure*** (C, H and N) ***(+)MIB*** (2.95g, 46%). It is a white crystalline solid, **m 65-67°**, that can be stored at ambient temperature for 3 months with no alteration in spectroscopic properties, or catalytic performance when compared with freshly prepared material. It has ^{1}H NMR (*C_6D_6) with δ_H at 0.69 (s, 3H), 0.73 (m, 1H), 0.88 (m, 1H), 1.04 (s, 3H), 1.31 (td, 1H), 1.52 (m, 1H), 1.67 (d, 1H), 1.99 (d, 1H), 2.13 (br, 2H), 2.31 (br, 2H), 3.32-3.42 (m, 5H total), 3.92 (br d, 1H); and for ^{13}C NMR see reference. [Nugent *JCS Chem Commun* 1369 *1999*, DOI: 10.1039/A904042K.]
MIB acts as an efficient catalyst for the enantioselective addition of the ethoxy vinyl zinc reagent to aldehydes providing hydroxy vinyl ethers, which in turn, are easily converted to chiral hydroxy aldehydes [Jeon et al. *Org Lett* **7** 1729 *2005*]. It generally catalyses the addition of organo-zinc reagents (e.g. from transmetalation of allylic boranes with alkylZn compounds) to aldehydes with very high enantiomeric preference, *viz* (*R*)-MIB providing the (*R*)-alcohol from the corresponding aldehyde [Nugent *JCS Chem Commun* 1369 *1999*, DOI: 10.1039/A904042K; Jeon et al. *Org Lett* **7** 1729 *2005*, DOI: 10.1021/ol050255n], and this catalytic method has been adopted for the preparation of α-amino acids [Chen et al. *J Am Chem Soc* **124** 12225 *2002*, DOI: 10.1021/ja027271p], of γ-unsubstituted β-amino acids [Lurain & Walsh *J Am Chem Soc* **125** 10677 *2003*, DOI: 10.1021/ja035213d] and for epoxy-alcohols with up to three contiguous stereocentres [Lurain et al. *J Am Chem Soc* **126** 13608 *2004*, DOI: 10.1021/ja046750g; Lurain et al. *J Org Chem* **70** 1262 *2005*, DOI: 10.1021/jo048345d].

Nickel(II) acetylacetonate [Ni(acac)$_2$] *[3264-82-2]* **($C_5H_7O_2$)$_2$Ni, M 256.9, m 229-230°, b 220-235°/11mm, d^{17} 1.455.** It is obtained by adding a solution of acetylacetone (50g, 0.5mole) in MeOH (100ml) to $NiCl_2.6H_2O$ (59.4g, 0.25mole) in H_2O (250ml) with stirring, followed by a solution of $NaOAc.3H_2O$ (68g, 0.5mole) in H_2O (150ml), heating briefly on a hot plate, cooling in a refrigerator for several hours, and filtering the crystals off. Wash the emerald green solid with H_2O, dry it in a vacuum desiccator and recrystallise it from MeOH. [Charles & Pawlikowski *J Phys Chem* **62** 440 *1958*, DOI: 10.1021/j150562a017.] The complex can be conveniently dehydrated by azeotropic distillation with toluene, and the crystals can be isolated by concentrating the toluene solution. [Wilkinson et al. *J Am Chem Soc* **76** 1970 *1954*, DOI: 10.1021/ja01636a080; *Beilstein* **1** IV 3677.] It is soluble in organic solvents such as EtOH, $CHCl_3$, and *C_6H_6 but insoluble in Et_2O and hexanes. Its UV spectrum has λ_{max} nm(logε) at 265 (4.44) and 298 (4.34) (10^{-4} M in $CHCl_3$). It is a ***trimer*** in the solid state and a ***monomer*** in the vapour phase. When the metal in Ni(acac)$_2$ is coordinated with the carbenes derived from IPr.Cl, IPr.BF_4, (see below) or related 1,3-dimesityl-imidazolium chloride *[141556-45-8]*, or with tri-*tert*-butylphosphine, it efficiently catalyses the cross-coupling of aryl- and heteroaryl- halides with aryl Grignard reagents [Böhm et al. *Angew Chem Int Ed* **39** 1602 *2000*, DOI: 10.1002/(SICI)1521-3773(20000502)39:9].

Nickel(II) bis(triphenylphosphine) dichloride [bis(triphenylphosphine)nickel(II) dichloride] *[14264-16-5]* **[(C_6H_5)$_3$P]$_2$NiCl$_2$, M 654.2, m 247-250°(dec), 250°(dec).** It is best prepared by adding $NiCl_2.6H_2O$ (2.38g, 10mmol) in H_2O (2ml) to a solution of Ph_3P (5.25g, 20mmol) in glacial AcOH (25ml) when an olive-green precipitate separates, but changes to dark blue crystals after standing in the mother liquors for 24 hours. These are filtered off washed with glacial AcOH and dried in a vacuum desiccator (H_2SO_4 and KOH) until AcOH is removed to give 84% of dark blue crystals. [Venanzi *J Chem Soc* 719 *1958*, DOI: 10.1039/JR9580000719; Cotton et al. *J Am Chem Soc* **83** 344 *1961*, DOI: 10.1021/ja01463a021; Kocienski et al. *J Org Chem* **54** 1215 *1989*, DOI: 10.1021/jo00266a047; *Beilstein* **16** IV 953.]. With butyl chloride at 150-180° in a sealed tube followed by crystallisation from BuOH, it provides blue crystals with **m 176°** of **[Ni(BuCl)(Ph_3P)$_2$Cl$_2$]** [Yamamoto *Bull Chem Soc Jpn* **27** 501 *1954*, DOI: 10.1246/bcsj.27.501; *Beilstein* **16** IV 953, for applications see Fieser **2** 110, **9** 147, **14** 125, **16** 118.] In small amounts it catalyses the formation of terminal alkenes, e.g. from alkyl bromides or iodides in the presence of BuLi/DBU in THF at 25° in 50-80% yields [Jeropoulos & Smith *JCS Chem Commun* 1621 *1986*, DOI: 10.1039/C39860001621]. It also catalyses the replacement of OH groups in allyl acohols with the alkyl group of alkylmagnesium bromide thus forming a C-C bond, and also causes dehydrohalogenation of alkylhalides to form the corresponding terminal olefin [Chuit et al. *JCS Chem Commun* 1604 *1968*, DOI: 10.1039/C19680001604].

Nickel(0) bis(1,5-cyclooctadiene) [bis-(1,5-cyclooctadiene)nickel(0), Ni(COD)$_2$] *[1295-35-8]* **$C_{16}H_{24}$Ni, M 275.1, m 60° (dec), 142°(dec).** It is available in sealed ampoules under N_2. All procedures should be carried out in a dry box and in an atmosphere of N_2 or argon in subdued light because the complex is light and oxygen sensitive, and flammable. The solid is washed with dry Et_2O (under argon) and separates from toluene as yellow

crystals. Filter this under argon gas pressure, place the crystals in a container and dry them under a vacuum of 0.01mm to remove adhered toluene, flush with argon and seal them under argon or N_2 in glass ampoules. It catalyses cycloaddition reactions of 1,3-dienes [Semmelhack *Org Reactions* **19** 115 *1972*, DOI: 10.1002/0471264180.or019.02; Bogdanović et al. *Justus Liebigs Ann Chem* **699** 1 *1966*, DOI: 10.1002/jlac.19666990102; Wender & Jenkins *J Am Chem Soc* **111** 6432 *1989*, DOI: 10.1021/ja00198a071; Fieser **4** 33, **16** 29, **17** 32]. It also catalyses the addition of allyl phenyl sulfide to alkynes leading to 1,4-dienes. The reaction with acetylenes affords high yields, and in the presence of chiral phosphine ligands the reaction proceeds with high stereoselectivity. The reaction tolerates a variety of functional groups [Hua et al. *Org Lett* **9** 263 *2007*, DOI: 10.1021/ol062686r]. **SUSPECTED CARCINOGEN**.

Oxime Palladacycle dimers (Nájera Catalysts, OPs) are Pd complexes of aromatic oximes, e.g. where palladium(II) is complexed with the oxime nitrogen atom and co-metalated with the *o*-position of the aromatic ring. They catalyse a variety of coupling reactions such as Suzuki-Miyaura, Heck, Stille, Sonogashira (all cross coupling) reactions and the Ullmann (homocoupling) reactions. ***Note that the concentration of Pd in the products from Suzuki-Miyaura coupling reactions can be reduced from ~8000ppm to 100ppm by treating the reaction mixture with toluene and 20% aqueous $NaHSO_3$ at ~60° for ~1 hour*** [Bullock, Mitchell and Toczko *Organic Process Research & Development* **12** 896 *2008*, DOI: 10.1021/op800064y].

Oximes are prepared by a common procedure: A solution of the required aryl-ketone (22mmol) in MeOH (10ml) is added to a solution of hydroxylamine hydrochloride (3.06g, 44mmol), anhydrous NaOAc (3.6g, 44mmol) in H_2O pre-heated at 60° for 1 hour. If some solid separates, add enough MeOH to obtain a clear solution, then stir at this temperature overnight. On cooling to ~25°, the oximes that separate in >90% yield are filtered off, washed with H_2O and recrystallised to ^{1}H NMR purity (>98%). ***Acetophenone oxime*** has **m 59.1-59.7°** (from MeOH then cyclohexane, Pearson & Ball *J Org Chem* **14** 118 *1949*, DOI: 10.1021/jo01153a018), ***4,4'-dichlorobenzophenone oxime*** has **m** 135.2-136.9° (from MeOH, Sieger & Klein *J Org Chem* **22** 951 *1957*, DOI: 10.1021/jo01359a026), ***4,4'-dihydroxybenzophenone oxime*** has **m 266-267°dec** (from EtOH, Zigeuner & Ziegler *Monatsh für Chemie* **89** 359 *1949*, DOI: 10.1007/BF00897769); ***4-hydroxyacetophenone oxime*** has **m 144-145°** (from aqueous MeOH), ***4-methoxyacetophenone oxime*** has **87°** (from petroleum ether, v. Auwers et al. *Chem Ber* **58** 36 *1925*, DOI: 10.1002/cber.19250580109), ***4-methyl-acetophenone oxime*** has **m 87-88°** (from MeOH then cyclohexane, Pearson & Ball *J Org Chem* **14** 118 *1949*, DOI: 10.1021/jo01153a018), and ***9-fluorenone oxime*** has **m 195°**, **198°** (yellow crystals from $*C_6H_6$ or xylene, Anet et al. *Can J Chem* **35** 180 *1957*, DOI: 10.1139/v57-027; Wislicenus & Waldmuller *Chem Ber* **41** 3334 *1908*, DOI: 10.1002/cber.19080410309).

Oxime palladacyles are generally dimers that can be prepared by a general procedure. A solution of the oxime (10mmol) in methanol (20ml) containing NaOAc.$3H_2O$ (1.63g, 10mmol) is added to a 0.5M solution of Li_2PdCl_4 (20ml, i.e.2.62g, 10mmol, see *[123334-21-4]* in this Chapter, 'Catalysts-Part 2') and stirred at ~25° for 2 to 3 days. Small quantities of precipitate may form and the colour of the reddish black solution turns to yellow. This is filtered and H_2O (10ml) is added to precipitate the palladacycles as yellow solids (~90% yields) that are filtered off, washed with a little MeOH and H_2O, and dried *in vacuo*. [Botella & Nájera *J Organomet Chem* **663** 46 *2002*, DOI: 10.1016/S0022-328X(02)01727-8; Onoue, Minami and Nakagawa *Bull Chem Soc Jpn* **43** 3480 *1970*, DOI: 10.1139/v57-027; for preparation *via* ligand exchange see Ryabov et al. *Inorg Chem* **31** 3083 *1992*, DOI: 10.1021/ic00040a018.] They can be used directly to catalyse reactions, their solubilities vary with the complex, but some can be crystallised from CH_2Cl_2-*n*-hexane, $*C_6H_6$/*n*-hexane or $CHCl_3$. They catalyse Heck couplings (in *N*-methylpyrrolidone with Et_3N as base), Heck couplings under Jeffrey's conditions (DMF with Bu_4NBr), Sonogashira reactions (with acetylenes in pyrrolidine and CuI), Stille coupling (in toluene), Suzuki coupling (in toluene with K_2CO_3 as base), and Ullmann-type homocoupling (in DMF, in the necessary presence hydroquinone), and typical reaction conditions have been described [Alonso, Nájera and Pacheco *Org Lett* **2** 1823 *2000*, DOI: 10.1021/ol0058644; Iyer & Ramesh *Tetrahedron Lett* **41** 8981 *2000*, DOI: 10.1016/S0040-4039(00)01594-X].

Di-chloro-bis[5-chloro-2-[(4-chlorophenyl)(hydroxyimino)methyl]phenyl-C]-di-palladium {Nájera Catalyst I, di-*μ*-chlorobis[5-chloro-2-[(4-chlorophenyl)(hydroxyimino-κN)methyl]phenyl-κC]-palladium (II) dimer} *[287410-78-0]* has **$C_{26}H_{16}Cl_6N_2O_2Pd_2$, M 814.0** and **m 208-210°.** [Alonso, Nájera and Pacheco *Org Lett* **2** 1823 *2000*, DOI: 10.1021/ol0058644].

Di-chloro-bis[5-hydroxy-2-[1-(hydroxyimino)ethyl]phenyl-C]-di-palladium {Nájera Catalyst II, di-*μ*-chlorobis[5-chloro-2-[1-(hydroxyimino-κN)ethyl]phenyl-κC]-palladium(II) dimer} *[419581-64-9]* has

$(C_8H_8ClNO_2)_2Pd_2$, M 584.1 and **m >250°, 251-255°.** It has IR (KBr) with ν_{max} at 3425 (OH), 1662 (C=N) cm^{-1}; the ^1H NMR (300MHz, DMF-d_7, TMS) has δ_H at 9.96 (brs, 2H, 2 x OH), 9.71(brs, 2H, 2 x OH), 7.20 (brs, 2H, ArH), 7.07 (d, *J* = 8.5Hz, 2H, ArH), 6.50 (dd, *J* = 7.9, 2.4 Hz, 2H, ArH), 2.24 (s, 6H, 2 x CH_3); and for ^{13}C NMR see references. Botella & Nájera [*J Organomet Chem* **663** 46 *2002*, DOI: 10.1016/S0022-328X(02)01727-8] obtained high turnover numbers and turnover frequencies in Suzuki-Miyaura cross-coupling reactions at room temperature conditions with this catalyst. Botella & Nájera [*J Org Chem* **70** 4360 *2005*, DOI: 10.1021/jo0502551] also studied this catalyst for Mirozoki-Heck couplings in aqueous *N,N*-dimethylacetamide in air using *N*-methyldicyclohexylamine (see *[7560-83-0]*) as base with or without Bu_4NBr.

Di-chloro-bis[2-[1-(hydroxyimino)ethyl]phenyl-C]-di-palladium {di-μ-chlorobis[-2-[1-(hydroxy-imino-κN)ethyl]phenyl-κC]-palladium(II) dimer} *[32679-19-9]* has **$(C_8H_8ClNO)_2Pd_2$, M 552.1** and **m 210°, 209-212°.** It has IR (KBr) with ν_{max} at 3426 (OH), 1640 (C=N) cm^{-1}. [Alonso, Nájera and Pacheco *Org Lett* **2** 1823 *2000*, DOI: 10.1021/ol0058644; Onoue, Minami and Nakagawa *Bull Chem Soc Jpn* **43** 3480 *1970,* DOI: org/10.1246/bcsj.43.3480 .]

Di-chloro-bis[5-hydroxy-2-[(4-hydroxyphenyl)(hydroxyimino)methyl]phenyl-C]-di-palladium, {di-μ-chlorobis[5-hydroxy-2-[(4-hydroxyphenyl)(hydroxyimino-κN)methyl]phenyl-κC]-palladium(II) dimer} *[419581-64-9]* has **$(C_{13}H_{10}ClNO_3)_2Pd_2$, M 740.74(777.0)** and **m >250°.** It has IR (KBr) with ν_{max} at 3405 (OH), 1612 (C=N) cm^{-1}; the ^1H NMR (300MHz, DMF-d_7, TMS) has δ_H at 10.50-9.40 (brs, 6H, 6 x OH), 7.41 (d, *J* = 8.5Hz, 4H, ArH), 7.26 (brs, 2H, 2 x OH), 7.20 (brs, 2H, ArH), 7.02 (d, *J* = 8.5Hz, 4H, ArH), 6.69 (d, *J* = 8.5Hz, 4H, ArH), 6.48 (dd, *J* = 7.9, 2.7 Hz, 2H, ArH); and its ^{13}C NMR (75MHz, DMF-d_7, TMS) has δ_C at 167.8, 160.0, 157.5, 152.9, 134.3, 131.5, 129.4, 123.7, 121.0, 115.8, 111.5. [Botella & Nájera *J Organomet Chem* **663** 46 *2002*, DOI: 10.1016/S0022-328X(02)01727-8.]

Di-chloro-bis[5-chloro-2-[(4-phenyl)(hydroxyimino)methyl]phenyl-C]-di-palladium, {di-μ-chloro-bis[5-chloro-2-[(4-phenyl)(hydroxyimino-κN)methyl]phenyl-κC]-palladium(II) dimer} *[1145982-32-6; 30471-18-2 for stereoisomer]* has **$(C_{13}H_9Cl_2NO)_2Pd_2$, M 745.6** and **m 139-141°.** It has IR (KBr) with ν_{max} at 3373 (OH), 1645 (C=N), 1569, 1435, 1340, 1024 cm^{-1}; the ^1H NMR (300MHz, DMSO-d_6, TMS) has δ_H at 6.69 (m, 4H), 7.09 (m, 4H), 7.35-8.10 (m, 10H). [Alonso, Nájera and Pacheco *Org Lett* **2** 1823 *2000*, DOI: 10.1021/ol0058644; Onoue, Minami and Nakagawa *Bull Chem Soc Jpn* **43** 3480 *1970*, DOI: org/10.1246/bcsj.43.3480.]

Di-chloro-bis[5-methoxy-2-[(4-methoxyphenyl)(hydroxyimino)methyl]phenyl-C]-di-palladium {di-μ-chlorobis[5-methoxy-2-[(4-methoxyphenyl)(hydroxyimino-κN)methyl]phenyl-κC]-palladium(II) dimer} *[287410-79-1]* has **$(C_{15}H_{14}ClNO_3)_2Pd_2$, M 796.9** and **m 135-137°.** It has IR (KBr) with ν_{max} at 3390 (OH), 1607 (C=N), 1579, 1559, 1253, 1233, 1177, 1026 cm^{-1}; the ^1H NMR (300MHz, DMSO-d_6, TMS) has δ_H at 3.71 (s, 6H), 3.83 (s, 6H), 6.71 (m, 4H), 7.08-7.25 (m with d at 7.10, *J* = 8.6Hz, 5H), 7.30-7.55 (m with d at 7.43, *J* = 8.6Hz, 5H). [Alonso, Nájera and Pacheco *Org Lett* **2** 1823 *2000*, DOI: 10.1021/ol0058644].

Palladium(II) acetate [$Pd(OAc)_2$] *[3375-31-3]* **$Pd(C_2H_3O_2)_2$, M 244.5, m 205°(dec.), pK_1^{25} 1.0, pK_2^{25} 1.2 (for Pd_2^{2+}).** It crystallises from $CHCl_3$ as purple crystals. It can be washed with AcOH and H_2O and dried in air. Large crystals are obtained by dissolving it in $*C_6H_6$, adding half its volume of AcOH and allowing it to evaporate slowly at room temperature. It forms green adducts with nitrogen donors, it dissolves in KI solution to form solid PdI_2 and a red solution of PdI_4^{2-}, but is insoluble in aqueous saturated NaCl, and NaOAc. It dissolves in HCl to form $PdCl_4^{2-}$. It is soluble in $CHCl_3$, CH_2Cl_2, Me_2CO, MeCN, Et_2O, but it is insoluble in H_2O, and decomposes when warmed in alcohols in which it is also insoluble. [Morehouse et al. *Chem Ind (London)* 544 *1964*, Stephenson et al. *J Chem Soc* 3632 *1965,* DOI: 10.1039/JR9650003632; Skapski & Smart *J Chem Soc (D)* 658b *1970*, DOI: 10.1039/C2970000658B; Heck *Acc Chem Res* **12** 146 *1979*, DOI: 10.1021/ar50136a006.] ***Pd(OAc)$_2$*** should be an orange/red solid. Sometimes **commercial** samples, or old samples, give lower yields in catalytic reactions and it is found that good results are obtained after recrystallisation from $*C_6H_6$ [Anderson et al. *Org Synth* **84** 148 *2007*, DOI: 10.15227/orgsyn.084.0148]. It is useful as a catalyst for coupling reactions [Kang et al. *J Am Chem Soc* **128** 6194 *2006*, DOI: 10.1021/ja060185v], and is a precursor for preparing heterogeneous and homogeneous catalysts [Jujjuri et al. *J Catal* **239 (2)** 486 *2006*, DOI: 10.1016/j.jcat.2006.02.022; Xu et al. *J Nano Res* **7** 449 *2005*, DOI: 10.1007/ sl1051-005-005-4273-3].

Palladium(II) acetylacetone [$Pd(acac)_2$] *[14024-61-4]* **$Pd(C_5H_7O_2)_2$, M 304.6, m 200-250°(dec).** It can be recrystallised from $*C_6H_6$/petroleum ether and sublimes *in vacuo*. It is soluble in heptane, $*C_6H_6$ (1.2% at 20°, 2.2 at 40°), toluene (0.56% at 20°, 1.4% at 40°) and acetylacetone (1.2% at 20°, 0.05% at 40°). [West & Riley *J*

Inorg Nucl Chem **5** 295 *1958*, DOI: 10.1016/0022-1902(58)80007-X; Fernelius & Bryant *Inorg Synth* **5** 105 *1957*, DOI: 10.1002/9780470132364.ch29; *Beilstein* **1** IV 3676; for applications see Fieser **6** 45, **17** 269.] It is a soluble Pd source for the preparation of various soluble Pd catalysts by transferring the metal to a variety of phosphorus and other ligands for homogeneous catalysis [cf. *Handbook of Organopalladium for Organic Synthesis* Negishi ed. Wiley, Hoboken NJ *2002*, ISBN 0-471-31506-0.]

A ***complex consisting of Cu 1.10-phenanthroline*** [which mediates decarboxylation of arylcarboxylic acids with formation of aryl Cu species] ***and Pd(acac)$_2$*** [for coupling] was made and used to catalyse the decarboxylative cross-coupling of the Cu species with aryl halides. This bimetallic system allows direct coupling of a variety of aryl, heteroaryl or vinyl carboxylic acids with aryl or heteroaryl bromides, chlorides or iodides at 160° in *N*-methylpyrrolidine in the presence of K_2CO_3. [Goossen et al. *J Am Chem Soc* **129** 4824 *2007*, DOI: 10.1021/ja068993+].

Palladium EnCat. Ley and co-workers [Ramarao et al. *JCS Chem Commun* 1132 *2002*, DOI: 10.1039/B200674J; Pears & Smith *Aldrichimica Acta* **38** 23 *2005*] have described a method of encapsulating $Pd(OAc)_2$ in the matrix of 20-250μm microcapsules prepared from a dispersion of an aromatic polyfunctional isocyanate and $Pd(OAc)_2$ in CH_2Cl_2 into H_2O containing stabilisers and surfactants. At the point when the oily dispersion reaches the desired size, e.g. 20-250μm, polymerisation is initiated (evolution of heat) whereby part of the isocyanate groups are hydrolyse to carbamate then to amino groups. The latter condense with the unhydrolysed isocyanate groups to form a ***crosslinked polyurea matrix entrapping the metal catalyst***. After the necessary washing etc., polyurea microcapsules (MC average size ~150μm) are formed which are hard, porous and highly crosslinked spheres. These beads are catalytically active, robust and recyclable and have been used in conventional and supercritical media (e.g. liquid CO_2). They catalyse ***MC-[Pd]*** mediated Heck coupling (*p*-aryl and 4-heteroaryl nitro, methoxy and fluoro compounds with acrylic esters), carbonylation of 4-substituted arenes or heterocycles, Suzuki-type ($ArB(OH)_2$ + Ar to form crossed biaryls) and Stille couplings without requiring supplementary ligands [Ley et al. *JCS Chem Commun* 1134 *2002*, DOI: 10.1039/B200677B]. For **EnPd(OAc)$_2$ [Pd EnCat™]** and **Pd$^{(0)}$ EnCat™** see entries in Chapter 7. Encapsulated Pd catalysts such as **Pd EnCat™** are available commercially. These particles are defined by their matrix content e.g. 30% or 40%, the latter having the smaller pore size. [See also Bremeyer et al. *Synlett* 1843 *2002*, DOI: 10.1055/s-2002-34862; Yu et al. *JCS Chem Commun* 678 *2003*, DOI: 10.1039/B300074P; Vickerstaffe et al. *Org Biomol Chem* **1** 2419 *2003*, DOI: 10.1039/B305713E.]

Palladium(II) trifluoroacetate *[42196-31-6]* **Pd$(C_2F_3O_2)_2$, M 332.4, m ~210°(dec).** Suspend it in trifluoroacetic acid and evaporate it on a steam bath a couple of times. The residue is then dried in vacuum (40-80°) to give a brown powder. It is ***hygroscopic*** and should be stored in a dry atmosphere, preferably aliquoted in sealed vials [Stephenson et al. *J Chem Soc* 3632 *1965*, DOI: 10.1039/JR9650003632; Trost & Metzner *J Am Chem Soc* **102** 3572 *1980*, DOI: 10.1021/ja00530a042.]

Pd(CF$_3$CO)$_2$ catalyses the decarboxylation of electron-rich aromatic acids (e.g. with OMe groups) in DMSO/DMF at 70-90° (1 to 24 hours) in high yields and is not affected by steric hinderance [Dickstein et al. *Org Lett* **9** 2441 *2007*, DOI: 10.1021/ol070749f], and (in the presence of $Cu(OAc)_2$ with Cesium pivalate + 3-nitropyridine as additives at 110-140° in a microwave) it catalysed direct cross-coupling between unactivated arenes and *N*-acetylindoles with coupling mostly at C3 of indoles but with no homo-coupling [Stuart & Fangou *Science* **316** 1172 *2007*, DOI: 10.1126/science.1141956]. In the presence of AcOH, benzoquinone (as oxidant) and *o*-methoxyacetophenone or Ph_3P as ligands, $Pd(tfa)_2$ catalyses selective allylic oxidation of olefins into their allyl acetates [McMurry & Kočotovský *Tetrahedron Lett* **25** 4187 *1984*, DOI: 10.1016/S0040-4039(01)81391-5]. [Fieser **10** 302, **12** 373, **13** 236, **14** 253.]

Phosferrox ligands and SK-Naud catalysts. The ligands are (diphenylphosphinoferrocenyl)oxazolines and are complexes where one of the cyclopentadienyl rings has two different substituents. These molecules have '***planar chirality***', i.e. are asymmetric, and exist in two enantiomeric forms. The oxazolines are 4,5-dihydro-oxazoles which for this use have a 4-sustituent, usually alkyl or aryl, thus introducing a chiral centre at C-4 of this heterocyclic ring. Phosferrox ligands are prepared by lithiation of chiral 4-alkyloxazolin-2-ylferrocene in which lithiation is directed predominantly to one of the *ipso* positions of the cyclopentadienyl ring, generating ***'planar asymmetry'*** in the ferrocene moiety. It is highly diastereoselective with *ortho*-lithiation yields of ~84~99% de, producing the *S*-stereochemistry at the ferrocene moiety as shown by X-ray analysis and CD spectra of the products. Reaction of the lithiated ferrocene with Ph_2PCl furnishes the desired chiral phosferrox

ligand. The stereochemistry of the reaction has been studied in detail [Sammakia et al. *J Org Chem* **60** 10 *1995*, DOI: 10.1021/jo00106a005; Sammakia & Latham *J Org Chem* **60** 6002 *1995*, DOI: 10.1021/jo00124a003; Richards & Mulvaney *Tetrahedron: Asymmetry* **7** 1419 *1996*, DOI: 10.1016/0957-4166(96)00159-0; Nishibayashi et al. *J Organomet Chem* **545-546** 381 *1997*, DOI: 10.1016/S0022-328X(97)00368-9.] Advantage is taken of the diastereoselectivity of the lithiation reaction in order to obtain the ***enantiomeric R-ferrocene***. Thus, after lithiation, the lithium is displaced by a trimethylsilyl group (by reaction with Me_3SiCl), the *S*-TMS derivative is lithiated again, but at the other *ipso* position of the same cyclopentadienyl ring, followed by reaction with Ph_2PCl to form the ***1-diphenylphosphino-3-TMS-2-(oxazolin-2-yl)ferrocene***. Finally, removal of the TMS group, e.g. with *tetra-n-butylammonium fluoride (TBAF,* see *[429-41-4; 3 H_2O 87749-50-6])*, provides the phosferrox where the stereochemistry at the ferrocene moiety is now ***R***. Chiral phosferrox ligands react with $RuCl_2(Ph_3P)_3$ *[15529-49-4]* to from ***Nauk catalysts*** which are ***phosferrox-$RuCl_2(Ph_3P)$*** complexes that reduce aryl ketones in the presence of *i*-PrOH/*i*-PrOK to form the respective alcohols with high stereoselectivity [Sammakia & Stangeland *J Org Chem* **62** 6104 *1997*, DOI: 10.1021/jo9711044; Nishibayashi et al. *Organometallics* **18** 2291 *1999*, DOI: 10.1021/om990210o].

S-2-[(S)-2-(Diphenylphosphino)ferrocenyl]-4-(1-methylethyl)oxazoline **(*S*,*S*-*i*-Pr-Phosferrox)** *[163169-29-7]* **$C_{28}H_{28}FeNOP$, M 481.4 , m 157-158°, $[\alpha]_D^{24}$ +112 (c 0.1, EtOH).** This phosferrox is prepared in a Schlenk tube at -78° under N_2, by adding dropwise *n*-BuLi (0.38ml, 0.7mmol) to a yellow-orange stirred solution of *S*-2-ferrocenyl-4-(1-methylethyl)oxazoline (0.158g, 0.53mmol) and TMEDA (0.10ml, 0.7mmol) in Et_2O (6ml) which had formed a yellow precipitate, and is stirred for 2 hours; the tube containing the orange non-homogeneous mixture is transferred to an ice-bath and stirred for 5 minutes further. To this now orange-red homogeneous solution is added Ph_2PCl (0.12ml, 0.7mmol, see *[1079-66-9]*), the mixture is allowed to warm to ~25°, and after 15 minutes it is quenched with saturated aqueous $NaHCO_3$ (10ml), the layers are separated, the aqueous layer is extracted with Et_2O (10ml), the combined Et_2O solutions are dried (Mg SO_4), filtered, and evaporated to give an orange crystalline solid. This is purified by column chromatography (pre-adsorbed on silica, eluting with 10% EtOAc/petroleum ether) to give a yellow-orange crystalline solid (0.163g, 64%) that provided ***S*,*S*-*i*-Pr-Phosferrox** as an analytically pure single diastereomer upon recrystallisation from hexane. It has CD ($CHCl_3$) λ_{max} ($\Delta\varepsilon$) 456 (+2.20), 368 (+0.49), 342 (-1.00), 315 (+216) nm; the IR has ν_{max} (nujol) at 1652 (C=N) cm^{-1}; the ^1H NMR (360Mz, $CDCl_3$) has δ_H at 0.68 (3H, d, *J* = 7 Hz, -C*H*$_3$), 0.82 (3H, d, *J* = 7 Hz, -C*H*$_3$), 1.61-1.69 (1H, m, C*H*(C*H*$_3$)$_2$), 3.61 (1H, brs, Fc), 3.67 (1H, t, *J* = 8 Hz, -OC*H*H), 3.83-3.90 (1H, m, -NC*H*-), 4.22 (5H, s, C_5H_5), 4.22-4.30 (1H, m, -OCH*H*-), 4.37 (1H, brs, Fc), 4.99 (1H, brs, Fc), 7.18-7.24 (5H, m, Ph), 7.36-7.37 (3H, m, Ph), 7.46-7.51 (2H, m, Ph); the ^{31}P NMR ($CDCl_3$) has a single peak with δ_P at -16.92, and for ^{13}C NMR and MS (EI) see references. [Richards & Mulvaney *Tetrahedron: Asymmetry* **7** 1419 *1996*, DOI: 10.1016/0957-4166(96)00159-0].

***R*,*R*-*i*-Pr-Phosferrox** *[541540-70-9]* **$C_{28}H_{28}FeNOP$, M 481.4, $[\alpha]_D^{24}$ -112 (c 0.1, EtOH)** is the mirror image of the preceding *phosferrox*.

S-2-[(R)-2-(Diphenylphosphino)ferrocenyl]-4-(1-methylethyl)oxazoline **[*S*-(*R*-*i*-Pr-Phosferrox)]** *[163169-10-6]* **$C_{28}H_{28}FeNOP$, M 481.4,** has **m 132-132.5°, $[\alpha]_D^{20}$ -53 (c 0.15, EtOH).** This diastereomer is obtained by de-trimethylsilylation of *S*-2-[*R*-2-(diphenylphosphino)-5-(trimethylsilyl)ferrocenyl]-4-(1-methyl-ethyl)oxazoline (0.14g 0.25mmol) with a yellow solution of 1M TBAF (see *[429-41-4; 3 H_2O 87749-50-6]*, in 'Catalysts-Part 2') in THF (10ml) containing *ca* 5% H_2O by boiling for 4 hours, evaporating *in vacuo* to a small volume, shaking with Et_2O (10ml) and H_2O (10ml), separating, the aqueous layer is extracted with Et_2O, the ethereal layers are combined, dried (Mg SO_4), filtered, evaporated *in vacuo*, and the residue is chromatographed in a silica column (eluted with 10% EtOAc/petroleum ether b 40-60°) to give ***S-(R-i-Pr-Phosferrox)*** as a yellow crystalline solid (0.090, 75%). Its CD ($CHCl_3$) has λ_{max} ($\Delta\varepsilon$) 492 (+0.45), 434 (-0.43), 361 (-0.31), 344 (+0.35), 314 (-2.38) nm; the IR has ν_{max} (nujol) at 1660 (C=N) cm^{-1}; the ^1H NMR (360Mz, $CDCl_3$) has δ_H at 0.63 (3H, d, *J* = 7 Hz, -C*H*$_3$), 0.65 (3H, d, *J* = 7 Hz, -C*H*$_3$), 1.50-1.58 (1H, m, C*H*(C*H*$_3$)$_2$), 3.62 (1H, brs, Fc), 3.89-4.08 (3H, m, -OC*H*$_2$CH-), 4.22 (5H, s, C_5H_5), 4.36 (1H, brs, Fc), 4.94 (1H, brs, Fc), 7.19-7.23 (5H, m, Ph), 7.35-7.37 (3H, m, Ph), 7.48-7.53 (2H, m, Ph); the ^{31}P NMR ($CDCl_3$) has a single peak at δ_P -18.03; for ^{13}C NMR and MS (EI) see refs. [Richards & Mulvaney *Tetrahedron: Asymmetry* **7** 1419 *1996*, DOI: 10.1016/0957-4166(96)00159-0].
Other phosferrox ligands prepared are ***S*,*S*-4'*Me*-Phosferrox**, ***S*,*R*-4'*Me*-Phosferrox**, ***S*,*S*-4'*Et*-Phosferrox**, ***S*,*S*-4'*n-Bu*-Phosferrox**, ***S*,*S*-4'*iso-Bu*-Phosferrox**, ***S*,*S*-4'*t-Bu*-Phosferrox**, and ***S*,*S*-4'*Ph*-Phosferrox**, ***S*,*S*-4'*benzyl*-Phosferrox** [Sammakia & Stangeland *J Org Chem* **62** 6104 *1997*, DOI: 10.1021/jo9711044; Nishibayashi et al. *J Organomet Chem* **545-546** 381 *1997*, DOI: 10.1016/S0022-328X(97)00368-9].

S-2-[S_p-2-(Diphenylphosphino)ferrocenyl]-4-iso-propyl-2-oxazoline triphenylphosphine ruthenium

(II) dichloride complex **[*S,S-i*-Pr-Phosferrox-Ru(II) Ph_3PCl_2 complex, SK-Naud Catalyst-N003-2z]** *[212133-11-4]* **$RuCl_2[(C_6H_5)_3P](C_{28}H_{28}FeNOP)$, M 915.6, $[\alpha]_D^{20}$ -1127 (c 0.1, $CHCl_3$).** This catalyst can be pepared *in situ* from the phosferrox and $RuCl_2(PhP_3)_3$, but it can also be isolated. Thus a mixture of $RuCl_2(PhP_3)_3$ (480mg, 0.50mmol) and *S,S-i*-Pr-Phosferrox (0.50mmol) and toluene (15ml) are stirred under N_2 at ~25° for 20 hours when the original purple solution changes to a red suspension. Addition of *n*-hexane caused the crystalline catalyst to separate, and the red crystals are recrystallised to analytical purity from CH_2Cl_2/*n*-hexane (~81% yield). The ^{1}H NMR (270Mz, $CDCl_3$) has δ_H at 0.57 (3H, d, *J* = 7 Hz, C*H*$_3$), 0.97 (3H, d, *J* = 7 Hz, C*H*$_3$), 2.12 (1H, dd, *J* = 8 and 8Hz), 3.21 (1H, m), 3.28 (1H, m), 3.80 (1H, dd, *J* = 3 and 8Hz), 4.02 (5H, s), 4.59 (1H, m), 4.68 (1H, m), 4.84 (1H, m), 6.5-8.4 (25H, m); and the ^{31}P NMR (107Mz, $CDCl_3$) indicated a diastereomerically pure complex with δ_P 40.1 (d, *J* = 45Hz) and 77.0 (d, *J* = 45Hz). It causes a high conversion with high stereoselectivity (with 88-<99% 'ee') in the Ru-catalysed asymmetric transfer hydrogenation of ketones using *i*-PrOH as H source, as well as catalysing the asymmetric oxidation of *sec*-alcohols to ketones [Nishibayashi et al. *Organometallics* **18** 2291 *1999*, DOI: 10.1021/om990210o].

R-2-[R_p-2-(Diphenylphosphino)ferrocenyl]-4-iso-propyl-2-oxazoline triphenylphosphine ruthenium(II) dichloride complex **(SK-Naud Catalyst-N003-1z]** *[849921-25-1]* **$RuCl_2[(C_6H_5)_3P]$ $(C_{28}H_{28}FeNOP)$, M 915.6, $[\alpha]_D^{20}$ +1127 (c 0.1, $CHCl_3$)** can be prepared and purified as in the preceding entry.

S-2-[S_p-2-(Diphenylphosphino)ferrocenyl]-4-phenyl-2-oxazoline triphenylphosphine ruthenium (II) dichloride complex **[*S,S-Ph*-Phosferrox-Ru(II) Ph_3P Cl_2 complex]** *[212210-73-6]* **$RuCl_2[(C_6H_5)_3P]$ $(C_{31}H_{26}FeNOP)$, M 949.6.** As above (SK-Naud catalyst-N003-2z), the catalyst can be prepared *in situ*, and can also be isolated in pure crystalline form, and its structure has been confirmed by X-ray crystallography. A mixture of ***S,S*-4'*Ph*-Phosferrox** [257mg, 0.50mol, red solid purified by flash chromatography with silica gel and eluting with hexanes the 10:1 hexanes/EtOAc, and recrystallisation from hexane, **m 184-185° dec, $[\alpha]_D^{23}$ +25.6 (c 0.67, $CHCl_3$)**] and $RuCl_2(PhP_3)_3$ (480mg, 0.50mmol) in toluene (15ml) are stirred under N_2 at ~25° for 20 hours when the original purple solution changes to a red suspension. Addition of *n*-hexane causes the crystalline catalyst to separate, and the red crystals are recrystallised to analytical purity from CH_2Cl_2/*n*-hexane to provide the catalyst (with 1 mol of CH_2Cl_2) in 80% yield. The ^{1}H NMR (270Mz, $CDCl_3$) has δ_H at 2.68 (1H, dd *J* = 8 and 9Hz), 3.29 (1H, dd, *J* = 1 and 9Hz), 4.12 (5H, s), 4.23 (1H, dd, *J* = 1 and 8Hz), 4.71 (1H, m), 4.80 (1H, m), 5.04 (1H, m), 6.6-8.2 (30H, m); and the ^{31}P NMR (107Mz, $CDCl_3$) indicated almost diastereomerically pure complex with δ_P 40.8 (d, *J* = 45Hz) and 75.7 (d, *J* = 45Hz). It has similar catalytic activity as the SK-Naud catalysts [Nishibayashi et al. *Organometallics* **18** 2291 *1999*, DOI: 10.1021/om990210o; Sammakia & Stangeland *J Org Chem* **62** 6104 *1997*, DOI: 10.1021/jo9711044].

Platinum(0) bis(1,5-cyclooctadiene) [Pt(COD)$_2$, Pt bis(1,2,5,6-η-1,5-octadiene)] *[12130-66-4]* **$(C_8H_{12})_2Pt$, M 411.6, m > ~200°.** $Pt(COD)_2$ is prepared in a dry, O_2-free, N_2 atmosphere by adding dropwise an ethereal solution of $Li_2(C_8H_8)$ [*ca* 40ml of a 0.24mol dm^{-3} of dilithium cyclooctatetraene *[40698-91-7]* in Et_2O (Katz *J Am Chem Soc* **82** 3784 *1960*, see also below)] to a finely powdered suspension of $Pt(COD)Cl_2$ (3.7g, 10mmol, see above entry) in 1,5-cyclooctadiene at -30°, stirring for 30 minutes as the temperature rises to -10°; and then the solvent is evaporated *in vacuo* to dryness. Extraction of the residue with toluene (6 x 50ml) gives a brown solution which is filtered through an Al_2O_3 column (8 x 2.5cm, Brockman Activity III), the filtrate is evaporated to ~15ml and the supernatant is decanted from the off-white product which is washed with several small volumes of cold toluene until the washings are almost colourless. This Pt catalyst (1.6-2.4g, 40-60%) is useful for most purposes. Analytically pure (C and H) white crystals can be obtained by dissolving it in petroleum ether (b 40°-60°) (~80ml for each mmol of catalyst), filtering through an Al_2O_3 column (6 x 2.5cm) and cooling to -78°. The ^{1}H NMR (100MHz, *C_6D_6) has τ at 5.80 (m, 8H, CH=CH, $J_{Pt\text{-}H}$ = 55Hz) and 7.81 (m, 16H, CH_2); and the ^{13}C NMR (25.15MHz, *C_6D_6-^{1}H decoupled) has ^{13}C shifts with δ measured relative to $SiMe_4$ (positive values to high frequency) 73.3 (C=C, $J_{Pt\text{-}C}$ = 143Hz) and 33.2 (CH_2, $J_{Pt\text{-}C}$ = 15Hz), and for IR see references. The white crystalline complex is ***stable in air*** and can be handled without difficulty. [Spencer et al. *Inorg Synth* **19** 213 *1979*, DOI: 10.1002/9780470132500.ch49; Crascall et al. *Inorg Synth* **28** 126 *1990*, DOI: 10.1002/9780470132593.ch34.] ***Note that attempts to prepare the corresponding Pd complex [Pd(COD)$_2$] in a similar manner failed; however, it was obtained by the reaction of [Pd(COD)Cl$_2$] with Li$_2$[C$_8$H$_8$] in the presence of excess of propene as a white crystalline solid which was stable below -20°, but decomposed rapidly to Pd and 1,5-cyclooctadiene at ambient temperatures***. [Green et al. *JCS Dalton Trans* 271 *1977*, DOI: 10.1039/DT9770000271; Crascall et al. *Inorg Synth* **28** 126 *1990*, DOI: 10.1002/9780470132593.ch34.] $Pt(COD)_2$ catalyses the *cis*-diborylation of olefins in >80% yields under ambient cond-

itions with e.g. CatB-BCat (see below). [Iverson & Smith *Organometallics* **16** 2757 *1997*, DOI: 10.1021/om970199x; Müller & Göser *Angew Chem Int Ed* **6** 364 *1967*, DOI: 10.1002/anie.196703642.]

Platinum(0) bis(dibenzylideneacetone) [Pt(dba)$_2$, bis(C^3,O^3-η-1,5-diphenyl-1,4-pentadien-3-one)-platinum (0)] *[33677-56-4]* **(C$_{34}$H$_{28}$O$_2$)Pt, M 663.8, m >170° (to Pt and dba).** Pt(dba)$_2$ is a deep purple air stable complex which is prepared in 41% yield from K_2PtCl_4 with 3 mol equivalents of dba in refluxing EtOH under N_2 in the presence of NaOAc. It crystallises from Me_2CO and is soluble in MeOH and $CHCl_3$. It is useful for preparing complexes with $(PPh_3)_2$, $(AsPh_3)_2$, $(PEt_3)_2$, $(AsEt_3)_2$, as well as with other ligands. The ***tris complex Pt(dba)$_3$*** is formed as a yellow microcrystalline solid in 40% yield by carrying out the above reaction in refluxing aqueous MeOH ***in the presence of air or oxygen***. It is stable in the solid form, and is soluble in organic solvents but gives green solutions that rapidly turns purple, from which Pt(dba)$_2$ and dba (1:1) can be isolated. Physical properties showed that complete dissociation of Pt(dba)$_3$ had occurred. Both complexes decompose >170° on heating to Pt and dba, on treatment with CO, or when solutions are set aside for long periods. The IR ($CHCl_3$) of Pt(dba)$_2$ has ν_{max} at 1656w(CO), 1613vs, br(C=C), 1579m(C=C aromatic), 1544m, br(CO) cm^{-1}; and complex Pt(dba)$_3$ has ν_{max} at 1652w(CO), 1624vs(C=C), 1593s, br(C=C aromatic), 1579m(C=C aromatic), 1527m br(CO) cm^{-1}. The UV-VIS ($CHCl_3$) of Pt(dba)$_2$ has λ_{max} nm (logε) at 235 (4.48), 336 (4.54), 378sh(4.27) 538 (3.92, metal→ ligand: $d \rightarrow \pi^*$); and Pt(dba)$_3$ has λ_{max} nm (logε) at 235 (4.27), 336 (4.48), 568 (3.51, metal→ ligand: $d \rightarrow \pi^*$); and dba has λ_{max} nm (logε) at 233 (3.90), 325 (4.38). The ^{1}H NMR (100MHz, $CDCl_3$) of Pt(dba)$_2$ and dba are surprisingly similar [see however: Müller & Gröser *Angew Chem Int Ed* **6** 364 *1967*, DOI: 10.1002/anie.196703642]. It is a useful catalyst for the oligomerisation of acetylenes [Moseley & Maitlis *JCS Chem Commun* 982 *1971*, DOI: 10.1039/C29710000982; Cherwinski et al. *JCS Dalton Trans* 1405 *1974*, DOI: 10.1039/DT9740001405], and is used in the Pt(dba)$_2$-catalysed selective *cis*-addition of bis(pinacolato)borane to terminal alkenes and cyclic alkenes with internal strain to form bis(boryl)alkanes in 76-86% yields at 50° [Ishiyama et al. *JCS Chem Commun* 689 *1997*, DOI: 10.1039/A700878C] among other uses in catalysis.

Rhodium(II) acetate dimer (2H$_2$O) [dirhodium tetraacetate, tetrakis(acetato)dirhodium(II)] *[15956-28-2]* **[Rh(C$_2$H$_3$O$_2$)$_2$]$_2$. 2H$_2$O, M 478.0.** Dissolve 5g of the dimeric salt in boiling MeOH (*ca* 600ml) and filter. Concentrate the filtrate to 400ml and chill overnight at *ca* 0° to obtain dark green crystals of the MeOH adduct. Concentration of the mother liquors gives a further crop of ***[Rh(OAc)$_2$]$_2$.2MeOH***. The adduct is then heated at 45° in a vacuum for 2 hours (all MeOH is lost) to leave the emerald green crystals of the acetate. [Legzdins et al. *J Chem Soc (A)* 3322 *1970*, DOI: 10.1039/J19700003322; Rempel et al. *Inorg Synth* **13** 90 *1972*, DOI: 10.1002/9780470132449.ch16.] *Alternatively*, dissolve the acetate in glacial AcOH and reflux for a few hours to give an emerald green solution. Evaporate most of the AcOH on a steam bath, then heat the residue at 120°/1hour. Extract the residue with boiling Me_2CO. Filter, concentrate to half its volume and keep at 0°/18hours. Collect the crystals, wash them with ice cold Me_2CO and dry them at 110°. It is moderately soluble H_2O, MeOH, Me_2CO (see above), and in many organic solvents to give green solutions. It forms adducts with MeOH, Me_3N and Me_2S, and gives solutions with different colours varying from green to orange and red depending on solvent and dilution. The IR(Nujol) has ν_{max} at 1580s, 1425s, and 1350m cm^{-1}, and the IR (hexachlorobutadiene) has ν_{max} at 1445s, 1415s and 1350m cm^{-1} among other bands. [UV: Johnson et al. *Inorg Chem* **2** 960 *1963,* DOI: 10.1021/ic50009a020; *Beilstein* **1** H 124, **2** 124; for applications see Fieser **5** 571, **8** 434, **13** 266, **15** 278, **16** 289, **17** 298.]

It is a homogeneous catalyst [Black *Aldrichimica Acta* **15** 13 *1982*], is used in an efficient synthesis for β-hydroxy-α-acrylates involving the decomposition of diazoester intermediates with concomitant 1,2-aryl migration [Xiao et al. *Tetrahedron Lett* **48** 1147 *2007*, DOI: 10.1016/j.tetlet.2006.12.062], and is an effective catalyst for the formation of allylsulfonium ylides (e.g. from 3,3-dimethylallyl methyl sulfide and trimethylsilyldiazomethane) which undergo [2.3] sigmatropic rearrangements (e.g. to 2,2-dimethyl-1-methylthio-1-trimethylsilylbut-3,4-ene) [Carter & Van Vranken *Tetrahedron Lett* **40** 1617 *1999*, DOI: 10.1039/J19700003322]. The reactions of alkyl diazoacetates with carbodiimides (to form 2-imino-4-oxazolines) [Drapier et al. *Tetrahedron Lett* 559 *1979*, DOI: 10.1016/S0040-4039(01)86000-7], with acetylenes (to form cyclopropenes) [Petiniot et al. *Tetrahedron Lett* 1239 *1978*, DOI: 10.1016/S0040-4039(01)94511-3], and with ROH, HOH and R'COOH (replacing H to form the respective O-CH_2CO_2Alkyl) [Paulissen et al. *Tetrahedron Lett* 2233 *1973*, DOI: 10.1016/S0040-4039(01)87603-6] are all catalysed by [Rh(OAc)$_2$]$_2$ at about room temperature.

Rhodium(III) acetylacetonate [2,4-pentanedione rhodium(III), $Rh(acac)_3$] *[14284-92-5]* **$Rh(C_5H_7O_2)_3$, M 400.2, m 263-264°.** It is prepared from $Rh(NO_3)_3$ solution (0.1g in Rh) in 0.2*N* HNO_3 (10ml) which is neutralised with aqueous $NaHCO_3$ (10%) to pH 4, whereby the light yellow hydroxide (or basic nitrate) begins to separate. Acetylacetone (5ml) is added, the mixture is refluxed, and after a few minutes orange-yellow crystals begin to separate while the pH of the solution decreases. After 30 minutes' reflux, the pH of the solution is re-adjusted and reflux is continued for a further 15 minutes. The orange-yellow complex is collected and forms monoclinic plates (0.3g, 75%, m 260°) upon recrystallisation from aqueous MeOH, and sublimes at 240°/1.0mm. It decomposes above 280° depositing a rhodium mirror. It is insoluble in H_2O, slightly soluble in EtOH and petroleum ether, but freely soluble in $*C_6H_6$ and $CHCl_3$. It is stable in boiling dilute acids and 10% aqueous NaOH. Molecular weight determination (~490, by Rast in camphor) indicates that it is ***monomeric***. [Dwyer & Sargeson *J Am Chem Soc* **75** 984 *1953*, DOI: 10.1021/ja01100a503; *Beilstein* **1** IV 3677.] $Rh(acac)_3$ is a very effective catalyst (~90% yields) for the hydrogenation of monocarboxylic or ω-dicarboxylic acids to the respective alcohols in DME at 100 atmospheres (16 hours at 160°) when combined with $Re(CO)_{10}$ or $Mo(CO)_6$ [He et al. *Tetrahedron Lett* **36** 1059 *1995*, DOI: 10.1016/0040-4039(94)02453-I].

Rhodium(I) bis(1,5-cyclooctadiene) tetrafluoroborate complex [bis(1,5-cyclooctadiene)rhodium(I) tertrafluoroborate, $Rh(COD)_2^+.BF_4^-$] *[35138-22-8]* **$RhC_{16}H_{24}BF_4Rh$, M 406.1, m ~190° (dec), the xHydrate** *[207124-65-0]* **has m 165° (dec).** This complex is prepared from the dimer $[Rh(COD)Cl]_2$ (1.47g, 2.98mmol, cf. *[12092-47-6]* in Catalysts-Part 2) in CH_2Cl_2 (20ml), to which is added COD (1.1ml, 8.97mmol) followed by $AgBF_4$ (1.33g, 6.83mmol) in Me_2CO (10ml) which results in a deep red solution containing a white precipitate. The mixture is stirred for 20 minutes, filtered through Celite, THF (20ml) is then added and the volume is reduced on a Rotovap at 25° down to 10ml. The deep red crystals are filtered off, washed with THF (2 x 5ml), Et_2O and dried in air (2.35g, 97%). [Schenck et al. *Inorg Chem* **24** 2334 *1985*, DOI: 10.1021/ic00209a003.] A general purification procedure involves dissolving the complex in the minimum volume of CH_2Cl_2, adding an equal volume of EtOH and completing the crystallisation by dropwise addition of Et_2O, filtration, and drying the solid *in vacuo*. It is used for preparing ***cationic COD-Rh complexes*** with phosphine ligands for enantioselective [2+2+2] cycloaddition of unsymmetrical diynes with styrene and norbornene derivatives to yield bi- and tetracyclic products with good (~50%) to very good (>90%) enantiomeric enrichment [Shibata et al. *Tetrahedron* **63** 12853 *2007*, DOI: 10.1016/j.tet.2007.10.053], for hydrogenation [Nagel et al. *Chem Ber* **119** 3326 *1986*, DOI: 10.1002/cber.19861191112; Ojima et al. *Tetrahedron* **45** 6901 *1989*, DOI: 10.1016/S0040-4020(01)89159-6; Sawamura et al. *J Am Chem Soc* **117** 9602 *1995*, DOI: 10.1021/ja00142a044], and for hydrosilylation [Takeuchi et al. *J Org Chem* **60** 3045 *1995*, DOI: 10.1021/jo00115a020].

[Rhodium(*S,S*-Chiraphos)(COD)] ClO_4.THF {[(1,2,5,6-η)-1,5-cyclooctdiene][1.2-dimethyl-1,2-ethanediyl-(di-phenylphosphine)-*P,P'*]rhodium(1^+) perchlorate. THF, η^4-1,5-cyclooctadiene[(*2S,3S*)-*2*,3-bis(diphenylphosphino)butane]rhodium(I) perchlorate.THF} *[61886-03-1, 61886-02-0 THF-free]* **$C_{36}H_{40}P_2Rh^+ ClO_4^-$ C_4H_8O, M 809.1, 737.0 (THF-free).** The *S,S*-catalyst is obtained by adding 70% perchloric acid (0.080g, 1 equivalent) in pure THF (1ml) under N_2 to a mixture of ***S,S-chiraphos*** (0.244g, see *[64896-28-2]*) and *[Rh(COD)(acac)] (0.180) in THF (4ml); and the red mixture is allowed to stand at 25° for 14 hours. The bright orange block crystals are collected, washed with cold THF and dried in air to give analytically pure (C, H, P and Cl analysis) catalyst *perchlorate THF* (0.40g). The presence of solvent is confirmed by NMR. A single crystal X-ray (absolute) structural determination of this THF-pre-catalyst shows that it is as predicted, i.e. the chiral centres are *S* and the methyl groups are equatorial to give a δ-chelate ring [Ball & Payne *Inorg Chem* **16** 1187 *1977*, DOI: 10.1021/ic50171a042]. The configuration in solution is assumed to be the same, being consistent with the stereochemistry of the catalytically produced products.

The above two complexes are ***efficient homogeneous catalysts*** for the hydrogenation of α-*N*-acylamioacrylic acids at room temperature and pressure in THF, dioxane or $*C_6H_6$, EtOH or aqueous EtOH to provide the amino acid derivatives in very high optical purity [e.g. of alanine (91%), DOPA (83%) and tyrosine (92%)], and in almost quantitative chemical yields with turnover numbers ranging from 3 x 10^{-2} to 6 x 10^{-4} sec^{-1}, from which essentially completely ***optically pure 'non-natural' R-α-amino acids*** can be obtained by recrystallisation. [Fryzuk & Bosnich *J Am Chem Soc* **99** 6262 *1977*, DOI: 10.1021/ja00461a014]. An ingenious application of this *S,S*-chiraphos catalyst using hydrogen, deuterium and tritium has been adopted for the asymmetric synthesis of chiral lactic acid in which the methyl group is chiral by virtue of its having a hydrogen, a deuterium and a

tritium atom on the methyl carbon atom. [Fryzuk & Bosnich *J Am Chem Soc* **101** 3043 *1979*, DOI: 10.1021/ja00505a035]. In the hydrogenation of selected Z-olefins with this pre-catalyst, addition of Et_3N appears to give higher optical yields of products [Onuma et al. *Bull Chem Soc, Jpn* **53** 2012 *1980*, DOI: org/10.1246/bcsj.53.2012].

*** [Rh(COD)(acac)]** *[12245-39-5]* **$C_{13}H_{19}O_2Rh$, M 310.2, m 138-140°,** is prepared from $[Rh(COD)Cl]_2$ (4.4g, 9 mmol, see *[12092-47-6]*, cf. Catalysts-Part 2) and acetylacetone (acacH, 0.9ml, 9 mmol) in CH_2Cl_2 (50ml) chilled to -80° by treating dropwise with a solution of Na_2CO_2 (5,7g) in H_2O (100ml) and shaking; then warming to 0° while shaking and more CH_2Cl_2 (50ml) is added. The layers are separated, and the organic layer is evaporated *in vacuo* until the complex crystallises out. [Fryzuk & Bosnich *J Am Chem Soc* **99** 6262 *1977*, DOI: 10.1021/ja00461a014].

Rhodium(*S,S*-Chiraphos)(NBD)] ClO_4 {(bicyclo[2.2.1]heptadiene)[(*2S,3S*)-*2,*3-bis(diphenylphosphino) butane]-rhodium (I) perchlorate, [(1,2,5,6-η)bicyclo[2.2.1]hepta-2,5-diene][*S,S*-1.2-dimethyl-1,2-ethanediyl)-bis(diphenylphosphine)-*P,P'*]rhodium(1+) perchlorate} *[65012-74-0; 65012-73-9 for cation; Rh(S,S-chiraphos)(MeOH)$_2^+$ has 71264-71-6]* **$(C_{28}H_{28}P_2)(C_7H_8)Rh^+$ ClO_4^-, M 720.97.** This catalyst can be prepared by two methods. In the ***first***, 7% $HClO_4$ (0.173g, 1 equivalent) in THF (6ml) is added to a solution of the complex *[Rh(NBD)(acac)] (0.356g) and *S,S*-chiraphos (0.516g, see *[64896-28-2]*) in dry, freshly distilled, THF (7.5ml) under N_2, and the deep red coloured solution is allowed to stand at 25° for 24 hours. The orange-red crystals that separate are collected, washed with cold THF, dried at 40° *in vacuo* to give the catalyst ***perchlorate*** (0.6g), which should be stored at 0° under N_2 in a sealed container. In the ***second***, *S,S*-chiraphos (0.308g) and the complex **$[Rh(NBD)_2]ClO_4$ (0.290g) are dissolved in CH_2Cl_2 (5ml) and THF (5ml) under N_2, followed by addition of hexane (6ml), allowing to stand at 25° for 1 hour, then at 5° for 2 hours. The orange-red needles of the catalyst ***perchlorate*** (0.43g) are collected, dried and stored as in the first method. ***Note*** that it loses catalytic activity if stored in air. [Fryzuk & Bosnich *J Am Chem Soc* **99** 6262 *1977*, DOI: 10.1021/ja00461a014.] Its ^{31}P NMR ($CDCl_3$, with external H_3PO_4 as reference) has δ at +56.9 (d, $J_{Rh\text{-}P}$ = 153Hz), i.e. downfield from H_3PO_4 [Slack et al. *Inorg Chem* **18** 3125 *1979*, DOI: 10.1021/ic50201a034]. The salt, **$(C_{28}H_{28}P_2)(C_7H_8)Rh^+$ BF_4^-** *[79790-89-9]* **M 708.3** forms orange-red crystals from CH_2Cl_2/Et_2O.

****[Rh(NBD)(acac)]** [32354-50-0]* **$(C_7H_8)Rh(C_5H_7O_2)$, M 294.2, m 176-177°,** is prepared from the dimer $[Rh(NBD)Cl]_2$ *[12257-42-0]* and Tl(acetylacetone) *([25955-51-6])* as described for [(hfacac)$(COE)_2$Ir] *[58616-58-3]* [see this chapter and Diversi et al. *J Organomet Chem* **125** 253 *1977*, DOI: 10.1016/S0022-328X(00)89444-9.]

**** *$[Rh(NBD)_2]^+ClO_4^-$*** *[60576-59-1]* **$(C_7H_8)_2Rh^+$ ClO_4^-, M 386.6,** is also prepared from the dimer $[Rh(NBD)Cl]_2$ (0.35g, *[12257-42-0]*) and NBD (0.14g) in CH_2Cl_2 (15ml) under N_2, adding $AgClO_4$ (0.315g), stirring for 1 hour, filtering and adding THF (15ml). When the CH_2Cl_2 in the mixture is evaporated off under a vacuum, $[Rh(NBD)_2]ClO_4$ separates as orange needles which are collected, washed with cold THF and dried *in vacuo* to give now orange-brown crystals (0.5g). *Alternatively*, add Et_2O instead of THF (15ml), filter, wash with Et_2O, and dry *in vacuo* (yield 90%). Its ^1H NMR in $(CD_3)_2CO$ has δ at 5.23 (br, olefin H), 4.09 (bridgehead CH) and 1.50 (CH_2). [Fryzuk & Bosnich *J Am Chem Soc* **99** 6262 *1977*, DOI: 10.1021/ja00461a014; cf. Cramer *J Am Chem Soc* **86** 217 *1964*, DOI: 10.1021/ja01056a022.] ***$[Rh(NBD)_2]^+BF_4^-$*** has *[36620-11-8]* **$(C_7H_8)_2Rh^+$ BF_4^-, M 373.99, m 157-159°**, and is prepared as for the perchlorate, but replacing $AgClO_4$ by an equivalent of $AgBF_4$, and recrystallising from CH_2Cl_2/Et_2O. The cation ***$[Rh(NBD)_2]^+$*** has *[35015-46-4]* **$(C_7H_8)_2Rh^+$, M 287.2.** [Green et al. *J Chem Soc (A)* 2334 *1971*, DOI: 10.1039/J19710002334; Osborn & Schrock *J Am Chem Soc* **93** 3089 *1971*, DOI: 10.1021/ja00741a069; Green & Kuc *JCS Dalton Trans* 832 *1972*, DOI: 10.1039/DT9720000832.]

[Rhodium(*R,R*-Chiraphos)(NBD)]ClO_4 {(bicyclo[2.2.1]heptadiene)[(*2R,3R*)-*2,*3-bis(diphenylphosphino) butane]-rhodium (I) perchlorate} *[74892-62-9]* **$(C_{28}H_{25}P_2)(C_7H_8)Rh^+$ ClO_4^-, M 720.97.** This pre-catalyst is prepared and purified as its enantiomer above in 77% yield in orange-red crystals after recrystallising from CH_2Cl_2/hexane. Its catalytic properties are very similar to those of its enantiomer above except that optically pure 'natural' *S*-α-amino acids are produced. [Köttner & Gerber *Chem Ber* **113** 2323 *1980*, DOI: 10.1002/cber.19801130627.] The mechanism of the above asymmetric hydrogenations has been studied in some detail [Brown & Chaloner *J Am Chem Soc* **102** 3040 *1980*, DOI: 10.1021/ja00529a029; Brown et al. *J Organomet Chem* **216** 263 *1981*, DOI: 10.1016/S0022-328X(00)85766-6].

[Rhodium (*R*-Prophos)(NBD)] ClO_4. $0.5CH_2Cl_2$ {(bicyclo[2.2.1]heptadiene)[*R*(+)-1,2-bis(diphenylphosphino)-propane]-rhodium(I) perchlorate. $0.5CH_2Cl_2$, [(2,3,5,6-η)bicyclo[2.2.1]hepta-2,5-diene][(1-methyl-1,2-ethanediyl)bis(diphenylphosphine)-*P,P'*]rhodium(1^+) perchlorate. $0.5CH_2Cl_2$} *[67881-59-8; 67884-58-7 for the cation; Rh(R-prophos)(MeOH)$_2^+$ has 71264-72-7]* **$(C_{27}H_{28}P_2)(C_7H_8)Rh^+ ClO_4^-$, M 706.9, decomposes on heating.** The precatalyst is made from freshly recrystallised $[Rh(NBD)_2]ClO_4$ (0.388g, 1mmol, [12257-42-0]) and ***R-prophos*** (0.437g, 1.106mmol) in a mixture of CH_2Cl_2 (4ml) and pure THF (4ml) under N_2; and to this orange red solution is added hexane (4ml) dropwise, and the mixture is then allowed to stand at 25° for 5 hours then at 5° for 12 hours. The orange-red solid is filtered off quickly, washed with ice-cold THF then hexane, and dried under a stream of dry N_2 to give analytically pure [Rh(*R*-Prophos)(NBD)]ClO_4 (with $0.5CH_2Cl_2$ by NMR). It remains catalytically active indefinitely if kept at 0° under N_2. Its ^{31}P NMR ($CDCl_3$, with external H_3PO_4 as reference) has δ at +60.5 (d, $J_{Rh\text{-}P}$ = 172Hz), +41.8 (q, $J_{Rh\text{-}P}$ = 139Hz, $J_{P\text{-}P}$ = 34Hz) i.e. downfield [Slack et al. *Inorg Chem* **18** 3125 *1979*, DOI: 10.1021/ic50201a034]. Its absolute crystal X-ray structure has been determined and is the one predicted, i.e. the chelate ring is λ, the methyl group is equatorially disposed and the absolute configuration of the diphosphine is *R*. The configuration in solution is assumed to be the same, being consistent with the stereochemistry of the catalytically produced products.
Like the above rhodium complexes of ***S,S-chiraphos***, this ***R-prophos*** rhodium complex is an efficient homogeneous catalyst for the production of α-amino acids, and the optical yields appear to be insensitive to the nature of the substituents on the substrates which provide the ***'natural' S-amino acids*** in 90±3% optical yields and high chemical yields (<87%) [compare with the ***S,S-chiraphos*** rhodium precatalysts above which give the 'non-natural' *R*- α-amino acids]. Furthermore, the catalyst ***R-prophos*** rhodium complex can breed its own chirality so that large quantities of *R*-prophos can be made from the catalytic hydrogenation of ethyl acetoxyacrylate, *via* ethyl *S-(-)*-O-acetyllactate, by the *R*-prophos catalyst itself. This procedure has been used to produce ***S-prophos*** *if the pre-catalyst used is* ***[Rh(S,S-chiraphos)(NBD)]ClO$_4$***. [Fryzuk & Bosnich *J Am Chem Soc* **100** 5491 *1978*, DOI: 10.1021/ja00485a037.] An ingenious application of this *R*-prophos rhodium pre-catalyst using hydrogen, deuterium and tritium has been adopted for the asymmetric synthesis of chiral lactic acid in which the ***methyl group is chiral*** by virtue of its having a hydrogen, a deuterium and a tritium atom on the methyl carbon atom. The orientations here being opposite to those obtained with the *S,S*-chiraphos rhodium precatalysts. [Fryzuk & Bosnich *J Am Chem Soc* **101** 3043 *1979*, DOI: 10.1021/ja00505a035.]
Note that these rhodium catalysts are in fact ***pre-catalysts*** because in the presence of hydrogen their {e.g. [Rh(*S,S*-chiraphos)NDB]$^+$} strong deep red-orange colours are reduced to a light straw yellow colour of the ***true catalyst*** {e.g. [Rh(*S,S*-chiraphos)$(H)_2]^+$}. The mechanism of these asymmetric hydrogenations has been studied in some detail [Brown & Chaloner *J Am Chem Soc* **102** 3040 *1980*, DOI: 10.1021/ja00529a029; Brown et al. *J Organomet Chem* **216** 263 *1981*, DOI: 10.1016/S0022-328X(00)85766-6].

Rhodium(III) chloride [$RhCl_3$ ± x H_2O] *[10049-07-7; 20765-98-4 x H_2O]* **$RhCl_3$, M 209.3 (anhydrous), m 100° (hydrate, dec).** The anhydrous form is crystalline and is ***hydrophobic***. It is a red powder insoluble in H_2O, but soluble in aqueous NaOH or cyanide solutions. The ***hydrate***, however, is soluble in H_2O. [cf. preparation of the ***trihydrate*** by Anderson, Basolo and Onstott [*Inorg Chem* **7** 214 *1963*, DOI: 10.1002/9780470132388.ch57].
It catalyses the direct conversion of methane to AcOH [Lin & Sen et al. *Nature* **368** 613 *1994*, DOI: 10.1038/368613a0], and is a catalyst for conjugate reduction of cinnamaldehydes followed by cross-coupling with arylboronic acids [Wang et al. *JCS Chem Commun* 1192 *2004*, DOI: 10.1039/B401511H]. It also catalyses the deuteration of saturated hydrocarbons [Takahashi et al. *J Am Chem Soc* **97** 7489 *1975*, DOI: 10.1021/ja00859a019], and in the presence of Ph_3P (***Wilkinson's catalyst***) the trimethylsilylation of methacrylic esters to 1-alkoxy-1-trimethylsilyl oxyethylenes with rearrangement of a methyl group in the presence of Me_3SiH in THF [see Revis & Hilty *J Org Chem* **55** 2972 *1990*, DOI: 10.1021/jo00296a080.]

Rhodium(II) pentafluorobenzoate dimer [tetrakis(pentafluorobenzoato)dirhodium(II)] *[75863-37-5]* **$C_{28}F_{20}O_8Rh_2$, M 1050.82.** This dimer is obtained from a solution of perfluorobenzoic acid (4.5g) and hydrated $RhCl_3$ (1g) in EtOH (80ml), to which is added NaOH (0.8g), and heated under reflux for 3 hours, cooled and the solid is filtered off. The solid is refluxed for a further hour with fresh EtOH (80ml) and is filtered again. The combined EtOH solutions are evaporated *in vacuo*, the solid green residue is extracted with several volumes of Et_2O until the extracts are colourless; the Et_2O is concentrated and chromatographed on SiO_2 (eluting with toluene/Et_2O 9:1). Some of the complex (1g) is collected in one of the fractions, and dried *in vacuo* for 3 hours

[150° at 10^{-2} mm] and is analytically pure. The IR(KBr) has ν_{max} at 1655m, 1597s, 1525m, 1500s, 1433s, 1405s, 1297w, 1118m, 997s, 942w, 768m cm^{-1}. Like the ***triflate salt*** (following entry) it catalyses the addition of carbenes (derived from alkyl diazoesters) to aromatic compounds; its catalytic efficiency is unaffected by the bulk of the diazo ester alkoxy group [Anciaux et al. *J Org Chem* **46** 873 *1981*, DOI: 10.1021/ jo00318a010].

Rhodium(II) trifluoroacetate dimer [dirhodium tetra-trifluoroacetate, tetrakis(trifluoroacetato)-dirhodium(II), $Rh_2(Tfl)_4$] *[31126-95-1]* **[$(CF_3CO_2)_2Rh]_2$, M 657.9.** It can be purified in much the same way as the preceding acetate dimer (see *[15956-28-2]*) and is recrystallised from *C_6H_6 before use. It is a homogeneous catalyst [Black *Aldrichimica Acta* **15** 13 *1982*]. Tetrakis(perfluorocarboxylato)dirhodium(II) catalyses the addition of carbenes (generated from diazo esters) to aromatic compounds at room temperature to generate 1-carbalkoxycyclohepta-2,4,6-trienes (with high kinetic selectivity for the *non*conjugated isomers) in very good yields. A competitive reduction of the catalyst occurs simultaneously causing the reaction to slow down, and should be taken onto account [Anciaux et al. *J Org Chem* **46** 873 *1981* DOI: 10.1021/jo00318a010].

Ruthenium(III) acetylacetonate [$Ru(acac)_3$] *[14284-93-6]* **($C_5H_7O_2)_3Ru$, M 398.4, m 240°(dec).** Purify the complex by recrystallisation from *benzene. [Wilkinson *J Am Chem Soc* **74** 6146 *1952*, DOI: 10.1021/ja01143a538; *Beilstein* **1** IV 3677.] It catalyses the hydrogenation of dimethyloxalate to ethylene glycol under mild conditions [70bar H_2 pressure at 100°] and the best ligand is $MeC(CH_2PPh_2)_3$ with a trace of Zn (0.07% of oxalate) in MeOH with yields of >84% and with turnover numbers of 875 (turnover frequency/hour of 53.5) [Teunissen & Elsevier *JCS Chem Commun* 667 *1997*, DOI: 10.1039/A700862G].

Ruthenium (benzylidine)dichloro-bis-(tricyclohexylphosphine) [phenylmethylene-bis-(tricyclohexyl-phosp-hine) dichlororuthenium (Grubbs catalyst—first generation) *[172222-30-9]* **$C_{43}H_{72}Cl_2P_2Ru$, M 823.0, m 153° (dec).** Wash it repeatedly with Me_2CO and MeOH and dry it in a vacuum. *Alternatively*, dissolve it in warm CH_2Cl_2, concentrate it to half its volume, filter, add MeOH to precipitate it as purple microcrystals. Filter these off, wash several times with Me_2CO and MeOH and dry them in a vacuum for several hours. [Schwab et al. *J Am Chem Soc* **118** 100 *1996*, DOI: 10.1021/ja952676d; Miller et al. *J Am Chem Soc* **118** 9606 *1996*, DOI: 10.1021/ja961626l; Furstner & Langemann *J Am Chem Soc* **119** 9130 *1997*, DOI: 10.1021/ja9719945.] It is used to catalyse ring-closing metathesis [Schrodi & Pederson *Aldrichimica Acta* **40** 45 *2007*, Schmidt *Angew Chem Int Ed* **42** 4996 *2003*, DOI: 10.1002/anie.200301688], and promotes olefin metathesis with ruthenium based catalysts [Grubbs *Tetrahedron* **60** 7117 *2004*, DOI: 10.1016/j.tet.2004.05.124]. § A polymer supported version is also commercially available [Schwab et al. *Angew Chem Int Ed* **34** 2039 *1995*, DOI: 10.1002/anie.199520391].

Ruthenium(III) chloride ($RuCl_3$) *[3H_2O 13815-94-6; xH_2O 14898-67-0; Anhydrous 10049-08-8]* **$RuCl_3$. xH_2O, M 207.4 (anhydrous), 261.5 (3H_2O), d^{20} 3.11.** The ***anhydrous salt*** exists in two forms. The ***α-form*** is produced by the slow reaction of Cl_2 with Ru metal in siliceous containers at >600° to give black lustrious hexagonal crystals which are ***antiferromagnetic*** and insoluble in H_2O or EtOH [Hill & Beamish *J Am Chem Soc* **72** 4855 *1950*, DOI: 10.1021/ja01167a002]. The second ***β-form*** is prepared by heating Ru metal in a stream of CO and Cl_2 at 340°, to avoid the formation of carbonyl compounds such as $Ru(CO)_2Cl_2$ and is free from the metal or α-$RuCl_3$. It is formed in dark brown fluffy hexagonal crystals that are soluble in EtOH. It is the metastable form because at or about the transition temperature of 450° the ***β-form*** is slowly ***converted*** to the ***α-form*** (irreversibly, with $t_{0.5}$ ~1 hour), and is the best way to prepare the ***α-form***. [Fletcher et al. *Nature* **199** 1089 *1963*, DOI: 10.1038/1991089a0.]

Hydrated $RuCl_3$ is one of the ***most useful*** inorganic ruthenium compounds, and particularly for the preparation of Ru coordinated compounds. It is prepared by evaporating RuO_4 in concentrated hydrochloric acid in a stream of HCl gas. Unlike the anhydrous form, the hydrate is soluble in H_2O, but a fresh aqueous solution (brown to brown-green colour) does not precipitate AgCl with $AgNO_3$ solution because the halogen atoms (as well as one molecule of H_2O) are coordinated to the metal. However, on warming in H_2O the halogen atoms are displaced by H_2O molecules and the Cl^- ions can be precipitated (or titrated) with $AgNO_3$ [Connick & Fine *J Am Chem Soc* **83** 3414 *1961*, DOI: 10.1021/ja01477a014]. It is a ***soluble catalyst*** used for the oxidative cyclisation of 1,7-dienes to oxepane diols [Piccialli et al. *Tetrahedron Lett* **48** 5131 *2007*, DOI: 10.1016/j.tetlet.2007.05.078], and promotes a site-specific hydroxylation of tertiary carbon-hydrogen bonds of cyclic ethers in the presence of periodate or bromate [Lee et al. *J Org Chem* **72** 5820 2007, DOI: 10.1021/jo070382s].

It also catalyses oxidation reactions with an oxidant, e.g. the methylene group in cyclopropylmethyl-compounds to a carbonyl group in the presence of ***metaperiodate*** [Hasegawa et al. *Chem Lett (Jpn)* 1385 *1985*, DOI: 10.1246/cl.1985.1385; Carlsen et al. *J Org Chem* **46** 3936 *1981*, DOI: 10.1021/jo00332a045; cf. Review Gore *Platinum Metals Rev* **27** 111 *1983*]. It catalyses the synthesis of 2-ethyl-3-methylquinolines from primary aromatic amines and triallylamine [Cho et al. *Tetrahedron Lett* **40** 1499 *1999*, DOI: 10.1016/S0040-4039(98)02661-6], and has been used for the selective hydrogenation of unsaturated aldehydes [Fujita et al. *J Catal* **255** 95 *2004*, DOI: 10.1016/j.jcat.2004.03.037]. [For further applicatios see Fieser **4** 421, **8** 437, **10** 343, **11** 462, **13** 268, **15** 280.]

Ruthenium [1,3-bis-(2,4,6-trimethylphenyl)-2-imidazolidinylidine] dichloro (benzylidene) (tri-cyclohexylphosphine) {Benzylidene-[1,3-bis(2,4,6-trimethylphenyl)-4,5-dihydro-2-imidazolinylidene]dichloro-(tricyclohexylphosphine)-ruthenium, [(1,3-Bis(2,4,6-trimethylphenyl)-2-imidazolinylidene) dichloro (phenylmethylene)(tricyclophosphine)ruthenium, (Grubbs catalyst—second generation)} *[246047-72-3]* **$C_{46}H_{65}Cl_2N_2PRu$, M 849.0, m 143.5-148.5°.** This catalyst is prepared by adding a solution of *tert*-BuOK (1.25g, 10.2mmol, 1.4 equiv) in dry THF (200ml) slowly to a suspension of 1,3-dimesityl-4,5-dihydroimidazolium tetrafluoroborate (4.2g, 10.2mmol, 1.4 equivalent) in dry THF (100ml) in a flame dried Schlenk flask (500ml) under N_2 (magnetic stirring) at ~20°. The BF_4^- salt dissolves immediately, the cloudy yellow mixture is stirred at ~20° for 1 hour, and then transferred (cannula) to a larger Schlenk flask (twice size) under argon. To this is added $RuCl_2(=CHPh)(PCy_3)_2$ (7.29, 7.29mmol, 1.0 equivalents) in dry $*C_6H_6$ (400ml) and heated at 80° for 30 minutes when the reaction is complete (by ^1H NMR). The volatiles are removed *in vacuo* and the residue is washed with dry MeOH, or pentane (4 x 100ml) to provide the active catalyst as a pink-brown microcrystalline powder (4.64g, 75%). It has ^1H NMR (400MHz, CD_2Cl_2) with δ at 19.16 (s, 1H), 7.37-7.05 (m, 9H), 3.88 (s, 4H), 2.56—0.15 (m, 51H); ^{31}P NMR (161.9MHz, CD_2Cl_2) with δ at 31.41 and HRMS (FAB) at 848.3306 for M^+ [Scholl et al. *Org Lett* **1** 953 *1999*, DOI: 10.1021/ol990909q].
It is used in ruthenium catalysed ***ring closure metathesis*** (***RCM***) and olefin metathesis [Kulkarni & Diver *J Am Chem Soc* **126** 8110 *2004*, DOI: 10.1021/ja0476922; Schmidt *Angew Chem Int Ed* **42** 4996 *2003*, DOI: 10.1002/anie.200301688; Scholl et al. *Org Lett* **1** 953 *1999*, DOI: 10.1021/ol990909q], and to generate unsaturated sultones (e.g. 2,7-3*H*-dihydro-[1,2]oxathiepine-2,2-dioxide) from olefinic sulfonates (e.g. but-3-enyl allyl-sulfonate) *via* ring closure metathesis [Le Flohic et al. *Tetrahedron* **62** 9017 *2006*, DOI: 10.1016/j.tet.2006.07.010].

Ruthenium [1,5-Cyclooctadiene][1,3,5-cyclooctatetraene] (Ru[cod][cot]) *[127382-91-6]* **$C_{16}H_{22}Ru$, M 315.4, m 88-94°, 92-94°.** For preparation see Chapter 4, 'Metal-Organic Compounds'. Purify the ruthenium complex (~ 0.3g) by dissolving it in *n*-pentane (~ 70ml) and filtering the solution through a column of alumina (Merck, Brockman activity II—III, 20cm). Collect the yellow band and reduce its volume to ~ 5ml then cool it at -70°, preferably under N_2 or argon. After ~ 6 hours collect the yellow solid (~ 0.2g) and dry it *in vacuo*. Recrystallisation from *n*-pentane results in a 75-85% recovery. [Itoh et al. *J Organomet Chem* **272** 179 *1984*, DOI: 10.1016/0022-328X(84)80465-9; Petrici et al. *JCS Dalton Trans* 1961 *1980*, DOI: 10.1039/DT9800001961]. It is a highly selective catalyst for amine alkylations in which, unlike other ruthenium catalysts, alkylates the amino group of e.g., 2-, 3-, or 4- aminopyridines as well as 2-aminopyrimidine to give the respective monoethylamino derivatives by using EtOH in high yields with very little, if any, of diethylamino derivatives. Thus it stops almost ***exclusively at monoalkylation***. [Watanabe et al. *J Org Chem* **61** 4214 *1996*, DOI: 10.1021/jo9516289]. It also catalyses the dimerisation of 2,5-norbornadiene *via* [2+2] cycloaddition reactions and eyne generation in the presence of dimethylfumarate in THF at 40° for 1 hour to form the ***'cup-shaped' molecule pentacyclo[6.6.0.0^{2,6}.0^{3,13}.0^{10,14}]tetradeca-4,11-diene*** in 96% yield. An alicyclic compound which would otherwise require many steps to synthesise. [Mitsudo et al. *J Am Chem Soc* **121** 1839 *1999*, DOI: 10.1021/ja9835741.]

Ruthenium [(*R*-P-Phos)(acac)$_2$] {Ruthenium [*R*-(+)-2,2',6,6'-tetramethoxy-4,4'-bis(diphenylphosphino)-3,3'-bipyridine)-bis(acetylacetonate)] is prepared by mixing equimolar amounts of *R*-P-Phos (see *R*-(+)-*[221012-82-4]* in 'Part-2') with $Ru(acac)_3$ *[14284-93-6]* in the presence of a reducing agent (Zn powder) in refluxing EtOH to give the solid catalyst in 97% yield which was characterised by ^1H, ^{31}P NMR, elemental analysis and X-ray crystallographic structure determination. ***Ru[(S- P-Phos)Cl$_2$(DMF)$_n$*** is prepared in a similar manner with the appropriate ingredients (using ***S-(-)-P-Phos*** *[362524-23-0]*) in DMF. [Pai et al. *J Am Chem Soc*

122 11513 *2000*, DOI: 10.1021/ja000163n.] These (see also below) ***atropisomeric*** bi-heteroaromatic diphosphines (P-Phos and its variants) which complex with transition metals are effective in catalysing asymmetric reactions including asymmetric hydrogenation of 2-arylacrylates, β-ketoesters, arylketones, hydrosilylation and C-C bond formation with high stereospecificity. [Wu & Chan *Acc Chem Res* **39** 711 *2006*, DOI: 10.1021/ar0680015; Au-Yeung & Chan *Coordination Chemistry Reviews* **248** 2151 *2004,* DOI: 10.1016/j.ccr.2004.08.026; Pai et al. *J Am Chem Soc* **122** 11513 *2000*, DOI: 10.1021/ja000163n.]

Ruthenium [(*R*-Xylyl-P-Phos)(C_6H_6)]Cl_2 {Ruthenium *R*-(+)-2,2',6,6'-tetramethoxy-4,4'-bis[di(3,5-xylyl)phosphino]-3,3'-bipyridine)(benzene) dichloride] is prepared in 88% yield by mixing equimolar amounts of [$RuCl_2(C_6H_6)]_2$ *[37366-09-9]* with *R*-Xylyl-P-Phos (see *R*-(+)- *[442905-33-1]* in 'Part-2') in EtOH/*C_6H_6 (8:1) and heating at 50-60° for 1 hour. This ruthenium complex is a highly active, enantioselective, air stable catalyst for the asymmetric hydrogenation of β-ketoesters (PH_2 = 200-350psi at 70-90° for 1-15 hours) to optically active β-hydroxyesters with ~100% conversion and >91% enantiomeric enrichment. It is ***very stable*** in the solid state in air; and a stirred solution for 10 hours under air showed no loss of activity or stereoselectivity; and its ^{31}P NMR (200MHz, $CDCl_3$) is not different from that obtained for the original sample under N_2 which has an AB set of signals with δ_P at 33.49 (d, $J_{PA\text{-}PB}$ = 62.9Hz) and 39.96 (d, $J_{PA\text{-}PB}$ = 62.5Hz). The coordination of ruthenium to benzene makes the phosphorus atoms ***non-equivalent***. The resonance observed in the ^1H NMR (500MHz, $CDCl_3$) at 5.65ppm is assignable to the 6H resonances of the η^6-coordinated benzene ring [Wu et al. *Tetrahedron Lett* **43** 1539 *2002*, DOI: 10.1016/S0040-4039(02)00062-X].
Other P-Phos related ligands, such as the chiral 4-bis(tolylphosphino) (***Tol-P-Phos***) and chiral 4-bis(cyclohexylphosphino) (***Cy-P-Phos***) ligands, were prepared and purified in a similar, or slightly modified, manner using the appropriate phosphines. They also form ruthenium complexes that have related catalytic activities [Wu & Chan *Acc Chem Res* **39** 711 *2006*, DOI: 10.1021/ar0680015; Au-Yeung & Chan *Coordination Chemistry Reviews* **248** 2151 *2004*, DOI: 10.1016/j.ccr.2004.08.026].

Ruthenium(II)-tris(triphenylphosphine) dichloride [tris(triphenylphosphine)ruthenium(II) dichloride] *[15529-49-4]* **[$(C_6H_5)_3P]_3RuCl$, M 958.8; 433 (in Me_2CO/N_2), m 132-134°.** This catalyst (compare with Wilkinson's Rhodium catalyst above) is obtained by heating under reflux $RuCl_3.3H_2O$ (0.26g, 1mmol) and Ph_3P (1.57g, 6mmol) in MeOH (65ml) under N_2 for 3 hours, when the reddish-brown tris-complex separates. It is washed well with MeOH, then Et_2O and dried *in vacuo* at 60° (yield 75%). It is soluble in $CHCl_3$, Me_2CO, *C_6H_6, EtOAc and hot *i*-PrOH, but insoluble in H_2O, Et_2O and sparingly soluble in alcohol. When less Ph_3P is used in e.g. MeOH, complexes such as ***Ru(III)-di(Ph_3P)(MeOH) Cl_2*** are formed. ***Note that if the above mixture is shaken, not refluxed, Ru(II)-tetrakis(triphenylphosphine) dichloride is formed which turns green on exposure to air***. [Stephenson & Wilkinson *J Inorg Nucl Chem* **28** 945 *1966*, DOI: 10.1016/0022-1902(66)80191-4; Sammakia & Stangeland *J Org Chem* **62** 6104 (footnote) *1997*, DOI: 10.1021/jo9711044.]
The ***tris-complex*** catalyses a variety of reactions including hydrogen transfer [Sasson & Blum *Tetrahedron Lett* 2167 *1971*, DOI: 10.1016/S0040-4039(01)96811-X; Regen & Whitesides *J Org Chem* **37** 1832 *1972*, DOI: 10.1021/jo00976a038], insertion of *t*-BuOO- into the carbon atom α to the N-atom of, e.g. *N*-methoxycarbonyl pyrrolidine and 1,2,3,4-tetrahydroisoquinoline with *t*-BuOOH [Kondo et al. *J Org Chem* **56** 487 *1991*, DOI: 10.1021/jo00002a003], intramolecular cyclisation of unsaturated α,α-dichloroesters or amides [Hayes at al. *J Org Chem* **51** 5501 *1986*, DOI: 10.1021/jo00376a109], the reduction of –CHO by HCOOH/Et_3N/THF without affecting NO_2, RCOR, ester or *tert*-amide groups [Kai & Arcelli *Tetrahedron Lett* **26** 3365 *1985*, DOI: 10.1016/S0040-4039(00)98299-6], in the synthesis of furans from allenyl sulfides [Peng et al. *Angew Chem Int Ed* **46** 1905 *2007*, DOI: 10.1002/anie.200604299], and for other examples of catalysis by this Ru-complex see Fieser **4** 564, **5** 740, **6** 654, **10** 141, **12** 179, **13** 107, **14** 130, **16** 126. When complexed further with chiral (phosphinoferrocenyl)oxazolines, hydrogen transfer is not only considerably enhanced but is also highly stereospecific [see further in this chapter].

Samarium (II) iodide (SmI_2) Samarium (II) iodide (SmI_2) see *[32248-43-4]*; **Silver acetate (AgOAc)** see *[563-63-3]*, and **Silver tetrafluoroborate [$AgBF_4$]** see *[14104-20-2]*, all in Chapter 4, 'Inorganic Compounds'.

Tetrakis(triphenylphosphino)palladium(0) [palladium-tetrakis(triphenylphosphine)] *[14221-01-3]* **[$(C_6H_5)_3P]_4Pd$, M 1155.6, m 100-105°, 115°, ~116° (dec, sealed tube under N_2), (m is unreliable and is not**

a criterion of purity because it varies). This catalyst is prepared from $PdCl_2$ (5.9g, 0.1mol), Ph_3P (43.7g, 0.5ml) in Me_2SO (400ml) under a vacuum N_2 system with pressure release, and the yellow mixture is heated (oil bath) with stirring until dissolution (140°). The bath is removed, the mixture is stirred rapidly for 15 minutes and hydrazine hydrate (6.7g 0.4mol) is injected within 1 minute. A vigorous evolution of N_2 occurs and the dark solution is rapidly cooled with a cool water bath and crystallisation takes place (~125°). When the temperature reaches ~20° the solid is filtered off (coarse sintered glass) under N_2, washed with EtOH (2 x 50ml), Et_2O (2 x 50ml) and the yellow crystalline solid is dried by a slow stream of N_2 through the funnel overnight (37.4g 97%). ***Alternatively***, it can be prepared freshly by mixing $Pd(NO_3)_2$ (2mmols) and PPh_3(2mmols) in hot $*C_6H_6$ when vigorous evolution of nitric oxide occurs (fume cupboard) and a solid mass separates. This is collected and crystallised from EtOH. It should not be heated excessively as it dissociates to $Pd(PPh_3)_3$ and PPh_3, and then further to $Pd(PPh_3)_2$ and PPh_3. It is also air sensitive as PPh_3 is oxidised to PPh_3O. It is stable only for short periods because on exposure to heat or air it turns from yellow to orange and dissociates in solution, so the solutions should be used directly. Its ***cryoscopic constant*** in $*C_6H_6$ (at 0.601g/20ml) corresponds to **M 1156** [Malatesta & Angoletti *J Chem Soc* 1186 *1957*, DOI: 10.1039/JR9570001186]. Molecular weight determination in $*C_6H_6$ indicates considerable dissociation, and the solution absorbs O_2 rapidly to give an insoluble green oxygen complex [Nyman et al. *J Chem Soc A* 561 *1968*, DOI: 10.1039/J19680000561]. It is moderately soluble in $*C_6H_6$ (5g/100ml), CH_2Cl_2 and $CHCl_3$ but less soluble in Me_2CO, THF and MeCN. $Pd(Ph_3P)_4$ may be handled in air but it is best stored under N_2. [Coulson et al. *Inorg Synth* **28** 107 *1990*, DOI: 10.1002/ 9780470132593.ch28; Malatesta & Angoletta *J Chem Soc* 1186 *1990*, DOI: 10.1039/JR9570001186; *Beilstein* **16** IV 954, Fieser **6** 571, **7** 357, **8** 472, **9** 451, **10** 384, **11** 503, **12** 468, **13** 289, **14** 295, **15** 300, **16** 317, **17** 327.]
$Pd(Ph_3P)_4$ is a very ***versatile catalyst*** for promoting the dimerisation of butadiene to 1,3,7-octatriene [Takahashi et al. *Bull Chem Soc Jpn* **41** 454 *1968,* DOI: org/10.1246/bcsj.41.454], catalysing various coupling reactions, without homo-coupling occurring [Brocato et al. *Tetrahedron Lett* **33** 7433 *1992*, DOI: 10.1016/S0040-4039(00)60208-3; Arcadi et al. *Tetrahedron Lett* **34** 2813 *1993*, DOI: 10.1016/S0040-4039(00)73569-6; McClure & Danishefsky *J Am Chem Soc* **115** 6094 *1993*, DOI: 10.1021/ja00067a026; Paquette & Astles *J Org Chem* **58** 165 *1993,* DOI: 10.1021/jo00053a031; Sahoo et al. *Org Lett* **8** 4141 *2006*, DOI: 10.1021/ol061763f], including ***Suzuki*** coupling [Trost *Tetrahedron* **33** 2615 *1977*, DOI: 10.1016/0040-4020(77)80284-6]. [*Beilstein* **16** IV 954.] This palladium catalyst bound to a polymer support (~0.06mmol/g) is also commercially available [cf. Fenger & Le Drain *Tetrahedron Lett* **39** 4287 *1998*, DOI: 10.1016/S0040-4039(98)00757-6].

Tetra-*n*-propylammonium perruthenate (TPAP, tetrapropyl tetraoxoruthenate) *[114615-82-6]* **$(C_3H_7)_4NRuO_4$, M 351.4, m 160°(dec).** This stable dark green solid is a useful catalyst for a variety of oxidation reactions at about room temperature. It is used at a concentration of about 5 mol% with an equivalent of ***N*-methylmorpholine *N*-oxide (NMO)** which provides the required oxygen with typical turnovers of about 250. The reactions are carried out in CH_2Cl_2 and/or MeCN, although the latter assists the reactions in CH_2Cl_2 considerably. ***Care*** should be taken to add TPAP slowly as the reaction can be vigorous. Addition of finely ground ***4Å molecular sieves moderate*** the rate and efficiency of the reaction. The reactions usually proceed to completion within 5 minutes to one hour. Cooling and slow addition of TPAP is necessary with reactions on a large scale. Workup is simple, and is carried out by passing the solution through a short silica-gel column and eluting with EtOAc followed by evaporation and crystallisation or distillation of the product. When MeCN is the solvent, or is present in the solvent, it is advisable to evaporate the solvent prior to passage through the silica-gel column. [Ley et al. *Synthesis* 639 *1994*, DOI: 10.1055/s-1994-25538: see entry in the 'Metal-Organic Compounds' chapter 4, for further information].

Triphenylphosphinegold(I) bis(trifluoromethanesulfonyl)imidate $([Ph_3PAu(I)]^+ [NTf_2]^-$) *[866395-16-6]* **$[(C_6H_5)_3PAu]^+ (CF_3SO_2]_2N^-$, M 739.4, m >230°.** $AgNTf_2$ is first prepared by mixing Ag_2CO_3 (276mg, 1.0mmol) and $HNTf_2$ (562mg, 2.0mmol, 2 equivalents *[82113-65-3]*) in H_2O (10ml), and refluxing for 3 hours (to eliminate CO_2); then evaporating to dryness *in vacuo*. It can be used as a solid or dissolved in dry CH_2Cl_2 (5ml). [Li et al. *J Org Chem* **73** 4323 *2008*, DOI: 10.1021/jo8003875.] The versatile catalyst is then prepared by dissolving Ph_3PAuCl (2mmol, *[14243-64-2]*) in CH_2Cl_2 (5ml) and adding to it solid $AgNTf_2$ (786mg, 2mmol) or the preceeding CH_2Cl_2 (5ml) solution. Immediate separation of AgCl occurs. After stirring for 15 minutes the ^{31}PMR reveals a single peak of the Au salt. The AgCl is removed by filtration through Celite, the pale col-

oured solution is evaporated *in vacuo*, and the residue is dried *in vacuo* to give a ***quantitative yield*** of the catalyst. It forms small white crystals which are air stable, but should be preferably stored in a dry inert atmosphere. It is soluble in Me_2CO, CH_2Cl_2, and $CHCl_3$ but insoluble in petroleum ethers. Its IR (CCl_4) has ν_{max} at 1482, 1437, 1405, 1384, 1216, 1196, 1133, 1103 and 960, cm^{-1}; the ^1H NMR (400MHz, $CDCl_3$) has δ_H at 7.47-7.55 (m, 12H, aromatic H) and 7.56-7.62 (m, 3H, aromatic H close to Au); the ^{31}P NMR (121.5MHz, CD_2Cl_2) has δ_P at 30.7, and for ^{13}C NMR see references. [Mézailles et al. *Org Lett* **7** 4133 *2005*, DOI: 10.1021/ol0515917.] **NTf_2** is a weakly coordinating counter ion that confers stability to the complex. ^{31}P NMR spectra of pre-formed solutions of the complexes Ph_3PAuBF_4, Ph_3PAuPF_6 and $Ph_3PAuSbF_6$, using the respective Ag salts, showed that they were not very stable. Attempts to isolate the complexes were unsuccessful. [Mézailles et al. *Org Lett* **7** 4133 *2005*, DOI: 10.1021/ol0515917.]
At concentrations of 1-2mol% in CH_2Cl_2 or Me_2CO, ***$[Ph_3PAu(I)]^+$ $[NTf_2]^-$*** catalyses the stereoselective isomerisation of butynediol monobenzoates into functionalised 2,5-dihydrofurans (in a sequence of two steps) in high yields at room temperature and in 15 to ~30 minutes [Buzas et al. *Org Lett* **8** 1957 *2006*, DOI: 10.1021/ol0606839]. It is ***exceedingly active*** in catalysing a wide variety of eyne cycloisomerisations [Mézailles et al. *Org Lett* **7** 4133 *2005*, DOI: 10.1021/ol0515917]. Also under similar mild conditions, in the presence of electrophilic bromine (e.g. from *N*-bromosuccinimide) or iodine (e.g. from *N*-iodosuccinimide), it catalyses the formation of linear α-halo-enones from propargyl acetates [Yu et al. *Tetrahedron* **65** 1846 *2009*, DOI: 10.1016/j.tet.2008.11.107], and 4-haloalkylidene-1,3-dioxalan-2-ones with propargyl *tert*-butylcarbonates [Buzas et al. *Tetrahedron* **65** 1889 *2009*, DOI: 10.1016/j.tet.2008.11.108], products which are suitable substrates for Pd-catalysed cross coupling reactions. Like the following OTf^- Au catalyst, it promotes the glycosylation of 1,2-anhydrosugars as donors using protected sugars with one free sterically unhindered OH group [Li et al. *J Org Chem* **73** 4323 *2008*. DOI: 10.1021/jo8003875].

Triphenylphosphinegold(I) trifluoromethanesulfonate ($[Ph_3PAu(I)]^+$ $[OTf]^-$) *[156397-47-6]* **$[(C_6H_5)_3PAu]^+ CF_3SO_3^-$, M 608.2, m >230°.** $Ph_3PAu(I)]^+$ $[OTf]^-$ differs from the preceding catalyst in the counter anion, and is ***much less air and moisture sensitive***. Due precautions need to be taken in use and storage however. It is prepared by dissolving Ph_3PAuCl (0.1mmol, [14243-64-2]) and silver trifluoromethanesulfonate (0.1mol, *[2923-28-6]*) in dry CH_2Cl_2 (1ml) and stirred for 5 minutes. Filtration from AgCl provides a 0.1M solution of catalyst in CH_2Cl_2. Generally the AgCl does not interfere in the catalytic process and so the catalyst can be prepared *in situ*. Colourless $Ph_3PAu(I)]^+$ $[OTf]^-$ can be obtained by evaporating the CH_2Cl_2 solution and stored appropriately. It is a superior catalyst to anhydrous $ZnCl_2$ for the well established glycolsylation reactions with 1,2-anhydrosugars as donors [Li et al. *J Org Chem* **73** 4323 *2008*, DOI: 10.1021/jo8003875], and it catalyses the intramolecular hydroamination of terminal alkenes in high yields with 1-5mol% of catalyst by heating in toluene at 100° for 12-48 hours, or the intra- and inter- molecular hydroamination in $ClCH_2CH_2Cl$ by microwave radiation as heat source in ~30 minutes in high yield [Liu et al. *Org Lett* **8** 2707 *2006*, DOI: 10.1021/ol060719x]. In a useful application, the catalyst ***$[Ph_3PAu(I)]^+$ $[OTf]^-$*** promotes a cascade cyclisation/oxidative cleavage of a carbon-carbon triple bond in Z-enynols, e.g. 5-Ph- or 5-*n*-butyl- pent-2-ene-4-yne-1-ols, in the presence of molecular oxygen to give high yields of the corresponding 2,5-dihydrofuran-2-ones and releasing C-5 with its substituent as the aldehyde or acid. The reaction involves free radicals as it is completely suppressed in the presence of the radical scavenger 4-hydroxy-TEMPO [Liu et al. *J Am Chem Soc* **128** 11332 *2006*, DOI: 10.1021/ja062610q].

Tris(dibenzylideneacetone)dipalladium(0) chloroform adduct $[Pd_2(dba)_3(CDCl_3)]$ *[52522-40-4]* **$(C_{17}H_{14}O)_3Pd_2$, M 1035.1, m 122-124°, 131-135°; solvent free tablet form (1μmol Pd per MgAlsilicate tablet) $Pd_2(dba)_3$** *[51364-51-3]* **M 915.7, m 152-155°.** When $PdCl_2$ (1.05g, 5.92mmol) is added to a solution of dibenzylidene acetone (dba, 4.60g, 19.6mmol) and NaOAc (3.9g, 47.5mmol) in MeOH (150ml at 50°), mixed at 40° for 4 hours then cooled, a reddish-purple precipitate separates. This is collected, washed with H_2O then Me_2CO and dried *in vacuo*. The precipitate (3.39g) is purified by dissolving it in hot $CDCl_3$ (120ml), filtering, and to the deep violet filtrate is added slowly Et_2O (170ml) when the ***chloroform adduct*** separates as deep purple needles which are collected and dried *in vacuo* (80% yield, **m 122-124°**). Recrystallisation from $*C_6H_6$ instead of $CHCl_3$ gives deep-violet needles of ***tris(dibenzylideneacetone)-dipalladium(0) benzene adduct*** (62.5% yield, m 141-142°). By using toluene instead of $CHCl_3$, deep-violet needles of ***tris(dibenzylidene-acetone) dipalladium(0) toluene adduct*** (36% yield, **m 140-141°**) are obtained. The solvates can be exchanged with each other (i.e. $CDCl_3$, $*C_6H_6$ or toluene) without affecting the coordinating reactivity of the complex with other ligands such as Ph_3P, Bipy, *o*-phen, olefins, *o*-quinones etc. [Ukai et al. *J Organomet Chem* **65** 253 *1974*,

DOI: 10.1016/S0022-328X(00)91277-4; for applications see Fustero *Org Lett* **8** 4129 *2006*, DOI: 10.1021/ol061733c.] If the procedure is used with bis(*p*-methoxybenzylidene)acetone and the complex crystallised from $CDCl_3/Et_2O$, ***Pd$_2$(p,p'-methoxy-dba)$_3$*** is obtained as deep violet needles (72.3% yield, m 141-143º) which do not complex with the solvent. [cf. **Pd(dba)$_2$** above.] [Ukai et al. *J Organomet Chem* **65** 253 *1974*, DOI: 10.1016/S0022-328X(00)91277-4.]

Tris(dibenzylideneacetone)palladium [Pd(dba)$_3$]: When a fourfold excess of dba is added to solution of $Pd(dba)_2$ or $Pd_2(dba)_3$ in $*C_6H_6$, heated and reduced in volume, the dark red colour of $Pd(dba)_2$ turns to brown, and on complete evaporation, orange brown crystals of **Pd(dba)$_3$** contaminated with yellow crystals of dba are obtained. Washing the crystals with $*C_6H_6$ leads to crystal decomposition. The IR of the complex has ν_{max} at 1651 (C=O) and olefine bands at 1598, 1580 and 1531 cm^{-1}. X-ray analysis of the $Pd(dba)_3—*C_6H_6$ crystals showed that each pentadienone ligand is coordinated through one olefin group, and the Pd atom is trigonal with ~C_3 symmetry [Mazza & Pierpont *Inorg Chem* **12** 2955 *1973*, DOI: 10.1021/ic50130a043; cf. *Handbook of Organopalladium for Organic Synthesis* Negishi ed. Wiley, NJ *2002*, ISBN 0-471-31506-0].

Tris[triphenylphosphinegold(I)]oxonium tetrafluoroborate ($[Ph_3PAu(I)]_3O^+$ $[BF_4]^-$) *[53317-87-6]* **$C_{54}H_{45}P_3OAu_3BF_4$, M 1480.6, m 207º (dec), 207-208º (dec), 220-221º (dec).** The catalytic oxonium salt is prepared by adding a solution of $AgBF_4$ (0.2g, 1.03mmol) in MeOH (5ml) to a solution of Ph_3PAuCl (0.5g, 1.01mmol, *[14243-64-2]*) in THF (20ml) and the AgCl that precipitated is filtered off. A solution of KOH (0.1g, 1.78mmol) and $NaBF_4$ (0.5g, 4.55mmol) in MeOH (100ml) is added to the filtrate, stirred for 1 hour, the solvent is evaporated off *in vacuo*, the residue is extracted with $CHCl_3$ (2 x 30ml). The combined extract is filtered, and hexane (100ml) is added to precipitate the oxonium salt which gives analytically pure $[Ph_3PAu(I)]_3O^+$ $[BF_4]^-$ (0.42g, 84%), **m 220-221º (dec)**, after recrystallisation from a saturated $CHCl_3$ solution on adding ~1.5-fold volume of Me_2CO. ***Alternatively***, Ag_2O freshly prepared from $AgNO_3$ (5.0g, 29.5mmol), and $NaBF_4$ (5.0g, 45.5mmol, finely powdered) are added to a solution of Ph_3PAuCl (4.0g, 8.08mmol) in Me_2CO (600ml), stirred vigorously for 1 hour, and the solvent evaporated *in vacuo*. The residue is extracted with $*C_6H_6$ to removed unreacted Ph_3PAuCl, and the oxonium salt is extracted with $CHCl_3$ (3 x 40ml), filtered, and hexane (400ml) is added to crystallise $[Ph_3PAu(I)]_3O^+$ $[BF_4]^-$ (3.6g, 90%) out. It is soluble in $CHCl_3$ and CH_2Cl_2 but insoluble in hexane and Et_2O. Its IR (nujol mull) has ν_{max} at 1050-1070 (br, BF_4^-) cm^{-1}. It is a versatile air and moisture tolerant catalyst that has been used in a variety of reactions (see below). X-ray crystallography showed that in the crystals the oxonium ions are ***dimeric***, with the two pyramidal monomeric $(Ph_3PAu)_3(\mu_3\text{-}O)^+$ fragments interacting *via* Au-Au' bonds (~3.16Å) involving two of the three Au atoms in each unit. The pyramidal structure has the O^+ atom centrally above the Au_3 triangular plane, and the resulting six-membered Au_2OAu_2O heterocycle has a chair conformation. The ***oxonium trifluoroacetate*** **m 209-210º (dec)** from $CHCl_3/*C_6H_6$, and the ***oxonium permanganate*** **m 131-131.5º (dec)** from $CHCl_3$/hexane (1.2:4.0 v/v) were prepared similarly. [Nesmeyanov et al. *J Organomet Chem* **201** 343 *1980*, DOI: 10.1016/S0022-328X(00)92589-0; cf. Bruce et al. *Inorg Synth* **26** 324 *1988*, DOI: 10.1002/9780470132579.ch59.] Oxonium complexes with other phosphine ligands have been similarly prepared and if $H_2{}^{17}O$ is used in the preparations, then it is incorporated into the oxygen of the cation. ***$[Ph_3PAu(I)]_3{}^{17}O^+$ $[BF_4]^-$*** has ^{31}P NMR (36MHz, CD_2Cl_2, external 85% H_3PO_4) with δ_P at 24.0, and ^{17}O NMR (CD_2Cl_2 and external H_2O) with δ_{17O} at +19.7 (br s, *w/2* = 152Hz). [Yang et al. *Inorg Chem* **32** 1946 *1993*, DOI: 10.1021/ic00062a012.]

$[Ph_3PAu(I)]_3O^+$ $[BF_4]^-$ catalyses the Claisen rearrangement of propargyl vinyl ethers, e.g. 1-phenylhept-2-yne-1-yl vinyl ether, to respective aldehydes which are usually reduced *in situ* with $NaBH_4$ to give the homoallenic alcohol, i.e. 1-phenyl-3-*n*-butyl-3-(2-hydroxyethyl)allene, in high yield with 1mole% of catalyst in CH_2Cl_2 at room temperature. Chirality is efficiently transferred in the rearrangement. [Sherry & Toste *J Am Chem Soc* **126** 15978 *2004*, DOI: 10.1021/ja044602k]. In the presence of sterically hindered secondary amines, e.g. $(iso\text{-}Pr)_2NH$ or (iso-Pr)CyNH, it catalyses the ***5-exo-dig cyclisation*** of formyl alkynes, e.g. 6-formyl-4,4-bis(methoxycarbonyl)hex-1-yne, to 1,1-(bismethoxycarbonyl)-3-formyl-4-exomethylenecyclopentane in $CDCl_3$, 70º/3-24 hours, in ~70% yields [Binder et al. *Org Lett* **10** 1025 *2008*, DOI: 10.1021/ol800092p]. In the presence of O_2 in THF at ~50º $[Ph_3PAu(I)]_3O^+$ $[BF_4]^-$ also catalyses the cascade cyclisation/oxidative cleavage of a carbon-carbon triple bond in Z-enynols efficiently [see$Ph_3PAu(I)]^+$ $[OTf]^-$ above, Liu et al. *J Am Chem Soc* **128** 11332 *2006*, DOI: 10.1021/ja062610q].

(Xantphos)Rh(H)(CO)(PPh$_3$) is prepared by stirring a solution of $(PPh_3)Rh(H)(CO)$ (100mg, 0.11mmol) and

Xantphos (63.6mg, 0.11mmol, see *[161265-03-8]* in 'Catalysts—Part 2') in $^*C_6H_6$ (10ml) at 30° for 4 hours, evaporating the solvent *in vacuo*, washing the residue with MeOH (1ml) and drying *in vacuo* to give the ***analytically pure*** complex with the formula ***$C_{58}H_{48}O_2P_3Rh$***. The complex has IR ($CHCl_3$) with ν_{max} at 1996.9vs, 1909.6m cm^{-1}; the ^1H NMR (300MHz, C_6D_6) has δ at 7.82 (apparent q, 4H, *J* = 4.8Hz, ar), 7.66 (m, 6H, ar), 7.53 (apparent q, 4H, *J* = 4.9Hz, ar), 7.11 (dd, 2H, *J* = 7.3, 1.3Hz, CHC*H*CC), 7.0-6.9 (ar), 6.79 ('d', 4H), 1.48 (s, 3H, CCH_3), 1.38 (s, 3H, CCH_3), -9.14 ($J_{H\text{-}P}$ = 12.2Hz, $J_{H\text{-}P'}$ = 18.2Hz, $J_{H\text{-}Rh}$ = 1.7Hz); and the $^{31}P\{^1H\}$NMR (121.5MHz, C_6D_6, referenced to external 85% H_3PO_4) has δ at 42.67 ($J_{P\text{-}Rh}$ = 151.1Hz, $J_{P'\text{-}P}$ = 119.1Hz, PPh_3), 25.65 ($J_{P\text{-}Rh}$ = 127.9Hz, $J_{P'\text{-}P}$ = 119.1Hz, Xantphos-P); and MS has *m/z* at 961 (M-CO), 726 (M-PPh_3-2H), 698 (M- PPh_3-CO-2H); HR-MS found M is 578.1916 (calc for $C_{39}H_{32}OP_2$ is 578.1928), and for $^{13}C\{^1H\}$NMR see references. [Kranenburg et al. *Organometallics* **14** 3081 *1995*, DOI: 10.1021/om00006a057.]

Xantphos-Ru complex formed *in situ* from equimolar amounts of Xantphos and $Ru(PPh_3)(CO)H_2$ in refluxing toluene containing piperidinium acetate is a good catalyst for akylating active methylene compounds, e.g. *t*-butyl cyanoacetate, and hydroxy compounds, i.e. $PhCH_2OH$, to provide α-substituted cyanoacetates, or *t*-butyl 2-cyano-3-phenylpropionate [Slatford et al. *Tetrahedron Lett* **47** 6787 *2006*, DOI: 10.1016/j.tetlet.2006.07.069].

Xantphos-Pd complexes formed *in situ* from xantphos and $Pd(OAc)_2$ or $Pd_2(dba)_3$ catalyse the cross-coupling reactions between the amide nitrogen and aryl and heteroaryl halides [Manley & Bilodeau *Org Lett* **6** 2433 *2004*, DOI: 10.1021/ol049165t] or *meso*-brominated porphyrins [Gao, Chen and Zhang *Org Lett* **6** 1837 *2004*, DOI: 10.1021/ol049440b] to form the corresponding aryl-N-CO- and *meso*-porphyrin-NCO- in high yields respectively in the presence of a base e.g. $CsCO_3$. Similar cross-coupling catalysis with *in situ* Xantphos and $Pd(OAc)_2$ between thenylbromides and 2-aminopyridines or aminoquinolines have been achieved in high yields [Begouin et al. *Synthesis* 2794 *2006*, DOI: 10.1055/s-2006-942510]. It should be ***noted*** that a detailed study of the mixing of Xantphos and $Pd_2(dba)_3$ identified the complexes ***(Xantphos)Pd(dba)*** and ***Pd(Xantphos)$_2$***. The former is a very active catalyst whereas the latter bis(xanthane based phosphine)$_2$Pd(0) is less soluble and inherently less active. It is therefore ***important***, when forming the pre-catalyst, to keep the ratio of xantphos to Pd source less than 1.5:1 for a more effective catalyst involving cross-coupling between a nitrogen atom and an organic halide. [Klingensmith et al. *Organometallics* **25** 82 *2006*, DOI: 10.1021/om050715g.]

(Xantphos)$_2$ Pd is prepared in flame dried Schlenk equipment, evacuated/backfilled with argon three times, by stirring xantphos (579mg, 1.00mmol) and $Pd_2(dba)_3$ (229mg, 0.25mmol) in toluene (300ml) under argon for 4 hours. This is filtered *via* a cannula into a separate dry flask under argon, concentrated somewhat overnight and any palladium black which may have settled is filtered off and the filtrate is evaporated to dryness. The yellow residue is stirred overnight with toluene (100ml) to remove excess (or unused) dibenzylidene acetone and unreacted Xantphos. The remaining yellow ***Pd(Xantphos)$_2$*** has **m 164° (dec.)**, is sparingly soluble in most common organic solvents, and is characterised by the correct elemental analyses for ***$C_{78}H_{64}O_2P_4Pd$***. Its IR (KBr) has ν_{max} at 2924, 2854, 1461, 1398, 1377, 1222 cm^{-1}; and MALDI-MS: calcd for $C_{78}H_{64}O_2P_4Pd$: *theoretical:* 1260.2894 (22.9%), 1262.2909 (63.4%), 1262.2911 (100.0%), 1263.2907 64.6%), 1264.2914 (77.2%), 1265.2933 (47.5%), 1266.2931 (35.5%), 1267.2949 (25.1%); *Found:* 1260.3405 (24.0%), 1261.3285 (67.4%), 1262.3166 (100.0%), 1263.3162 (73.2%), 1264.3300 (79.3%), 1265.3424 (47.5%), 1266.3491 (35.5%), 1267.3104 (25.1%). [Klingensmith et al. *Organometallics* **25** 82 *2006*, DOI: 10.1021/om050715g.]

Zirconocene chloride hydride (bis[cyclopentadienyl]zirconium(IV) hydride chloride, Cp_2ZrClH) (Schwartz' reagent) *[37342-97-5]* **$C_{10}H_{11}ClZr$, M 257.9.** It is moisture and light sensitive. Determine its purity by reaction with a slight excess of Me_2CO whereby the active H reacts to produce ***$Cp_2ZrClOPr^i$*** and the integrals of the residual Me_2CO in the ^1H NMR will show its purity. The presence of ***Cp_2ZrH_2*** can be determined because it forms ***$Cp_2Zr(OPr^i)_2$***. For a very active compound, it is best to prepare it freshly from the ***dichloride*** {see below by reduction with Vitride [$LiAl(OCH_2CH_2OH)_2H_2$]}, the white precipitate is filtered off, washed with tetrahydrofuran, then Et_2O and dried in a vacuum. Store it dry in the dark. [Carr & Schwartz *J Am Chem Soc* **101** 3521 *1979*, DOI: 10.1021/ja00507a017; Negishi & Takahashi *Aldrichimica Acta* **18** 31 *1985*, Buchwald et al. *Tetrahedron Lett* **28** 3895 *1987*, DOI: 10.1016/S0040-4039(00)96413-X; Negishi & Takahashi *Synthesis* 1 *1988*, DOI: 10.1055/s-1988-27453; for applications see Fieser **6** 175, **7** 101, **8** 84, **9** 104, **14** 81, **15** 80, **16** 72, **17** 70.] It has been used for functionalising olefins and alkynes [Sun et al. *Org Synth* **71** 83 *1992,* DOI: 10.15227/orgsyn.071.0083; Negishi & Takahashi *Aldrichimica Acta* **18** 31 *1985*, Ganem & Franke *J Org Chem* **72** 3981 *2007*, DOI: 10.1021/jo070129s]. It was used also for mild and selective ***hydrozirconation*** of amides to aldehydes [Spletstoser et al. *J Am Chem Soc* **129** *3408* 2007, DOI: 10.1021/ja066362+].

Zirconocene dichloride (bis[cyclopentadienyl]zirconium dichloride, Cp_2ZrCl_2) *[1291-32-3]* **$C_{10}H_{10}Cl_2Zr$, M 292.3, m 242-245°, 248°**. Recrystallise the dichloride from $CHCl_3$ or xylene and dry it in a vacuum. ^1H NMR ($CDCl_3$) has δ at 6.52 from Me_4Si. Store it dry in the dark under N_2. [Reid et al. *Aust J Chem* **18** 173 *1965*, DOI: 10.1071/CH9650173; *Beilstein* **16** IV 1770; for applications see Fieser **10** 131, **14** 122, **15** 120, **16** 121, **17** 106.] Together with Zn and CH_2Cl_2 it is used for methylenation of carbonyl compounds [Tour et al. *Tetrahedron Lett* **30** 3927 *1989*], and has been useful for the synthesis of a wide range of early transition-metal complexes and organometallic compounds [Negishi & Takahashi *Aldrichimica Acta* **18** 31 *1985*].

NANO METAL CATALYSTS: see 'Nanomaterials and Nanotechnology' in Chapter 7.

ORGANOCATALYSIS

An important area of chemical research is in the development of efficient catalysts for carrying out organic transformations. Traditionally this field is dominated by metals, although increasingly *organocatalysis* and biocatalysis are gaining prominence. **Organocatalysts** are low molecular weight (<1000g/mol) metal-free organic molecules, or metal-containing compounds where the metal is ***not*** involved in the catalytic process. They efficiently and selectively catalyse a large variety of chemical reactions when used in small non-stoichiometric amounts. The potential advantages that organocatalysts can offer over metal catalysts include the ease of handling, good stability, low costs and their environmentally friendly nature. Their major disadvantage is the limited particular substrate and transformation scope. It should be noted that the field of organocatalysis is in its relative infancy but stunning progress has been made in the last ten years or so. For example, readily available organic compounds have been found to be capable of catalyzing a range of reactions. These include carbon-carbon bond forming reactions (Aldol, Mannich, Diels-Alder, alkylations, cyclopropanations, etc), epoxidation reactions, desymmetrisation reactions and so on [for excellent books, see Berkessel and Gröger 'Asymmetric Organocatalysis: From Biomimetic Concepts to Applications in Asymmetric Synthesis', Wiley-VCH 2005, ISBN-10:3-527-30517-3, 13:978-3-527-30517-9, and Dalko (Ed.) 'Enantioselective Organocatalysis: Reactions and Experimental Procedures,' Wiley-VCH, 2007. ISBN-10: 3527315225, ISBN-13: 978-3527315222.]. Classes of compounds that have demonstrated applications as organocatalysts include α-amino acids [Jarvo & Miller *Tetrahedron* **58** 2481 *2002*, DOI: 10.1016/S0040-4020(02)00122-9], N-heterocyclic carbenes [Marion et al. *Angew Chem Int Ed* **46** 2988 *2007*, DOI: 10.1002/anie.200603380], thioureas [Connon *Chemistry-A Eur J* **12** 5418 *2006*, DOI: 10.1002/chem.200501076], cinchona alkaloids [see below, Dalaigh *Synlett* 875 *2005*, DOI: 10.1055/s-2005-864796] and so on. One of the earliest practical demonstrations of the use of organocatalysts is exemplified by the Hajos-Parrish-Eder-Sauer-Wiechert reaction which was patented as early as 1971 [Eder, Sauer & Wiechert *Angew Chem Int Ed* **10** 496 *1971*, DOI: 10.1002/anie.197104961; Hajos & Parrish *J Org Chem* **39** 1612 *1974*, DOI: 10.1021/jo00925a002]. The Robinson aldol annulation reaction utilising a proline molecule as the organocatalyst is another, and is an early example of a highly enantioselective carbon-carbon bond forming reaction. Recent advances in organocatalysis have progressed to the level of sophistication that has enabled the synthesis of relatively complex organic molecules with multiple stereocenters in high chemical and optical yields [see Bertelsen& Jørgensen 'Organocatalysis-after the gold rush' *Chem Soc Rev* **38** 2178 *2009*, DOI: 10.1039/B903816G; Ting et al. 'Bronsted base catalysts' *Topics in Current Chemistry* (Ojima Ed) **291** 145 *2010*, Sereda et al. 'Lewis acid organocatalysts' *Topics in Current Chemistry* (Ojima Ed) **291** 349 *2010*; Kampen et al. 'Chiral Bronsted acids for asymmetric organocatalysis' *Topics in Current Chemistry* (Ojima Ed) **291** 395 *2010*; Lelais & MacMillan 'Modern Strategies in Organic Catalysis: the Advent and Development of Iminium Activation' *Aldrichimica Acta* **39** 79 *2006*; List 'The Ying and Yang of Organic Asymmetric Aminocatalysis' *JCS Chem Commun* 819 *2006*, DOI: 10.1039/B514296M; List, Yamamoto & Gong 'Organocatalysis: a web Collection' *JCS Chem Commun* **48** 10703 *2012*, DOI: 10.1039/C2CC90327J, Editorial; Zhong & X. Shi 'When organocatalysts meets transition metal catalysis' *Eur J Org Chem* 2999 *2010*, DOI: 10.1002/ejoc.201000004; also see ChemFiles, Vol 6, no 4 from Sigma-Aldrich for a compilation of some commercially available organocatalysts]. For the definition of Lewis and Brønsted/Lowry acids and Bases see at the end of 'Catalysts—Part 2' in this Chapter.

This section deals with some individual examples that have proved useful. Several are commercially available and the purification of some are described here. The preparations in some entries are also mentioned as these

assist in devising methods of purification. The purification of a number of organocatalysts is also described inother chapters. Specific examples include **(-)-*quinine*** [see *130-95-0*] and **(+)-*quinidine*** [see *56-54-2*] used to catalyse α-halogenation of carbonyl compounds, intramolecular Michael additions, cyclopropanation of enones, enolates etc, β-lactam synthesis from imines and ketenes, β-lactone synthesis from aldehydes and ketenes, Morita-Baylis-Hillman reactions, hydrophosphonylation of aldehydes, Diels-Alder reactions and desymmetrisation of *meso*-anhydrides; **(-)-*cinchonidine*** [see *405-71-2*] and **(+)-*cinchonine*** [see *118-10-5*] which catalyse additions to prochiral ketenes, desymmetrisation of *meso*-diols and of *meso*-epoxides; and their respective ***N-benzyl salts*** [see *69257-04-1*, and *69221-14-3*] are efficient chiral ***phase transfer catalysts*** (see below); ***L-proline*** [see *147-85-3*] which catalyses intramolecular Michael addition, Mannich reactions, inter- and intra- molecular aldol reactions, addition to N=O (α-aminoxylation/hydroxylation of C=O compounds), addition to nitrones and to N=N double bonds (α-amination of C=O compounds); ***L-phenylalanine*** [see *63-91-2*] which catalyses intramoleculer aldol reactions; and the ***metal-free Jacobsen's ligand*** *N,N'*-bis(3,5-di-*tert*-butylsalicylidene)-1,2-*trans*-cyclohexanediamine [see *R,R'-135616-40-9* or *S,S'- 135616-36-3*] which catalyses hydrocyanation (with TMS-CN) of aldehydes. It should be noted that the ***Phase Transfer Catalysts*** described in a later section of this Chapter are ***organocatalysts***.

RS*-(±)-1,1'-Bi(2-naphthol) (± 1,1'-binaphthyl-2,2'-diol)** *[602-09-5]* **$C_{20}H_{14}O_2$, M 286.3, m 214-217°, 216-218°, 217-218°, 218°, pK $^{20}_{Est\,(1)}$ ~7.5, pK $^{20}_{Est\,(2)}$ ~11.8; *R*-(+)-1,1'-bi(2-naphthol) (*R*-(+)-BINOL)** *[18531-94-7]* **m 208-210°, 207.5-208.5°, $[\alpha]_D^{20}$ +34 (c 1, THF), $[\alpha]_{546}^{25}$ +50.9 (c 1, THF); *S*-(−)-1,1'-bi(2-naphthol) (*S*-(−)-BINOL)** *[18531-99-2]* **m 207-208°, 208-210°, $[\alpha]_D^{22}$ −34 (c 1, THF), $[\alpha]_{546}^{25}$ +51.3 (c 1, THF).** 1,1'-Bi(2-naphthol) is easily prepared by slowly adding a solution of $FeCl_3.6H_2O$ (28g, 104mmol, see *[10025-77-1]*) in H_2O (60ml) to a vigorously stirred and refluxing suspension of 2-naphthol (14.4g, 100mmol, see [135-19-3]) in H_2O (600ml) and boiled until the oily drops of 2-naphthol disappear and the ***binaphthol separates out in flakes. Boiling is continued for 10 minutes, and the solid is filtered off, washed with boiling H_2O and dried first in air then *in vacuo*, to give ***(±)-BINOL*** in almost quantitative yield. Recrystallisation from hot EtOH, toluene or $*C_6H_6$ (~150ml, using charcoal) gives colourless glistening plates **m 218°**. The ***(±)-dimethyl ether*** *[75640-87-8, 75685- 01-7]* has **m 190°** (from AcOH). [A.I.Vogel *Practical Organic Chemistry* Longmans, Green & Co, London, p 639 *1948*, Pummerer et al. *Ber* **59** 2159 *1926*, DOI: 10.1002/cber.19260590881; Walder *Ber* **15** 2166 *1882*, DOI: 10.1002/cber.188201502162] The FT-IR (Nujol) has ν_{max} at 3486.6, 1617.9, 1508.8, 1322.7, 1252.4, 1177.2, 1126.4, 827.3 and 751.3 cm^{-1} (note below how it is different from its enantiomers). [*Beilstein* **6 6** I 519, **6** II 1026, **6** III 5877, **6** IV 7020; for applications see Fieser **12** 190, **13** 113, **15** 135, **16** 132, **17** 116.]

R*- and *S*- BINOL** have been obtained by a variety of ways which attest to their usefulness. They have been prepared by resolution of the (±)-BNP-acid (see below), the (±)-BINOL-boron ester (*via* the quinine salt), the (±)-BINOL dibenzoate (*via* pancreas acetone powder), or by oxidative coupling of 2-naphthol in the presence of chiral amines [see Zimmer & Suhrbier *J Prakt Chem* **339** 758 *1997*, DOI: 10.1002/prac.199733901138]. The preparations involving reduction of the (±)-BNP acid directly with $LiAlH_4$, or *via* the methyl phosphate derivative with RedAl [sodium bis(2-methoxyethoxy)aluminium hydride] in 3.4M toluene solution [Truesdale *Org Synth* Coll Vol **8** 46 *1993*, DOI: 10.15227/orgsyn.067.0013] appear to be most convenient, and do ***not involve racemisation. The former is described here as it does not require an esterification step. Pure *R*-(+)-BNP acid (115.4g, 331mmol, below) in dry THF at 0° under N_2, is treated with $LiAlH_4$ (31.4g, 830mmol) in small portions (exert extreme care here because of the large quantities used — fire hazard) during 1 hour with stirring. A further volume of dry THF (400ml) is added and the mixture is stirred at 25° under N_2, for 17 hours, cooled to 0° under N_2, and cold 6N aqueous HCl (250ml) is added very carefully. The upper phase is then decanted off, and the lower phase is mixed with 6N aqueous HCl (150ml) and THF (150ml), stirred, and is allowed to settle. The phases are separated and the lower phase is extracted with Et_2O. The combined organic phases are washed with brine, decolorised with charcoal and evaporated *in vacuo*. The residual oil is dissolved in $*C_6H_6$ (1L, toluene may be used) and evaporated until crystallisation sets in. The solid is collected (90.6g, 96%, m 202-207°), which upon crystallisation from $*C_6H_6$ or toluene gives optically pure BINOL (84.5g, 89%, **m 207-208°**) with (+) or (−) **$[\alpha]_{589}^{25}$ 34.3, $[\alpha]_{578}^{25}$ 37.8, $[\alpha]_{546}^{25}$ 51.3, $[\alpha]_{436}^{25}$ 228 (c 1.1, THF)**. The FT-IR (Nujol) of the BINOL enantiomers are identical, though different from that of the racemate (see above), and have ν_{max} at 3509.9, 1617.9, 1511.5, 1319.1, 1220.9, 1148.9, 815.6, 749.6 and 566.0 cm^{-1}; and the ^1H NMR (1:1 $CDCl_3$/DMSO-d_6, TMS) has δ at 7.04 (d, 2H, *J* = 8.8Hz), 7.20-7.35 (m, 4H), 7.40 (d, 2H, *J* = 8.8Hz), 7.92 (d, 2H, *J* = 8.8Hz) and 9.21 (s, 2H). **Racemisation studies** showed that: BINOL (0.1g) is optically stable in an H_2O (10ml)/dioxane (12ml) mixture at 100° under N_2 during 26 hours; loses 44% and 66% of optical activity in

BuOH (10ml) containing KOH (0.71m-mol) per BINOL (0.33mmol) at 118° under N_2 in 13 and 23 hours respectively; and loses 37% and 72% of optical activity of BINOL (100mg) in a 20% aqueous HCl (10ml)/dioxane (12ml) mixture at 100° under N_2 during 7 and 26 hours respectively. [Kyba et al. *J Org Chem* **42** 4173 *1977*, DOI: 10.1021/jo00862a001.] BINOL and 3,3'-diaryl derivatives act as organocatalysts for ***Mirata-Baylis-Hillman reactions*** involving C-H activation, e.g. condensation of a variety of aldehyde with cyclohex-2-en-1-one to provide chiral 2-(1-substituted-1-hydroxymethyl)cyclohe-2-en-1-ones in 40 to 80% yields and 'ee' values of ~90 in the presence of Et_3P [McDougal & Schaus *J Am Chem Soc* **125** 12094 *2003*, DOI: 10.1021/ja037705w], they catalyse hydrocyanation (with TMS-CN) of aldehydes with high 'ee' at -78° [Holmes & Kagan *Tetrahedron Lett* **41** 7453 DOI: 10.1016/S0040-4039(00)01275-2; and 7457 *2000*, DOI: 10.1016/S0040-4039(00)01276-4], and the ***titanium complexes*** catalyse the stereoselective reduction [with $(MeO)_3SiH$] of carbonyl compounds [Schiffers & Kaga *Synlett* 1175 *1997*, DOI: 10.1055/s-1997-982], as well as C-C forming reactions [Zimmer & Suhrbier *J Prakt Chem* **339** 758 *1997*, DOI: 10.1002/prac.199733901138] and Diels-Alder reactions [Mikami et al. *Tetrahedron*: *Asymmetry* **2** 643 *1991*, DOI: 10.1016/S0957-4166(00)86118-2]. The rare earth ***La-S-BINOL complex*** realises an asymmetric nitroaldol reaction with nitromethane in high product yield and enantomeric enrichment [Sasai et al. *J Am Chem Soc* **115** 10372 *1993*, DOI: 10.1021/ja00075a068].

RS*-(±)-1,1'-Binaphthyl-2,2'-diylhydrogen phosphate (1,1'-binaphthyl-2,2'-phosphoric acid, BNP)** *[36193-63-6]* **$C_{20}H_{13}O_4P$, M 348.3, m 217°, pK^{20} 0.74; *R*-(−)-1,1'-binaphthyl-2,2'-diylhydrogen phosphate** *[39648-67-4]* **m 217°, $[\alpha]_D^{20}$ −608 (c 1, MeOH), $[\alpha]_{546}^{22}$ −562.7 (c 0.97, $CHCl_3$), $[\alpha]_{546}^{22}$ −113 (c 0.95, $CHCl_3$); *S*-(+)-1,1'-binaphthyl-2,2'-diylhydrogen phosphate** *[35193-64-7]* **m 217°, $[\alpha]_D^{20}$ +608 (c 1, MeOH).** Recrystallise it from EtOH. Reflux for 3 hours in N NaOH is required to hydrolyse the cyclic phosphate. The ***R-enantiomer has been prepared by a general procedure in which ***R-(+)-1,1'-binaphthyl-2,2'-ol*** (1.90mmol, see *R*-BINOL *[18531-94-7]*) in pyridine (7.8ml) is treated with $POCl_3$ (250µl, 2.68mmol) and stirred at ~25° for 3 hours. The mixture is then quenched with H_2O (154µl) at 0°, stirred for 1 hour at ~25°, evaporated *in vacuo*, the residue is acidified with 6N HCl (20ml) at 0° then refluxed for 2 hours. After cooling to 0°, the ***phosphoric acid*** separates, is filtered off, washed with H_2O and dried *in vacuo*. Recrystallisation by dissolving in CH_2Cl_2 and pouring it into hexane provides pure crystals of the ***R*-(−)-*acid*** (1.58mmol, 83%). [Yamanaka et al. *J Am Chem Soc* **129** 6756 *2007*, DOI: 10.1021/ja0684803; for general procedure see Jacques & Fouquey *Org Synth* **67** 1 *1989*, DOI: 10.15227/orgsyn.067.0001.] Its ^1H NMR (400MHz, $CDCl_3$, TMS) has δ at 8.01 (d, 2H, *J* = 8.8 Hz), 7.94 (d, 2H, *J* = 8.2 Hz), 7.55 (d, 2H, *J* = 8.8 Hz), 7.49-7.44 (m, 2H), 7.38 (d, 2H, *J* = 8.2 Hz), 7.32-7.27 (m, 2H) and 3.22 (s, 1H); and for IR and ^{13}C NMR see references. [Jacques et al. *Tetrahedron Lett* **48** 4617 *1971*, DOI: 10.1016/S0040-4039(01)97544-6; Arnold et al. *Tetrahedron* **24**, 343 *1983*, DOI: 10.1016/S0040-4039(00)81402-1; *Beilstein* **6** II 1027.] ***Alternatively***, (and more useful as it can be carried out on a 100g scale), the ***R*-(−) and *S*-(+) BNP *acids*** are obtained by optical resolution of the diastereoisomeric ***(+)-cinchonine salts*** of the ***(±)-BNP acid*** *via* recrystallisation from hot MeOH. The crude *(+)-acid (+)-base salt* [which contains 91% of (+)-acid (+)-base and 9% of (−)-acid (+)-base] has $[\alpha]_{546}^{25}$ +424 (c 0.99, MeOH) and the more soluble crude *(−)-acid (+)-base salt* obtained by evaporation of the mother liquors [which contains 81% of (−)-acid (+)-base and 19% of (+)-acid (+)-base] has $[\alpha]_{546}^{25}$ −113 (c 0.95, MeOH). Pure ***(+)-acid (+)-base salt*** $[\alpha]_{546}^{25}$ +492 (c 1, MeOH) and pure ***(−)-acid (+)-base salt***, $[\alpha]_{546}^{25}$ −256 (c 1, MeOH) as obtained from the pure enantiomeric BNP acids and (+)-cinchonine are recrystallised from MeOH/EtOAc and MeOH/Me_2CO/EtOAc respectively. The BNP acids are obtained from the respective salts (e.g. 77g) in boiling EtOH (e.g. 500ml) and adding 6N aqueous HCl (e.g. 570ml) with vigorous stirring during 30 minutes while keeping the temperature between 75° and 80°. After cooling the BNP acid is collected, washed with H_2O (e.g. 5 x 90ml), and air dried to give (~50 yield of ~99% 'ee') of almost pure acid (by NMR and HPLC). BNP acids from the filtrates can be purified by recrystallisation from hot MeOH or EtOH and are sparingly soluble in H_2O. The solubilities at 25° in g/100ml are: 5.7±0.2 for enantiomers (EtOH) and 10.3±0.5 for racemate (EtOH); and 2.1±0.1 for enantiomers (MeOH) and 2.5±0.1 for racemate (MeOH). Two recrystallisations from EtOH of the BNP enantiomeric acids obtained did not alter the rotations at 25° which are (+) or (−): 595° ±7 (589nm), 624° ±7 (578nm), 720° ±8 (546nm), 1328 ±15 (436nm), 2050° ±25 (365nm) in MeOH; 574° ±16 (589nm), 602° ±17 (578nm), 694° ±20 (546nm), 1267 ±25 (436nm), 1828° ±40 (365nm) in EtOH. [Jacques & Fouquey *Org Synth* Coll Vol **8** 50 *1993*, DOI: 10.15227/orgsyn.067.0001; see also Kyba et al. *J Org Chem* **42** 4173 *1977*, DOI: 10.1021/jo00862a001].

The BNP acids, and their 3,3'-aryl derivatives, are useful asymmetric organocatalysts in being efficient ***Brønsted acid catalysts*** for enantioselective Mannich reactions. [Yamanaka et al. *J Am Chem Soc* **129** 6756 *2007*, DOI: 10.1021/ja0684803.] [For applications see Fieser **12** 49, **16** 25.]

2,2'-Bis(diphenylphosphino)-1,1'-binaphthyl (BINAP) *[RS* see *98327-87-8]* **[$(C_6H_5)_2PC_{10}H_6-]_2$, M 622.7, m 283-286°**, *[R-(+)-*see *76189-55-4]* **m 241-242°,** *[S-(-)-* see *76189-56-5]* **m 241-242°.** In addition to being ligands for Pd, Rh and Ru catalysts, *S*-BINAP also acts as an organocatalyst for Mirata-Baylis-Hillman reactions involving C-H activation, e.g. in the condensation of 5-formylpyrimidine and derivatives with methyl acrylate to form methyl β-hydroxy-β–(pyrimidin-5-yl)-α-methylenepropionates with moderate enantiomeric excess at the chiral hydoxy centre [Hayase et al. *Chem Commun* 1271 *1998*, DOI: 10.1039/A802594K].

Bode-Rovis-Enders NHC precatalysts

These are a group of 3,4-fused-2-aryl substituted 1,2,4-triazolium salt pre-catalysts, which when converted into the corresponding NHCs (N-heterocyclic carbenes) where C-5 of the heterocyclic ring becomes a carbene carbon atom, are ***organocatalysts*** that promote a wide variety of organic reactions. The carbene is usually generated *in situ* on addition of diisopropylamine or BTU. Among the reactions that these NHCs catalyse are cyclo-condensation reactions, enantioselective azadiene Diels-Alder reactions, aza-Claisen reactions, annulation reactions, formation of trisubstituted indanes *via* catalysed cascade annelations, desymmetrisation of cyclo-hexadienones, benzoin condensations, Stetter reaction, a^3 to d^3 Umpolung, transesterification, 1,2-additions, etc. [Bode *Speciality Chemicals Magazine* **27(6)** 28 pages *2007*, Moor & Rovis *Top Curr Chem* **291** 77-144 *2010*, DOI: 10.1007/978-3-642-02815-1_18, PMID: 21494949; Enders, Niemeier and Henseler *Chem Rev* **107** 5606-5655 *2007*, DOI: 10.1021/cr068372z.] Described below are such four chiral organoprecatalysts whose carbenes catalyse highly stereospecific reactions in good to very good yields and with very high enantiomeric excess(ee), and two related non-chiral salts which also catalyse non-chiral reactions in high yields.

(4aR,9aS)-4,4a,9,9a-Tetrahydro-1-oxa-4-azafluoren-3-one, **(4*aR*,9*aS*)-indeno[2,1-*b*]-1,4-oxazin-3(2*H*)-one)** *[862095-79-2]* **$C_{11}H_{11}NO_2$, M 189.2, m 180-183°(dec), $[\alpha]_D^{23}$ −17.3 (c 1.08, MeOH)**. This is the key chiral intermediate ***fluorine-3-one*** that uses **(+)-*cis-(1R,2S)-1-aminoindan-2-ol*** (see *[136030-00-7]*) for the preparation of chiral ***indeno-triazolo-oxazinium*** pre-catalysts. Details of its synthesis are not given here because they have been reported in great detail by Rovis and coworkers [Vora et al. *Org Synth* **87** 350 2010; DOI: 10.15227/orgsyn.087.0350], but the physical and spectroscopic properties, and final purification procedures are provided in order to assess the purity of the commercial product and to purify it further if necessary. Thus the aminoindanol is converted to the –ONa salt with NaH/THF that is reacted with $ClCH_2CO_2Et$ to form the ***fluorenone***. The final purification is carried out by stirring vigorously the crude light brown solid with hexanes under a reflux condenser in an oil bath at 70° for 2 hours, cooling to ~25°, filtering the solid off and drying it at 70° *in vacuo* (2mm Hg) for 1 hour to give the ***fluoreneone*** as a white solid in 80-86% yield of almost analytical (C, H and N) purity. The ^{1}H NMR (400MHz, Me_2CO-d_6) with δ at 2.97 (d, *J* = 16.8Hz, 1H), 3.23 (dd, *J* = 16.6, 4.9Hz, 1H), 3.89 (d, *J* = 16.2Hz, 1H), 4.05 (d, *J* = 16.2Hz, 1H), 4.57 (t, *J* = 4.6Hz, 1H), 4.82 (t, *J* = 4.0Hz, 1H), 7.23-7.29 (m, 3H), 7.46-7.49 (m, 1H), 8.21 (br s, 1H); and for IR, ^{13}C NMR and HRMS (APCI$^+$) see references. The enantiomeric ***(4aS,9aR)-4,4a,9,9a-1-oxa-4-azafluorenone*** can be similarly prepared by starting from (–)-*cis-(1S,2R)-1-aminoindan-2-ol* (see *[126456-43-7]*) and differs only in the sign of the specific rotation.

(5aR,10bS)–5a,10b-Dihydro-2-(2,4,6-trimethylphenyl)-4H,6H-indeno[2,1-b]-1,2,4-triazolo[4,3-d]-1,4-oxazinium chloride monohydrate *[903571-02-8 for anhydrous]* **$C_{21}H_{22}ClN_3O.H_2O$, M 385.9, m 217-219°, 226-230° (anhydrous ?), $[\alpha]_D^{20}$ −133.5° (c 1.00, EtOH), $[\alpha]_D^{20}$ −156.0 (c 1.00, $CHCl_3$).** Here also details of its synthesis are not given because they have been reported in great detail by Bode and coworkers [see Struble & Bode *Org Synth* **87** 362 2010, DOI: 10.15227/orgsyn.087.0362], but the physical and spectroscopic properties, and final purification procedures are provided in order to assess the purity of the commercial products and to purify further if necessary. The preceding **(4*aR*,9*aS*)-*fluorenone*** is treated with Me_3OBF_4/CH_2Cl_2 (~25°/16 hours) then $NaHCO_3$, and dried in a high vacuum (12 hours) to give a 92-93% yield (95% purity) of ***(4aR,9aS)-3-methoxy-2,4a,9,9a-tetra-hydroindeno[2,1-b][1,4]oxazine*** as a pale brown solid with **m 73-75°**, **$[\alpha]_D^{20}$ −15.7 (c 1.26, EtOH)**, and consistent IR, NMR and MS. This ***methoxy-oxazine*** is then added to a solution containing one equivalent of ***2,4,6-trimethylphenylhydrazinium chloride**** in MeOH and a catalytic amount of 4M HCl/dioxane (obligatory) and heated at 60° under a reflux condenser and N_2 atmosphere for 48 hours. The solvent is removed *in vacuo* and the crude orange solid residue is suspended in EtOAc (must be absolutely dry for high yields; dry by passing through an Al_2O_3 drying column in an argon atmosphere) with vigorous stirring

at 90° (under N_2) for 30 minutes, cooled to 0°, and the light yellow solid is filtered off, washed with EtOAc and dried at ~25° (<1 mbar, 12 hours) to provide an 81-82% yield of ***(Z)-2-mesityl-1-[(4aR,9aS)-4,4a,9,9a-tetrahydroindeno-[2,1b][1,4]-oxazin-3-(2H)ylidene)hydrazinium chloride*** as a light yellow powder which has **m 200-201°(dec)**, $[\alpha]_D^{20}$ **+66.7 (c 1.42, EtOH),** and consistent IR, NMR and MS. The precatalyst is then obtained by cyclising the hydrazium chloride with triethylorthoformate (8 equivalents) in chlorobenzene (dried over 4Å molecular sieves) and anhydrous HCl (4M in dioxane, 1 equivalent) by stirring under N_2 at 120° for 1 hour, and the clear brown solution is evaporated *in vacuo*. The brown residue is treated with toluene, heated at 120° for 5 minutes, cooled in ice/water, the white solid is filtered off and the filtrate is evaporated at 60° *in vacuo* and dried at high vacuum (<0.75mm). The brown residue dissolves in toluene at 60° within 3-5 minutes then a white precipitate is formed rapidly. The cooled solution is filtered, the white solid is washed with a little toluene and dried at high vacuum (<1 mbar) to constant weight (>24 hours) to give a 60-64% yield of the desired ***(5aR,10bS)-oxazinium chloride*** pre-catalyst as an analytically pure (C, H and N) white powder with **m 217-219°**. The ^{1}H NMR (400MHz, DMSO-d_6) has δ at 212 (s, 6H), 2.37 (s, 3H), 3.16 (d, *J* = 17.0Hz, 1H), 3.50 (dd, *J* = 16.9, 4.8Hz, 1H), 4.99 (t, *J* = 4.4Hz, 1H), 5.08 (d, *J* = 16.0Hz, 1H), 5.26 (d, *J* = 16.0Hz, 1H), 6.12 (d, *J* = 4.0Hz, 1H), 7.21 (s, 2H), 7.33-7.45 (m, 3H), 7.65 (d, *J* = 7.2Hz, 1H), 11.34 (s, 1H); and for IR, ^{13}C NMR and HRMS (ESI) see references. The enantiomeric ***(5aS,10bR)–5a,10b-Dihydro-2-(2,4,6-trimethylphenyl)-4H,6H-indeno[2,1-b]-1,2,4-tri-azolo[4,3-d]-1,4-oxazinium chloride monohydrate*** **$C_{21}H_{22}ClN_3O.H_2O$, M 385.9, m 212-216°, $[\alpha]_D^{20}$ +158.0 (c 1.00, $CHCl_3$)** can be prepared by starting from the enantiomeric ***(4aS,9aR)-4,4a,9,9a-tetrahydro-1-oxa-4-azafluoren-3-one*** and is purified in the same way.

*The purity of ***2,4,6-mesitylhydrazinium chloride*** *[76195-82-9]* **M 186.7** is critical for obtaining pure mesityl-pre-catalysts. The preparation from 2,4,6-trimethylaniline is described in great detail by Struble and Bode [*Org Synth* **87** 362 *2010*, DOI: 10.15227/orgsyn.087.0362] who emphasise that it is imperative for diazotisation and reduction to be strictly monitored. It is paramount that $NaNO_2$ and $SnCl_2$ solutions be added at such a rate that the internal temperature is carefully monitored at <5°. The final purification is by suspending the salt (~7.5g) in absolute EtOH/Et_2O (1:1, 15ml), and sonicating (85W) for 5 minutes while maintaining the temperature below 30°. The pale orange solid is filtered off using a fine porosity filter, washed with EtOH/Et_2O (1:1, 3 x 5ml), and dried under high vacuum (~25°, <0.75mm) for 12 hours to give analytically pure (C, H and N) ***2,4,6-mesitylhydrazinium chloride*** (36-40% yield). ***Note*** that the material may be very fine to filter in a short period, in which case it should be dissolved in dry MeOH and concentrated by evaporation to give a more crystalline product that can be filtered more easily. *Alternatively*, it should be collected by centrifugation, decantation of the supernatant, washed with EtOH/Et_2O (1:1, 3 x 5ml) also by decantation and sonication in the same way in between washes. It has **m 195-197°(dec)** (**167-173°** also reported); the ^{1}H NMR (400MHz, DMSO-d_6) has δ at 2.20 (s, 3H), 2.35 (s, 6H), 6.60 (br s, 1H), 6.86 (s, 2H), 9.27 (variable br s, 3H, N*H*,NH_2); and for IR, ^{13}C NMR and HRMS (ESI) see references. [Struble and Bode *Org Synth* **87** 362 *2010*, DOI: 10.15227/orgsyn.087.0362].

(5aR,10bS)–5a,10b-Dihydro-2-(pentafluorophenyl)-4H,6H-indeno[2,1-b]-1,2,4-triazolo[4,3-d]-1,4-oxazinium tetrafluoroborate *[740816-14-2]* **$C_{18}H_{11}BF_9N_3O$, M 467.1, m 223-226°, 235°(dec), $[\alpha]_D^{23}$ –130.8 (c 1.28, MeCN)**. Details of its synthesis are not given here because they have been reported in great detail by Rovis and coworkers [Vora et al. *Org Synth* **87** 350 *2010*, DOI: 10.15227/orgsyn.087.0350], but the physical and spectroscopic properties, and final purification procedures are provided in order to assess the purity of the commercial product and to purify it further if necessary. The common intermediate ***(4aR,9aS)-4,4a,9,9a-1-oxa-4-azafluorenone*** (1.0 equivalent see *[862095-79-2]* above) is added with stirring, and under anhydrous conditions in an argon atmosphere, to a mixture of Me_3OBF_4 (1.0 equivalent ***and no more***, care **Toxic**) in CH_2Cl_2 (containing <20ppm of H_2O, by filtering through activated Al_2O_3 under argon) and stirred at ~25° until the homogeneous reaction is complete (1-2 hours by ^{1}H NMR). Pentafluorophenylhydrazine (1.0 equivalent) is then added to the mixture under argon, stirred until the reaction is complete (~4 hours, when ^{1}H NMR signals of activated amidate disappear), the mixture is evaporated *in vacuo*, dried at 100°/2mm; then chlorobenzene (as solvent) followed by triethyl orthoformate (2.5 equivalents) are added and heated under reflux to 130° with stirring (open to atmosphere) for 24 hours. A second portion of $(EtO)_2O$ (2.5 equivalents, syringe) is added and stirred for a further 24 hours, and this process is repeated once more. Excess of toluene is added, the slurry is filtered, and the solid washed with toluene and hexanes. The solid is triturated with EtOAc and MeOH (4:1), filtered through a medium frit funnel, washed with cold EtOAc to give the ***oxazinium tetrafluoroborate*** pre-catalyst which is dried (100°/2mm) to constant weight (~ 1 hour, 61-64% yield), gave an off white solid that analysed as the ***~0.5 hydrate***. The ^{1}H NMR (400MHz, Me_2CO-d_6) has δ at 3.28 (d, *J* = 17.2Hz, 1H), 3.55 (dd, *J* = 17.1, 4.9Hz, 1H), 5.19 (t, *J* = 4.5Hz, 1H), 5.25 (d, *J* = 16.4Hz, 1H), 5.39 (d, *J* = 16.4Hz, 1H), 6.33 (d, *J* = 16.4

Hz, 1H), 6.33 (d, *J* = 4.0Hz, 1H), 7.34 (t, *J* = 7.3Hz, 1H), 7.43 (q, *J* = 7.4Hz, 2H), 7.63 (d, *J* = 7.6Hz, 1H),11.09 (br s, 1H); for IR, ^{13}C NMR and HRMS (APCI+) see references. [see Vora et al. above].

The enantiomeric ***(5aS,10bR)–5a,10b-Dihydro-2-(pentafluorophenyl)-4H,6H-indeno[2,1-b]-1,2,4-triazolo-[4,3-d]-1,4-oxazinium tetrafluoroborate*** can be prepared and purified in a similar way but starting with the enantiomeric ***(4aS,9aR)-4,4a,9,9a-1-oxa-4-azafluorenone***

2-Pentafluorophenyl-6,7-dihydro-5H-pyrrolo[2,1-c][1,2,4]triazol-2-ium tetrafluoroborate **(2-pentafluoro-2,5,6,7-tetrahydro[2,1-*c*][1.2.4]-tetrazol-4-ium tetrafluoroborate)** *[862095-91-8]* **$C_{11}H_7BF_9N_3$, M 363.0, m 242-245°, 245°.** Details of its synthesis are not given here because they have been reported in great detail by Rovis and coworkers [Vora et al. *Org Synth* **87** 350 2010, DOI: 10.15227/orgsyn.087.0350], but the physical and spectroscopic properties, and final purification procedures are provided in order to assess the purity of the commercial product and to purify it further if necessary. Starting with 2-pyrrolidinone (1.0 equivalent, *[616-45-5]*) which is converted into 2-methoxy-3,4-dihydro-5*H*-pyrrolidinium tetrafluoroborate by reaction with trimethyloxonium tetrafluoroborate (1.0 equivalent) in CH_2Cl_2 under argon with stirring at ~25° until homogeneous, then pentafluorophenylhydrazine (1.0 equivalent, [828-73-9]) is added with stirring for 4 hours (when amidate signals disappear in the ^{1}H NMR spectrum), the mixure is evaporated *in vacuo*, chlorobenzene and triethyl orthoformate (2.0 equivalents, syringe) are added and heated at 130° for 24 hours under a reflux condenser open to the atmosphere. Addition of triethyl orthoformate (2.0 equivalents, syringe) and heating is repeated for 24 hours, followed by evaporation to dryness *in vacuo*, excess of toluene is added to the residue and the slurry is filtered, and the solid is washed with toluene and hexanes, then with EtOAc. Final purification is by washing well with cold EtOAc, and the off-white solid is thoroughly dried at 100° *in vacuo* (2mm) to constant weight (~ 1 hour) to give the ***pre-catalyst tetrafluoroborate*** in 74-76% yield. The ^{1}H NMR (400MHz, Me_2CO-d_6) has δ at 3.00 (ddd, *J* = 15.0, 7.7, 7.7Hz, 2H), 3.42 (t, *J* = 8.0Hz, 2H), 4.76 (t, *J* = 8.0Hz, 2H), 10.19 (s, 1H); and for IR, ^{13}C NMR and HRMS (APCI+) see references. [Vora et al. *Org Synth* **87** 350 *2010*, DOI: 10.15227/orgsyn.087.0350].

2-Mesityl-6,7-dihydro-5H-pyrrolo[2,1-c][1,2,4]triazol-2-ium chloride **(2-mesityl-2,5,6,7-tetrahydropyrrolo[2,1-*c*][1.2.4]-tetrazol-4-ium chloride) [Bode Catalyst 3] $C_{14}H_{18}lN_3$, M 263.8, m 202-205°.** This is prepared and purified in much the same way as the preceding salt except for using trimethyloxonium chloride for preparing the ethoxy pyrrolidinium chloride followed by reaction with mesitylhydrazinium chloride instead of perfluorophenyl-hydrazine. This is a highly selective, ***N-heterocyclic carbene (NHC) Bode catalyst*** that promotes aza-Diels-Alder reactions with ***exceptional*** diastereo- and enantio- selectivities (>99% 'ee') [He et al. *J Am Chem Soc* **128** 8418 *2006*, DOI: 10.1021/ja062707c].

Boron trifluoride diethyl etherate *[109-63-7]* **$(C_2H_5)_2O.BF_3$, M 141.9, m -58°, b 46°/10mm, 126-129°/atm, d_4^{25} 1.15, n_D^{20} 1.344.** If the liquid has darkened due to oxidation by air it can be redistilled to give a colourless liquid. It is recommended that excess dry Et_2O (10ml) be added to the etherate (500ml) and distilled from CaH_2 (2g) in an all glass still at (b 46°/10mm) which removes volatile acids and avoids bumping [Zwiefel & Brown *Organic Reactions* **13** 28 *1963*, DOI: 10.1002/0471264180.or013.01]. It is a fuming liquid which hydrolyses in moist air forming highly toxic fluorides on decomposition. Store it under N_2 or argon and work in an efficient fumecupboard. It is a versatile ***Lewis acid*** for catalysis, acetylation, alkylation, dehydration, condensations, Beckmann rearrangements and polymerisation reactions. It catalyses the synthesis of cyclopentyl- and cycloheptyl[*b*]indoles from aryl cyclopropyl ketones *via* [3+2] cycloaddition [Venkatesh et al. *Eur J Org Chem* 5378 *2006*, DOI: 10.1002/ejoc.200600342], and is a mild and efficient catalyst for Beckmann rearrangement in anhydrous MeCN [An et al. *Chin J Chem* **29** 947 *2011*, DOI: 10.1002/cjoc.201190193]. [*Beilstein* **1** IV 1321; for applications see Fieser in vols **1** to **17** 52.] It is available as a ***BF_3.EtNH$_2$ complex*** *[75-23-0]* **M 112.9, m 85-89°** [*Beilstein* **4** II 588]; and as a 50% w/w ***BF_3.MeOH*** solution *[373-23-0]* **M 99.9** in MeOH, is used for making germinal bis-peroxides from ketals and enol ethers with *t*-BuOOH [Terent'ev et al. *Synthesis* 2215 *2005*, DOI: 10.1055/s-2005-872093], and used for the mild deacetylation of amines [Miltsov et al. *Tetrahedron Lett* **44** 2301 *2003*, DOI: 10.1016/S0040-4039(03)00271-5.] [*Beilstein* **1** IV 1220; Fieser **1** 73, **9** 64.]

CBS (Corey-Bakshi-Shibata) Catalysts:

R-(+)-2-Methyl-CBS-oxazaborolidine **(*R*-1-methyl-3,3-diphenyltetrahydro-1*H*,3*H*-pyrrolo[1,2-*c*][1,3,2]-oxazaborole, α,α–diphenyl-D-prolinolmethylboronic acid cyclamide)** *[112022-83-0]* **$C_{18}H_{20}BNO$, M 277.2, m 74-87°, 77-82°, 85-95°, $[\alpha]_D^{22}$ +76.8 (c 1, toluene) and *S*-(-)-2-methyl-CBS-oxazaborolidine** *[112022-81-8]* **$C_{18}H_{20}BNO$, M 277.2, m 85-95°.** These CBS (**C**orey-**B**akshi-**S**hibata) catalysts effect the asym-

metric reduction of *pro*-chiral ketones, the stereoselective synthesis of α-amino acids and α-hydroxy acids, the preparation of ferrocenyl diols and propargyl alcohols. The catalyst is usually best prepared *in situ* from the respective α,α–diphenyl-(*R* or *S*)-prolinol [*22348-32-9 or 79815-20-6*] and a slight excess of trimethylboroxine [*823-96-1*]. Their suitability are determined by capillary GC [DB-1. 200º, retention time 4.9 minutes] and ^{1}H NMR, where possible impurities have signals at δ ($CDCl_3$) for starting prolinol at ~ 4.3(t), trimethylboroxine at 0.45(s), the B—OH intermediate at 0.35 to -0.50 multiple B-Me singlet's, and/or the ring-B-O-B(Me)-OH intermediate at -0.25 B-Me brs. An ***analytical sample*** is obtained by dissolving it in toluene, filtering, then evaporating at 50º/0.001mm to give the catalyst as a white solid. Store it under dry N_2 or argon. The ^{1}H NMR (0.2M in $CDCl_3$) has δ at 7.65-7.15 (m, 10 H, ArH), 4.4 (dd, *J* = 5.8, 10.0 Hz, 1 H, C3a-H), 3.45-3.30 (m, 1 H, C6-H), 3.15-3.00 (m, 1 H, C6-H), 1.90-1.55 (m, 3 H, C4-H, C5-H_2), 0.95-0.75 (m, 1 H, C4-H), 0.40 (s, 3 H, B-CH_3); and for IR see references. They are also available commercially as 1M solutions in toluene or tetrahydrofuran. [Mathre et al. *J Org Chem* **56** 751 *1991*, DOI: 10.1021/jo00002a049; Corey et al. *J Am Chem Soc* **124** 3808 *2002*, DOI: 10.1021/ja025848x; Ryu & Corey *J Am Chem Soc* **126** 8106 *2004*, DOI: 10.1021/ja0475959; Ryu et al. *J Am Chem Soc* **124** 9992 *2002*, DOI: 10.1021/ja027468h; Hu et al. *J Am Chem Soc* **126** 13708 *2004*, DOI: 10.1021/ja046154m; Quallich & Woodall *Tetrahedron Lett* **34** 785 1993, DOI: 10.1016/0040-4039(93)89012-F.] They are excellent catalysts for asymmetric reductions [Corey & Helal *Angew Chem Int Ed* **37** 1986 *1998*, DOI: 10.1002/(SICI)1521-3773(19980817)37:15<1986::AID-ANIE1986>3.0.CO;2-Z; Baar et al. *J Am Chem Soc* **126** 8216 *2004*, DOI: 10.1021/ja040021j].

R-(+)- and S-(–)- 2-o-Tolyl-CBS-oxazaborolidine **{*R*- and *S*- 3,3-diphenyl-1-*o*-tolyltetrahydro-1*H*,3*H*-pyrrolo[1,2-*c*] [1,3,2]-oxazaborole}** *[R-865812-10-8; S 463941-07-3]* **$C_{24}H_{24}BNO$, M 353.3, $[\alpha]_D^{20}$ +18 and −18 (c 1, toluene).** These Corey-Bakshi-Shibata (CBS) oxazaborolidines are available commercially as 0.5M solutions in toluene (d_4^{25} 0.9009g/ml). They produce chiral ***Lewis acids*** when protonated with trifluoromethanesulfonamide and are used in enantioselective Diels-Alder reactions. They are prepared and purified as for the 2-methyl-CBS-oxazaborolidines above except that they are obtained as liquids on evaporation of the toluene solutions. [For applications see Ryu & Corey *J Am Chem Soc* **125** 6388 *2003*, DOI: 10.1021/ja035393r; Stemmler *Synlett* 997 *2007*, DOI: 10.1055/s-2007-973876; Corey et al. *J Am Chem Soc* **109** 7925 *1987*, DOI: 10.1021/ja00259a075; Cho & Kim *Tetrahedron: Asymmetry* **12** 2043 *2001*, DOI: 10.1016/S0957-4166(01)00359-7; Cho et al. *JCS Perkin Trans I* 1204 *2001*, DOI: 10.1039/B010155I; Lebsack et al. *J Am Chem Soc* **123** 4851 *2001*, DOI: 10.1021/ja015802o; and references therein.]

2-Methyl-CBS-oxazaborolidines derived from 1S,2R-(-)- [126456-43-7] and 1R,2S-(+) –cis-1-Amino-2-hydroxyindane *[136030-00-7]* are also best prepared *in situ* by reaction of *cis*-1-aminoindan-2-ol (1*S*,2*R* see [*126456-43-7*]; 1*R*,2*S* see [*136030-00-7*]) with trimethylboroxine (see *[823-96-1]*) in a solvent (usually toluene), and they are ***sensitive to moisture and air***. They catalyse the reduction of ketones and α-haloketones to their respective alcohols by ***BH_3*** or some of its complexes, e.g. BH_3-DMS, BH_3-THF, with high stereospecificities ('ee' above 80%) at room temperature or below because of the steric effects of the methyl and indane groups around the heterocyclic boron atom. In a ***typical preparation***, trimethylboroxine (0.19ml, 1.34mmol) is added to a solution of pure 1*R*,2*S*-1-aminoindan-2-ol (2.01mmol) in dry toluene (10ml), stirred at ~25º for 30 minutes, more toluene (10ml) is added, and the solution is concentrated by distillation to *ca* 2ml. The procedure is repeated twice then the toluene is removed *in vacuo* to give the ***CBS-catalyst*** as a white solid. Dry THF (~2ml) is added to produce an approximately 1.0M solution of the catalyst in THF for later reactions. The solution should be stored under dry N_2 or argon and is stable for about 48 hours. For reduction reactions, the borane hydride (1.83mmol) is added to a solution of the chiral B-methylaminoindanol (0.17ml, 0.166mmol) in the desired solvent (e.g. toluene) (2ml) stirred under N_2 at ~25º for 30 minutes, cooled to 0º and the ketone (1.67mmol) in the desired solvent (e.g. toluene, 1ml) is added *via* a cannula, stirred at ~25º for 30 minutes, quenched with MeOH (5ml), H_2O (20ml) is added, the MeOH is removed *in vacuo*, and the resulting optically active alcohol is isolated from the aqueous solution. [Gilmore & Jones *Tetrahedron*: *Asymmetry* **14** 2115 *2003*, DOI: 10.1016/S0957-4166(01)00359-7; Hong et al. *Tetrahedron Lett* **35** 6631 *1994*, DOI: 10.1016/S0040-4039(00)73453-8.]

4-Dimethylaminopyridine (DMAP) *[1122-58-3]* **$C_7H_{10}N_2$, M 122.2, m 108-109º, 112-113º, b 191º/atm (under N_2), $pK^{5.4}$ 10.14, pK^{20} 9.70, pK^{25} 9.61, pK^{35} 9.33 (in H_2O).** Recrystallise DMAP from toluene [Sadownik et al. *J Am Chem Soc* **108** 7789 *1986*, DOI: 10.1021/ja00284a050], or from EtOH or *C_6H_6 and dried *in vacuo*. It is prepared easily from 4-chloropyridine and Me_2NH in EtOH (2 hours/100º, or in a sealed tube for 12 hours/115-130º, Wibaut & Broekman *Recl Trav Chim Pays-Bas* **80** 309 *1961*, DOI: 10.1002/recl.

19610800309), or in very high yield from 4-trimethylsilyloxypyridine with $Me_2NH/HgCl_2$ (48 hours at 120°, Vorbrüggen *Angew Chem Int Ed* **11** 305 *1972*, DOI: 10.1002/anie.197203041). This ***organocatalyst*** is a strong base (see pKa) and promotes a large variety of acylation reactions, e.g. of *m*-chloroaniline and of benzyl alcohol at relative rates that are 3.14 x 10^6 and 3.45 x 10^8 compared with those of the uncatalysed reactions. It is useful industrially. The acylating agent is an acid chloride or an acid anhydride. Typically, catalytic amounts of DMAP are used together with one equivalent of a tertiary base, e.g. Me_3N, to neutralise the anion formed, i.e. Cl^- from the acid chloride or AcO^- from the anhydride, and to avoid protonating the catalyst. [Scriven *Chem Soc Rev* **12** 129 *1983*, DOI: 10.1039/CS9831200129.] Its ***picrate*** has **m 108°** (EtOH), and its ***tetrafluoroborate salt*** has **m 126°** (from MeCN/Et_2O). The UV has λ_{max} (ε) at 261nm (18,300 $cm^2.mole^{-1}$) for ***free base*** at pH >12.0, and 280.5nm (19,600 $cm^2.mole^{-1}$) for the ***mono-cation*** at pH <7.0 in H_2O (Essery & Schofield *J Chem Soc* 3939 *1961*, DOI: 10.1039/JR9610003939); and the IR ($CHCl_3$) has ν_{max} (ε_A) at 2840 (sh, 45), 1448 (95, Me bend)), 1380 (155, CN str), 1346 (35), 1179 (35, Me_2 rock), 1108 (30, Me_2 rock), 1063 (35, NMe_2, C-N-C stretch) and 951 (55, NMe_2, C-N-C stretch) cm^{-1} (Katritzky & Jones *J Chem Soc* 3674 *1959*, DOI: 10.1039/JR9590003674). [*Beilstein* **22** III/IV 4101, **22/9** V 112; for applications see Fieser vols **3** to **16**.]
DMAP is an efficient ***desymmetrisation*** catalyst. [Willis *JCS Perkin 1* 1765 *1999*, DOI: 10.1039/A906269B.] Thus it allows the use of an achiral or *meso* molecule, e.g. 3-substituted glutaric anhydride to react with chiral alcohols e.g. *R*-1-(1'-naphthyl)ethanol to produce (1'*R*,3*R*)-1(1'-naphthyl)ethyl methyl 3-substituted-pentanoate di-esters (after treatment with diazomethane), which are now chiral at C-3. The achiral carbon atom at C-3 in the glutaric anhydride becomes chiral in the pentanoate (mono-ester of glutarate) produced. [Theisen & Heathcock *J Org Chem* **53** 2374 *1988*, DOI: 10.1021/jo00245a051; Theisen & Heathcock *J Org Chem* **58** 142 *1993*, DOI: 10.1021/jo00053a027.] § It is commercially available in 0.04mmol impregnated tablets, and a polystyrene supported version (PS-DMAP) with a loading of ~3.0mmol/g is also available for recyclable acylation purposes.

N,N'*-Dimethylethylenediamine [DMEDA, bis(methylamino)ethane]** *[110-70-3]* **$C_4H_{12}N_2$, M 88.2, 110-112°/750mm, 119°/atm, d^{25} 0.819 g/ml, n_D^{20} 1.431, pK_1^0 8.30, pK_2^0 10.89, pK_1^{25} 6.80 (7.01), pK_2^{25} 9.88 (10.03).** It has been prepared in several ways, but most commonly when ethylene dibromide (1mol), $MeNH_2$ (5mols) and H_2O (*ca* 3mols) are boiled under reflux for 15 hours. A 32% aqueous solution of NaOH is added, excess $MeNH_2$ is distilled out, and the rest of the liquid is distilled off. The diamine in the distillate is salted out with solid NaOH, dried (Na_2CO_3, or KOH), filtered and fractionally distilled (in *ca* 50% yield) until the NMR indicates that it is free from impurties. Store it in sealed containers under N_2 or argon as it is a strong base (see pKa). The ***N,N'-bis(p-toluenesulfonamide) has **m 164°** (from AcOH), ***N,N'-bis(benzenesulfonamide)*** has **m 129-131°** (from EtOH and AcOH, or EtOAc), the ***N,N'-bis(benzamide)*** has **m 177-178°** (from $*C_6H_6$), the ***monopicrate*** has **m 140°** (plates from EtOH or Me_2CO) and the ***dihydrochloride*** decomposes at **m 235°**. [Kermack & Wight *J Chem Soc* 1421 *1935*, DOI: 10.1039/JR9350001421; Boon *J Chem Soc* 307 *1947*, DOI: 10.1039/JR9470000307; Woodburn & O'gee *J Org Chem* **17** 1235 *1953*, DOI: 10.1021/jo50009a008; Bauer *J Am Chem Soc* **78** 1945 *1956*, DOI: 10.1021/ja01590a049.]
In the presence of resublimed *tert*-BuOK (1.5mmol), DMEDA (0.1mmol) ***catalyses*** cross-coupling between aryl and substituted aryl halides (0.5mmol) with arenes, e.g, *benzene, naphthalene (0.5mmol) at 80°/~4 hours, to provide the corresponding biaryls in high yields (~70 to >90%). *Ortho* substitution leads to decreased yields, and replacing $KOBu^t$ with other bases (e.g. KOH, Na_2CO_3, KOAc, *tert*-BuONa, or *tert*-BuOLi) results in no reaction or extremely low yields. Of the amines studied, DMEDA is the ***most effective catalyst*** and evidence is presented that a ***radical reaction*** is involved. ***It is the first example of a cross-coupling reaction that does not require a metal***. [Liu et al. *J Am Chem Soc* **132** 16737 *2010*, DOI: 10.1021/ja103050x; *Beilstein* **4** H 250, **4** I 425, **4** II 689, **4** III 512, **4** IV 1171.]

R*-(+)-Indoline-2-carboxylic acid** *[98167-06 -7]* **$C_9H_9NO_2$, M 163.2, m 177°(dec), $[\alpha]_D^{20}$ +11.0 (c 0.3, MeOH).** Purify it as for the ***S-enantiomer below. The ***R-(+)-hydrochloride*** has *[172152-19-1]*. It is a proline based organocatalyst which promotes the enantioselective formation of cyclopropanes by reaction between 2-(dimethyl-λ4-sulfanylidene)-1-phenyl-ethanone (for stable sulfonium ylides see Ratts & Yao *J Org Chem* **31** 1185 *1966*, DOI: 10.1021/jo01342a047) and but-2-enals in high yields and very high stereoselectivity involving ***Direct Electrostatic Activation*** (**DEA**) [Kunz & MacMillan *J Am Chem Soc* **127** 3240 *2005*, DOI: 10.1021/ja042774b.]

chloride *[82923-76-0]* **M 199.7, m 133°(dec), [α] $^{20}_{D}$ -70 (c 1, EtOH)** crystallises from Et_2O/propan-2-ol. It is a proline based organocatalyst which promotes the enantioselective formation of cyclopropanes by reaction between 2-(dimethyl-λ4-sulfanylidene)-1-phenyl-ethanone (for stable sulfonium ylides see Ratts & Yao *J Org Chem* **31** 1185 *1966*, DOI: 10.1021/jo01342a047) and but-2-enals in high yields and very high stereoselectivity involving Direct Electrostatic Activation (DEA) [Kunz & MacMillan *J Am Chem Soc* **127** 3240 *2005*, DOI: 10.1021/ja042774b.]

α-Methyl-L-proline (*S*-2-methylproline) *[42856-71-3]* **$C_6H_{11}NO_2$, M 129.2, m 248-252°(dec), [α] $^{25}_{D}$ -75 (c 2.0, MeOH), and (*R*-2-methylproline)** *[58123-62-9]***.** This derivative catalyses reactions similar to those of proline. The general three-step synthesis from proline devised by Seebach and co-workers provides enantiomerically pure compound [*Helv Chim Acta* **64** 2704 *1981*, DOI: 10.1002/hlca.19810640829; *J Am Chem Soc* **105** 5390 *1983*, DOI: 10.1021/ja00354a034; Beck et al. *Org Synth* **72** 62 *1993*, DOI: 10.15227/orgsyn.072.0062]. It has been prepared on a 20-40g scale starting from *S*- or *R*- proline which is converted into ***2S,5S- (or 2R,5S)- 2-tert*-butyl-1-aza-3-oxabicyclo[3.3.0]octan-4-one** (*tert*-BuCHO, CF_3CO_2H as catalyst, in pentane and reflux for 114 hours with removal of H_2O) in 67-74% yield, which is methylated to ***2S,5S- (or 2R,5S)- 2-tert*-butyl-5-methyl-1-aza-3-oxabicyclo[3.3.0]octan-4-one** *[86046-11-9]* (MeI, *iso*-Pr_2NLi/THF/-78°) with ***complete retention of configuration*** at C-5 in 93-95% yield; and hydrolysed (1.3M HCl/reflux for 1 hour, or 15% aqueous HBr/~25° for 8 hours) to give the respective ***2-methyl-proline hydrochloride*** which is purified through a Dowex 50W x 8 (H^+ form) column by washing with H_2O, then eluting with 3N aqueous NH_3 and evaporating to give the free ***2-methylproline*** in 85-90% yield. The last step is apparently quite tedious to carry out and is time consuming. The following procedure is more convenient and gives better than 90% yields of **pure *2-methylproline***. The above butyl-methyl-azaoxa-bicyclooctanone (13.4mmol) in MeOH/H_2O (6:1, 35ml) is treated with Silica gel 200-400 mesh, 60Å (3.0g) and stirred overnight. The silica gel is filtered off, washed with MeOH, the combined washings and filtrate are evaporated *in vacuo*, the pale yellow residue is dissolved in $CHCl_3$/MeOH (20:1), filtered through a 0.45μ filter disk (Acrodisk® CR PTFE), evaporated to dryness and the residue is triturated with Et_2O and dried *in vacuo*. Although it may be yellow in colour, it is almost spectroscopically pure, and can be purified further by dissolving in MeOH, treating with activated charcoal (5% w/w), filtering the whole suspension through Celite and evaporating. It can be crystallised by slow evaporation of the $CHCl_3$/MeOH solution, or from an MeOH/Et_2O mixture to give a first crop (50-70% yield) of white crystals leaving remaining *2-methylproline* and traces of yellow impurities in the mother liquors. Additional product crystallisation can be achieved by vapour diffusion of the supernatant against Et_2O in a closed desiccator. It also crystallises nicely from MeOH/EtOAc in colourless plates, unlike many α-amino acids. [Genin et al. *Tetrahedron Lett* **35** 4967 *1994,* DOI: 10.1016/S0040-4039(00)73294-1.]

S-2-Methylproline with $[\alpha]_D$ -72.1 (c 1.0, MeOH) was shown to have an enantiomeric excess 'ee' of 99.0 ±0.5% by chiral capillary gas chromatography. For this purpose the amino acid (5mg) is heated with *iso*-propyl isocyanate (0.3ml) in CH_2Cl_2 (0.3ml) at 100° for 15 minutes, cooled, excess of volatiles are removed by a strong stream of dry air, the residue is dissolved in Et_2O (1ml), filtered through cotton wool and 10μl applied to the chiral capillary column. A Chirasil-Val fused-silica capillary column of Machery-Nagel (25m, 0.4mm) in a Carlo-Erba-Fraftovap 4160 HR GC unit has been used. The column was heated at 160° for 15 minutes then raised by 2°/min up to 200° (argon as carrier gas ?). The amino acid has ^{1}H NMR (200MHz, D_2O, HDO at d 4.80) with δ at 1.52 (s, 3H, C***H***$_3$), 1.75-2.40 (m, 4H, 3-C***H***$_2$ + 4-C***H***$_2$), and 3.20-3.45 (m, 2H, 5-C***H***$_2$); and its ^{13}C{^{1}H decoupled}NMR (50MHz, D_2O) has δ at 179.87 (***C***O_2H), 73.2 (***C***-2), 48.06 (***C***H_3-2), 38.27 (N-***C***-5), 25-85 (***C***-3) and 23.99 (***C***-4). [Beck et al. *Org Synth* **72** 62 *1993*, DOI: 10.15227/orgsyn.072.0062]. ***S-2-Methylproline hydrobromide*** *[42856-71-3]*, prepared, by hydrolysis with 15% aqueous HBr (see above) evaporating and triturating with dry Et_2O, as colourless crystals (80%), has **m 136-137°(dec), [α] $^{20}_{D}$ -28.9 (c 1.0, MeOH)** and its ^{1}H NMR (200MHz, D_2O, HDO at d 4.70) has δ at 1.60 (s, 3H, C***H***$_3$), 1.80-2.45 (m, 4H, 3-C***H***$_2$ + 4-C***H***$_2$), and 3.36 (t, 2H, *J* = 7 Hz, 5-C***H***$_2$) [Seebach et al. *J Am Chem Soc* **105** 5390 *1983*, DOI: 10.1021/ja00354a034; Overberger & Jon *J Polym Sci, Polym Sci Ed* **15** 1413 *1977*, DOI: 10.1002/pol.1977.170150612].

α-Methyl-DL-proline **(*RS*-2-methylproline)** *[68078-09-1]* **$C_6H_{11}NO_2$, M 129.2, m 263-264.5°.** The racemic 2-methylproline was prepared by hydrolysing 5-(3-chloropropyl)-5-methylhydantoin (2g, 10mmol) with $Ba(OH)_2$ (6.3g, 20mmol) and H_2O (50ml) in a pressure bomb at 160° for 30 minutes, cooling, adjusting the pH to 6 with 6N H_2SO_4, filtering off the $BaSO_4$, applying the filtrate through a column of Amberlite IRC 120 (H^+ form), washing with H_2O, eluting with 4N NH_4OH, and evaporating the eluate to give a white solid m 252-258°

(1.2g, 90%). Recrystallisation of the solid from MeOH/Et_2O gave ***analytically pure*** *RS*-2-methylproline **m 263-264.5°**. It has IR (KBr) with ν_{max} at 3450 and 3200 (OH and NH), and 1600 (C=O) cm^{-1}; and its ^1H NMR (60MHz, CD_3OD, TMS) has δ at 1.6 (s, 3H, C***H***$_3$), 1.9 (m, 4H, 3-C***H***$_2$ + 4-C***H***$_2$), and 3.3 (m, 2H, 5-C***H***$_2$). [Ellington & Honigberg *J Org Chem* **39** 104 *1974*, DOI: 10.1021/jo00915a026]. It should be possible to prepare it by Seebach's procedure (see preceding entry) and starting with *RS*-proline.

Tetra-*n*-butylammonium fluoride (TBAF) *[anhydrous, 1 M in THF 429-41-4; 3H_2O 87749-50-6; hydrate 22206-57-1]* **$C_{16}H_{36}N^+$ F^-, M 261.5** (anhydrous), **315.5** (3 H_2O)**, m liquid** (anhydrous), **62-63°** (3 H_2O)**, 37°** (18 H_2O)**.** It is a powerful catalyst for the regioselective ring opening of epoxides with thiols [Albanese et al, *Synthesis* 34 *1994*, DOI: 10.1055/s-1994-25399], the addition reactions of trimethylallylsilane [Majetich et al. *J Org Chem* **51** 1745 *1986*, DOI: 10.1021/jo00360a021], Michael, Knoevenagel, aldol condensations, and by acting as a base in organic synthesis [Clark *Chem Rev* **80** 429 *1980*, DOI: 10.1021/cr60327a004]. It is a mild and highly efficient ***source of nucleophilic (naked) fluoride ions***, causing substitution of halogen or tosyl groups by fluorine. TBAF is also used for ***cleaving*** silyl ethers and silyl protecting groups [cf. P.G.M. Wuts and T.W. Greene in *Green's Protective Groups in Organic Synthesis* 4t edn, J. Wiley, NY *2006*, ISBN: 978-0-471-69754-1]. When an aqueous solution of tetra-*n*-butylammonium hydroxide is titrated with hydrofluoric acid, a homogeneously melting ***octadecahydrate*** (**m 37°**) is obtained [Fowler et al. *J Am Chem Soc* **62** 1140 *1940*, DOI: 10.1021/ja01862a039]. When the octadeca- or tri- hydrates are heated under high vacuum at temperatures of above 80°, decomposition occurs giving tetrabutylammonium bifluoride, tributylamine and 1-butene; with loss of a lot of its useful properties. When the ***trihydrate*** is warmed at 40° under high vacuum, almost ***'anhydrous' TBAF*** is obtained. This salt contained 0.1-0.3 molar equivalents of H_2O (by ^1H NMR). It is an oil at room temperature [Cox et al. *J Org Chem* **49** 3216 *1984*, DOI: 10.1021/jo00191a035]. ***Virtually anhydrous TBAF* in *DMF*** can be prepared without heating by using aliquots (~10 to 30mg) of the trihydrate and placing them under high vacuum (<0.1mm Hg) for 0.5 hour at ~25°, the flask is flushed with N_2, and dry DMF (2ml) is added. The solution is transferred (syringe) to a round-bottomed flask (under N_2), containing 4Å Molecular sieves (which had been activated by flame-drying for 5 minutes under high vacuum), and stirred with a micro stirrer bar for 30 minutes [Majetich et al. *J Org Chem* **51** 1745 *1986*, DOI: 10.1021/jo00360a021]. This is then used for catalytic or other reactions in anhydrous media. [*Beilstein* **4** III 292.]

TBAF is also available commercially as a 1 M solution in THF, 75% solution in H_2O, on alumina support 15wt% loading *[429-41-4]*, on silica gel at ~1.5mmol/g F^- as a non-hygroscopic support for use as a source of ***'naked' fluoride ions*** [Ricci et al. *Tetrahedron Lett* **23** 577 *1982*, DOI: 10.1016/S0040-4039(00)86894-X; Gambacort et al. *Synth Commun* **19** 2441 *1989*, DOI: 10.1080/00397918908052645]. [For applications see Fieser **4** 477, **5** 645, **7** 353, **8** 467, **9** 444, **10** 379, **11** 499, **12** 458, **13** 286, **14** 293, **15** 298, **17** 324.]

PHASE TRANSFER CATALYSTS

Phase transfer catalysts (PTCs) are agents that are soluble in both lipophilic and hydrophilic solutions, i.e. soluble in aqueous solutions and in non-water soluble organic solvents, in varying degrees. They are mostly cationic species that assist the transfer of anions. e.g. CN^-, from the aqueous phase into the non-aqueous phase, e.g. hexane, $CHCl_3$, which would contain the reactive compound, e.g. 1-octyl chloride, to form the product, i.e. 1-octylnitrile, in the non-aqueous phase in high yields. However, the catalysts can also be essentially neutral as with ***crown ethers, cryptands*** (tricyclic ethers containing nitrogen atoms at the bridgehead allowing formation of three rings) and ***ionophores*** that are useful for transferring metal ions through the bilayer interface. Some PTCs are polymer-bound making it easy for their removal and recycling. Other reactions that are phase transfer catalysed include: β-eliminations, *N*-alkylations, nucleophilic aromatic substitutions, metal-organic reactions, oxidation and reduction reactions. The reactions may proceed in either phase and/or at the interphase of the phases. They invariably occur in the organic phase, but in ***Reverse Phase Transfer*** reactions they occur in the aqueous phase. This section provides a selection of such agents, some of which are chiral and are capable of promoting stereoselective, or stereospecific reactions. [Starks *J Am Chem Soc* **93** 195 *1971*, DOI: 10.1021/ja00730a033; Brändström *Adv Phys Org Chem* **15** 267 *1978*, DOI: 10.1016/S0065-3160(08)60120-3; G.W. Adogen 464 [methyl trialkyl(C8—C10)ammonium chloride] *[72749-59-8]* **M 416.2, d ^{25} 0.898, n $^{20}_{D}$ 1.4665.** This is purified in the same way as Aliquat 336 in the following entry. [US Patent 3 992 432].

Aliquat 336 (methyltricaprylylammonium chloride, tri-*n*-octylmethylammonium chloride) *[5137-55-3, a replacement product, Aliquat 128, has 63393-96-4]* **$[CH_3(CH_2)_6CH_2]_3N^+CH_3\ Cl^-$, M 404.2, d ^{25} 0.884, n $^{20}_{D}$ 1.4665.** A 30% (v/v) of Aliquat 336 solution in *benzene is washed twice with an equal volume of 1.5M HBr. [Petrow & Allen, *Anal Chem* **33** 1303 *1961*, DOI: 10.1021/ac60178a004.] It is purified by dissolving 50g in $CHCl_3$ (100ml) and shaking with 20% NaOH solution (200ml) for 10 minutes, and followed by 20% NaCl (200ml) for 10 minutes. It is then washed with a small volume of H_2O, and filtered through a dry filter paper [Starks *J Am Chem Soc* **93** 195 *1971*, DOI: 10.1021/ja00730a033; Adam & Pribil *Talanta* 18 733 *1971*, DOI: 10.1016/0039-9140(71)80114-5.]

N*-Anthracenylmethyl)cinchonidinium chloride** *[199588-80-2]* **$C_{34}H_{33}ClN_2O$, M 521.1, m ~158-161°**. The salt can be purified by recrystallisation from CH_2Cl_2/Et_2O and dried *in vacuo*. This ***chiral phase–transfer-catalyst (PTC) assists in the allyl alkylation of the α-carbon of glycine imino ester to yield finally α-allyl-substituted α-amino acids. Thus with a ***ratio of imino ester to allyl compound***: i.e. achiral phosphines (e.g.1,2-bis[diphenyl-phosphino]ethane DIPHOS, DPPE [*1663-45-2*], its oxide, triphenoxyphosphine or its oxide): base (KOH): [Pd(p-allyl)Cl]$_2$: PTC of 100:200:150:3.5:10 produced the α-allyl imino ester in varying yields and stereoselectivity. However, the derivative ***N*-(9-anthracenylmethyl)-*O*(9)-methyl-cinchonidinium iodide** (prepared from the chloride with MeI/50% aqueous NaOH/20°/4 hours) was a ***more effective PTC***, providing better yields and with up to ~94% enantiomeric excess. The orange ***iodide***, which is soluble in CH_2Cl_2, is crystallised from CH_2Cl_2/Et_2O and has $[\alpha]_D^{19}$ -288 (c 1, CH_2Cl_2); the ^{1}H NMR (500MHz, $CDCl_3$) has δ_H at 1.38-1.55 (m, 2H), 1.95-2.03 (m, 1H), 2.12-2.21 (m, 1H), 2.35-2.43 (m, 1H), 2.64-2.72 (m, 1H), 3.09 (dd, 1H, *J* = 5.6, 5.6Hz), 3.83 (s, 3H), 4.42-4.51 (m, 1H), 4.84 (d, *J* = 4.8Hz, 1H), 5.07 (d, *J* = 5.2Hz, 1H), 5.19 (d, *J* = 8.5Hz, 1H), 5.25 (bs, 1H), 5.87-6.02 (m, 2H), 6.52 (bs, 1H), 6.97 (d, *J* = 6.9Hz, 1H), 7.54-7.60 (m, 3H), 7.69-7.73 (m, 2H), 7.82-7.89 (m, 2H), 7.97 (brs, 1H), 8.05 (d, *J* = 4.3Hz, 1H), 8.14 (d, *J* = 4.1Hz, 1H), 8.20 (d, *J* = 4.3Hz, 1H), 8.32 ((d, *J* = 4.6Hz, 1H), 8.65 (s, 1H), 9.06 (d, *J* = 2.3Hz, 2H), 9.65 (d, *J* = 4.4Hz, 1H); and for IR and ^{13}C NMR (125MHz, CD_3OD) see references. This ***iodide*** in CH_2Cl_2 was converted to another useful PTC ***N*-(9-anthracenylmethyl)-*O*(9)-methyl-cinchonidinium hexafluorophosphate** [by addition of NH_4PF_6 in H_2O at 25°/1 hour, dilution with CH_2Cl_2 and H_2O, drying the organic layer ($MgSO_4$) and evaporating] which gave yellow crystals from CH_2Cl_2/$CHCl_3$ with **m 163-164°**, $[\alpha]_D^{23}$ -314 (c 1.1, CH_2Cl_2), with IR and NMR quite similar to those of the iodide. [Nakoji et al *J Org Chem* **67** 7418 *2002*, DOI: 10.1021/jo0260645.]

8*S*,9*R*-(-)-*N*-Benzylcinchonidinium chloride (BCDC) *[69257-04-1]* **$C_{26}H_{29}ClN_2O$, M 421.0, m 212-213° (dec), $[\alpha]_D^{20}$ -180, -183 (c 5, H_2O), pK_{Est} ~5.** Dissolve the chloride in the minimum volume of H_2O and add absolute Me_2CO. Filter it off and dry it in a vacuum. It can also be recrystallised from hot EtOH or EtOH/Et_2O. It is a good ***chiral phase transfer catalyst*** producing the ***opposite enantiomer*** to the one using *N*-benzylcinchoninium chloride as catalyst — see below. [Colonna et al. *JCS Perkin Trans 1* 547 *1981*, DOI: 10.1039/P19810000547; Imperiali & Fisher *J Org Chem* **57** 757 *1992*, DOI: 10.1021/jo00028a068.] [*Beilstein* **23** H 446.] See cinchonidine [*485-71-2*].

8*R*,9*S*-(+)-*N*-Benzylcinchoninium chloride (BCNC, *N*-benzyl-9*S*-hydroxycinchoninium chloride) *[69221-14-3]* **$C_{26}H_{29}ClN_2O$, M 421.0, m 265° (dec), $[\alpha]_D^{20}$ +169 (c 0.4, H_2O), pK_{Est} ~ 5.** Recrystallise the chloride from isoPrOH, toluene or small volumes of H_2O. It is a good ***chiral phase transfer catalyst*** producing the ***opposite enantiomer*** to the one using the above *N*-benzylcinchonidinium chloride as catalyst — see above. [Juliá et al. *JCS Perkin Trans 1* 574 *1981*, DOI: 10.1039/P19810000574; Dolling et al. *J Am Chem Soc* **106** 446 *1984*, DOI: 10.1021/ja00314a045; Hughes et al. *J Org Chem* **52** 4745 *1987*, DOI: 10.1021/ jo00230a017; *Beilstein* **23** IV 2832; Fieser **12** 380.] See cinchonine [*118-10-5*].

***Trans*-4-*n*-Butyl-4'-hydroxyethyoxy-(ethoxy)$_2$-azobenzene (C-4-Azo-PEG1, $C_4AzoOC_2E_2$) $C_{22}H_{30}N_2O_4$,**

M 386.5, m 60°. This ***micellar phase transfer catalyst*** is a photochromic ionic surfactant with a photochromic core (azobenzene), a hydrophobic C4 butyl chain and a hydrophilic polyethylene glycol hydrophilic head group. It is prepared by the diazo-coupling of 4-*n*-butylbenzenediazonium ion with phenol and the resulting 4-*n*-butyl-4'-hydroxyazobenzene is condensed with trimethyleneglycol monotosylate. It is purified by silica gel chromatography (EtOAc/cyclohexane 7:3), the yellow eluate is evaporated and the residual yellow solid is recrystallised from pentane. The ^{13}C NMR (100MHz, $CDCl_3$, TMS) has δ 160.9, 150.9,147.2, 145.8, 129.0(2x), 124.5(x2), 122.5(2x), 114.7(2x), 72.4, 70.8, 70.3, 69.6, 67.6, 61.7, 35.5, 33.4, 22.3, 13.9 (the ^{1}H NMR is also reported). The surfactant undergoes reversible photoisomerisation when irradiated alternately with 365 and 254nm 500W lamp causing reversible conversion of *trans* to *cis* to *trans* with ***photo-organising*** and ***de-organising*** in the medium. UV-analysis showed that the CMCs (critical micellar concentrations) of the *trans*-form and *cis*-form in water are 4.1μM and 8μM respectively. Experimentation using Pd catalysed Tsuji-Trost reactions (cross-coupling for constructing C-C, C-N, C-S and C-O bonds [Trost & Van Vranken *Chem Rev* **96** 395 *1996*, DOI: 10.1021/cr9409804; Trost & Crawley *Chem Rev* **103** 2921 *2003*, DOI: 10.1021/cr020027w; Poli et al. *Top Organomet Chem* **38** 1 *2012*, DOI 10.1007/978-3-642-22749-3, ISBN 978-3-642-22748-6]) revealed that it is superior to other surfactants (such as SDS, Tween 20 and CTAB) when used at 3CMC (between the two isomers), when irradiated at 365nm during ~30 minutes before extraction of products, using microwave and heating. This ***photochromic surfactant*** was efficient (shorter time, high yields and high chemo-, regio- and stereoselectivities), recyclable and versatile for Pd-catalysed coupling reactions. [Billamboz et al. *J Org Chem*. **79** 493 *2014*, DOI: 10.1021/jo401737t; Shang et al. *Langmuir* **19** 10763 *2003*, DOI: 10.1021/la0350958.]

(11b*R*)-(–)- and (11b*S*)-(+)- 4,4-Dibutyl-4,5-dihydro-2,6-bis(3,4,5-trifluorophenyl)-3H-dinaphth[2,1-c:1′,2′-e]azepinium bromide [*R- 887938-70-7; S- 851942-89-7]* **$C_{42}H_{36}BrF_6N$, M 748.6, m 223-228°, 224-229°, $[\alpha]_D^{29}$ - and + 11.7 (c 1.01, $CHCl_3$).** The precursor ***chiral 2,2'-bisbromomethyl-1,1'-binaphthyl*** (280mg, 0.4mmol), di-*n*-butylamine (140μl, 0.8mmol) and K_2CO_3 (82mg, 0.6mmol) in MeCN (5ml) is refluxed with stirring for 10 hours. The mixture is poured into H_2O, extracted with CH_2Cl_2, the extract is dried (Na_2SO_4), filtered and evaporated to dryness. The residue is purified by column chromatography on silical gel (eluting with MeOH/CH_2Cl_2, 1:20) to give the ***bromide salt*** (275mg, 92%) which may be recrystallised from MeOH/Et_2O. The ***S-enantiomer*** has ^{1}H NMR (400MHz, $CDCl_3$) with δ_H at 7.97-7.95 (4H, m, Ar-H), 7.55-7.51 (2H, m, Ar-H), 7.27-7.23 (8H, m, Ar-H), 4.99 (2H, d, *J* = 14.1Hz, Ar-CH_2), 3.74 (2H, d, *J* = 14.1Hz, Ar-CH_2), 3.32 (2H, t, *J* = 12.5Hz, N-CH_2 –CH_2), 2.56 (2H, t, *J* = 12.3Hz, N-CH_2 –CH_2), 1.06-0.97 (6H, m, CH_2), 0.71 (6H, t, *J* = 6.9Hz, CH_3), 0.23 (2H, bs, CH_2); and for IR and ^{13}C NMR see references. [Kitamura et al. *Angew Chem Int Ed* **44** 1549 *2005*, DOI: 10.1002/anie.200462257; Ooi et al. *J Org Chem* **68** 4576 *2003*, DOI: 10.1021/jo030032f.]
These are potent phase transfer organocatalysts for asymmetric α-alkylation of *N*-arylideneglycine *tert*-butyl ester derivatives for the synthesis of chiral α-substituted α-amino acids at extremely low concentrations of catalyst [Ooi et al. *Tetrahedron: Asymmetry* **17** 603 *2006*, DOI: 10.1016/j.tetasy.2006.01.019].

Cetyltrimethylammonium bromide (cetrimonium bromide, CTAB) *[57-09-0]* **$CH_3(CH_2)_{15}N^+(CH_3)_3$ Br^-, M 364.5, m 227-235°(dec).** Crystallise it from EtOH, EtOH/*benzene or from wet acetone after extracting twice with petroleum ether. Shake it with anhydrous diethyl ether, filter and dissolve it in a little hot MeOH. After cooling in the refrigerator, the precipitate is filtered off at room temperature and re-dissolved in MeOH. Anhydrous ether is added and, after warming to obtain a clear solution, it is cooled and the crystalline material is collected. [Dearden & Woolley *J Phys Chem* **91** 2404 *1987*, DOI: 10.1021/j100293a040; Hakemi et al. *J Phys Chem* **91** 120 *1987*, DOI: 10.1021/j100285a028; *Beilstein* **4** IV 819; Fieser **15** 77.] It is a cationic surfactant with a micellar average weight of 62,000 Daltons, aggregation number of 170 and a CMC (critical micellar concentration) of 1mM (~25°). ***Cetyltrimethylammonium chloride*** *[112-02-7]* **$CH_3(CH_2)_{15}N^+(CH_3)_3$ Cl^-, M 320.0.** Crystallise the chloride from acetone/ether mixture, EtOH/ether, or from MeOH. [Moss et al. *J Am Chem Soc* **109** 4363 *1987*, DOI: 10.1021/ja00248a038; *Beilstein* **4** IV 819.]
Decyltrimethylammonium bromide *[2082-84-0]* **$CH_3(CH_2)_9N^+(CH_3)_3$ Br^-, M 280.3, m 239-242°.** Crystallise the salt from 50% (v/v) EtOH/Et_2O, or from acetone and wash with ether. Dry it under vacuum at 60°. Also recrystallise it from EtOH and dry it over silica gel. [McDowell & Kraus *J Am Chem Soc* **73** 2170 *1952*, DOI: 10.1021/ja01149a074; Dearden & Woolley *J Phys Chem* **91** 2404 *1987*, DOI: 10.1021/j100293a040]
Didodecyldimethylammonium bromide *[3282-73-3]* **$[CH_3(CH_2)_{11}]_2N^+(CH_3)_2$ Br^-, M 463.6, m 157-162°.**

Recrystallise the salt from acetone, acetone/ether mixture, then from ethyl acetate, wash with ether and dry it in a vacuum oven at 60° [Chen et al. *J Phys Chem* **88** 1631 *1984*, DOI: 10.1021/j150652a038; Rupert et al. *J Am Chem Soc* **107** 2628 *1985*, DOI: 10.1021/ja00295a012; Rupert et al. *J Am Chem Soc* **108** 3920 *1986*, DOI: 10.1021/ja00274a011; Allen et al. *J Phys Chem* **91** 2320 *1987*, DOI: 10.1021/j100293a022].

Dioctadecyldimethylammonium bromide *[3700-67-2]* **$[CH_3(CH_2)_{17}]_2N^+(CH_3)_2$ Br^-, M 630.9, m 161-163°.** Crystallise the bromide from acetone, then MeOH [Lukac *J Am Chem Soc* **106** 4386 *1984*, DOI: 10.1021/ja00328a016]. Also purify it by chromatography on alumina by washing with *C_6H_6 and eluting with Me_2CO, evaporating and crystallising from MeCN [Swain & Kreevoy *J Am Chem Soc* **77** 1122 *1955*, DOI: 10.1021/ja01610a012]. [*Beilstein* **4** IV 829.]

N,N-Dioctadecyl methylamine (hydrogen ionophore III) *[4088-22-6]* **$[CH_3(CH_2)_{17}]_2NCH_3$, M 536.0, m 40°, 44-46°, 48-49°, b 252-259°, pK_{Est} ~10.** It can be distilled at high vacuum, but by dissolving in *C_6H_6, filtering and evaporating, a waxy solid suitable for electrode use can be obtained. It recrystallises from Me_2CO or MeCN. It is a ***neutral ionophore*** for polymeric membrane electrodes in proton sensitive solvents. [Hoerr et al. *J Org Chem* **9** 201 *1944*, DOI: 10.1021/jo01184a011; Wu & Yu *Talanta* **34** 577 *1987*, DOI: 10.1016/0039-9140(87)80193-5; *Beilstein* **4** III 435.]

Dodecyltrimethylammonium chloride *[112-00-5]* **$CH_3(CH_2)_{11}N^+(CH_3)_3$ Cl^-, M 263.9, m 246°(dec).** Dissolve the chloride in MeOH, treat with active charcoal, filter and dry it *in vacuo* [Walderhaug *J Phys Chem* **88** 1655 *1984*, DOI: 10.1021/j150652a043], or recrystallise it several times from 10% EtOH in acetone. It has also been repeatedly crystallised from EtOH/ether or MeOH, and its solubility in H_2O is 50mg/ml at ~25°. [Cella et al. *J Am Chem Soc* **74** 2061 *1952*, DOI: 10.1021/ja01128a061; *Beilstein* **4** IV 79.]

Hexyltrimethylammonium bromide *[2650-53-5]* **$CH_3(CH_2)_5N^+(CH_3)_3$ Br^-, M 224.3, m 186°.** Recrystallise it from acetone. It is extremely *hygroscopic*. [McDowell and Kraus *J Am Chem Soc* **73** 2170 *1951*, DOI: 10.1021/ja01149a074; *Beilstein* **4** IV 710.]

It is very soluble in Me_2CO. It is also a bactericide. [Shelton et al. *J Am Chem Soc* **68** 753 *1946*, DOI: 10.1021/ja01209a012; Grieger & Kraus *J Am Chem Soc* **70** 3803 *1948*, DOI: 10.1021/ja01191a078; *Beilstein* **4** IV 827.]

Tetra-n-amylammonium bromide (tetra-n-pentylammonium bromide) *[866-97-7]* **$[CH_3(CH_2)_4]_4N^+$ Br^-, M 378.5, m 100-101°.** Crystallise it from petroleum ether, *benzene or acetone/ether mixtures and dry it *in vacuo* at 40-50° for 2 days. It is used in ion-paired chromatography (Sagara et al. *J Chromatogr* **328** 289 *1985*, DOI: 10.1016/S0021-9673(01)87399-4). [*Beilstein* **4** IV 677.]

Tetra-n-amylammonium iodide *[2498-20-6]* **$[CH_3(CH_2)_4]_4N^+$ I^-, M 425.5, m 135-137°.** Crystallise the iodide from EtOH and dry it at 35° under a vacuum. It has also been purified by dissolving in acetone and precipitating by adding diethyl ether, and drying at 50° for 2 days. [*Beilstein* **4** IV 677.]

Tetradecyltrimethylammonium bromide **(myristyl trimethylammonium bromide)** *[1119-97-7]* **$CH_3(CH_2)_{13}N^+(CH_3)_3$ Br^-, M 336.4, m 244-245°, 244-249°, 245-250°.** Crystallise the bromide from acetone or a mixture of Me_2CO and >5% MeOH, or Me_2CO/EtOH. Wash it with diethyl ether and dry it in a vacuum oven at 60°. It is a ***cationic detergent*** with a micellar average weight of 27,000 Daltons, aggregation number 80 and CMC (critical micellar concentration) of 4-5mM ~25°. Its solubility is 1g/5g H_2O. [Dearden & Woolley *J Phys Chem* **91** 2404 *1987*, DOI: 10.1021/j100293a040; Shelton et al. *J Am Chem Soc* **68** 753 *1946*, DOI: 10.1021/ja01209a012; *Beilstein* **4** III 419, **4** IV 813.]

Tetra-n-heptylammonium iodide *[3535-83-9]* **$[CH_3(CH_2)_6]_4N^+$ I^-, M 537.7, m 102-103°.** Crystallise the iodide from EtOH or aqueous EtOH. [Eriksen et al. *J Org Chem* **25** 849 *1960*, DOI: 10.1021/jo01075a616; *Beilstein* **4** IV 736 for triheptylamine.]

Tetra-n-hexylammonium bromide *[4328-13-6]* **$[CH_3(CH_2)_5]_4N^+$ Br^-, M 434.6, m 99-100°.** Wash the bromide with ether, and dry it in a vacuum at room temperature for 3 days. [For application see Fieser **10** 383.]

Tetra-n-hexylammonium chloride *[5922-92-9]* **$[CH_3(CH_2)_5]_4N^+$ Cl^-, M 390.1, m 111-113°.** Crystallise the chloride from EtOH.

Tetra-n-hexylammonium iodide *[2138-24-1]* **$[CH_3(CH_2)_5]_4N^+$ I^-, M 481.6, m 99-101°, 102-103°.** Wash the iodide with diethyl ether and dry it at room temperature *in vacuo* for 3 days. It is soluble in CH_2Cl_2. [Eriksen et al. *J Org Chem* **25** 849 *1960*, DOI: 10.1021/jo01075a616; *Beilstein* **4** IV 711 for trihexylamine.]

Tetrahexylammonium perchlorate *[4656-81-9]* **$[CH_3(CH_2)_5]_4N^+$ ClO_4^-, M 454.1, m 104-106°.** Crystallise the salt from acetone and dry it *in vacuo* at 80° for 24 hours.

Tetra-n-propylammonium bromide *[1941-30-6]* **$[CH_3CH_2CH_2]_4N^+$ Br^-, M 266.3, m >280°(dec).** Crystallise it from ethyl acetate/EtOH (9:1), acetone or MeOH. Dry it at 110° under reduced pressure. [*Beilstein* **4** IV 471.]
Tetra-n-propylammonium iodide *[631-40-3]* **$[CH_3CH_2CH_2]_4N^+$ I^-, M 313.3, m >280°(dec).** Purify the iodide by crystallising it from EtOH, EtOH/diethyl ether (1:1), EtOH/water or aqueous acetone. Dry it at 50° under a vacuum and store it over P_2O_5 in a vacuum desiccator. Store it away from light. [*Beilstein* **4** IV 472.]
Tri-n-butylhexadecylphosphonium bromide **(TBHDTB, hexadecyltributylphosphonium bromide)** *[14937-45-2]* **$CH_3(CH_2)_{15}P^+[(CH_2)_3CH_3]_3$ Br^-, M 507.7, m 54°, 56-58°.** It is made by heating 1-bromohexadecane (1 mol, 112-82-3) and tri-*n*-butylphosphine (1 mol, 998-40-3) at 65° for 3 days. The mixture solidifies on cooling, and the solid is recrystallised from hexane and dried *in vacuo* to give 68% of the phosphonium salt. [Starks *J Am Chem Soc* **93** 195 *1971*, DOI: 10.1021/ja00730a033; for preparing fluorides see Landini et al. *Synthesis* 37 *1974*, DOI: 10.1055/s-1974-23231; Landini et al. *Synthesis* 428 *1974*, DOI: 10.1055/s-1974-23333; for making disulfides see Landini & Rolla *Synthesis* 565 *1974*, DOI: 10.1055/s-1974-23371; and Fieser **5** 322, **6** 271.]
Tri-n-dodecylamine **(Hydrogen ionophore I)** *[102-87-4]* **$[CH_3(CH_2)_{11}]_3N$, M 522.0, m 15.7°, b 220-228°/0.03mm, d_4^{24} 0.833, n_D^{20} 1.4577, pK_{Est} ~11.0.** Distil tridodecylamine under high vacuum and N_2, and store it in the absence of CO_2. It can be recrystallised from 95%EtOH/*C_6H_6 at low temperature under vacuum. The ***hydrochloride*** has **m** 78-79°. [Ralston et al. *J Org Chem* **9** 259 *1944*, DOI: 10.1021/jo01185a009; *Beilstein* **4** III 413, **4** IV 801.]
Tri-n-dodecylammonium nitrate *[2305-34-2]* **$[CH_3(CH_2)_{11}]_3N^+$ NO_3^-, M 585.0.** Crystallise the salt from *n*-hexane/acetone (95:5) and keep it in a desiccator over P_2O_5 under vacuum. [*Beilstein* **4** IV 801 for tridodecylamine.]
Tri-n-dodecylammonium perchlorate *[5838-82-4]* **$[CH_3(CH_2)_{11}]_3N^+$ ClO_4^-, M 622.4.** Recrystallise the salt from *n*-hexane or acetone and keep it in a desiccator over P_2O_5. (Potentially explosive.)

Tri-*n*-octylammonium chloride *[1188-95-0]* **$[CH_3(CH_2)_7]_3N^+$ Cl^-, M 384.2, m 78-79°, pK^{25} 8.35 (in 70% aqueous EtOH).** Crystallise it from Et_2O, then *n*-hexane (see above). [Burrows et al. *J Chem Soc* 197 *1947*, DOI: 10.1039/JR9470000197; *Beilstein* **4** H 196.]
Tri-n-octylammonium perchlorate *[2861-99-6]* **$[CH_3(CH_2)_7]_3N^+$ ClO_4^-, M 454.2, m >300°(dec).** Crystallise the perchlorate from *n*-hexane. (Possibly explosive.) [*Beilstein* **4** IV 754.]

IMIDAZOLINIUM IONIC LIQUID CRYSTAL CATALYSTS

—A general discussion on ionic liquid crystals has already been made (see Chapter 2), and this section includes some commercially available liquid crystal 1,3-dialkylimidazolinium salts that participate in the catalytic process, i.e. by coordination with the metal component of catalysts, as well as assisting in other ways such as acting as a solvent, affecting the dielectric, and in phase transference of reagents. Depending on the *N*-alkyl substituents and the counter anion the salts may be more, or less, soluble in water or organic solvents. They are non-volatile (i.e. environmentally friendly), stable to water and air, and many may be heated to temperatures as high as 300°, making it possible to distil off some products from them. They can be recovered for re-use. [See P. Wasserscheid and T. Welton, *Ionic Liquids in Synthesis* (2 volume set), Wiley VCH, Weinheim, *2008*. ISBN-10: 3527312390, ISBN-13: 978-3527312399.]
Preparation: Alkylation of *N*-1 of imidazole can be carried out using alkyl halide and alkoxide as for 1-ethylimidazole *[1072-62-4]*, and the second alkylation onto *N*-3 is performed by further reaction with the desired alkylbromide (slightly less than a molar equivalent) in a solvent, e.g. 1,1,1-trichloroethane, at reflux for 2 hours. The molten bromide salt is separated from the solvent, washed with trichloroethane, dried on a Rotavap at 70°/0.1mm to give the bromide salt as a white solid or a liquid in high yield (~>90%) and high state of purity if the starting reagents are pure. Check purity by ^1H NMR and elemental analysis. The imidazolinium bromide salts are most useful as they can be converted into other salts, e.g. AcO^- with AgOAc, TfO^- with AgOTf, bis(trifluoromethylsulfonyl)imide [NTf_2^-] with NTf_2Li, nonafluorobutanesulfonate [NfO^-] with NfOK, etc. Generally the imidazolinium bromide and the metal salt of the required anion are dissolved in the least volume of H_2O at 70°, stirred for 1 hour (if silver halide precipitates it is filtered off), and the imidazolinium salt can be extracted into an organic solvent, e.g. CH_2Cl_2 or 1,1,1-trichloroethane, and the extract is then evaporated *in vacuo* and dried at 50°/0.1mm for 2 hours or until there is no further loss in weight. ***Alternatively***, where possible, the 1-alkylimidazole is alkylated with e.g. alkyl tosyl ester to provide the 1,3-dialkylimidazolinium toluene-*p*-sulfonate directly. [Bonhôte et al. *Inorg Chem* **35** 1168 *1996*, DOI: 10.1021/ic951325x].

The following liquid crystal salts can be readily prepared in small or large quantities:

1-Butyl-3-methylimidazolinium Salts (BMIM$^+$ X$^-$, see Park & Kazlauskas *J Org Chem* **66** 8395 *2001*, DOI: 10.1021/jo015761e; for improved preparation, purification and use at ambient temperature of some of the folowing ionic liquids in lipase-catalysed enantio- and regio- selective acylation reactions)**:**

EMIM$^+$ Br$^-$ *[65039-08-9]* **$C_6H_{11}BrN_2$, M 191.1,** [it is ***hydrophobic*** and a highly conductive salt melting at ~25°, Bonhôte et al. *Inorg Chem* **35** 1168 *1996*, DOI: 10.1021/ic951325x]; **EMIM$^+$ Cl$^-$** *[65039-09-0]* **$C_6H_{11}ClN_2$, M 146.6, m 77-79°; EMIM$^+$ (*n*-BuO)$_2$P(O)O$^-$** *[869858-84-4]* **$C_{14}H_{29}N_2O_4P$, M 320.4, n$_D^{20}$ 1.469; EMIM$^+$ AcO$^-$** *[143314-17-4]* **$C_8H_{14}N_2O_2$, M 170.2, n$_D^{20}$ 1.502; EMIM$^+$ (CF$_3$CF$_2$-SO$_2$)$_2$N$^-$** *[216299-76-2]* **$C_{10}H_{11}F_{10}N_3O_4S$, M 491.3, m ≤1°,** [very stable fluorinated ionic liquids that are ***extremely***

hydrophobic*]. EMIM$^+$ NTf$_2^-$** *[174899-82-2]* **$C_8H_{11}F_6N_3O_4S$, M 391.3, m ≥15°,** is a useful medium for the enantioselective cyclopropanation of styrene with ethyldiazoacetate, promoted by two different Cu-bis(oxazoline) complexes and its recovery, Fraile et al. *Tetrahedron: Asymmetry* **12** 1891 *2001*, DOI: 10.1016/S0957-4166(01)00315-9. Good synthetic activity of soluble *Candida antarctica* lipase B in this ionic liquid was obtained towards the enantioselective and operational stability for butyl butyrate synthesis and kinetic resolution of 1-phenyl ethanol in supercritical CO_2, Lozano et al. *JCS Chem Commun* 692 *2002*, DOI: 10.1039/B200055E]; **EMIM$^+$ (CN)$_2$N$^-$** *[370865-89-7]* **$C_8H_{11}N_5$, M 177.2,** [its conductivity is ~26,000 μS/cm, and its electrochemical window is -2.4 to +3.3 V, cf. Bonhôte et al. *Inorg Chem* **35** 1168 *1996,* DOI: 10.1021/ic951325x; **EMIM$^+$ PF$_6^-$** *[155371-19-0]* **$C_6H_{11}F_6N_2P$, M 256.1, m 58-62°,** [it is prepared by mixing EMIM$^+$ Cl$^-$ (29.3g, 200mmol) and 60% aqueous HPF_6 (9.g, 200mmol) in H_2O (300ml), the resulting mixture of white solid and liquid are cooled in an ice bath for 2 hours and the EMIM$^+$ PF$_6^-$ (31.8g 62%) is dried *in vacuo*. Recrystalisation from MeOH provides crystals for X-ray structural analysis. [Fuller et al. *JCS Chem Commun* 299 *1994*, DOI: 10.1039/C39940000299]; and **EMIM$^+$ BF$_4^-$** *[143314-16-3]* **$C_6H_{11}BF_4N_2$, M 198.0, m 15°, b >350°, d_4^{25} 1.294, n_D^{20} 1.413,** [its conductivity is ~11,500 μS/cm, and its electrochemical window is -2.2 to +3.5 V, cf. Bonhôte et al. *Inorg Chem* **35** 1168 *1996*, DOI: 10.1021/ic951325x]; the salt is prepared by stirring Ag_2O (23.2g, 100mmol) with 48% aqueous HBF_4 (36.9g, 200mmol) in H_2O (300ml) until the Ag_2O has reacted completely to give a clear solution, then EMIM$^+$ Cl$^-$ (29.2g, 200mmol) dissolved in H_2O is added and the mixture is stirred for 2 hours, the AgCl is filtered off, the filtrate is evaporated *in vacuo* and the colourless residue is dried in a vacuum oven at 60° to give the ***BF$_4^-$ salt (33.6g, 85%). [Fuller et al. *JCS Chem Commun* 299 *1994*, DOI: 10.1039/C39940000299].

Enzymes as catalysts: see 'Introduction' and 'Proteins and Enzymes' in Chapter 6.

CATALYSTS—Part 2

ORGANIC COMPOUNDS USED FOR MAKING LIGANDS THAT ASSIST CATALYSIS

Ligands and reagents in this section are mainly ones that are used within this and the former section Catalysts-Part 1. *Other such ligands and related reagents not included here will be found scattered in Chapters 3, 4 and 6, and can be located by their CAS Registry Numbers (CASRNs) in the CASRN Index, in the General Index (as abbreviations) or from their commonly used names in the relevant chapters.*

(η^3-Allyl)(η^5-cyclopentadienyl)palladium(II) [(allyl)(cyclopentadienyl)palladium(II)] *[1271-03-0]* **$C_8H_{10}Pd$, M 212.5, m 61° (dec), 63-63.5°** This complex is volatile and should be handled in an efficient fume hood. Using Schlenk equipment under N_2 or argon and strictly dry conditions, a clear yellow solution of bis(η^3-allyl)di-μ-chloro-dipalladium(II) (9.9g, 27mmol, see *[12012-95-2]*) in THF (100ml) and $*C_6H_6$ (100ml) is prepared, and cooled in an ice-NaCl bath to -20°. A solution of sodium cyclopentadienyl (54mmol in 28ml of THF, *[4984-82-1*]) in a N_2 flushed syringe is added dropwise to the yellow solution at -20° with stirring, whereby the colour changes to dark red. The ice bath is removed after stirring for 1 hour, the temperature is allowed to rise to ~25°, stirring is continued for 30 minutes and the solvents are removed by evaporation *in vacuo* (30-60 torr; no higher than 20° because the Pd complex will begin to sublime at ~25°) to yield a dark red solid. The residue is extracted with hexane (80ml), the extract is filtered under N_2 (use fluted filter paper as a glass frit is likely to become clogged). The filtrate is evaporated as before (*in vacuo* at 30-60 torr) to give red needles of the ***palladium(II) complex*** (9.2g, 80%). ***Note*** that by using mechanical stirring the yield can be improved to 98%. This product is satisfactory for most preparations of Pd(0) complexes, but an analytical sample is readily obtained as red needle-like crystals by recrystallisation from light petroleum (b 40-60°), or by subliming it at 40°(bath temperature)/30mm. It has an ***unpleasant odour***, is relatively stable in air at ~25° for a few days, unchanged in a refrigerator for several weeks, but decomposes gradually in air at ~25° to form a black solid which is not soluble in hexane. Best to stored below -20° under N_2 or argon in sealed glass tubes. It is ***diamagnetic*** and has a low dipole moment (< 1.5D) consistent with both the cyclopentadienyl and the allyl groups as sandwich ligands. The ^{1}H NMR ($*C_6D_6$) has δ at 2.14 (d, *J* = 11Hz, 2H), 3.11 (d, *J* = 6Hz, 6H) and 4.63 (m, 1H) complex for allyl protons and 8.1 (s, 5H, cyclopentadienyl protons). [Shaw *Proc Chem Soc (London)* 247 *1960*, ***notes*** *start on p 233*, DOI: 10.1039/PS9600000233; Tatsuno et al. *Inorg Synth* **19** 220 *1979*, DOI: 10.1002/ 9780470132500.ch51;] The complex is useful for preparing Pd(0) complexes by reaction with hindered alkyl phosphines [Otsuka et al. *J Am Chem Soc* **98** 5850 *1976*, DOI: 10.1021/ja00435a017], reacts with isonitriles to form $Pd(CNR)_2$ complexes [Fischer & Werner *Chem Ber* **95** 703 *1962*, DOI: 10.1002/cber.19620950321; Otsuka et al. *J Am Chem Soc* **91** 6994 *1969*, DOI: 10.1021/ja01053a017], and has been used to prepare BINAP complexes such as Pd[(*R*)-BINAP]$_2$ for asymmetric catalysis [Ozawa et al. *Organomet* **12** 4188 *1993*, DOI: 10.1021/om00034a064].

Ammonium perrhenate (NH_4ReO_4) *[13598-65-7]* **NH_4ReO_4, M 268.2, m 365°(dec.), d ^{25} 3.97g/ml, pK^{25} -1.25 (for $HReO_4$).** The higher solubility of the ammonium salt in H_2O (17g/L at 0°, and 162g/L at ~50°) compared to that of the potassium salt (see *[10466-65-6]*) has made this salt preferable for use in the preparation of a variety of rhenium compounds. It is prepared from perrhenic acid (see *[13768-11-1]*) which is obtained from $KReO_4$ (10.0g, 0.036mol) using the procedure of Watt et al. (*Inorg Synth* **7** 187 *1963*, DOI: 10.1002/9780470132388.ch51) whereby a solution in H_2O (100ml, solubility is 14% at 100°) at 90° is passed through a column of cation exchange resin (Dowex 50-Wx2, but not x8) held at 90° (preferably coated with 'Instatherm', Ace Glass Co., Inc Vineland, NJ, USA, to withstand the temperature), washed with H_2O, and the combined aqueous eluates are concentrated *in vacuo* down to the critical volume of 5ml. If it is concentrated further and the colour darkens, then one drop of 30% aqueous H_2O_2 should be added to decolourise it. The solution is cooled to ~0°, and while being stirred, a chilled mixture of 2-propanol (15ml, saturated with gaseous NH_3) and Et_2O (50ml) is added. The cold mixture is allowed to stand for 1 hour, and the white hexagonal plates (~90% yield) are filtered onto a sintered-glass funnel, washed three times with 2-propanol/Et_2O (1:9), dried *in vacuo*, then at 110° to give NH_4ReO_4 (8.9g, 96% yield) that is **99.4-99.95% pure** by microanalysis, and by passage through a cation-exchange resin in H_2O and titrating with standard base. [Thompson et al. *Inorg*

Synth **8** 171 *1966*, DOI: 10.1002/9780470132395.ch44; see also Smith & Long *J Am Chem Soc* **70** 354 *1948*, DOI: 10.1021/ja01181a110.]

Benzotriazol-1-yloxy-tris(dimethylamino)phosphonium hexafluorophosphate (BOP.PF_6, Castro's reagent) *[56602-33-6]* **$C_{12}H_{22}F_6N_6OP_2$, M 442.3, m >130°, 147-148°. 130°.** Castro's reagent is prepared by adding dropwise hexamethylphosphoric triamide (180g, 1 mol, see *[680-31-9]*) to a vigorously stirred solution of phosgene in toluene (180ml, 20%) during 4 hours (use a bubbler to control the evolution of CO_2). After stirring for 16 hours at ~25°, excess of $COCl_2$ is removed under reduced pressure, CH_2Cl_2 (300ml) is added to ensure a homogeneous solution, and solid hydroxybenzotriazole monohydrate (153g, see *[123333-53-9]*) is added. The mixture is cooled to -5° (Me_2CO/Dry-ice) and Et_2NH (100ml, 1mol) is added during 15 minutes, and stirring is continued at 0° for 4 hours. The precipitated Et_2NH.HCl is filtered off (sintered glass funnel), the solvent is evaporated *in vacuo*, H_2O (500ml) is added and the aqueous solution is extracted with Et_2O (3 x 100ml). This aqueous solution of BOP chloride is added to a filtered solution of KPF_6 (200g) in H_2O (2L) and the precipitated BOP.PF_6 is extracted into CH_2Cl_2. The organic layer is dried ($MgSO_4$), filtered and concentrated under reduced pressure. Addition of Et_2O causes the separation of the first crop of BOP.PF_6 which is collected, and further crops are obtained by addition of CH_2Cl_2 to the mother liquors, concentrating and adding Et_2O. The combined crops are washed with Et_2O and dried *in vacuo* to give the salt (354g, m 147-149°, 80%) which may be recrystallised further from Me_2CO/ Et_2O. The reagent is usually pure enough for efficient coupling of peptides without this recrystallisation. Its IR(KBr) has ν_{max} at 1010 (P-N), 840, 770, and 560 (PF_6^-) cm^{-1}; the ^1H NMR (acetone-d_6) has δ_H at 3.0 (d, 18H, $N(CH_3)_2$, $J_{H\text{-}P}$ = 10Hz), 7.9 (m, $4H_{arom}$); and the ^{31}P NMR (CH_2Cl_2/D_3PO_4) has δ at -43.7 (s, P^+), +144.2 (septet, PF_6^-). [Castro et al. *Synthesis* 751 *1976*, DOI: 10.1055/s-1976-24189.]

Benzotriazol-1-yloxy(tripyrrolidino)phosphonium hexafluorophosphate (PyBOP) *[128625-52-5]* **$C_{18}H_{28}N_6OP.BF_6$, M 520.4, m 154-156°, 156-157°.** It can be prepared and purified in a similar manner as for BOP except that pyrrolidine replaced Et_2NH [cf. Castro's reagent above, see *[56602-33-6]* and Dormoy & Castro *Tetrahedron Lett* 3321 *1979*, DOI: 10.1016/S0040-4039(01)95397-3] by recrystallisation from Me_2CO/ Et_2O and drying *in vacuo*. It is non-hygroscopic and can be stored at ~25°. It has ^{31}P NMR ($CDCl_3$) at δ: 31.8 (s) and -143.7 (heptet, J = 713Hz). It is an analogue of the BOP and a very good coupling agent which does not form the carcinogenic HMPA as byproduct [Coste et al. *Tetrahedron Lett* **31** 205 *1990*, DOI: 10.1016/S0040-4039(00)94371-5; Seebach et al. *Helv Chim Acta* **77** 1313 *1994*, DOI: 10.1002/hlca.19940770513].

(2-Biphenyl)-di-*tert*-butylphosphine [JohnPhos, 2-(di-*tert*-butylphosphino)biphenyl] *[224311-51-7]* **$C_6H_4C_6H_4P$ [$C(CH_3)_3]_2$, M 298.4, m 86-88°.** This ***Buchwald ligand*** is prepared in Schlenk-type equipment under argon containing Mg turnings (617mg, 25.4mmol) and a small crystal of I_2 (to activate the metal) at ~25°, which is treated with a solution of 2-bromobiphenyl (5.38g, 23.1mol, see *[2052-07-5]*) in THF (40ml), the mixture is refluxed for 2 hours and allowed to cool to 25°. Anhydrous Cu(I) Cl (2.40g, 24.2mmol) is added, the flask is capped with a septum, purged with argon for 2 minutes and di-*tert*-butylchlorophosphine (5.0g, 24.2mmol; see *[13716-10-4]*) is injected *via* a syringe, and the mixture is refluxed for 8 hours. The reaction mixture is cooled to ~25°, diluted with 1:1 hexanes/Et_2O (200ml) and the suspension is filtered, the solids are washed with hexanes (60ml), and the solid material is added to 1:1 hexanes/EtOAc (150ml) followed by H_2O (100ml) and 30% aqueous NH_4OH (60ml). This slurry is stirred at ~25° for 5 minutes, the layers are separated and the organic layer is washed with brine (100ml), dried (Na_2SO_4), filtered, evaporated *in vacuo* and the residue is recrystallised from MeOH (2 crops are collected) to provide ***JohnPhos*** as a white solid (4.46g, 67%) with **m 86-86.5°**. It has ^1H NMR (300MHz, $CDCl_3$) with δ_H at 7.95-7.85 (m, 1H), 7.40-7.21 (m, 8H), 1.15 (d, J = 11.6Hz, 18H); the ^{31}P NMR (121MHz, $CDCl_3$) has δ_P at -18.7; and for IR and ^{13}C NMR see references.
This ligand with $Pd(OAc)_2$ catalyses Suzuki coupling at ~25° between aryl halides (Br and Cl) with arylboronic acids with 0.5-1.0mol%Pd in high yields [Wolfe et al. *J Am Chem Soc* **121** 9550 *1999*, DOI: 10.1021/ja992130h; see cyclohexyl-JohnPhos below]. The ligand was used for the amination of aryl halides and aryltriflates [Wolfe et al. *J Org Chem* **65** 1158 *2000*, DOI: 10.1021/jo991699y]. This bulky biarylphosphine ligand was also used in the Pd-catalysed Stille cross-coupling reaction [Artamkina et al. *Synlett* **2** 235 *2006*, DOI: 10.1055/s-2005-923596], and in the Pd-catalysed 2,3-diarylation of α,α-disubstituted-3-thiophenemethanols *via* cleavage of C-H and C-C bonds [Nakano et al. *J Org Chem* **71** 8309 *2006*, DOI: 10.1021/jo061412e].

(2-Biphenyl)-dicyclohexylphosphine [cyclohexyl-JohnPhos, 2-(dicyclohexylphosphino)biphenyl]

[247940-06-3] **$C_{24}H_{31}P$, M 350.5, m 102-106°.** This ***Buchwald ligand*** is prepared in a way similar to the preceding JohnPhos except that 2-bromobiphenyl in THF is converted to the 2-lithiobiphenyl with *n*-BuLi at -78°/45 minutes, followed by reaction with dicyclohexylchlorophosphine at -78°/15 minutes. The desired product is recystallised from MeOH to give ***cyclohexyl-JohnPhos*** (71%) as white crystals **m 103°**. The ^{1}H NMR (300MHz, $CDCl_3$) has δ_H at 7.62-7.51 (m, 1H), 7.40-7.10 (m, 8H), 1.95-1.45 (m, 13H), 1.35-0.95 (m, 9H); and the ^{31}P NMR (121MHz, $CDCl_3$) has δ_P at -12.7; and for IR and ^{13}C NMR see references.
This ligand with $Pd(OAc)_2$ allows Suzuki coupling at low catalyst loadings (0.000001-0.02mol%Pd) between aryl halides (Br and Cl) with arylboronic acids in high yields, and tolerates a wide range of functional groups and substrate combinations including sterically hindered substrates. It was the most active catalyst system in terms of temperature of reaction, turnover numbers and steric tolerance in *1999* [Wolfe et al. *J Am Chem Soc* **121** 9550 *1999*, DOI: 10.1021/ja992130h]. This ligand was also used for the amination of aryl halides and aryltriflates [Ali & Buchwald *J Org Chem* **66** 2560 *2001*, DOI: 10.1021/jo0008486], and was employed in the Pd-catalysed synthesis of 1,3,5-tris(2'aminophenyl)-benzene from *o*-aminophenylboronic acid and 1,3,5-triiodobenzene, which may be used as a three-directional core building block for potential ionic receptors [Piatek & Slomiany *Synlett* 2027 *2006*, DOI: 10.1055/s-2006-948199].

2,2'-Bipyridine (2.2'-dipyridyl, α,α'-dipyridyl) *[366-18-7]* **$C_{10}H_8N_2$, M 156.2, m 69.7°, b 272-273°/atm, pK^{25} 4.50.** The reaction of pyridine with Na produces a mixture of bipyridyls which can be separated by fractional distillation where the 2,2'-isomer distils at 272.5°/atm and solidifies on cooling (**m 69.5°**). The distilled oil can be purified further by dissolving in Et_2O, adding an equal volume of petroleum ether then the 2,3'- and 3,3'- isomers are washed out with several portions of H_2O. The organic layer is evaporated and the oily residue is recrystallised from aqueous EtOH. 2.2'-Bipyridyl also sublimes at 65°/0.01mm. Its solubility in H_2O is 0.5%, but it is very soluble in organic solvents. Its UV spectrum has λ_{max} nm(ε) 233 (10,200) and 280 (13,300) for the neutral species in H_2O. Unlike the other isomers it complexes with metals, e.g. it gives an intense red colour with ferrous salts. The ***picrate*** has **m 69.7°** (from aqueous EtOH). It is a metalloprotease inhibitor with high affinity for Fe^{2+} containing enzymes at 10^{-8} M. [Smith *J Am Chem Soc* **46** 414 *1924*, DOI: 10.1021/ja01667a016; UV Krumholz *J Am Chem Soc* **73** 3487 *1951*, DOI: 10.1021/ja01151a146; *Beilstein* **23/8** IV 28, **23/16** V 8.] **[TOXIC]**

1,3-Bis(1-adamantyl)-1,3-dihydro-2*H*-imidazol-2-ylidene (IAd) *[131042-77-8]* **$C_{23}H_{32}N_2$, M 336.3, m 240-241°.** This is a stable ***N*-h**eterocyclic **c**arbene (NHC) which has been prepared in 96% yield from IAdCl by deprotonation in THF with catalytic amounts of the dismyl anion [$CH_3S(O)CH_2^-$] in the presence of 1 equivalent of NaH, or with *tert*-BuOK. In this reaction H_2 is liberated and NaCl is precipitated. The carbene is stable in the absence of oxygen and moisture, and recrystallises from toluene to give clear, colourless rectangular prisms with a sharp melting point that is unaltered by melting and re-solidifying. The ^{1}H NMR (*C_6H_6-d_6) has δ_H at 1.58 (s, $Ad_{4',6',10'}$, 12H), 2.01 (s, $Ad_{3',5',7'}$, 6H), 2.29 (s, $Ad_{2',8',9'}$, 12H), 6.91 (s, 3,4-C*H*, 2H); and for IR, ^{13}C NMR and EI-MS see references. The X-ray crystal structure has been determined and showed a small N-C-N angle at the carbene centre. [Arduengo et al. *J Am Chem Soc* **113** 361 *1991*, DOI: 10.1021/ja00001a054; see also Arduengo et al. *J Am Chem Soc* 114 5530 *1992,* DOI**:** 10.1021/ja00040a007.] It is as effective, if not better in some cases, in many of the metal mediated catalytic reactions as other NHCs (Nitrogen Heterocyclic Carbenes). For further detail see the entry on IPr.Cl *[250285-32-6]*. [Arduengo USPatent 5 077 414 *1991, Chem Abstr* **116** 106289 *1002*, Kantchev, O'Brien & Organ *Aldrichimica Acta* **39** 97 *2006*, Phillips, Chan & Scheidt *Aldrichimica Acta* **42** 55 *2009*].

1,3-Bis(1-adamantyl)imidazolium tetrafluoroborate (IAd.BF_4) *[286014-42-4]* **$C_{23}H_{33}N_2$. BF_4, M 424.3, m 277-282°.** This NHC (N-Heterocyclic Carbene) precursor is prepared by established procedures from 2 mols of amine, 1 mol of glyoxal and one mol of formaldehyde in toluene/H_2O in the presence of HBF_4. It is as effective, if not better in some cases, in many of the metal mediated catalytic reactions as other NHCs. For further detail see the entry on IPr.Cl *[250285-32-6]*. [Arduengo USPatent 5 077 414 *1991, Chem Abstr* **116** 106289 *1002*, Kantchev, O'Brien & Organ *Aldrichimica Acta* **39** 97 *2006*, Phillips, Chan & Scheidt *Aldrichimica Acta* **42** 55 *2009*].

2,2'-Bis(1,3,2-benzodioxaborole) [bis(catcholato)diboron, Cat-BB-Cat] *[13826-27-2]* **$C_{12}H_8BO_4$, M 237.8, m 189-196°, 195-198°.** This borole is prepared by distilling B_2Cl_4 (3.95mmol) [Wartik et al. *J Am Chem Soc* **71**

3265 *1949,* DOI: 10.1021/ja01177a538; Urry et al. *J Am Chem Soc* **76** 5293 *1954*, DOI: 10.1021/ja01650a010] and CH_2Cl_2 (30ml) into a reaction vessel containing catechol (8.03mmol) at -196°, and then the reaction is allowed to proceed over the temperature range ~78 to 25° for 15 hours to give a clear solution (slightly less than 16mmol of HCl is liberated). CH_2Cl_2 and HCl are distilled off *in vacuo* from the reaction vessel leaving a white residue which is sublimed at 120-130°/10^{-4}mm to give the ***pure borole*** in ~70% yield. A similar result is obtained by using $B_2[NMe_2]_4$ instead of B_2Cl_4. Cat-BB-Cat has one peak at -30.7ppm (from BF_3OEt_2 external reference) in the ^{11}B NMR (19MHz, CH_2Cl_2), and one peak for the aromatic protons at 2.69ppm (from solvent reference) in the ^1H NMR (60MHz, CH_2Cl_2); and for IR see references. Molecular weight determination in $*C_6H_6$ indicated that it is a ***monomer***, and alkaline hydrolyses provided 0.96 mole of hydrogen per mole of B-B compound. [Welch & Shore *Inorg Chem* **7** 225 *1968*, DOI: 10.1021/ic50060a011.] Cat-BB-Cat is efficient in olefin diboration catalysed by base-free Pt complexes such as $Pt(COD)_2$ and $Pt(norbornene)_2$ [Iverson & Smith *Organometallics* **16** 2757 *1997*, DOI: 10.1021/om970199x], consequently producing useful synthons for cross-coupling reactions and related conversions to other functional groups [Miyaura & Suzuki *Chem Rev* **95** 2457 *1995*, DOI: 10.1021/cr00039a007].

Bis[(*R,R,S*)-diazaPhos-SPE] {2,2',2",2"'-(1,2-phenylenebis(1*R*,3*R*)-tetrahydro-5,8-dioxo-1*H*-[1,2,4]-diaza-phospholo[1,2-*a*]pyridazine-2,1,3(3*H*)-triyl)tetrakis(*N*-[(1*S*)-1-phenethyl)benzamide} *[851609-33-1]* **$C_{78}H_{72}N_8O_8P_2$, M 1311.40, m 183-195°, $[\alpha]_D^{20}$ -82 (c 1, THF), and the diastereomeric bis[(*S,S,S*)-DiazaPhos-SPE] {2,2',2",2"'-(1,2-phenylenebis(1*S*,3*S*)-tetrahydro-5,8-dioxo-1*H*-[1,2,4]-diaza-phospholo-[1,2-*a*]pyridazine-2,1,3(3*H*)-triyl)-tetrakis(*N*-[(1*S*)-1-phenethyl)benzamide}** *[851770-14-4]* **$C_{78}H_{72}N_8O_8P_2$, M 1311.40, m 289-299°, $[\alpha]_D^{20}$ +15 (c 1, THF).** The central diazaphospholane tetracarboxylic acid in the two molecules are enantiomeric and these are converted to the phenethylamide using the same *S*-phenethylamine. Thus the two substances are diastereomeric. They are prepared by mixing the diazaphospholane tetracarboxylic acid (0.34mmol) with 5 equivalents of PyBOP {(benzotriazol-1-yloxy)tripyrrolidinophosphonium hexafluorophosphate, m 154-156° cf. *[128625-52-5]*} under N_2, adding degassed CH_2Cl_2 (100ml) followed by 5 equivalents of *N,N*-diisopropylethylamine and 5 equivalents of (α*S*)-α-methylbenzmethanamine (*S*-2-phenylethylamine), and stirring overnight. The solution is exposed to the atmosphere and washed with saturated $NaHCO_3$ (50ml), 2M HCl (50ml), saturated $NaHCO_3$ (50ml) again, then H_2O (50ml). The organic layer is dried ($MgSO_4$), filtered, and evaporated *in vacuo*. The residue is purified by flash chromatography (Al_2O_3, eluted with 2:1 CH_2Cl_2/EtOAc), and the separation of diastereoisomers is accomplished by liquid chromatography using a Zorbax Rx-Sil column (4.6 x 250 column). The ***R,R,S- diastereomer*** (21% yield) has ^1H NMR (500MHz, d-THF) with δ_H at 1.37 (d, 6H, *J* = 6.7Hz, CH_3), 1.56 (d, 6H, *J* = 6.7Hz, CH_3), 2.2-2.7 (m, 6H, CH_2CH_2), 2.65-3.0 (m, 2H, CH_2CH_2), 5.06 (dq, 2H, *J* = 7.5, 6.9Hz, C*H*CH_3), 5.41 (dq, 2H, *J* = 7.7, 6.9Hz, C*H*CH_3), 6.39 (d, 2H, *J* = 7.3Hz), 6.5-6.9 (m, 10H), 7.06-7.36 (m, 26H), 7.51 (m, 2H), 7.60 (d, 4H, *J* = 7.4Hz), 7.97 (d, 2H, *J* = 8.3Hz, N*H*CH CH_3), 9.23 (d, 2H, *J* = 7.8Hz, N*H*CH CH_3); the for ^{13}C NMR see references. The NMR spectra of the ***S,S,S-diastereomer*** is similar but is ***not*** identical. [Clark et al. *J Am Chem Soc* **127** 5040 *2005*, DOI: 10.1021/ja050148o; Clark & Landis *J Am Chem Soc* **125** 11792 *2003*, DOI: 10.1021/ja036359f.]
It is a diazaphospholane ligand which displays high conversion and selectivity in Rh catalysed asymmetric hydroformylation reactions [Axtel et al. *Angew Chem Int Ed* **44** 5834 *2005*, DOI: 10.1002/ anie.200501478; Clark et al. *J Am Chem Soc* **127** 5040 *2005*, DOI: 10.1021/ja050148o; US Pat 7.071.357B.]

***R,R*-(-)- *and S,S*-(+)- *N,N'*-Bis(3,5-di-*tert*-butylsalicylidene)-1,2-*trans*-cyclohexanediamine (Jacobsen's ligand)** *[R,R- 135616-40-9, S,S- 135616-36-3]* **$C_{36}H_{54}N_2O_2$, M 546.8, m 203-206°, 205-208°, 205-208°, $[\alpha]_D^{20}$ (+)** and **(-) 310 (c 1, CH_2Cl_2).** If this general ligand is to be purified, dissolve it in boiling EtOH and while cooling add H_2O to the yellow solution until a yellow solid separates. This is filtered off, washed with a little of 95% aqueous EtOH and dried *in vacuo*. It is the ligand for preparing Jacobsen's Catalysts [Jacobsen et al. *J Am Chem Soc* **113** 7063 *1991*, DOI: 10.1021/ja00018a068; Deng & Jacobsen *J Org Chem* **57** 4320 *1992*, DOI: 10.1021/jo00041a054].
On a large scale, the *R,R*-ligand (~60g) is dissolved in CH_2Cl_2 (500ml), washed with H_2O (2 x 300ml) and brine (100ml), dried (Na_2SO_4), and the solvent is removed to yield a yellow powder with **m 200-203°**, $[\alpha]_D^{20}$ (+) and (-) 315 (c 1, CH_2Cl_2), the required ^1H and ^{13}C NMR, and IR with ν_{max} (KBr) at 1595, 1631, 2869, 2960 cm^{-1}. However, if it is felt that the product is of insufficient purity then it should be crystallised in two crops from Me_2CO (1:20 w/v with typical 86-93% recovery) [Larrow et al. *J Org Chem* **59** 1939 *1994*, DOI: 10.1021/

jo00086a062.]
A **dimeric Jacobsen ligand**, formed by joining two units with a methylene bridge has been prepared and crystallised from CH_2Cl_2/pentane. Its ***bis-Mn catalyst*** exhibited improved retention in a poly-dimethylsiloxane membrane for the asymmetric epoxidation of olefins [Janssen et al. *Tetrahedron Asymmetry* **8** 3481 *1997*, DOI: 10.1016/S0957-4166(97)00465-5].

1,5-Bis(3',5'-dimethoxyphenyl)penta-1*E*,4*E*-dien-3-one (dm-dba)** *[39777-58-7]* **$C_{21}H_{22}O_5$, M 354.1, m 132-134°.** To a cooled (ice-water bath) solution of NaOH (1.8g, 2.5equivalents) in H_2O (18ml) diluted with EtOH (15ml) is added slowly 3',5'-dimethoxybenzaldehyde (3g, 1equivalent) and analytical grade acetone (0.52g, 0.5 equivalent) during 15 minutes, then it is stirred at 25° for 1 hour. A yellow solid separates, and after a further hour it is filtered off, washed with Et_2O (3 x 50ml) and dried *in vacuo*. Purification by flash chromatography (*ca* 150 mesh Al_2O_3 deactivated with 6% v/w H_2O prior to use) and elution with petroleum ether (b 40°-60°)/EtOAc (4/1 v/v) gives ***dm-dba as a yellow solid (2.2g, 69%) which is recrystallised by layering a concentrated solution of CD_2Cl_2 with Et_2O (CD_2Cl_2/Et_2O, 1/3). The IR (CH_2Cl_2) has ν_{max} at 1652m (C=O), 1621vs (C=C), 1596w (C= C aromatic), 1572w (C= C aromatic) and 989m (CH trans) cm^{-1}; the UV has λ_{max} (THF) at 239 (π- π*) and 371 (n- π*) nm; the ^1H NMR (400MHz, $CDCl_3$) has δ_H at 6.48 (d, 1H, ^3J = 15.7Hz, H-2), 7.01 (1H, d, ^3J = 15.7Hz, H-1), 6.71 (2H, t, ^3J = 6.7Hz, 7.9Hz, H-6'), 7.62 (1H, d, ^3J = 8.2Hz, H-4'), 3.70 (s, 12H); and for the ^{13}C NMR see references. [Fairlamb et al. *Org Lett* **6** 4435 *2004*, DOI: 10.1021/ol048413i; *Beilstein* **7** IV 1747.]

2,2'-Bis(diphenylphosphino)-1,1'-binaphthyl (BINAP) *[RS 98327-87-8]* **$[(C_6H_5)_2PC_{10}H_6—)]_2$, M 622.7, m 283-286°**, *[R-(+)-76189-55-4]* **m 241-242°,** *[S-(-)- 76189-56-5]* **m 241-242°, $[\alpha]_D^{20}$ *R* (+) and *S* (-) 233 (c 0.3, toluene).** It has been prepared from (±)-BINOL which is converted to (±)-2,2'-dibromo-1,1-binaphthyl (with Ph_3PBr_2) then to (±)-2,2'-bis(diphenylphosphinyl)-1,1-binaphthyl (**BINAPO**) [with Mg/$Ph_2P(O)Cl$] which is resolved into ***S*-(−)- and *R*-(+)- BINAPO** *via* separation of the diastereoisomeric (−)-2,3-di-*O*-benzoyl-L-tartrate salts in $CHCl_3$/EtOAc followed by treatment with 0.75N NaOH, extraction into $CHCl_3$, and isolation. The chiral BINAPO enantiomers are reduced to the respective ***S*-(−)- and *R*-(+)- BINAP** with excess of Cl_3SiH [see *10025-78-1*] and Et_3N in toluene (100-120°) followed by treatment with 30% aqueous NaOH, extraction into toluene, isolation and purification as follows. Dissolve the enantiomer in toluene, wash it with 30% aqueous NaOH, three times with H_2O, dry (Na_2SO_4), evaporate to ~15% of its volume and add an equal volume of degassed MeOH. Collect the solid, wash it with MeOH and dry it at 80°/0.005mm for 6 hours. Recrystallise it from a 1:1 mixture of toluene/EtOH to ***optical purity*** (**m 241-242°**). ***Pure (99%) (S)-(−)-BINAP*** has ^1H NMR (300MHz, $CDCl_3$, TMS) with δ_H at 6.81 (d), 6.90 (t), 7.10 (m), 7.23 (s), 7.33 (t), 7.43 (dd), 7.82 (d) and 7.89 (d) where multiplicities are not necessarily coupled signals; and for the ^{13}C NMR see reference. The purity is determined by GLC analysis using an OV-101 5m capillary column at 200-280° (argon carrier gas ?). TLC analysis (Kieselgel 60 PF_{254}, with MeOH/$CHCl_3$ 1:19) is used to identify BINAP (R_F 0.83), BINAPO (R_F 0.4.2) and BINAP-monooxide (R_F 0.67). **(±)-BINAPO** *[86632-33-9]* crystallises from hot toluene (solubility is 3.6g/100ml at 110°) or from hexane/toluene, and analytically pure crystals have **m 304-306°** (299-300° also reported). ***S*-(−)-BINAPO** *[94041-18-6]* crystallises from a hexane/toluene mixture and has **m 261-262°**, **$[\alpha]_D^{24}$ −396 (c 0.47, C_6H_6)**, **$[\alpha]_D^{24}$ −168 (c 0.5, EtOH)**; and ***R*-(+)-BINAPO** *[94041-16-4]*, similarly recrystallised, has **m 262-263°**, **$[\alpha]_D^{24}$ +396 (c 0.5, C_6H_6)**. [Takaya et al. *Org Synth* Coll Vol **8** 57 *1993*, DOI: 10.15227/orgsyn.067.0020]. § A polymer supported version of BINAP is available.

2*R*,3*R*-(+)-2,3-Bis(diphenylphosphino)butane (*R*,*R*-CHIRAPHOS) *[74839-84-2]*, **2*S*,3*S*-(-)-2,3-bis(diphenylphosphino)butane (*S*,*S*-CHIRAPHOS)** *[64896-28-2]* **$C_{28}H_{28}P_2$, M 426.5, m 108-109°, *R*- $[\alpha]_D^{20}$ (+) and *S*- $[\alpha]_D^{20}$ (-) 200 (c 1.5, $CHCl_3$). For *S*,S-CHIRAPHOS:** Ph_2PLi [*prepared in situ from Ph_3P (95g) and Li (5g) in THF (300ml) under N_2 at ~55°/1 hour then at 25°/2 hours, and the PhLi formed is decomposed with tert-BuCl (33g) for 45 minutes; the clear orange solution is boiled for 5 minutes then cooled to -4°*] solution is treated with ***(+)-(2R,3R)-butanediol bis(tosylate)*** (35g, *[64896-27-1]*) in dry THF (100ml) over 1 hour with stirring, the temperature is allowed to rise to 25° and stirring is continued for 30 minutes. N_2 purged H_2O (100ml) is added, the THF layer is separated and evaporated *in vacuo* to give impure ***S*,*S*-chiraphos** (***note***

inversion of configuration) as a colourless oil. The oil is extracted under N_2 with Et_2O (2 x 150ml), dried (Na_2SO_4), and filtered (under N_2) into a solution of $Ni(ClO_4)_2.6H_2O$ (15g) in EtOH. The Na_2SO_4 is washed with Et_2O which is added to the Ni solution. The oily red-brown deposit of the ***Ni-chiraphos*** sometimes contains some yellow solid of the ***Ni-perchlorate complex*** which is discarded (***pyrophoric***?). To the brown-oily (or part crystalline) mixture is added NaCNS (15g) in hot EtOH and stirred vigorously until a homogenous yellow-brown crystalline **[Ni(*S,S*-chiraphos)$_2$NCS]NCS** is obtained. It is collected, washed thoroughly with EtOH then finally Et_2O.

This ***Ni-NCS complex*** (15g), suspended in 95% EtOH (150ml) under N_2 is stirred, brought to the boil, and NaCN (4g) in H_2O (20ml) is added rapidly when the Ni complex slowly dissolves to give a clear blood-red solution which then turns cloudy beige in colour. The hot solution is stirred until all the complex which had dissolved is converted to a yellow slurry. After cooling in ice-water, the solid is collected, washed with H_2O (2 x 25ml) then rapidly with ice-cold EtOH (25ml) to give impure beige coloured *S,S-chiraphos*. This solid is purified by drying at 25º, dissolving in boiling absolute EtOH (~125ml), filtering through a frit under N_2 and allowing to stand at ~25º for 12 hours, whereby ***S,S-chiraphos*** deposits as lustruous colourless plates. A second crystallisation from absolute EtOH (60ml) provides ***optically pure*** **(-)-(2*S*,3*S*)-bis(diphenylphosphino)butane (*S,S*-CHIRAPHOS)** (5.5g), **m 108-109º** (sealed tube under N_2) as colourless plates with $[\alpha]_D^{27}$ -211 (c 1.5, $CHCl_3$), which is unchanged on further recrystallisation [Fryzuk & Bosnich *J Am Chem Soc* **99** 6262 *1977*, DOI: 10.1021/ja00461a014]. Its ^{31}P NMR ($CDCl_3$, with external H_3PO_4 as reference) has δ at -10.7, i.e. upfield from H_3PO_4 [Slack et al. *Inorg Chem* **18** 3125 *1979*, DOI: 10.1021/ic50201a034].

For *R,R*-CHIRAPHOS: This enantiomeric ligand is obtained essentially by the same synthesis as its enantiomer above. The **(-)-*(2S,3S)*-butanediol bis(tosylate)** *[74839-83-1]* is prepared in 94% yield, and has **m 63-64º**, **$[\alpha]_D^{25}$ -36.8 (c 2.1, $CHCl_3$)**, and ^1H NMR ($CDCl_3$) with δ at 1.20 (d, *J* = 6Hz; 6H, CH_3), 2.50 (s; 6H, tosyl-CH_3), 4.70 (q, *J* ~ 7Hz; 2H, CH), 7.70 (m; 8H, aromatic-H). It is converted into **bis[(2*R,3R*)-2,3-bis(diphenylphosphino)butan]thiocyanato-nickel(II) thiocyanate** in 56% yield (***note*** inversion of configuration) after washing with EtOH and Et_2O, and decomposed with NaCN to give ***R,R*-CHIRAPHOS** in 32% yield with **m 106-107º**, **$[\alpha]_D^{27}$ +197 (c 1.5, $CHCl_3$)**, and ^1H NMR ($CDCl_3$) with δ at 1.10 (d, *J* = 7Hz; 3H, CH_3), 1.40 (d, *J* = 6Hz; 6H, CH_3), 2.60 (q, *J* ~ 7Hz; 2H, CH), 7.50 (m; 20H, aromatic-H). [Köttner & Gerber *Chem Ber* **113** 2323 *1980*, DOI: 10.1002/cber.19801130627.]

1,4-Bis-(diphenylphosphino)butane (dppb) *[7688-25-7]* **$(C_6H_5)_2P(CH_2)_4P(C_6H_5)_2$, M 426.5, m 135-136º, 136-137º.** Recrystallise it from EtOH [Trippett *J Chem Soc* 4263 *1961*, DOI: 10.1039/JR9610004247]. 1,2-Bis-(diphenylphosphino)ethane (DIPHOS, ethylene bis(diphenylphosphine)) *[1663-45-2]* **$(C_6H_5)_2P(CH_2)_2P(C_6H_5)_2$, M 398.4, m 139-140º, 140-142º, 143-144º, pK_{Est} ~4.5.** Recrystallise it from aqueous EtOH or $*C_6H_6$. The ***dimethiodide***, when recrystallised from MeOH has **m 305-307º**, and the ***dioxide*** when recrystallised from toluene or DMF (needles), or $*C_6H_6$ (plates) has **m 252-254º** (**276-278º**) [Isslieb et al. *Chem Ber* **92** 3175 *1959*, DOI: 10.1002/cber.19590921221; NMR: Aguiar & Beiser *J Org Chem* **29** 1660 *1964*, DOI: 10.1021/jo01029a524; Baeckvall et al. *J Org Chem* **52** 5430 *1987*, DOI: 10.1021/jo00233a023]. [*Beilstein* **16** IV 958.]

R*-(+)-1,2-Bis(diphenylphosphino)propane (*R*-PROPHOS)** *[67884-32-6]* **$(C_6H_5)_2PCH(CH_3)CH_2—P(C_6H_5)_2$, M 412.4, m 68.5º (sealed tube under N_2), 71-73º, $[\alpha]_D^{26}$ *R* +186.0 (c 1.0, Me_3CO).** ***S*-(-)-** Propane-1,2-diol bis(*p*-toluenesulfonate) (51.9g, *[60434-71-1]*) in dry THF (75ml) is reacted with Ph_2PLi to give the ***R-diol (***note*** change in absolute configuration) which is converted to its Ni-perchlorate salt and then converted into its NiNCS complex (45-55g) essentially as described for ***chiraphos*** above. This NCS complex (22g) is decomposed with NaCN essentially as described for ***chiraphos*** above, and finally the crude oily ***R-prophos*** is dissolved in absolute EtOH at 50º under N_2, allowed to cool to 25º, then held at 5º for 24 hours and the ***diphosphine*** (10g) that separated is collected and recrystallised from absolute EtOH (100ml) to give small colourless prisms of **analytically pure *R-prophos*** (7.5g) whose optical rotation is unchanged by further recrystallisation. [Fryzuk & Bosnich *J Am Chem Soc* **101** 3043 *1979*, DOI: 10.1021/ja00505a035]. Its ^{31}P NMR ($CDCl_3$, with external H_3PO_4 as reference) has δ at -20.6 (d, J_{P-P} = 20.6Hz), i.e. upfield, and +1.7 ppm, i.e

downfield from H_3PO_4 [Slack et al. *Inorg Chem* **18** 3125 *1979*, DOI: 10.1021/ic50201a034]. Pure ***S-prophos*** may be prepared in a similar way.

Bis(2-hydroxyethyl)sulfide (2.2'-thiodiglycol, thiodiglycol) *[111-48-8]* **$(HOCH_2CH_2)_2S$, M 112.2, m -16°, b 121-121.8°/0.01mm, 130°/2mm, 136-137°/3mm, 148°/4mm, 165°/20mm 168°/20mm, 185.5°/40mm, 194°/50mm, 282°/760mm, d_4^0 1.1973, d_4^{25} 1.1793, n_D^{20} 1.5203, n_D^{26} 1.5146.** The sulfide has been prepared on large scales for the manufacture of 'Mustard Gas'. The thioglycol has been prepared from ethylene oxide and H_2S, and the crude compound prepared from chlorohydrin contains considerable quantities of dithiane and polymeric impurities. These can be removed by distillation at 150°/8mm and the polymeric material breaks down at ~160° [Masson *J Chem Soc* **49** 233 *1886*, DOI: 10.1039/CT8864900233]. The distillate is then diluted with H_2O until its boiling point at atmospheric pressure is reduced to 165°, and superheated steam is passed through it. After evaporating off the H_2O, the thiodiglycol is distilled at 147°/6mm. It is soluble in H_2O, lower alcohols, $CHCl_3$, EtOAc; and at 25° its solubility (w/w) in $*C_6H_6$ is 1.07%, in absolute Et_2O it is 7.09 and in ligroin it is 0.06%. In organic acids, or alone, it is stable at 180° for many hours, but when heated at 100° with 2.5 parts of 0.1N aqueous NaOH for 30 minutes sulfide ions are formed, much more so (50%) with 1N NaOH at 140°/10 hours. $Pb(OAc)_2$, and $Cu(NO_3)_2$ decompose it at 100°, but it is stable with BaO, CaO and Al_2O_3 even at 180°/10 hours, in unsuccessful attempts to dehydrate it to vinyl sulfide. Of the several esters of aliphatic alcohols that were reported, the ***diacetate*** had **b 139.5°/8mm**, the ***dibutyrate*** had **b 172°/8mm**, and the ***dicaproate*** had **b 207°/7mm** [Clayton & Reid *J Am Chem Soc* **64** 908 *1942*, DOI: 10.1021/ja01256a048]. The ***bis-3,4-diphenylcarbamoyl derivative*** had **m 141.4-142.5°** (from EtOH) [Beaver et al. *J Am Chem Soc* **79** 1236 *1957*, DOI: 10.1021/ja01562a053], and the ***bis-4-nitrobenzoate ester*** had **m 107.7°** (from EtOH) [Major *Bull Soc Chim Fr* **41** 634 *1927*]. [Nenitzescu & Scârlâtescu *Chem Ber* **68** 587 *1935*, DOI: 10.1002/cber.19350680406; *Beilstein* **1** H 470, **1** I 244, **1** II 525, **1** III 2122, **1** IV 2437.]

1,2-Bis[(*4S*)-4-isopropyl-2-oxazolin-2-yl]benzene [(4*S*,4'*S*)-2,2'-(phen-1,2-diyl)bis(4-isopropyl-4,5-dihydro-oxazole)] *[131380-80-8]* **$C_{18}H_{24}N_2O_2$, M 300.4, b 175°/10^{-2} mbar, $[\alpha]_{589}^{25}$ -98.8 (c 2.13, CH_2Cl_2), $[\alpha]_{546}^{25}$ -119.4 (c 2.13, CH_2Cl_2), $[\alpha]_{365}^{25}$ -415.2 (c 2.13, CH_2Cl_2).** This ligand is prepared by melting a small amount of anhydrous $ZnCl_2$ (68mg, 0.50mmol, m 293°) in high vacuum under argon, cooling to ~25°, adding chlorobenzene followed by *o*-phthalonitrile (1.28g, 10mmol) and *S*-valinol (3.09g, 30mmol), and boiling under reflux for 24 hours. The cooled solution is extracted with H_2O (2 x 20ml), and the aqueous phase is extracted with CH_2Cl_2 (30ml). The combined organic extracts are dried (Na_2SO_4), filtered, evaporated *in vacuo*, and the residual oil is purified by flash chromatography and MPLC (pentane/EtOAc 4:1); and distilled at high vacuum to provide optically (by NMR and chiral HPLC on CHIRACEL OD) and analytically pure (C, H and N) colourless ***bis-oxazoline*** (2.68g, 89%). It has IR(film) with ν_{max} at 1655 (C=N) and 1250 (C-O) cm^{-1}; the ^1H NMR (300MHz, $CDCl_3$) has δ at 0.95 [d, *J* = 6.8Hz, 6H, $CH(CH_3)_2$], 1.04 [d, *J* = 6.8Hz, 6H, $CH(CH_3)_2$], 1.88 [sept, *J* = 6.8Hz, 2H, $CH(CH_3)_2$], 4.04-4.13 (m, 4H, OCH_2), 4.34-4.42 (m, 2H, CHN), 7.45-7.50 (m, 2H, 4- and 5-H), 7.74-7.77 (m, 2H, 3- and 6-H) from TMS; and for ^{13}C NMR see reference. 2,2-Bis[(*4S*)-4-isopropyl-2-oxazolin-2-yl]propane {4,5-dihydro-2-[2(4,5-dihydro-(4*S*)-4-isopropyloxazol-2-yl)propan-2-yl)]-(4*S*)-4-isopropyloxazole, (4*S*,4'*S*)-2,2'-(propane-2,2-diyl)bis(4-isopropyl-4,5-dihydrooxazole)} *[relative stereochemistry 929270-13-3; absolute stereochemistry 797757-81-4]* **$C_{15}H_{26}N_2O_2$, M 266.4, b 95-100°/0.5 mm, d_4^{25} 0.9864, n_D^{20} 1.4665, $[\alpha]_D^{24}$ -107.5 (c 1, CH_2Cl_2).** The propane ligand for metal assisted asymmetric catalysis is prepared in two steps. The ***first*** step is the synthesis of the bis-oxazoline precursor (-)-(*S,S*)-*N,N'*-bis(1-hydroxymethyl-2-methylpropyl)-2,2-dimethylmalonamide which is prepared in a flask under nitrogen purge at 0° (ice bath) containing a mixture of *S*-valinol (5.13g, 50mmol) and dry EtNH$_2$ (17.4ml, 124mmol, distilled from CaH$_2$) to which 2,2-dimethylmalondioyl chloride (3.3ml, 250mmol; Evans et al. *J Org Chem* **63** 4541 *1998*, DOI: 10.1021/jo980296f] is added dropwise during 25 minutes (temperature rising from 0° to 10°), then allowing to warm to ~25°. After stirring for 45 minutes the colourless precipitate in the mixture is dissolved by adding CH_2Cl_2 (120ml). Aqueous N HCl (30ml) is then added, the mixture is extracted with CH_2Cl_2 (3 x 13ml), the combined organic layers are washed with saturated aqueous $NaHCO_3$ (30ml), brine (30ml), dried ($MgSO_4$), filtered and evaporated *in vacuo* to provide a yellow solid which is crystallised from EtOAc (~40ml) to give the ***malonamide*** (6.4g, 84% in three crops). The amide has **m 98-99°**, $[\alpha]_D^{24}$ -6.0 (c 0.5, CH_2Cl_2); the ^{1}H NMR (300MHz, $CDCl_3$) has δ at 0.92 (d, *J* = 6.8Hz, 6H), 0.96 (d, *J* = 6.8Hz, 6H), 1.50 (s, 6H), 1.82 (oct, *J* = 6.8Hz, 2H), 2.66 (br s, 2H), 3.52 (m, 2H), 3.69-2.86 (m, 4H), 6.41 (d, *J* = 8.6Hz, 2H); correct elemental analysis for C, H and N, and for IR and ^{13}C NMR see references.

The ***second*** step is carried out, with stirring, under N_2 purge in a flask containing the preceding malondiamide (5.5g, 18.4mmol), 4-dimethylaminopyridine (204mg, 1.67mmol) in dry CH_2Cl_2 (130ml, filtered through activated Al_2O_3) at ~25°, and dry EtNH$_2$ (10.25ml, 73.4mmol, distilled from CaH$_2$) is added slowly (*via* syringe) followed by tosyl chloride (7.10g, 37mmol, 2 equivalents) dissolved in dry CH_2Cl_2 (15ml) dropwise during 30 minutes *via* a funnel which is rinsed with CH_2Cl_2 (2.5ml), and the mixture is stirred for 27 hours at ~25°. The mixture is then treated with saturated aqueous NH_4Cl (70ml), H_2O (40ml), the aqueous layer is separated, extracted with CH_2Cl_2 (3 x 55ml), the combined organic layers are dried ($MgSO_4$), filtered and evaporated. The oily residue is mixed with hot pentane (40ml), stirred for 5 minutes, the supernatant liquid is decanted, and the procedure repeated three times. The pentane layers are combined and evaporated *in vacuo* and the oily residue (4.05g 83%) is distilled (Kügelrohr) to give the ***analytically pure bis-oxazole***; its ^{1}H NMR (300MHz, $CDCl_3$, TMS) has δ at 0.95 (d, *J* = 6.8Hz, 6H), 0.91 (d, *J* = 6.8Hz, 6H), 1.51 (s, 6H), 1.88-1.73 (m, 2H), 4.06-3.93 (m, 4H), 4.26-4.15 (m, 2H); and for IR and ^{13}C NMR see Evans et al. [*Org Synth* **83** 97 *2006*, DOI: 10.15227/ orgsyn.083.0097]. Like many chiral bis(oxazolin-2-yl) ligands it complexes with metals such as

Zn (see the crystalline Zn complex *[131380-93-3]* in the 'Catalysts' section, Part 1) Cu, Ir, Pd, W, being involved (with or without further ligands) in a variety of metal catalysed asymmetric synthesis such as allylation, aziridination, cyclopropanation, Diels-Alder and retro Diels-Alder, Mukaiyama aldol condensation and hydrosilylation [see reviews by Ghosh et al. *Tetrahedron: Asymmetry* **9** 1 *1998*, DOI: 10.1016/S0957-4166(97)00593-4; Pflatz *Acta Chem Scand* **50** 189 *1996*, DOI: 10.3891/acta.chem.scand.50-0189; Johnson & Evans *Acc Chem Res* **33** 325 *2000*, DOI: 10.1021/ar960062n; Jørgensen et al. *Acc Chem Res* **32** 605 *1999*, DOI: 10.1021/ar970347f.]

1,3-Bis(2,6-isopropylphenyl)imidazolium chloride (IPr. Cl) *[250285-32-6]* **$C_{27}H_{37}N_2^+$ Cl^-, M 425.1, m 278°(dec).** IPr.Cl is a ligand precursor of an NHC (N-heterocyclic carbene— Kantchev, O'Brien & Organ *Aldrichimica Acta* **39** 97 *2006*, Phillips, Chan & Scheidt *Aldrichimica Acta* **42** 55 *2009*) which coordinates with transition metals to form soluble catalysts that promote a variety of reactions. IPr.Cl can be prepared in two steps. *1,4-Bis(2,6-diisopropylphenyl)diazabutadiene [1,2-bis(2,6-diisopropylphenylimino)-ethane]* is first prepared by dissolving 2,6-diisopropylaniline (100g, 560mmol) and glyoxal (31.5ml, 280mmol, in 40% H_2O) in absolute EtOH (500ml), and adding a few drops of formic acid as catalyst. The yellow coloured solution produces a yellow precipitate after a few hours, the mixture is stirred for 2 days, and the yellow solid is collected, washed with cold MeOH, and dried *in vacuo* to give **analytically pure *diazabutadiene-ethane*** (81.7g, 77.5%). It has ^{1}H NMR (400MHz, $CDCl_3$) with δ at 1.28 (d, J = 7.6 Hz, 24H, $CH(CH_3)_2$), 3.03 (sep, J = 6.4Hz, 4H, $CH(CH_3)_2$), 7.27 (m, 6H, $CH(CH_3)_2$-C_6H_3), 8.19 (s, 2H, NC*H*). In the second step the ***diazabutadiene-ethane*** (25g, 66mmol) in toluene (500ml) is treated with solid paraformaldehyde (2.0g, 66mmol) with stirring under N_2, heated to 100° until clear, then cooled to 40° and HCl (16.5ml, 66mmol, 4M in dioxane) is introduced with a syringe. The colour of the mixture turns to brown and a white precipitate separates within a few hours, but stirring is continued at ~25° for 36 hours. The solid is filtered off, washed with THF, and dried *in vacuo* to give off-white IPr.Cl (13.1g, 47%). It has ^{1}H NMR (400MHz, CD_2Cl_2) with δ at 1.24 (d, J = 7.2 Hz, 12H, $CH(CH_3)_2$), 1.27 (d, J = 7.2 Hz, 12H, $CH(CH_3)_2$), 2.42 (sep, J = 6.8Hz, 4H, $CH(CH_3)_2$), 7.18 (t, J = 7.2Hz, 2H, *p*-C_6H_3), 7.4 (m, 4H, *m*-C_6H_3), 7.80 (s, 2H, NC*H*), 11.0 (s, 1H, NC(*H*Cl)); and its ^{13}C NMR (100MHz, CD_2Cl_2) has δ_C{H} at 23.9 ($CH(CH_3)_2$), 26.1 ($CH(CH_3)_2$), 86.4 (NCHCHN), 125.2 (q C, phenyl), 125.8 (*C*H, phenyl), 128.7 (quaternary C, phenyl), 129.5 (*C*H, phenyl), 145.7 (*C*HCl).
IPr.Cl has been used, in dioxane under argon, as a ligand with $Pd_2(dba)_3$ (see above) to catalyse cross-coupling reactions between arylhalides and arylmagnesium bromides in a Kumada reaction to form diaryls efficiently [Huang & Nolan *J Am Chem Soc* **121** 9889 *1999*, DOI: 10.1021/ja991703n]; and in the presence of a base (*tert*-BuOK, or Cs_2CO_3) and $Pd(OAc)_2$ {or $PdCl_2$, $[Pd(allyl)Cl]_2$, $PdCl_2(PCy_3)_2$} and CO under pressure it catalyses the carbonylative cross-coupling of bromopyridines with arylboronic acids to provide high yields of arylpyridylketones [Maerten et al. *Tetrahedron* **63** 682 *2007*, DOI: 10.1016/j.tet.2006.11.008].
When IPr.Cl is treated with a base (e.g. Bu^{t}OK, Bu^{t}ONa, K_2CO_3 or Cs_2CO_3), the carbene **1,3-bis(2,6-diisopropylphenyl)-1,3-dihydro-2*H*-imidazol-2-ylidene** *[244187-81-3]* **$C_{27}H_{36}N_2$, M 388.6, m 213-217°**, is formed and is stable enough to be isolated, stored and is available commercially. The carbene-carbon atom at C2 coordinates with metals; and catalyses the formation of C-C bonds, by C-H insertion, with acetylene, MeCN, $HCCl_3$, $PhSOCH_3$, and the structures of some of the products have been confirmed by X-ray analysis [Arduengo et al. *Helv Chim Acta* **82** 2348 *1999*, DOI: 10.1002/(SICI)1522-2675(19991215)82:12<2348]. The reduced **4,5-dihydro-1,3-bis(2,6-diisopropylphenyl)dihydroimidazolium tetrafluoroborate (SIPr-HBF$_4$)** has **$C_{27}H_{39}N_2$.BF$_4$, M 478.4,** and **m >300°.**

Bis(pinacolato)diboron [bis(pinacolylborane), 4, 4, 4', 4', 5, 5, 5', 5'-octamethyl-2,2'-bi-1,2,3-dioxaborolane, B_2pin_2] *[73183-34-3]* **$C_{12}H_{24}B_2O_4$, M 253.9, m 138°, 137-140°.** This versatile borylating agent is prepared in four steps* from BBr_3 by conversion to tris(dimethylamino)borane {$(Me_2N)_3B$, m -16°, b 45°/12mm, 147-148°/atm *[4375-83-1]*} upon treatment with Me_2NH/pentane, followed by further reaction with BBr_3/pentane to give ***bromobis(dimethylamino)borane*** {$(Me_2N)_2BBr$, b 20-28°/0.5mm, 56-58°/12mm *[6990-27-8]*}, which on reaction with Na in toluene under reflux for ~3 hours provides ***tetrakis(dimethylamino)diboron*** [$(Me_2N)_2B$-$B(Me_2N)_2$, b 55-57°/2.5mm, 92°/12mm in 72% yield [Brotheron et al. *J Am Chem Soc* **82** 6242, 6245 *1962*, DOI: 10.1021/ja01509a009]. Then a mixture of $(Me_2N)_2B$-$B(Me_2N)_2$ [53.7g, 271mmol, one signal in the ^{1}H NMR at δ 2.67 (s, 24H) in $CDCl_3$] in dry toluene (510ml) and pinacol (64.4g, 545mmol) in dry toluene (340ml) under dry N_2 is stirred in an ice-water bath, and 5.4M HCl in Et_2O (203ml, 1.10 mol) is added dropwise during 2 hours. A white precipitate of Me_2NH.HCl separates immediately but the mixture is stirred further for 4

hours at ~25°; the precipitate is filtered off and the filtrate is evaporated to dryness. The white residue is dissolved in pentane (~700ml), washed with H_2O (3 x 500ml), dried ($MgSO_4$), filtered and evaporated to ~150ml. This is warmed to dissolve any solid and chilled in a freezer (-30°). The first crop of **B_2pin_2** is collected and washed with cold pentane (2 x 30ml). The mother liquor is concentrated to give further crops of **B_2pin_2** which are combined with the first crop, and dried for 16 hours at ~25°/0.1mm to give colourless plates, **m 138°**, in 79-91% yield. The diboron is air stable and is stored in a capped container. Its IR (KBr) has ν_{max} at 2978, 2930, 1372, 1289, 1189, 1177, 1127, 960, 850, 744, 660, 547 cm^{-1}; the ^1H NMR (300MHz, $CDCl_3$) has δ_H at 1.25 (s, 24H); the ^{13}C NMR (100MHz, $CDCl_3$) has δ_C at 83.4, 24.9; and the ^{11}B NMR (128.3MHz, toluene) has δ_B at 30.61 (BF_3. Et_2O as external reference with δ 0.00). [Ishiyama et al. *Org Synth* **77** 176 *2000*, DOI: 10.15227/orgsyn.077.0176; Ishiyama et al. *Org Synth* **82** 126 *2005*, DOI: 10.15227/orgsyn.082.0126, and DOI: 10.1002/0471264229.os082.20.] It borates ethylenes, acetylenes, allenes, conjugated olefins, replaces the halogen atom or a triflate group in arenes with a $–B(OR)_2$ group effectively in the presence of catalysts such as $Pt(PPh_3)_4$, $Pt(dba)_2$, or $PdCl_2(dppf)$, $Pd(dba)_2$ [Ishiyama et al. *J Am Chem Soc* **115** 11018 *1993*, DOI: 10.1021/ja00076a081; Lesley *Organometallics* **15** 5137 *1996*, DOI: 10.1021/om950918c; Ishiyama et al. *JCS Chem Commun* 689 *1997*, DOI: 10.1039/A700878C; Iverson & Smith *Organometallics* **16** 2757 *1997*, DOI: 10.1021/om970199x; Ishiyama et al. *JCS Chem Commun* 2073 *1996*, DOI: 10.1039/CC9960002073; Ishiyama et al. *Tetrahedron Lett* **39** 2357 *1998*, DOI: 10.1016/S0040-4039(98)00199-3; Ishiyama et al. *J Org Chem* **60** 7508 *1995*, DOI: 10.1021/jo00128a024; Ishiyama et al. *Tetrahedron Lett* **38** 3447 *1997*, DOI: 10.1016/S0040-4039(97)00642-4].

* **Caution**: All operations should be carried out under N_2 in a well ventilated fume cupboard because bromoborane derivatives fume in air by hydrolysing rapidly with evolution of heat.

Bis(trifluoromethanesulfonyl)amine [NTf_2, bis(trifluoromethanesulfon)amide, $(CF_3SO_2)_2NH$] *[82113-65-3]* $(CF_3SO_2)_2NH$, M 281.2, m 49-50°, 46-57°, b 90-91°/atm, has a pK of a superacid [ΔG_{acid} = 291.8 kcal/mol]. NTf_2 is a very strong neutral ***Brønsted acid*** which is to be compared with CHF_2CO_2H (ΔG_{acid} = 323.8) < HBr (ΔG_{acid} = 318.3) < CF_3CO_2H (ΔG_{acid} = 316.3) and < CF_3SO_3H (ΔG_{acid} = 299.5) [Koppel et al. *J Am Chem Soc* **116** 3047 *1994*, DOI: 10.1021/ja00086a038; see pK values in AcOH below]. For purification see at the end of its synthesis below. NTf_2 is a white crystalline solid that should be handled in closed systems (Schlenk equipment), or under very efficient ventilation as it is quite volatile, fumes in moist air and is very corrosive. However, it is soluble in H_2O, and it is stable in aqueous solutions where it can be titrated with NaOH as a typical acid with a pKa of ~1.7. In glacial acetic acid, the pK value, by measuring δ(OH) chemical shifts in the ^1H NMR spectra, is 7.8 for NTf_2, as compared with CF_3CO_2H (11.4), HNO_3 (10.1), H_2SO_4 (7.0), HI (5.8), $HClO_4$ (4.9) and CF_3SO_3H (4.2) measured in the same way. If these comparisons are valid then NTf_2 is a ***remarkably strong acid***. [Foropoulos & DesMarteau *Inorg Chem* **23** 3270 *1984*, DOI: 10.1021/ic00191a011; see also Nie et al. *J Fluorine Chem* **87** 45 *1989*, DOI: 10.1016/S0022-1139(97)00103-6.] The preparation of NTf_2 in several steps from CH_3SO_2Cl [Foropoulos & Desmarteau *Inorg Chem* **23** 3720 *1984,* DOI: 10.1021/ic00191a011;] has been improved from 48% to 80% overall yield [Desmarteau & Witz *J Fluorine Chem* **52** 7 *1991*, DOI: 10.1016/S0022-1139(00)80317-6], and is described here.

Methanesulfonyl chloride (286g, *[124-63-0]*, b 60°/21mm, 161°/atm, redistilled from P_2O_5, [Hearst & Noller *Org Synth* Coll Vol **4** 571 *1963*, DOI: 10.15227/orgsyn.030.0058) is added slowly to solid KF (170g) and stirred for 1 hour at 25°, then CH_3SO_2F is distilled off, fraction b 123-124° is collected and redistilled from P_2O_5 to give pure ***acid fluoride*** (208g). Electrochemical fluorination of the methanesulfonyl fluoride in anhydrous HF at 4-5Volts and 7-9Amps contiuously for 24 hours (as described by Gramstad & Haszeldine *J Chem Soc* 173 *1956*, DOI: 10.1039/JR9560000173) gave ***CF_3SO_2F*** (~180g, *[335-05-7]*) and was isolated *via* condensation at -78° and redistillation at -21.7°.

CF_3SO_2F (76g) is bubbled into semi-frozen NH_3 (600ml, at ~ -77°) with dry N_2, during 0.5 hours while stirring with external cooling at -78°. Excess of NH_3 is allowed to evaporate under N_2 flow into a fume cupboard; NaOMe (54g) in MeOH (500ml) is then added to the residual slush and the mixture is heated to 60° for a few minutes, the NaF is filtered off, the filtrate is evaporated, the residue is dried in a high vacuum to give CF_3SO_2NHNa (81g, 95%, *[91742-21-1]*). This Na salt (81g) is refluxed with hexamethyldisilazane (645ml, 500g, HMDS see *[999-97-3]*) under N_2 flow (oil bath temperature <145° to avoid excessive darkening) with strong mechanical stirring as the mixture thickens progressively. After release of NH_3 is complete (~12 hours), HMDS is distilled off (while increasing the vacuum), and the residual moisture sensitive solid is dried under high vacuum (in the same flask) to give $CF_3SO_2NNa(SiMe_3)$ (106g, 92%, [91742-20-0]). This salt (106g) in dry

THF (370ml) is transferred to a stirrable stainless steel autoclave (~600ml) and gaseous CF_3SO_2F (67g, ~26% excess) is transferred under N_2 pressure *via* a metal vacuum system, as it is not usually possible to cool the autoclave to below -50°. The autoclave is sealed and the mixture is stirred at 100° overnight, the volatile products are vented into an efficient hood, the autoclave is washed out with H_2O, the combined H_2O/THF mixture is washed with CH_2Cl_2, evaporated in a rotavap, and the residual solid is dried under high vacuum at 110° to give **$(CF_3SO_2)_2NNa$** (129g, 98%, *[91742-21-1]*). This Na salt (129g) and 96% H_2SO_4 (150ml) are heated in a single necked flask at 60-90°/2 x 0.01mm and the *$(CF_3SO_2)_2NH$* (NTf_2) (111g,93%) is collected in an ascending tube cooled at -22°. If necessary (cf. spectra below), it is sublimed twice at 60° and/or recrystallised from $CFCl_3$ at -50°. The ***analytically pure crystalline white solid*** has **m 49-50°** and can be stored in a sealed container in a drybox.
NTf_2 has IR (gas in equilibrium with solid at 25°) with ν_{max} at 3395 (m), 3320 (br), 1463 (m), 1440 (m), 1300 (w), 1240 (s), 1224 (s), 1138 (s), 860 (m), 643 (vw), 614 (m), 570 (vw) and 505 (w) cm^{-1}; Raman (solid -180°) has ν_{max} at 3205 (w), 1464 (vw), 1458 (w), 1450 (w), 1343 (w), 1263 (s), 1142 (m, 839 (w), 778 (s), 646 (w), 591 (w), 566 (w), 537 (w), 510 (w), 392 (m), 386 (m), 346 (s), 311 (s), 276 (s), 212 (w), 195 (w) and 128 (m) cm^{-1}; the ^1H NMR (60MHz, external TMS) has peaks at 10.42 (in Me_2CO d_6), 7.92 (in $CFCl_3$) ppm; the ^{19}F NMR (20MHz, in $CFCl_3$ as solvent and internal standard) has a peak at -75.97 (s) ppm, i.e. is at higher field than that of $CFCl_3$; the MS[EI] has *m/z* at 281 (M^+), 211 ($CF_3SO_2NSO_2^+$), 147 ($CF_3SO_2N^+$), 133 ($CF_3SO_2^+$) and 69 (CF_3^+); and the MS[CI] has major *m/z* at 282 (MH^+), 150 ($CF_3SO_3H^+$ or $CF_3SO_2NH_3^+$) and 115 ($CF_2SO_2H^+$ or $CF_2SONH_2^+$). [Foropoulos & DesMarteau *Inorg Chem* **23** 3720 *1984*, DOI: 10.1021/ic00191a011.]
NTf_2 forms several derivatives including ***$(CF_3SO_2)_2NCl$*** (viscous acrid liquid, **m -96° to -93°**, *[91742-17-5]*), ***$(CF_3SO_2)_2NNO$*** (white solid, **m ~118°**, *[91742-19-7]*), ***$(CF_3SO_2)_2NNO_2$*** (white crystals **dec ~107°**, *[91742-18-6]*), ***$(CF_3SO_2)_2Si(Me)_3$*** (low-volatile colourless liquid, *[82113-18-5]*), and with CsF in MeCN it gives the cesium salt ***$(CF_3SO_2)_2NCs$*** (white crystals **m 115°**, *[91742-16-4]*) [Foropoulos & DesMarteau *Inorg Chem* **23** 3720 *1984*, DOI: 10.1021/ic00191a011]. It forms an ***N-trimethylsilyl derivative*** (**$TMSNTf_2$** prepared from allylTMS and NTf_2, see above) which catalyses Diels-Alder reactions between methyl acrylate and various dienes [Mathieu & Ghosez *Tetrahedron Lett* **38** 5497 *1997*, DOI: 10.1016/S0040-4039(97)01208-2], as well as Friedel-Crafts acylations of anisole; and allylation and bis-allylation of carbonyl derivatives [Oshii et al. *Synlett* 1145 *1997*]. It readily forms the silver salt, **$AgNTf_2$**, e.g. with Ag_2CO_3.

1,3-Bis(2,4,6-trimethylphenyl)imidazolium chloride (IMes.Cl) *[141556-45-8]* **$C_{21}H_{25}N_2^+$ Cl^-, M 340.9, m >300°.** This NHC (N-Heterocyclic Carbene) precursor is prepared by established procedures from 2 mols of amine, 1 mol of glyoxal and one mol of formaldehyde [Arduengo USPatent 5 077 414 *1991, Chem Abstr* **116** 106289 *1002*, cf. Herrmann et al. *Chem Eur J* **2** 1627 *1996*, DOI: 10.1002/chem.19960021222] and washed with THF before use. It is useful for making IMesCuCl which in turn is used for making IMesAuCl and $[IMesPtCl]_2$ [Furst & Cazin *Chem Commun* **46** 6924 *2010*, DOI: 10.1039/C0CC02308F].

1,3-Bis(2,4,6-trimethylphenyl)imidazol-2-ylidene (IMes) *[141556-42-5]* **$C_{21}H_{24}N_2$, M 304.4, m 150-155°(dec.).** By using Schlenk equipment and techniques under dry N_2, this NHC is prepared from the preceding IMes.Cl (10.0g, 29.3mmol) suspended in dry THF (80ml) and stirred for 15 minutes, then solid *tert*-BuOK (3.5g, 31.2mmol) is added at ~25° in one portion. The dark grey solution is stirred for 20 minutes, and the volatiles are removed *in vacuo*. The residue is extracted into warm toluene (2 x 50ml), filtered through Celite and the solvent is removed *in vacuo* to provide small crystals of the carbene (7.55g, 84%). The crystals are recrystallised from hexane to yield colourless crystals, **m 150-155°(dec)** which are analytically pure and suitable for X-ray structural analysis. Its ^1H NMR (300MHz, THF-d_8, TMS) has δ_H at 2.02 (s, 2',6'-CH_3, 12H), 2.30 (s, 4'-CH_3, 6H), 6.94 (s, ArH, 4H), 7.04 (s, 4,5-C*H*, 2H); and its ^{13}C NMR (75MHz, THF-d_8, TMS) has δ_C at 18.04 (s, 2',6'-*C*H_3), 21.04 (s, 4'-*C*H_3), 121.28 (s, *C*-4 and *C*-5), 129.69 (s, Mes *C*-3',5'), 135.73 (s, Mes *C*-2',6'), 137.55 (s, Mes *C*-4), 139.73 (s, Mes *C*-1), 219.69 (s, N*C*N carbene-*C*); and the ^{15}N NMR (30MHz, THF-d_8, $NH_4{}^{15}NO_3$) has δ at -178.85. [Arduengo et al. *J Am Chem Soc* **114** 5530 *1992*, DOI: 10.1021/ja00040a007.] It is useful for making a variety metal complexes of ruthenium (among other metals) for catalysing olefin metathesis [Grubbs *Tetrahedron* **60** 7117 *2004*, DOI: 10.1016/j.tet.2004.05.124], and other metathesis reactions [Love et al. *Angew Chem Int Ed* **41** 4035 *2002*, DOI: 10.1002/1521-3773(20021104)41:21<4035; Schrodi & Pederson *Aldrichimica Acta* **40** 45 *2007*, Kanemitsu & Seeberger *Org Lett* **5** 4541 *2003*, DOI: 10.1021/ol035463z].

4-Bromobiphenylboronic acid MIDA ester {[2-(4-bromophenyl)-6-methyl-1,3,6,2-dioxazaborocane-4,8-di-

one], (4-bromophenyl)[*N*-[(carboxy-κ*O*)methyl]-*N*-methylglycinato(2-)-κ*N*,κ*O*] boron *[943552-04-3]* **M $C_{11}H_{11}BBrNO_4$, 311.9, m 238-240°, 248-253°.** This ester is obtained from 4-bromophenylboronic acid (24.99g, 124.4mmol) and MIDA (18.31g, 124.4mmol, see *[4408-64-4]*) to which is added a freshly prepared mixture of DMSO (6.3ml) and toluene (118.7ml) in a flask to give a white solid suspension in a clear colourless solution. The flask is fitted with a Dean-Stark trap and a reflux condenser, and the mixture is boiled under reflux with stirring (magnetic Teflon coated bar) for 6 hours during which time the mixture became clear and about 2.1ml of H_2O are collected in the trap. Heating is stopped and the reaction is allowed to cool, with stirring, to ~25° during 1 hour; the apparatus is washed down with toluene and the combined liquids are evaporated (40°/15mm) to remove most of the toluene and give a crude tan, chunky, solid. Acetone (15ml) is added to the residue and swirled vigorously to give a white solid in a tan solution. To this mixture is added Et_2O (150ml, dried through neutral Al_2O_3 columns) in small portions (25ml) with stirring each time to allow further separation of white solid, and is finally filtered onto a medium porosity glass frit. The solid is washed with Et_2O (3 x 50ml), dried by suction, and is dried further in a vacuum (~25°/1mm) for 4 hours to give ***4-bromophenylboronic acid MIDA ester*** as an air stable, free-flowing white powder (36.3g, 94%) with **m 238-240°**. *Alternatively*, the crude tan solid can be purified by silica gel chromatography to provide the white MIDA ester in almost quantitative yield. An analytical sample has ^{1}H NMR (400MHz, CD_3CN) with δ_H at 2.50 (s, 3H), 3.89 (d, *J* = 16.0Hz, 2H), 4.07 (d, *J* = 16.0Hz, 2H), 7.41 (d, *J* = 8.0Hz, 2H), 7.55 (d, *J* = 8.0Hz, 2H); the ^{11}B NMR (100MHz, CD_3CN) has δ_B at 12.0; and for IR, ^{13}C NMR and EI-MS see reference. [Ballmer, Gillis and Burke *Org Synth* **86** 344 *2009*, DOI: 10.15227/orgsyn.086.0344.] The ***2-bromophenyl-*** and ***3-bromophenyl- MIDA esters*** have **m 205-315°** and **m 237-242°** respectively.

trans*-(2-Bromovinyl MIDA boronate {*trans*-2-bromovinylboronic acid MIDA ester 6-methyl-2-*trans*-bromovinyl-1,3,6,2-dioxazabronane-4,8-dione, [(1*Z*)-2-bromoethenyl][*N*-[(carboxy-κ*O*)methyl]-*N*-methylglycinato(2-)-κ*N*,κ*O*]-boron}** *[trans E 1104636-68-1; cis Z has 1105069-27-9]* **$C_7H_9BBrNO_4$, M 261.9.** The ester is prepared using Schlenk equipment in subdued daylight under dry N_2 by adding dropwise *via* a syringe freshly distilled ***(E)-(2-bromoethenyl)dibromoborane (21.0g, 75.9mmol, prepared from BBr_2 and acetylene, Hyuga et al. *Chem Lett* **16** 1757 *1987*, DOI: 10.1246/cl.1987.1757) to a stirred mixture of MIDA (16.9g, 114mmol, 1.5 equivalents, see *[4408-64-4]*) and 2,6-lutidine (17.7g, 151.9mmol, 2 equivalents) in DMSO (250ml) at 0° over 15 minutes, and allowed to warm to ~25° then kept at that temperature for 48 hours. The yellow mixture is treated with H_2O (300ml) and extracted with 1:1 THF:Et_2O (3 x 500ml), the combined extracts are washed with brine (3 x 350ml), dried ($MgSO_4$), filtered and evaporated *in vacuo*. The light yellow solid residue is purified by flash chromatography on silica gel and eluting with Et_2O/petroleum ether (1:1), then EtOAc, then EtOAc/MeCN (9:1) to give the desired boronate as colourless crystals (12g, 60%). On TLC it has R_F 0.46 (Merck silica gel plate grade 9385, 60Å, 230-400 mesh, eluting with EtOAc and visualised with $KMnO_4$). [A preparation similar to the one for vinyl MIDA boronate (this chapter) using the MIDA-di Na salt gave similar yields [cf. Uno, Gillis and Burke *Tetrahedron* **65** 3130 *2009*, DOI: 10.1016/j.tet.2008.11.010]. The material stored under air at room temperature for 1.5 years showed no signs of deterioration. Crystals grown by slow evaporation of an EtOAc solution at ~25° were suitable for X-ray analysis which revealed a ***trans* configuration** while confirming the expected structure with a pyramidalised boron centre. Its ^{1}H NMR (500MHz, CD_3CN, δ = 1.93 centre line, TMS) has δ_H at 6.69 (d, *J* = 15.0Hz, 1H), 6.63 (d, *J* = 14.5Hz, 1H), 3.97 (d, *J* = 17.0Hz, 2H), 3.82 (d, *J* = 17.0Hz, 2H), 2.80 (s, 3H); the ^{11}B NMR (100MHz, CD_3CN, $BF_3.Et_2O$ internal standard) has δ at 10.5; and for IR, ^{13}C NMR and HRMS (EI) see references. It is very useful in the reactions stated for vinyl MIDA boronate and for ***iterative cross-coupling***. [Lee, Gray, Peak and Burke *J Am Chem Soc* **130** 466 *2008*, DOI: 10.1021/ja078129x; Uno, Gillis and Burke *Tetrahedron* **65** 3230 *2009*, DOI: 10.1016/j.tet.2008.11.010; Gillis & Burke *Aldrichimica Acta* **42** 17 *2009*].

Chloro(dimethylsulfide)gold(I) [(dimethylsulfide)gold(I) chloride, aurochloro dimethylsulfide, AuCl.Me_2S] *[29892-37-3]* **$(CH_3)_2SAuCl$, M 295.6, m >100°(dec), 100-102°(dec), 120°(dec).** All procedures for preparing this complex should be carried out in an efficient fume cupboard because Me_2S is **toxic** and has a **foul** odour. The gold complex has been prepared by adding Me_2S (1 mole, see *[75-18-3]*) slowly to a stirred solution of NH_4AuCl_4 (1mole) in dilute *Aqua Regia* when the complex separates and is collected [Allen & Wilkinson *Spectrochimica Acta* **28B** 2257 *1972*, DOI: 10.1016/0584-8539(72)80200-9]. *Alternatively*, Me_2S is added to a solution of auric chloride ($AuCl_3$) in HCl [which forms ***aurichloric acid (chloroauric acid)*** $HAuCl_4$ see *[16903-35-8]*) when much heat is evolved and a flocculent white precipitate of ***AuCl.Me_2S*** separates. It is

filtered off, washed with H_2O (in which it is insoluble) and a little EtOH (in which it is slightly soluble), and dried at room temperature in air in the dark. It is air stable and can be recrystalised from $*C_6H_6/Me_2CO$. Clearly, the Me_2S reduces Au(III) to Au(I) before the complex separates. It is rapidly decomposed by sunlight to give metallic gold, Me_2S and HCl. In the absence of sunlight it can be kept in the solution in which it has been prepared for long periods, or in the presence of a slight excess of Me_2S in which colourless crystalline needles are formed. It is soluble in many organic solvents, e.g. CH_2Cl_2, $*C_6H_6$, but solutions deposit metallic gold in time. The gold content can be determined by exposing solutions to sunlight, and the gold that deposits can be collected and weighed. On heating in N_2, Me_2S begins to evolve above 100° until 200°, after which a residue of gold is obtained. [Phillips *J Am Chem Soc* **23** 250 *1901*, DOI: 10.1021/ja02030a008.] In a third synthesis, a suspension of freshly prepared Au(I)Cl (0.23g, 1mmol, *[10294-29-8]*) in dry $*C_6H_6$ (25ml) is treated with an excess of Me_2S which causes the solid to dissolve on stirring at 20°. After half an hour, the solution is evaporated *in vacuo*, and the crystalline residue is recrystallised from $*C_6H_6/Me_2CO$ (1:1) to give a 70% yield of the pure complex, **m 100-102°(dec)**. [Dash & Schmidbaur *Chem Ber* **106** 1221 *1973*, DOI: 10.1002/cber.19731060418.]

For the **Au(III) complex**, aurochloric acid (10g) in H_2O (5ml) and a 1:1 v/v mixture of HNO_3 (d 1.4) and HCl (d 1.2) (1ml) are cooled in an ice bath for 10 minutes, and then Me_2S (0.5g) in Me_2CO (5ml) is added gradually (1ml at a time, at 3-5 minutes interval), heat is evolved and a yellow oil separates which soon solidifies to an orange yellow solid (some white ***aurochloro dimethylsulfide*** separates simultaneously). After allowing to stand in contact with a further quantity of acid mixture, all the solid is converted to ***aurichloro dimethylsulfide*** (**$AuCl_3$. Me_2S**). This is filtered off, washed with a 1:1v/v mixture of N/10 HNO_3 and N/10 HCl then H_2O and finally with EtOH, and dried in air. It is recrystallised from $CHCl_3/Et_2O$ to give yellow prismatic crystals of analytically pure ***auri complex*** **$AuCl_3.Me_2S$** with **M 365.5** *[29826-91-3]* and **m 160°**, which is soluble in $CHCl_3$, Et_2O, Me_2CO, and warm $*C_6H_6$. When this auri complex is warmed with EtOH on a water bath, it is converted into the ***auro complex $AuCl.Me_2S$*** and the colour changes to white. The latter can be converted back to the former complex by treatment with aqua regia or chlorine water. [Ray & Sen *J Indian Chem Soc* **7** 67 *1930*.]

$AuCl.Me_2S$ is ***monomeric*** with M^+ at *m/e* at 294; its IR (Nujol mulls between polyethylene discs or CsI plates) has bands at 730vw (SC_2 *asym*), 675vw (SC_2 *sym*), 345s (Au-S, str), 326s and 319sh (Au-Cl str), 279m (SC_2 *def*), 198s (CSAu *def*), 109m, 93m and 83m (SAuCl *bend and lattice modes*) cm^{-1} [Goggin et al. *JCS Dalton* 1904 *1972*, DOI: 10.1039/DT9720001904], the ^1H NMR (100MHz, CH_2Cl_2, TMS) has one peak at $\tau = 8.1$ ppm [Allen & Wilkinson *Spectrochim Acta* **28A** 2257 *1972*, DOI:10.1016/0584-8539(72)80200-9], and the ^1H NMR (60MHz, $CHCl_3$, TMS) also has one peak at $\delta = -2.81$ [Dash & Schmidbaur *Chem Ber* **106** 1221 *1973*, DOI: 10.1002/cber.19731060418].

It is a very useful compound for preparing a variety of gold complexes and gold catalysts [e.g. IMesAuCl in Part 1 of this Chapter].

Chlorotris(triphenylphosphine)cobalt [$CoCl(PPh_3)_3$] *[26305-75-9]* **[$(C_6H_5)_3P]_3CoCl$, M 881.2, m 135-139°(dec), 176-179°(dec.), 177°(dec.), 188°(dec).** The complex is prepared under N_2, and preferably in Schlenck-type equipment. $CoCl_2.6H_2O$ (9.6, 40.3mmol), PPh_3 (32g, 122mmol) and EtOH (600ml) are stirred while being purged with N_2 for several minutes, then vigorously at 60-70° for 30 minutes to ensure complete formation of the blue-coloured fine powder of $CoCl_2(PPh_3)_2$. Then under vigorous stirring the mixture is cooled to ~30° and $NaBH_4$ (1.28g, 33.9mmol) is added during ~10 minutes (in ~10 portions) whereby the colour of the solution changes from blue to green, then to brown. The green-brown precipitate is collected by filtration (in air), washed with portions of EtOH until the filtrate is no longer blue in colour, then with H_2O, EtOH again and finally with hexane, and dried *in vacuo* to give $CoCl(PPh_3)_3$ (24g, 67%). In the solid state it decomposes quite slowly in air, but is stable indefinitely under argon or N_2 in a refrigerator. It is soluble in $*C_6H_6$ and CH_2Cl_2 and the spectra in $*C_6H_6$ have λ_{max} at 745, ~940sh, 1100, 2200nm. [Wakatsuki et al. *Inorg Synth* **26** 189 *1989*, DOI: 10.1002/9780470132579.ch34; Aresta et al. *Inorg Chim Acta* **3** 227 *1969*, DOI: 10.1016/S0020-1693(00)92484-8.]

$CoCl(PPh_3)_3$ is a useful stoichiometric reagent for radical dimerisation of halogenated organic compounds as in the biomimetic synthesis of the bis-sesquiterpene lactones (±)-biatractylolide and (±)-biepiasterolide [Bagal et al. *J Org Chem* **69** 9100 *2004*, DOI: 10.1021/jo0488053], and alkaloid dimerisation in the total synthesis of the alkaloids (-)-calycanthine and (+)-chimonanthine [Movassaghi & Schmidt *Angew Chem Int Ed* **46** 3725 *2007*, DOI: 10.1002/anie.200700705]. It is used for the preparation of COPs (**c**obalt **o**xazoline **p**alladacycles) catalysts

[see above, Stevens & Richards *Organometallics* **18** 1346 *1999*, DOI: 10.1021/om980812s].

(1,3,5,7-Cyclooctatetraene)dilithium (2,4,6-cyclooctatriene-1,2-diyl dilithium) *[40698-91-7]* **$C_8H_8Li_2$, M 118.1.** It is prepared by suspending lithium foil (1.0g, 144mmol) under N_2 in Et_2O (20ml) and stirring at 0° with 1,3,5,7-cyclooctatetraene (5.0g, 48mmol) for 16 hours. The small amount of white precipitate is allowed to settle, and an aliquot sample of the orange solution is sucked into a syringe, and the molarity of the solution is determined by hydrolysis with H_2O and titrating with standard acid. A saturated solution of $Li_2C_8H_8$ in Et_2O is ~0.24M. Store in the cold and away from air and moisture. The solution is not more flammable than an Et_2O solution, but the dry solid $Li_2C_8H_8$ is **pyrophoric** in air. [Spencer et al. *Inorg Synth* **19** 213 *1979*, DOI: 10.1002/9780470132500.ch49; Crascall et al. *Inorg Synth* **28** 126 *1990*, DOI: 10.1002/9780470132593.ch34.]

(1*R*,2*R*)-(+)-1,2-Diaminocyclohexane-*N*,*N*′-bis(2-diphenylphosphinobenzoyl) [(*R*,*R*)-DACH-phenyl Trost ligand] *[138517-61-0]* **and (1*S*,2*S*)-(–)-1,2-diaminocyclohexane-*N*,*N*′-bis(2-diphenylphosphinobenzoyl) [(*S*,*S*)-DACH-phenyl Trost ligand]** *[169689-05-8]* **$C_{44}H_{40}N_2O_2P_2$, M 690.8, m 137-142°, $[\alpha]_D^{20}$ *R,R*- +134, *S,S*- -134 (c 1.0, MeOH), $[\alpha]_D^{20}$ *R,R*- +55.1, *S,S*- -55.1 (c 2.85, CH_2Cl_2).** The (1*R*,2*R*)-enantiomer is prepared from (1*R*,2*R*)-1,2-diaminocyclohexane (0.535g, 4.68mmol), 2-(diphenylphosphino)benzoic acid (3.02g, 9.83mmol, [17261-28-8]), DMAP (61.0g, 0.5mmol) and DCC (2.13g, 10.3mmol) in CH_2Cl_2 (30ml) for 6 hours. The residue is chromatographed on silica gel and eluted with a 15—30% gradient of EtOAc/hexanes followed by recrystallisation from CH_2Cl_2/Et_2O to give the ***(+)-DACH-phenyl Trost ligand*** (2.96g, 90%). It has an R_F of 0.43 on silica TLC (1:1 EtOAc-pentanes) and its ^1H NMR (200MHz, $CDCl_3$) has δ at 7.57 (m, 2H), 7.15-7.26 (m, 24H), 6.91 (m, 2H), 6.31 (br d, *J* = 7.7Hz, 2H, N-H), 3.77 (m, 2H), 1.87 (m, 2H), 1.62 (m, 2H), 0.9-1.3 (m 6H); has correct elemental analyses for C, H, N and P; and for IR and ^{13}C NMR see ref. [Trost et al. *J Am Chem Soc* **114** 9327 *1992*, DOI: 10.1021/ja00050a013.]
The Pd complexes have found extensive use in catalysing Asymmetric Allylic Alkylation (AAA) and palladium-catalysed Dynamic Kinetic Asymmetric Transformations (DKYATs), i.e. kinetic resolutions [Trost & Fandrick *Aldrichimica Acta* **40** 59 *2007*].

(–)-*N*,*N*′-(1*R*,2*R*)-1,2-Diaminocyclohexanediylbis(2-pyridinecarboxamide) [(*R*,*R*)-DACH-pyridyl Trost ligand] *[218290-24-5]* **and (+)-*N*,*N*′-(1*S*,*SR*)-1,2-diaminocyclohexanediylbis(2-pyridinecarboxamide) [(*R*,*R*)-DACH-pyridyl Trost ligand]** *[172138-95-3]* **$C_{18}H_{20}N_4O_2$, M 324.4, m 171-176°, 174-176°, $[\alpha]_D^{20}$ *R,R* -97.0, *S,S* +98.0 (c 1.0, MeOH).** The (*RS,RS*)-1,2-diaminocyclohexanediylbis(2-pyridinecarboxamide) is readily prepared by treating a mixture of 1,2-diaminocyclohexane (5.7g, 50mmol) in pyridine (20ml) and pyridine-2-carboxylic acid (12.3g, 100mmol) in pyridine (40ml) with triphenylphosphite (31.0g, 100mmol), and heating on a steam bath for 12 hours. The resulting brown oil is extracted into $CHCl_3$, washed twice with aqueous $NaHCO_3$, and H_2O, dried ($MgSO_4$), filtered, evaporated to a small volume and set aside overnight whereby brown crystals of the product are obtained (7.6g, 47%). Recrystallisation from $CHCl_3$ gives ***analytically pure (±)-ligand*** as white crystals, **m 201-202°**, with IR (KBr) ν_{max} at 3300, 3050, 2940, 2850, 1655, 1535 cm^{-1}; and the ^1H NMR (60MHz, $CDCl_3$) has δ at 8.6 (m), 8.4 (br), 8.1 (m, combined 8H), 7.8 (m, 2H), 7.4 (m, 2H), 4.1(br, 2H), 2.3 (br), 1.6 (br, combined 6H) downfield from TMS (peaks are not well separated at 60MHz). [Barnes et al. *J Chem Eng Data* **23** 349 *1978*, DOI: 10.1021/je60079a006.] **(1*R*,2*R*)-DACH-pyridyl Trost ligand** and **[(1*S*,2*S*)-DACH-pyridyl Trost ligand** are prepared similarly, but starting from *(1R,2R)(-)-[20439-47-8] and (1S,2S)(+)-[21436-03-3]* 1,2-diaminocyclohexanes respectively [cf. their resolution in Chapter 3, 'Alicyclic Compounds'].
These ligands readily form complexes with Cu, Zn, Co, Pt and Pd [Mulqi et al. *Inorg Chim Acta* **53** L91c *1981*, DOI: 10.1016/S0020-1693(00)84752-0; Adolfsson & Moberg *Tetrahedron: Asymmetry* **6** 2023 *1995*, DOI: 10.1016/0957-4166(95)00263-O] and the Pd complexes have found extensive use in catalysing Asymmetric Allylic Alkylation (AAA) and palladium-catalysed Dynamic Kinetic Asymmetric Transfomations (DKYATs), i.e. kinetic resolutions [Trost & Fandrick *Aldrichimica Acta* **40** 59 *2007*].

Di-*tert*-butylchlorophosphine *[13716-10-4]* **$[(CH_3)_3C]_2PCl$, M 180.7, b 48°/3mm, 72-73°/13mm, d_4^{25} 0.951, n_D^{20} 1.482.** This chlorophosphine is prepared from two equivalents of *tert*-butylmagnesium bromide and PCl_3 followed by the usual workup and fractional distillation in a vacuum, and redistillation of the desired fraction. With MeLi it provides ***di*-tert-*butylmethylphosphine* b 95-105°/3mm (170-172°/atm)**, which with MeI provides ***di*-tert-*butyl-dimethylphosphinium iodide* m 95-105°** (from EtOH). Hydrolysis of the chlorophos-

phine with H_2O provides ***di*-tert-*butylphosphine oxide*** *[684-19-5]* **M 162.2, m 55-59°** (hygroscopic crystals), **b 112°/9mm**, with IR which has ν_{max} ($CHCl_3$) 2950s, 2290, 1470s, 1394w, 1370, 1142s, 918, 815 (P-Bu^t) and 656 cm^{-1}; the ^{1}H NMR (CD_2Cl_2) has τ at 3.53 (d, J_{HP} = 453Hz), 8.65 (d, J_{HCCP} = 15Hz, Bu^t). ***Note*** that this phosphine oxide is tautomeric with ***di*-tert-*butylphosphinous acid***. [Hoffmann & Schellenbeck *Chem Ber* **99** 1134 *1966*, DOI: 10.1002/cber.19660990408; Hoffmann & Schellenbeck *Chem Ber* **100** 692 *1967*, DOI: 10.1002/ cber.19671000241; Issleib & Krech *J Organometal Chem* **13** 283 *1968*, DOI: 10.1016/S0022-328X(00)82755-2; Crofts et al. *J Chem Soc C* 332 *1970*, DOI: 10.1039/J39700000332.]
The complex from $Pd(OAc)_2$ and this bulky *di*-tert-*butylchlorophosphine* ligand, after condensation with *P*-imino-azaphosphatrane, catalyses efficiently the cross-coupling of arylboronic acids with aryl halides in the Suzuki-Miyaura reaction to provide specific unsymmetrical biphenyls in well over 90% yields [Kingston & Verkade *J Org Chem* **72** 2816 *2007*, DOI: 10.1021/jo062452l.]

4,4'-Di-*tert*-butyl-2.2'-bipyridyl (dtbpy) *[72914-19-3]* **$C_{18}H_{24}N_2$, M 268.4, m 159-160°, 159-161°, b 235°/32mm, pK_{Est} ~4.2.** The bipyridyl has been prepared by reaction of *tert*-butylpyridine with $NaNH_2$ (ratio 2:1) in xylene at 144-218° during 26 hours, then cooled, hydrolysed with H_2O, the organic layer is separated, dried, and distilled *in vacuo*. The bipyridyl solidified and can be sublimed. [McGill USP 4177349, *Chem Abstr* **92** 110871 *1980*, *Beilstein* **23/8** IV 181.] By coordinating with Ir(COD) and Ir(COE), complexes formed with **dtbpy** assist in C-H borylations [see Ir complexes above and Ishiyama et al. *Angew Chem Int Ed* **41** 3056 *2002*, DOI: 10.1002/1521-3773(20020816)41:16<3056; Ishiyama et al. *J Am Chem Soc* **124** 390 *2002*, DOI: 10.1021/ja0173019.]

Di-*tert*-butylneopentylphosphine [DTBNpP, (Pbu$^t_2$(-CH_2Cme$_3$)] *[60633-21-8]* **$C_{13}H_{29}P$, M 216.3, b 40°/0.1 mm, d ^{25} 0.839 g/ml, n $^{20}_D$ 1.478.** This ligand, with increased steric bulk, can be obtained by adding a solution of di-*tert*-butylchlorophosphine (108.4g, 114.0ml, 0.6mol, see *[13716-10-4]*) in THF (250ml) to neopentylmagnesium chloride (from 16g, 0,67g-atom of Mg turnings, 74ml, 64g, 0.6mol of neopentyl chloride in 250ml of dry THF containing a small amount of 1,2-dibromoethane as initiator, and stirred until all the Mg has dissolved, then cooled to 0°) at 0° with stirring, allowing to warm to ~25°, boiling under reflux for *ca* 15 minutes, then the solvent is removed at ~40°/40mm). The residue is diluted with Et_2O, the mixture is hydrolysed by stirring with saturated aqueous NH_4Cl, the layers are separated and the organic phase is dried ($MgSO_4$), filtered, the Et_2O is removed at ~25°/50mm, and the residual phosphine is distilled at high vacuum. There are also alternative syntheses for DTBNpP. ***Work with protective gloves, with eyes and face protection, and in an efficient fume cupboard***. [cf. King et al. *J Org Chem* **41** 972 *1976*, DOI: 10.1021/jo00868a016.] It is, however, better to store and use it in the form of its salts, e.g. DTBNpP.HBF_4 (see below). In that case an equivalent amount of base, e.g. *t*-BuONa, must be added to the reaction mixture to liberate the free ligand. With a Pd source, e.g. $Pd(Oac)_2$ or $Pd_2(dba)_3$, catalysed H—B coupling (Hartwig—Buchwald) of various aryl halides has been achieved with a variety of aromatic primary or secondary amines, or saturated heterocyclic amines, e.g. morpholine, to form di- or tri-substituted amines in toluene solutions at 23° to 140° in high yields. [Hill et al. *J Org Chem* **71** 5117 *2006*, DOI: 10.1021/jo060303x.]
Unlike with Pd complexes, when DTBNpP is mixed with $Pt(PhCN)_2Cl_2$ (1:1 mol per Pt atom) in CH_2Cl_2 at 20° for a few minutes, a white binuclear complex is formed. It was characterised by spectroscopic and Xray diffraction methods to have the structure **[PtCl(Pbu$^t_2$CH$_2$Cme$_2$CH$_2$)]$_2$**, i.e. one of the methyl groups of the neopentyl moiety is folded back and is metallated by the Pt to form a five membered Pt heterocyclic ring — and the molecule is ***dimeric***. Such metallation does not occur with Pbu$^t_2$Pr^n under similar conditions, and in this case the ***monomeric*** *cis* and *trans* **[PtCl$_2$(PhCN)(Pbu$^t_2$Pr^n)]** square planar complexes are formed. [Mason et al. *JCS Chem Commun* 292 *1976*, DOI: 10.1039/C39760000292.]

Di-*tert*-butylneopentylphosphonium tetrafluoroborate (DTBNpP$^+$.HBF_4^-) *[886059-84-3]* **$C_{13}H_{30}P^+$ BF_4^-, M 304.2, m 258-262°(dec).** This air stable salt is prepared in the same manner as [(*tert*-Bu)$_3$PH$^+$ BF_4^-, *[131274-22-1]* by mixing DTBNpP and aqueous HBF_4. It is easier to handle [cf. Netherton & Fu *Org Lett* **3** 4295 *2001*, DOI: 10.1021/ol016971g], and is a useful ligand in Pd-catalysed cross-coupling amination reactions of aryl bromides and chlorides [Hill et al. *J Org Chem* **71** 5117 *2006*, DOI: 10.1021/jo060303x].

3,3'-Di-*tert*-butyl-5,5',6,6'-tetramethyl-1,1'-biphenyl-2,2'-diol {H$_2$[BIPHEN], 1,1'-biphenyl-2,2'-diol, 3,3'(1,1'-dimethylethyl)-5,5',6,6'-tetramethyl-} *[R- 329735-68-4, S- 205927-03-3, RS- 101203-31-0]*

$C_{24}H_{34}O_2$, M 354.5, m 160.5-161.5º. This biphenyl is prepared by the oxidation of 2-*tert*-butyl-4,5-dimethylphenol. The oxidation is carried out by slowly adding a solution of $K_2Cr_2O_7$ (130g, 0.442 mole, i.e. 1.02 equivalents being twice the theoretical amount to form the biphenyl) in a mixture of concentrated H_2SO_4 (260ml) and H_2O (780ml, **CARE** since much heat is evolved on mixing) at ~25º, to a solution of 2-*tert*-butyl-4,5-dimethylphenol (231.7g, 1.3 moles, see *[1445-23-4]*) in AcOH (1300ml) over 10 minutes at 55-60º and keeping at this temperature range. The colour of the solution changes from orange to green and a tan coloured solid separates during the reaction which is then cooled to room temperature. The solid is collected, washed sequentially with H_2O (2 x 250ml) and MeOH (3 x 200ml) until the solid is almost colourless, dried *in vacuo* and recrystallised from hot MeOH or dioxane/MeOH to give racemic ***3,3'-di-tert-butyl-5,5',6,6'-tetramethyl-1,1'-biphenyl-2,2'-diol*** *[101203-31-0]* **(~115g, ~50%) m 160.5-161.5º** (m 140-142º before recrystallisation). Its ^{1}H NMR (400MHz, $CDCl_3$, TMS) has δ at 7.12 (s, 2H, aromatic C*H*), 4.79 (s, 2H, OH), 2.24 (s, 6H, CH_3), 1.80 (s, 6H, CH_3), 1.38 (s, 18H, C(CH_3)$_3$); and for IR and ^{13}C NMR see references. [Albert *J Am Chem Soc* **76** 4983 *1954*, DOI: 10.1021/ja01648a068; Alexander et al. *J Am Chem Soc* **120** 4041 *1998*, DOI: 10.1021/ja974353i; Alexander et al. *Organometallics* **19** 3700 *2000*, DOI: 10.1021/om000336h.]

Optical Resolution of H_2[BIPHEN]*:** Two procedures have been used: **(i)** preparation of the respective 2,2'-cyclic phosphoric acid (*via* reaction with $POCl_3$ with the di-Na salt in THF) followed by hydrolysis and recrystallisation of the ***(±)-acid (-)-cinchonidine salt in EtOH, followed by hydrolysis of the optically salts, conversion of the optically active cyclic acids to their respective optically active cyclic methyl esters, and finally cleavage with 'Red-Al' [Na $AlH_2(OCH_2CH_2OMe_2)$] in toluene to give optically pure *H_2[BIPHEN]*s. [Alexander et al. *J Am Chem Soc* **120** 4041 *1998*, DOI: 10.1021/ja974353i]; and **(ii)** which is decribed here in some detail as it can be used generally for the resolution of racemic 2,2'-dihydroxybiphenyls. ***Firstly***: A solution of (1*R*,2*S*,5*R*)(-)-menthol (44g, 282mmol) in CH_2Cl_2 (100ml) is added to a solution of PCl_3 (58g, 423mmol, 1.5 equivalents) in CH_2Cl_2 (200ml) at 0º during 30 minutes. The cold bath is removed, the mixture is kept at ~25º for 1 hour, and the volatiles are removed at <25º/100mm. The residual oil, which consists of ***menthyl phosphorochloridite*** (see *l*-MenOPCl_2 *[95456-31-8]* in 'Miscellaneous As, B, P,….', in Chapter 3), is dissolved in CH_2Cl_2 (250ml), and a mixture of Et_3N (118ml, 847mmol, 3 equivalents) in CH_2Cl_2 (400ml) and H_2[Biphen] (100g, 282mmol) is added during 30 minutes. After 2 hours the mixture is filtered; H_2O_2 (30%, 200ml, ***extremely violent reaction*** take great **CARE**, wear body protection) is added **very** slowly with stirring, the biphasic mixture is then stirred vigorously for 2 hours, the layers are allowed to settle, the organic phase is washed with H_2O and brine (200ml), dried ($MgSO_4$), filtered and evaporated *in vacuo* to give a mixture of (*R*)- and (*S*)- BiphenP(O)(OMen) (124g, 85%) with ^{31}P NMR (121MHz, THF, external ref 85% H_3PO_4) which has δ at -4.89 and -3.37 respectively due to the diasereomeric menthyl phosphates. ***Secondly*:** The diastereomeric mixture of phosphates is dissolved in the minimum volume of refluxing AcOH (~450ml), allowed to cool, and after 16 hours white crystals are filtered off, washed with cold AcOH (2 x 50ml) and dried *in vacuo* to give *(S)-BiphenP(O)(OMen)* (42g, 97-99% de). Recrystallisation from refluxing **AcOH** gives ***pure S-diastereomer*** (37.8g, >99%de, in 61% yield). The mother liquors from the first crystallisation are evaporated to give ***pure (R)-BiphenP(O)(OMen)*** (26.8g, >99%de, 43% *R*-diastereomer) after two recrystallisations from refluxing **MeOH** and cooling to 0º. [Partly racemic ester from the mother liquors are re-used in subsequent resolution processes.]

Thirdly*:** To the preceding (*S*)-biphenP(O)(OMen) (37.83g, 70.3mmol) in toluene (500ml) in a 2L Schlenk flask at 0º is treated dropwise with 'Red-Al' (53ml, 65%wt in toluene, introduced into the separating funnel *via* a cannula) at 0º, and stirred for 16 hours. The mixture is carefully quenched with H_2O (75ml) then bleach (75ml), the slurry is filtered through a Celite pad, the pad is washed with toluene (250ml), the combined filtrates are allowed to settle, the toluene layer is separated, washed with bleach (200ml), brine (200ml), dried ($MgSO_4$), filtered, then the toluene is removed *in vacuo* at 0º, any menthol (minty odour) is removed by trituration with MeOH (50ml), to provide after drying, the resolved **(*S*)-H_2[BIPHEN]** (17.5g, 70%, >99% ee) which has **$[\alpha]_D^{20}$ -53.0** (c 0.352, THF, also reported **$[\alpha]_D^{20}$ -83.0** with c 0.4). The absolute configuration of this diastereoisomer was deduced from the X-ray crystallographic structure of its *syn*-Mo(*N*-2,6-di-*iso*-PrC_6H_3)(CHCMe$_2$Ph)[(*S*)-BIPHEN] complex (see Schrock-Hoveyda catalyst *[205815-80-1]* in Part 1). (*R*)-H_2[BIPHEN] is prepared from (*R*)-BiphenP(O)(OMen) using an identical procedure and the optical purity is deduced from that of its precursor as ***no racemisation occurs in these reactions. ***Note*** that the NMR spectra of the *RS*- (see above), *R*- and *S*-H_2[BIPHENS] are the same. About 20g each of the *R*- and *S*- H_2[BIPHENS] are usually obtained from 100g of *RS*-H_2[BIPHEN]Me; and ~60g of the latter are pooled from the mother liquors which can be recycled. [Alexander et al. *Organometallics* **19** 3700 *2000*, DOI: 10.1021/om000336h; Alexander et al. *J Am Chem Soc* **120** 4041 *1998*, DOI: 10.1021/ja974353i.]

By using identical compounds and reactions, but in which the *tert*-butyl group is replaced by a 1-adamantyl group the corresponding ***1-adamantyl (H$_2$BIAD) derivatives*** are obtained in almost similar yields and used to prepare related molybdenum catalysts. For example **(*S*)-3,3'-bis(1-adamantyl)-5,5',6,6'-tetramethyl-1,1'-biphenyl-2,2'-diol {(*S*)-H$_2$(BIAD) {*S*-(-)-3,3'-biphenyl-2,2'-diol, 5,5',6,6'-tetramethyl-3,3'-bis(tricyclo-[3.3.1.13.7]dec-1-yl, *[255728-57-5]*}** with **[α] $^{20}_{D}$** -32.1 (c 3.3, THF), whose absolute configuration was also deduced by X-Ray crystallography of its related respective Mo complex catalyst, was prepared starting from 2-(1-adamantyl)-4,5-dimethylphenol **m 135-138°**. [Alexander et al. *Organometallics* **19** 3700 *2000*, DOI: 10.1021/om000336h.]

Dicyclohexyl(2-methylphenyl)phosphine (Cy$_2$P-*o*-Tol) *[173593-25-4]* **C$_{19}$H$_{29}$P, M 288.4, m 90-93°, pK$_{Est}$ ~4.0.** This phosphine is prepared and purified in the same way as Cy$_2$PPh (following entry), and is used in the same manner as a phosphorus ligand for catalyst systems in coupling reactions. It has the advantage that it is less susceptible to oxidation, has a higher melting point and is easier to handle.

Dicyclohexylphenylphosphine (Cy$_2$PPh) *[6476-37-5]* **(C$_6$H$_{11}$)$_2$PC$_6$H$_5$, M 274.4, m 56-57°, 57-58°, pK^{25} 3.40.** Cy$_2$PPh is a 'foul smelling' solid which is a good ligand for Cr, Hg and Group VIII metals. It can be prepared by reaction of PhPCl$_2$ with CyMgCl in 50% yield [Issleib & Völker *Chem Ber* **94** 392 *1961*, DOI: 10.1002/cber.19610940215], or in 90% yield from PhPCl$_2$ and CyLi [Screttas & Isbell *J Org Chem* **27** 2573 *1973*, DOI: 10.1021/jo01054a064], and is recrystallised from oxygen-free Me$_2$CO or EtOH. **In detail**: to the Grignard solution, at ice-salt bath temperature, made from Mg turnings (24.1g, 0.99mol) in dry Et$_2$O (350ml) and CyBr (162g, 122ml, 0.99mol) in dry Et$_2$O (130ml), is added dropwise (2 hours) a solution of PhPCl$_2$ (81g, 61.4ml, 0.45mol) in dry Et$_2$O (100ml). The mixture is then boiled under reflux for 30 minutes and hydrolysed by stirring with saturated, deoxygenated, aqueous NH$_4$Cl. The Et$_2$O layer is separated and evaporated at ~20°/30mm leaving an oil that crystallises after all the solvent is removed. It may be recrystallised by slowly cooling a hot, oxygen-free EtOH solution (1ml/g), with gentle stirring to prevent formation of an oil, to give analytically pure (Cy$_2$PPh) as white needles (98g, 79.5%). [Bianco et al. *Inorg Synth* **18** 169 *1978*, DOI: 10.1002/9780470132494.ch30.] It is a phosphorus ligand used in catalytic systems for coupling reactions. ***Dicyclohexylphenylphosphine oxide*** (Cy$_2$PPhO), crystallises from petroleum ether, EtOH or Me$_2$CO and melts at **157.5°** (m 165° was also reported).

Dicyclohexylphosphine (Cy$_2$PH) *[829-84-5]* **(C$_6$H$_{11}$)$_2$PH, M 198.3, b 105-108°/3mm, 128°/8mm, 281-283°/atm, n $^{25}_{D}$ 1.5142, pK$_a$ 4.55.** This phosphine is a useful ***air sensitive ligand*** and should be used preferably in an inert atmosphere. It has been prepared in 80% yield by heating Cy$_2$PSSPCy$_2$ with excess Cu and distilling [Niebergall & Langenfeld *Chem Ber* **95** 64 *1962*, DOI: 10.1002/cber.19620950114], or in 55% yield by the addition of PH$_3$ to cyclohexene under pressure in the presence of α, α -azobis(isobutyronitrile) followed by fractional distillation [Rauhut et al. *J Org Chem* **26** 5138 *1961*, DOI: 10.1021/jo01070a087]. It is a phosphorus ligand in catalytic systems used in coupling reactions. It forms a pale yellow ***Li salt*** *[19966-81-5]* which is slightly soluble in dioxane but insoluble in Et$_2$O, *C$_6$H$_6$ and petroleum ether. [cf. Edmundson *Dictionary of Organophosphus Compounds*, Chapman & Hall, London, *1988*, p 221, ISBN 0-412-25790-4.]

Dicyclohexylphosphine oxide (Cy$_2$PHO) *[14717-29-4]* **(C$_6$H$_{11}$)$_2$PHO, M 214.3, m 72.5-74.5°, 73-75°, b 324°/atm.** The oxide crystallises from hexane or *C$_6$H$_6$. It is ***tautomeric*** with dicyclohexylphosphinous acid (Cy$_2$P-OH), whose ***ethyl ester*** (*[80413-46-3]* **M 242.3**, is obtained from Cy$_2$PCl *[16523-54-9]* and EtOH) distils at **111-113°/1mm**, **n $^{20}_{D}$ 1.4950** [Kabachnik et al. *Izv Akad Nauk SSSR, Ser Khim,* 949, 923 *(Engl Trans) 1967*]; and the ***trimethylsilyl ester***, **M 286.5**, distils at **108-110°/1mm**, **n $^{20}_{D}$ 1.4919** [Foss et al. *Zh Obhsch Khim* **49** 2418, 2134 *(Engl Trans) 1979*, cf. Edmundson *Dictionary of Organophosphus Compounds*, Chapman & Hall, London, *1988*, p 222, ISBN 0-412-25790-4]. It is used for preparing six-coordinate octahedral adducts with lanthanide(II) chlorides, see Kapoor & Saraswati [*Inorganica Chim Acta* **110** 63 *1985*, DOI: 10.1016/S0020-1693(00)81356-0].

2-Dicyclohexylphosphino-2',6'-dimethoxybiphenyl (S-Phos) *[657408-07-6]* **C$_{26}$H$_{35}$O$_2$P, M 410.5, m 162-162.5°, 164-166°.** This Buchwald phosphine can be synthesised in one pot under argon by adding *n*-BuLi (6.20ml, 2.5M solution in hexanes, 15.5mmol, 1.1 equivalents) *via* a syringe over 5 minutes to a cold (0°) solution of 1,3-dimethoxybenzene (2.00ml, 15.3mmol, 1.1 equivalents, [151-10-0]) in dry THF (35ml), allowing

the temperature to rise to ~25º, then it is stirred for 3.5 hours. The mixture is re-cooled (0º) and 2-bromochlorobenzene (1.60ml, 13.7mmol, 1.0 equivalents, *[694-80-4]*) is added dropwise *via* a syringe over 15 minutes while stirring vigorously; and the burgundy coloured solution is stirred for a further 15 minutes at 0º. At this stage GC analysis of an aliquot quenched with Et_2O/H_2O should show that all the bromochlorobenzene has been used up and a clean conversion to 2-bromo-2',6'-dimethoxybiphenyl has occurred. The mixture is cooled to -78º and *n*-BuLi (6.20ml, 2.5M solution in hexanes, 15.5mmol, 1.1 equivalents) is added dropwise *via* a syringe during 5 minutes and stirred further (with swirling if necessary) at -78º for further 30 minutes. Neat chlorodicyclohexylphosphine (3.03ml, 13.7mmol, 1.0 equivalents *[16523-54-9]*) is then added dropwise *via* syringe, stirred at -78º for 1 hour and allowed to warm to ~25º. The mixture is filtered through a pad of Flash silica gel topped with a layer of Celite, eluted with EtOAc (400ml) and the combined filtrates are evaporated *in vacuo* to give a yellow solid residue which is recrystallised from Me_2CO to give ***S-Phos*** (2.90g) as a white solid. A further crop can be obtained by concentrating the mother liquors and triturating with MeOH to provide a total yield of 3.32g (59%) as a white solid **m 162-162.5º**. Its ^{1}H NMR (300MHz, C_6D_6) has δ at 7.59 (dm, *J* for the doublet 7.2Hz, 1H), 7.39-7.42 (m, 1H), 7.15-7.25 (m, 3H), 6.43 (d, *J* = 8.5 Hz, 2H), 3.33 (s, 6H), 1.60-1.94 (m. 12H), 1.06-1.36 (m, 10H) from TMS; the ^{31}P NMR (121MHz, C_6D_6) has δ at -8.6; and for IR and ^{13}C NMR see reference. [Barder et al. *J Am Chem Soc* **127** 4685 *2005*, DOI: 10.1021/ja042491j.]
Complexation of S-Phos to form a Pd-catalyst [e.g. with $Pd(OAc)_2$] provides a system with *unprecedented scope*, reactivity and stability for Suzuki-Miyaura coupling processes, e.g. *it generates truly hindered highly chiral biaryls and heterobiaryls* [Walker et al. *Angew Chem Int Ed* **43** 1871 *2004*, DOI: 10.1002/anie.200353615; and for quinine-quinidine syntheses see Raheem et al. *J Am Chem Soc* **126** 706 *2004*, DOI: 10.1021/ja039550y; Huang et al. *J Am Chem Soc* **125** 6653 *2003*, DOI: 10.1021/ja035483w; Nguyen et al. *J Am Chem Soc* **125** 11818 *2003*, DOI: 10.1021/ja036947t; Gelman & Buchwald *Angew Chem Int Ed* **42** 5993 *2003*, DOI: 10.1002/anie.200353015]; and is useful for C-N bond formation [Strieter & Buchwald *Angew Chem Int Ed* **45** 925 *2006*, DOI: 10.1002/anie.200502927].

2-Dicyclohexylphosphino-2',4',6'-triisopropylbiphenyl (X-Phos, 2,4,6-triisopropyl-2'-dicyclohexyl-phosphinobiphenyl) *[564483-18-7]* **$C_{33}H_{49}P$, M 476.7, m 182-184º, 187-190º.** This *Buchwald ligand* is prepared by reacting 2,4,6-triisopropylphenylmagnesium bromide with *o*-bromochlorobenzene in the presence of CuCl, and the resulting biphenyl is condensed with dicyclohexylphosphorus chloride. X-Phos is purified by solubilising it in Et_2O/CH_2Cl_2 (2:1, *ca* 30ml/g) by sonication, seeding it, and setting aside at -40º for 24 hours to give a first crop which is collected and washed with cold Et_2O. A second crop can be obtained by concentrating the mother liquors then mixing with hot MeOH (~10ml, at 65º), cooling and while sonicating Et_2O/CH_2Cl_2 is added until homogeneous and set aside as before. The combined crops are dried *in vacuo* for 24 hours to give white crystals **m 182-184º**. The ^{1}H NMR (300MHz, C_6D_6) has δ_H at 7.48-7.42 (m, 1H), 7.24-7.06 (m, 5H), 2.85 (septet, *J* = 6.9Hz, 1H), 2.71 (septet, *J* = 6.9Hz, 2H), 1.94-1.52 (m, 12H), 1.42 (d, *J* = 6.9Hz, 6H), 1.24 (d, *J* = 6.9Hz, 6H), 1.30-1.02 (m, 10H), 1.12 (d, *J* = 6.9Hz, 6H); the ^{31}P NMR (121MHz, C_6D_6) has δ_P at -11.5; and for IR and ^{13}C NMR see references. [Huang et al. *J Am Chem Soc* **125** 6653 *2003*, DOI: 10.1021/ja035483w; Tomori et al. *J Org Chem* **65** 5334 *2000*, DOI: 10.1021/jo000691h.] X-Phos has been used for the amidation of arylsulfonates, in Pd catalysed Suzuki coupling [Johnson et al. *J Org Chem* **71** 7899 *2006*, DOI: 10.1021/jo061243y], in annulation of *o*-haloanilines [Jia & Zhu *J Org Chem* **71** 7826 *2006*, DOI: 10.1021/jo061471s], and in the synthesis of regioregular polythiophenes [Liversedge et al. *Tetrahedron Lett* **47** 5143 *2006*, DOI: 10.1016/j.tetlet.2006.05.063.] It is also available commercially in tablets containing 2μmol of reagent per tablet.

***R*-(+)- and *S*-(-)- *N,N*-Dimethyl-1-ferrocenylethylamine (α-ferrocenylethyldimethylamine)** *[(R) 31886-58-5; (S) 31886-57-4; (RS) 31904-34-4]* **$C_{14}H_{19}FeN$, M 257.2, *R or S* b 120-121º/0.7mm, d ^{25} 1.222g/ml, n $^{20}_D$ 1.589, *RS* b 111º/0.65mm (part dec), n $^{25}_D$ 1.5883, *R* $[\alpha]^{25}_D$ + 14.1 (c 1, EtOH), *S* $[\alpha]^{25}_D$ -14.1 (c 1.6, EtOH).** The *RS*-amine has been prepared from ferrocenyldimethylaminoacetonitrile and MeMgI [Hauser & Lindsay *J Org Chem* **22** 906 *1957*, DOI: 10.1021/jo01359a013], but it is easily obtained by adding a solution of 1-ferrocenylethanol (23.0g, see *[1277-49-2]*) in toluene (150ml) at -20º dropwise to a stirred solution of phosgene (12.5g) in toluene (100ml) at -20º during ~30 minutes, then allowing to warm to ~20º; and without isolating the chloro-derivative, the mixture is added to a solution of Me_2NH (22.5g) in propan-2-ol (200ml) at ~20º. The temperature is then allowed to rise to ~25º, the solution is filtered, evaporated to dryness, treated with $*C_6H_6$ which is washed with 8.5% aqueous H_3PO_4, more $*C_6H_6$ is added, neutralised with Na_2CO_3, the $*C_6H_6$ layer is

dried (K_2CO_3), filtered and evaporated to give the ***RS*-amine** (24.2g, 95% crude), which after distillation (b 110°/0.45mm with some decomposition) gives the base as a ***clear amber oil*** (17.5g, 68%). Its ***picrate*** *[39699-90-6]* forms red plates **m 136-137°** from EtOH. The crude (±)-base is satisfactory for optical resolution. The ***resolution*** is carried out by stirring a solution of the (±)-base (51.4g) and *R*(+)-tartaric acid (30.0g) in MeOH (100ml) at 55°, seeding, lowering the temperature slowly (2°/hour), and after 24 hours the ***(-)-base-(+)-acid*** (30.0g) is obtained which gives the (-)-base (19.0g, $[\alpha]_D^{25}$ -11.0, c 1.5, EtOH). This is purified further by mixing it again with the (+)-acid (11.1g), each in MeOH (50ml) at 55°, seeded, and cooled as before to give pure (-)-base-(+)-acid from which ***pure (-)-base*** (17.0g, b 120-121°/0.7mm, $[\alpha]_D^{25}$ -14.1, c 1.6, EtOH) is isolated. From the mother liquors, the crude (+)-base is converted to the (+)base-(+)tartrate, recrystallised twice from Me_2CO/H_2O (10:1), from which ***pure (+)-base***, $[\alpha]_D^{25}$ -14.1 is obtained as a ***clear amber oil***. [Marquarding et al. *J Am Chem Soc* **92** 5389 *1970*, DOI: 10.1021/ja00721a017.] The absolute configuration was determined by X-ray analysis of the ***(S,R,S)-2-(p-methoxyphenyl)hydroxymethyl-N,N-dimethyl-1-ferrocenylethylamine*** [yellow powder from *n*-heptane has **m 110-111°**, **$[\alpha]_D^{22}$ -120.8 (c 1.6, EtOH)**] which is obtained by lithiation of the (+)-base (which is highly stereoselective), followed by reaction with *p*-anisaldehyde [Battelle et al. *J Am Chem Soc* **95** 482 *1973*, DOI: 10.1021/ja00783a030.]

This **ferrocene** is a very useful compound for preparing a variety of chiral ferrocene derivatives [see Marquarding et al. *J Chem Res (S)* 82 *1977* and *(M)* 0915 *1977*], and is a remarkable phosphine ligand for catalysts by virtue of its highly stereoselective lithiation (with BuLi) in the position *ortho* to the dimethylaminoethyl group that allows substitution to give chiral 2-phosphines [Hayashi et al. *Tetrahedron Lett* 4405 *1974*, DOI: 10.1016/S0040-4039(01)92175-6], e.g. 2—$SiMe_3$, 2—CH_2OH and 2—CPh_2OH derivatives [Marquarding et al. *J Am Chem Soc* **92** 5389 *1970*, DOI: 10.1021/ja00721a017]. The chiral 2-lithio derivative (prepared with *sec*-BuLi/Et_2O) reacts with sulfur, selenium or tellurium to give the yellow, red or red-brown ***dichalcogenides*** *(R,S)*-{[E-C_5H_3-$CHMe(NMe_2)$]$Fe(C_5H_5)$}$_2$ (from the *R-(+)-base*) and *(S,R)*-{[E-C_5H_3-$CHMe(NMe_2)$]$Fe(C_5H_5)$}$_2$ (from the *R-(+)-base*), where E is S, Se or Te respectively. These dichalcogenides are effective chiral ligands for the rhodium(I) {using $[Rh(COD)Cl]_2$} –catalysed asymmetric hydrosilylation of alkyl and aryl ketones with high enantiomeric excesses. The iridium(I) catalyst exhibits lower selectivity [Nishibayashi et al. *JCS Chem Commun* 1375 *1994*, DOI: 10.1039/C39940001375]. The tellurium dichalcogenide ***(R,S)*-{[Te-C_5H_3-$CHMe(NMe_2)$]$Fe(C_5H_5)$}$_2$**, **[*R,S*-(-)-(Fc*Te)$_2$]** is prepared from lithiated *R*-(+)-*N,N*-dimethyl-1-ferrocenylethylamine (with *sec*-BuLi/Et_2O) in Et_2O under N_2 at 0° which is then treated with Te powder in portions, and the mixture is subjected to ultrasonic irradiation for 1 hour. The mixture is poured into H_2O, and air is bubbled through it for 3 hours at ~25°. The solid is collected and purified by column chromatography on activated Al_2O_3, and eluting with EtOAc/hexane to give analytically pure **[*R,S*-(-)-(Fc*Te)$_2$]** as a red-brown solid (42%) with **m 57-58°**, **$[\alpha]_D^{25}$ -622 (c 1, $CHCl_3$)**, the ^1H NMR (270MHz, $CDCl_3$) has δ_H at 1.25 (d, *J* = 6.9Hz. 6H), 2.18 (s, 12H), 4.01 (q, *J* = 6.9Hz, 2H), 4.06 (s, 10H), 4.18 (q, *J* = 1.3Hz, 2H), 4.23 (q, *J* = 1.1Hz, 2H), 4.48 (q, *J* = 1.3Hz, 2H); and for ^{13}C NMR see reference. **[*S,R*-(+)-(Fc*Te)$_2$]** is prepared similarly, but from *S*-(-)-*N,N*-dimethyl-1-ferrocenylethylamine in 47% yield and has identical physical properties except for **$[\alpha]_D^{25}$ +613 (c 1, $CHCl_3$)**. After conversion into their anions (e.g. Te^- Fc*, with $NaBH_4$/EtOH), they react with allylic bromides, e.g. geranyl bromide, to form **allylic-TeFc*** which produce the corresponding allylic alcohols (on treatment with Bu^tOOH/toluene) in 14-22% enantiomeric excess by chirality transfer, possibly *via* a [2.3]-sigmatropic rearrangement [Chiba et al. *Tetrahedron Lett* **36** 1519 *1995*, DOI: 10.1016/0040-4039(95)00074-M].

Similarly, but using Se instead of Te, *R*-(+)- and *S*-(-)-*N,N*-dimethyl-1-ferrocenylethylamine provides **[*R,S*-(Fc*Se)$_2$] (m 98-100°** from hexane), and **[*S,R*-(Fc*Se)$_2$] (m 103°** from hexane) respectively are produced as red solids, and these catalysts induce highly enantioselective selenoxide elimination to form axially chiral allene carboxylic esters with high enantiomeric excesses [Nishibayashi et al. *Tetrahedron Lett* **35** 3115 *1994*, DOI: 10.1016/S0040-4039(00)76844-4].

[*R,S*-(Fc*S)$_2$] (m 169-170° from hexane) is obtained as a yellow solid in the same way, but using S instead of Se or Te. [See above for the Rh(I)-catalysed asymmetric hydrosilylation reaction of ketones with these dichalcogenide ligands.]

(1*R*,2*R*)-(+)- and (1*S*,2*S*)-(-)- 1,2-Diphenylethylenediamine [(1*R*,2*R*)-(+)- and (1*S*,2*S*)-(-)- 1,2-diamino-1,2-diphenylenediamine, 1,2-diamino-1,2-diphenylethane, stilbenediamine, DPEN, STEIN) *[(R) 35132-20-8]; (S) 29841-69-8; (RS±) 16635-95-3]* **$C_{14}H_{16}N_2$, M 212.3, *R or S* m 79-83°, *RS* m 82°, $[\alpha]_D^{20}$ *R,R* +102, *S,S* -102° (c 1, EtOH), $[\alpha]_D^{23}$ *R,R* +106, *S,S* -106 (c 1.1, MeOH), $pK_{(Est1)}^{25}$ ~5.86, $pK_{(Est2)}^{25}$ ~8.92.** The racemate is

prepared in two steps. In the ***first step***, a mixture of benzil (158g, 0.75mol, *[134-81-6]*), anhydrous NH_4OAc (400g) and cyclohexanone (80ml, 0.77mol) in glacial AcOH (1.0L) are stirred and heated under reflux (colour changing from light yellow to dark green) for 1.5 hours, and while hot it is poured into H_2O (3.0L) with vigorous stirring. After cooling to ~25° overnight, the crystals are collected, washed with H_2O (4 x 300ml), and crushed in a mortar (*in vacuo*) to give *2,2-**spirocyclohexane-4,5-diphenyl-2**H**-imidazole (2,3-diphenyl-1,4-diazaspiro-**[4,5]**deca-1,3-diene)* *[5396-98-5]*) (~208g, 96%) as yellow-green crystals, **m 107-108°**, on recrystallisation from hexane or aqueous MeOH. Its ^{1}H NMR (400MHz, $CDCl_3$, TMS) has δ_H at 1.65-1.92 (m, 6H), 1.95-2.00 (m, 4H), 7.33-7.53 (m, 10H); and for ^{13}C NMR see references. In the ***second step***, under argon and a Dry-ice condenser, the preceding crude spiro-imidazole (72.0g, 0.25mol) in dry THF (400ml, distilled from Na/benzophenone) is stirred until clear, cooled to -78° (Dry-ice/Me_2CO bath), a stream of gaseous NH_3 is passed through until the volume of the homogeneous solution increases to 400ml. Lithium metal (6.94g, 1.0mol, *via* a powder funnel, from wire cut with scissors under a gentle stream of argon) is added at such a rate that the temperature is kept below -65°. The mixture is stirred for 30 minutes, absolute EtOH (30ml, 1.0mol) is added carefully, the mixture is stirred further for 20 minutes and NH_4Cl (70g) is added. The cooling bath is removed, the reaction temperature is made to rise to 0°, H_2O (400ml) is carefully added and the liquid phases are allowed to separate. The aqueous phase is extracted with Et_2O (3 x 300ml), the combined organic phases are washed with saturated aqueous NaCl (brine), dried (Na_2SO_4), filtered, evaporated down (to 200ml), and while being kept at 0°, 2 N aqueous HCl (300ml) is added slowly, then the two phases are stirred vigorously for 1 hour at ~25°, H_2O (500ml) is added and the phases are separated. The organic layer is treated with H_2O (150ml) and extracted with CH_2Cl_2 (to remove any cyclohexanone). All the aqueous acidic phases are combined, and carefully (cool if necessary) basified with 2N aqueous NaOH (300ml) and extracted with CH_2Cl_2 (4 x 300ml); the combined extracts are washed with brine, dried (Na_2SO_4), filtered and evaporated *in vacuo* to give **crude ±*STEIN*** (~40g, ~90%) as a light yellow solid **m 81-82°**. Its ^{1}H NMR (400MHz, $CDCl_3$, TMS) has δ_H at 1.59 (br s, 4H), 4.10 (s, 2H), 7.2-7.3 (m, 10H); and for ^{13}C NMR see references.

The ***optical resolution*** is carried out by adding carefully a hot (70°) homogeneous solution of (L)-(+)-tartaric acid (30.0g, 0.20mol) in EtOH (230ml) to a hot (70°) solution of ±*STEIN* (42.5g, 0.20mol) in EtOH (230ml) (care exothermic, EtOH may boil) with stirring. The tartrate salts separate immediately and the mixture is cooled to ~25°, the salts are filtered off, washed with EtOH (2 x 60ml), dried *in vacuo*, dissolved in boiling H_2O (230ml), EtOH (230ml) is added and the clear solution is cooled slowly to ~25°. The crystals are collected by filtration, washed with EtOH (40ml), dried *in vacuo*, and recrystallised twice as before [from boiling H_2O (230ml), and EtOH (230ml)] to give the colourless ***(-)-diamine-(+)-tartrate salt*** (~24g, ~66%) with $[\alpha]_D^{23}$ -10.8 (c 1.2, H_2O). To this (-)-(+)-salt suspended in H_2O (300ml) and vigorously stirred at 0-5°, is added dropwise an aqueous solution of 50% NaOH (23ml) followed by CH_2Cl_2 (150ml), and is stirred for 30 minutes; the phases are separated, the aqueous phase is extracted with CH_2Cl_2 (2 x 50ml), the organic layers are combined, washed with brine, dried (Na_2SO_4), filtered and evaporated *in vacuo* to give a colourless solid that is recrystallised from hexane to provide >98% optically pure ***S,S*-(-)-*diphenylethylenediamine*** as colourless crystals with the properties stated in the title and with NMR spectrum same as the racemate.

To obtain the enantiomeric diamine, all the filtrates from above are combined, evaporated to dryness *in vacuo*, the residue is stirred vigorously in H_2O (250ml), treated with aqueous 50% NaOH (25ml) then CH_2Cl_2 (200ml), stirred further for 30 minutes, the phases are separated, the aqueous phase is extracted with CH_2Cl_2 (2 x 50ml), the combined extracts are washed with brine, dried (Na_2SO_4), filtered and evaporated *in vacuo* to give enriched *R,R*-(+)-diamine (~26g) as pale yellow crystals. This is treated with (D)-(-)-tartaric acid as in the above and gives relatively impure ***(+)-diamine-(-)-tartrate salt*** (~31g, ~85%, $[\alpha]_D^{23}$ +4 (c 1.2, H_2O). However, recrystallisation of this salt did not improve its optical purity, but treatment with 50% NaOH and extraction as above etc, and crystallisation from hexane gave optically pure ***R,R*-(+)-*diphenylethylenediamine*** as colourless crystals with $[\alpha]_D^{23}$ +106° (c 1.1, MeOH), and NMR spectrum as obtained with the racemate. The optical purity can be confirmed by the ^{1}H NMR spectra of their (L)-mandelate salts (cf. Benson et al. *J Org Chem* **53** 5335 *1988*, DOI: 10.1021/jo00257a024). These diamine ligands were used successfully in highly stereoselective epoxidation [Zhang et al. *J Am Chem Soc* **112** 2801 *1990*, DOI: 10.1021/ja00163a052], in aldol and Diels-Alder reactions[Corey et al. *J Am Chem Soc* **111** 5493 *1989*, DOI: 10.1021/ja00196a081], in allylation reactions [Corey et al. *J Am Chem Soc* **111** 5495 *1989*, DOI: 10.1021/ja00196a082], in osmylation reactions [Corey et al. *J Am Chem Soc* **111** 9243 *1989*, DOI: 10.1021/ja00208a025], as well as in enantioselective Michael additions [Bruner & Hammer *Angew Chem Int Ed* **23** 312 *1984*, DOI: 10.1002/anie.198403121] and in asymmetric hydrogenations [Fiorini & Giongo *J Mol Cat* **5** 303 *1979*, DOI: 10.1016/0304-5102(79)80027-9]. [Corey et al.

J Am Chem Soc **111** 5493 *1989*, DOI: 10.1021/ja00196a081; Pikul & Corey *Org Synth* **71** 22 *1993*, DOI: 10.15227/orgsyn.071.0022; and references herein.]
This diamine has been used successfully as a **Trost ligand** with $Pd(dba)_2$ to catalyse a Heck reaction, but it is not, albeit, as commonly used as DACH (*trans*-1,2-diaminocyclohexane) ligands.

***(1S,2S)*-1,2-diphenylethylenediamine bis-triflamide** *[121788-77-0]* **$C_{18}H_{14}F_6N_2O_2$, M 404.3, m 213-214°, $[\alpha]_D^{23}$ -6.6 (c 1.4, $CHCl_3$).** The bis-amide is obtained from (1*S*,2*S*)-(-)-1,2-diphenylethylenediamine (see DPEN, *[29841-69-8]*) by treatment with triflic anhydride *[358-23-6]*, Et_3N and 4-dimethylaminopyridine (DMAP, see *[1122-58-3]*) in CH_2Cl_2; and purified by flash chromatography on silica gel (15% EtOAc-hexane, v/v). Its ^1H NMR (400MHz, $CDCl_3$, TMS) has δ_H at 4.81(s, 2H), 6.80 (br s, 2H), 7.25 (s, 6H), 7.0 (s, 4H); and for ^{13}C NMR see references. It is a useful reagent for enantioselective Diels-Alder and aldol reactions using a chiral controller system. [Corey et al. *J Am Chem Soc* **111** 5493 *1989*, DOI: 10.1021/ja00196a081; Pikul & Corey *Org Synth* **71** 30 *1993*, DOI: 10.15227/orgsyn.071.0030 and references therein.]

meso*-1,2-Diphenylethylenediamine (*meso*-DPEN, stilbene-1,2-diamine)** *[951-87-1]* **$C_{14}H_{16}N_2$, M 212.3, m 118°, 119°, 121°, 122°.** A 1:1 mixture of *meso*- and *rac*- DPEN is obtained by reaction of benzaldehyde, hexamethyldisilazane and BuLi, in THF, in the presence of $TiCl_4$ and TiO at ~25°/15hrs which gave, after workup and Kügelrohr distillation (bath temperature150°/0.1mm), an oil (25% yield) that on repeated crystallisation from Et_2O/hexane gave crystalline *meso*-DPEN, **m 115-117°**. *Rac*-DPEN is recovered from the mother liquors [Betschart & Seebach *Helv Chim Acta* **70** 2215 *1987*, DOI: 10.1002/hlca.19870700826]. Purify it further by recrystallisation from Et_2O (leaflets). The *meso-**dihydrochloride has **m 156°(dec)** (from HCl), the ***picrate*** has **m 225°**, and the *meso-**N,N,N',N'-tetramethyl derivative*** *[94533-51-4]*, **m 195-197°**, crystallises from hexane. Store it at <10°. A simpler preparation of *meso*-DPEN has been described which involves boiling ammonium acetate (0.52 mol) and benzaldehyde (0.99 mol) for 3 hours, and the resulting thick white precipitate is washed with EtOH and recrystallised from *n*-BuOH to give ***N-benzoyl-N'-benzylidene*-meso-*1,2-diphenylethylene diamine*** (**m 259°**, 44% yield). This *derivative* is then heated with H_2O (100ml) and H_2SO_4 (54ml) while steam is passed through to remove PhCHO and $PhCO_2H$, concentrated until the distillate is no longer acidic, ice-cooled, neutralised with 880 NH_3/H_2O (1:1), and the flaky white crystals are extracted into Et_2O, dried (KOH), filtered and evaporated to give pure *meso*-DPEN (**m 120°**, 75% yield) after recrystallisation from petroleum ether (b 60-80°). [Irvine & Parkins *J Inorg Nucl Chem* **27** 270 *1965*, DOI:10.1016/0022-1902(65)80230-5]. [*Beilstein* **13** H 543, **13** IV 403.] *meso*-DPEN, and related 1,2-diphenylethylenediamines are highly sensitive ***fluorogenic reagents for catecholamines*** (norepinephrine, epinephrine and dopamine) [Umegae et al *Analyt Chim Acta* **208** 59 *1988*, DOI: 10.1016/S0003-2670(00)80736-9].

R*-(+) and *S*-(-)-2-[2-(Diphenylphosphino)phenyl]-4-isopropyl-2-oxazoline [*R*-(+)- and *S*-(-)-2-[2-(diphenylphosphino)phenyl]-4,5-dihydro-4-isopropyloxazole** *[R- 164858-78-0; S- 148461-14-7]* **$C_{24}H_{24}NOP$, M 373.4, m 85-89°, $[\alpha]_D^{20}$ *R* +48 and *S* -48 (c 1.4, $CHCl_3$).** The 4*S*-(-)- enantiomer can be obtained by decomposing the 4*S*-(+)-*Zinc II dichloride complex* [crystallises from *tert*-butyl-methyl-ether/$CHCl_3$ as colourless crystals **m 221-223°**, $[\alpha]_D^{20}$ +53 (c 1.52, $CHCl_3$)] (9.5g, 17.5mmol) in $CHCl_3$ (130ml) under argon with 2,2'-dipyridyl (2.72g, 1.74mmol) at ~25° for 1 hour (stirring), then the mixture is applied directly onto a silica-gel column (6 x 7 cm), eluted with $CHCl_3$ or EtOAc (800ml), and the eluate is evaporated to yield the desired ***4S*-(-)-*oxazoline (6.78g 95%) as a colourless solid which can be recrystallised from petroleum ether/Et_2O. On TLC (silica gel 60 Merck, 0.25mm F_{245}) it has R_F 0.40 (hexane/EtOAc 6/1); the ^1H NMR (300MHz, $CDCl_3$) has δ_H at 0.70 (d, *J* = 6.8Hz, 3H, $CH(CH_3)_2$), 0.81 (d, *J* = 6.8Hz, 3H, $CH(CH_3)_2$), 1.43-1.54 (m, 1H, $CH(CH_3)_2$), 3.80-3.90 (m, 2H, $H_2C(5)$), 4.09-4.19 (m, 1H, HC(4), 6.85-6.89 (m, 1H, HC (4')), 7.24-7.37(M, 12 H, arom. H), 7.88-7.92 (m, 1H, HC(6')); the ^{31}P NMR (121MHz, $CDCl_3$, triphenyl phosphate external standard at -18ppm) has δ at -5.8; and for IR and ^{13}C NMR see references below.
S*-(+)-*2-[2-(diphenylphosphino)phenyl]-4,5-dihydro-4-phenyloxazole *[148461-15-6]* **$C_{27}H_{22}NOP$, M 407.4, m 89-93°, $[\alpha]_D^{20}$ +29.5 (c 1, $CHCl_3$)** and ***R*-(-)-*2-[2-(diphenylphosphino)phenyl]-4,5-dihydro-4-phenyloxazole*** *[167171-03-1]* **M 407.4, m 89-93°, $[\alpha]_D^{20}$ -29.5 (c 1, $CHCl_3$)** were prepared as for the 4-isopropyloxazole above and have R_F 0.27 (hexane/EtOAc 5/1). [Koch et al. *Recl Trav Chim Pays-Bas* **114** 206 *1995*, DOI: 10.1002/recl.19951140413.]
With an iridium catalyst they promote asymmetric alkylation [Janssen & Helmchen *Tetrahedron Lett* **38** 8025 *1997*, DOI: 10.1016/S0040-4039(97)10220-9], and are chiral ligands for asymmetric reduction reactions

[Lightfoot et al. *Angew Chem* **110** 3047 *1998*, DOI: 10.1002/(SICI)1521-3757(19981016)110:20<3047]. These ligands, when complexed with $Ni(COD)_2$, promote the regio and stereoselective addition of allylic sulfides to alkynes; a reaction which tolerates a variety of functional groups [Hua et al. *Org Lett* **9** 263 *2007*, DOI: 10.1021/ol062686r]. These types of ligands also promote Pd-catalysed allylic substitution reactions [von Matt & Pflatz *Angew Chem* **105** 614 *1993*, DOI: 10.1002/ange.19931050430; Dawson et al. *Tetrahedron Lett* **34** 3149 *1993*, DOI: 10.1016/S0040-4039(00)93403-8].

Diphenylphosphine *[829-85-6]* **$(C_6H_5)_2PH$, M 186.2, b 100-102°/1.5mm, 150-151°/12mm, 156-157°/16mm, 165°/25mm, 280°/atm, d ^{25} 1.07g/ml, n_D^{20} 1.6269, pK 0.03.** This toxic and flammable phosphine is prepared under N_2 by adding dropwise a solution of chlorodiphenylphosphine (50g, *[1079-66-9]*) in dry Et_2O (75ml) to a solution/suspension of LiAlH (2.6g) in absolute Et_2O (75ml), then boiling the mixture under reflux for 1 hour, adding H_2O (6ml, carefully and with cooling) and stirring for 2-3 hours. The Et_2O layer is collected, dried ($CaCl_2$), decanted, evaporated and the residue is distilled *in vacuo* to give the phosphine (70%) as a colourless oil [Kuchen & Buchwald *Chem Ber* **91** 2871 *1958*, DOI: 10.1002/cber.19580911246]. *Alternatively*, Ph_2PCl is reacted with Na in dry *n*-Bu_2O under N_2 to give Ph_2PNa which is treated with EtOH, boiled under reflux for 30 minutes, poured into H_2O, extracted with Et_2O, the extract is dried ($CaCl_2$), decanted, evaporated and the residue is distilled *in vacuo* to give the phosphine (72%) [Kuchen & Buchwald *Chem Ber* **92** 227 *1959*, DOI: 10.1002/cber.19590920126]. [*Beilstein* **16** H 758, **16** II 371, **16** III 833, **16** IV 950.]

2-(Diphenylphosphino)benzoic acid [(2-carboxyphenyl)diphenylphosphine) *[17261-28-8]* **$(C_6H_5)_2P C_6H_4CO_2H$, M 306.3, m 174-177°, 175-176° (187-188°), pK_{Est} ~2.7.** The benzoic acid is prepared by first adding Na (15.3g, 667mmol, cut in ~1g pieces) carefully to liquid NH_3 (1.5L) with stirring until a blue colour is persistent (**use an efficient fume cupboard**), then adding PPh_3 (87.4g, 330mmol) in small portions during 30-40 minutes with swirling to dissolve any Na on the sides of the flask. After 2.5 hours the red-orange colour of the solution of $NaPPh_2$ is treated with 2-chlorobenzoic acid (52.2g, 330mmol) in small portions over 30-40 minutes followed by anhydrous THF (500ml, using a syringe), and the resulting solution is allowed to warm to room temperature overnight under a blanket of argon. As the solution warms, the colour of the red solid turns to gold as mild evolution of heat results. The residue is dissolved in H_2O (1.4L) and extracted with Et_2O (400ml) which is discarded. The aqueous layer is acidified to pH 2 with concentrated HCl (~60ml), and extracted with CH_2Cl_2 (3 x 200ml), the extract is washed with H_2O (500ml), evaporated to *ca* 125ml, and MeOH (~50ml) is added to precipitate the pale-yellow crystalline acid (requiring inducement sometimes) which is collected and dried to give the phosphino-acid (50g, 49%) which provides analytically pure acid (C, H and P) on recrystallisation from a minimum amount of boiling MeOH. The ***air stable*** compound forms yellow needles from aqueous EtOH, is soluble in halogenated solvents and Et_2O, but is less soluble in other solvents. Its IR (Nujol) has ν_{max} at 3200 (OH), 1690 (CO), 1275 cm^{-1}. The ***methiodide*** crystallises from $Me_2CO/*C_6H_6$ with **m 169-173°(dec)**, and the ***phosphine oxide*** *[2572-40-9]* M 322.3 has **m 262-264°** (**252-254°** and **274-275°** are also reported), **pKa 5.06** and **5.37** (in 50% aqueous EtOH) and crystallises from EtOH, aqueous EtOH or aqueous AcOH. With diazomethane, ***methyl 2-(diphenylphosphino)benzoate*** is obtained in 85% yield; it forms colourless crystals from MeOH with **m 96-97°**, its IR (Nujol) has ν_{max} at 1712 (C=O) cm^{-1}, and the ^1H NMR (90MHz, $CDCl_3$) has δ_H at 7.6-6.9 (m, 14H), 3.70 (s, 3H), and the ^{31}P NMR (40.5MHz, $CDCl_3$) has δ at 5.10 upfield of 85% H_3PO_4. [Rauchfuss et al. *J Am Chem Soc* **103** 6769 *1981*, DOI: 10.1021/ja00412a050; Hoots et al. *Inorg Synth* **21** 175 *1982*, DOI: 10.1002/9780470132524.ch39.] It is used for preparing the DACH-Trost phenyl ligand above.

S*-(-)-2-Ferrocenyl-4-(1-methylethyl)oxazoline [*S*-(-)-4-isopropyloxazo-2-yl ferrocene]** *[162157-03-1]* **$C_{16}H_{19}NOFe$, M 297.0, m 71.5-72.5° (m 61-62°), $[\alpha]_D^{22}$ -129 (c 1.5, EtOH), CD ($CHCl_3$) λ_{max} (Δε) 464 (-080), 358 (+1.0)nm.** This complex is prepared in three steps from ferrocenecarboxylic acid (1.33g, 4.49mmol, 1271-42-7), ***firstly by converting it into the acid chloride with oxalyl chloride (0.79g, 9mmol) in CH_2Cl_2 (15ml) under N_2 at ~25° until gas evolution ceases (~10 minutes), stirring for 10 minutes further, and the solution is evaporated to dryness *in vacuo*. ***Secondly*** the crude dark red oily acid chloride (that solidified on standing) is dissolved in CH_2Cl_2 (10ml) and added (syringe) to a solution of *S*-(+)-valinol (0.554g, 5.37mmol) and Et_3N (1.25ml, 9mmol) in CH_2Cl_2 (7ml) under N_2 at ~25°. After standing overnight, the mixture is washed with H_2O (2 x 20ml), dried (Na_2SO_4), filtered, and evaporated to dryness *in vacuo*. The residue is purified by column chromatography on SiO_2 (40-83mm), eluting with 3% MeOH/CH_2Cl_2, to give analytically pure **2*S*-*N*-(1-hydroxy-3-methylbutyl)-ferrocenamide** (1.184g, 84%) with **m 109-110°, $[\alpha]_D^{21}$ -8 (c 1.34, EtOH)**. It has IR

(nujol) with ν_{max} at 3284 (N-H), 3192 (O-H), 1611 (C=O amide I), 1551 (amide II) cm^{-1}; the ^1H NMR (360MHz, $CDCl_3$) has δ_H at 0.97 (d, 3H, *J* = 6.8Hz, -C*H*$_3$), 0.98 (d, 3H, *J* = 6.8Hz, -C*H*$_3$), 1.93 (octet, 1H, *J* = 6.8Hz, -C*H*$(CH_3)_2$), 2.71 (brt, 1H, -O*H*), 3.56-3.83 (m, 3H, -C*H*$_2$OH and –NHC*H*-), 4.16 (s, 5H, C_5H_5), 4.30 (brs, 2H, Fc), 4.60 (brs, 1H, Fc), 4.62 (brs, 1H, Fc), 5.80 (brd, 1H, -NH-); and for ^{13}C NMR and EI-MS see reference. ***Thirdly***, to a light orange solution of the preceeding ***S-(-)-amide*** (0.817g, 2.59mmol) and Ph_3P (2.49g, 9.5mmol) in dry MeCN (60ml) is added Et_3N (1.6ml, 11.5mmol) followed by CCl_4 (2.2ml, 22.8mmol), and the mixture is stirred at ~25° overnight. Water (80ml) is added to the mixture, extracted with petroleum ether (5 x 50ml), the combined organic layers are dried ($MgSO_4$), filtered, and evaporated to dryness *in vacuo*. The residue is contaminated with Ph_3PO, and is purified by column chromatography [SiO_2, 40-83mm, and eluting with 30% EtOAc/petroleum ether (b 40-60°)] to give analytically pure ***ferrocenyl oxazoline*** as dark yellow crystals (0.685g, 89%) with **m 71.5-72.5°**. ***Note that much lower yields of product are obtained if the solvent is removed from the reaction mixture before work-up***. It has IR (nujol) with ν_{max} at 1657 (C=N) cm^{-1}; the ^1H NMR (360MHz, $CDCl_3$) has δ_H at 0.87 (d, 3H, *J* = 6.8Hz, -C*H*$_3$), 0.94 (d, 3H, *J* = 6.8Hz, -C*H*$_3$), 1.78 (hextet, 1H, *J* = 6.6Hz, -C*H*$(CH_3)_2$), 3.41 (q, 1H, *J* = 7.0Hz, –NHC*H*-), 3.89-3.95 (m, 1H, -OC*H*H-), 4.00 (t, 1H, *J* = 7.7Hz, -OCH*H*-), 4.06 (s, 5H, C_5H_5), 4.26 (brs, 2H, Fc), 4.66 (brs, 1H, Fc), 4.70 (brs, 1H, Fc); and for ^{13}C NMR and EI-MS see references. [Richards & Mulvaney *Tetrahedron Asymm* **7** 1419 *1996*, DOI: 10.1016/0957-4166(96)00159-0.] The ***R-enantiomer*** is prepared in the same way by using *R*-(+)-valinol. Similarly prepared while using the respective chiral *S*-2-aminoethanols were ***S-(-)-4-methyloxazol-2-yl ferrocene*** [red solid, 96% yield, **m 84-85°**, **$[\alpha]_D^{27}$ -60 (c 0.2, EtOH), CD ($CHCl_3$) λ_{max} ($\Delta\varepsilon$) 461 (+0.34), 336 (-0.25)nm**], ***S-(-)-4-ethyloxazol-2-yl ferrocene*** [orange solid, 34% yield, **m 47-48°**], ***S-(-)-4-tert-butyloxazol-2-yl ferrocene*** [orange-red solid, 34% yield, **m 127-128°**, **$[\alpha]_D^{24}$ -150 (c 2.1, CH_2Cl_2)**], and among others, *where the 4-alkyl group was replaced by isobutyl, sec-butyl, benzyl, phenyl, 4,5-diphenyl, 1-hydroxy-1-methylethyl, 1-methoxy-1-methylethyl, 1-hydroxy-1-ethylpropyl, 1-methoxy-1-ethylpropyl, hydroxymethyl, methoxymethyl, and several more,* were synthesised in the same way [Sammakia et al. *J Org Chem* **60** 10 *1995*, DOI: 10.1021/jo00106a005; Nishibayashi et al. *J Organomet Chem* **545-546** 381 *1997*, DOI: 10.1016/S0022-328X(97)00368-9; Richards & Mulvaney *Tetrahedron Asymm* **7** 1419 *1996*, DOI: 10.1016/0957-4166(96)00159-0.] An independent synthesis of the title compound was achieved from *S*-(-)-valinol, $ZnCl_2$, cyanoferrocene in refluxing chlorobenzene under N_2 for 72 hours followed by column chromatography (SiO_2, eluting with hexane/EtOAc) which gave a red solid (40% yield based on cyanoferrocene) **m 61-62°** [**note** difference in m.p.] but with similar ^1H and ^{13}C NMR. Other chiral derivatives, some mentioned above, were also obtained in this way. [Nishibayashi et al. *J Organomet Chem* **545-546** 381 *1997*, DOI: 10.1016/S0022-328X(97)00368-9.]

Iridium(III) acetylacetonate [tris(pentane-2,4-dionato)iridium, Ir(acac)$_3$] *[15635-87-7]* **$(C_5H_7O_2)_3Ir$, M 489.5, m 269-271°.** Iridium sulfate solution is made from freshly precipitated iridium dioxide (from 1.0g of potassium hexachloridate) by heating it with 1*N* H_2SO_4 (25ml) until the acid begins to fume. The solution is diluted to its orginal volume, and undissolved iridium oxide is removed by centrifugation. The light green solution is treated with 10% aqueous NaOH until the green iridium III hydroxide precipitate just begins to redissolve. This precipitation should be rapid in order to avoid oxidation; the pH of the solution is adjusted to 6, and the mixture is heated at 60° with acetylacetone (2ml) for one hour. The solution then becames red and deposits a yellow crystalline precipitate. This iridium complex is collected and crystallises from aqueous MeOH in rhombic plates (0.1g, 10%, m 269°). It is insoluble in H_2O, sightly soluble in EtOH and petroleum ether, but freely soluble in $*C_6H_6$ and $CHCl_3$. It is stable in boiling dilute acids and 10% aqueous NaOH. It sublimes at 260°/1mm, but decomposes above 290° depositing an iridium mirror. Molecular weight determination (~400, by Rast in camphor) indicates that it is ***monomeric***. [Dwyer & Sargeson *J Am Chem Soc* **75** 984 *1953*, DOI: 10.1021/ja01100a503; *Beilstein* **1** IV 3678.] It is a useful precursor for making Iridium complexes.

3,4-O-isopropylidene-(3*S*,4*S*)-dihydroxy-(2*R*,5*R*)-bis(diphenylphosphino)hexane (*RSSR*-dimeDIOP, or *R*,S,S,*R*-DIOP*, the **DIOP starred** in dedication to Professor Kagan) *[258873-45-9]* **$C_{33}H_{36}O_2P_2$, M 526.2, low melting oil, $[\alpha]_D^{24}$ (+) 41.8 (c 0.88, $PhCH_3$), pK_{Est} ~0.0.** The starting material for this ligand is the readily available D-mannitol that is converted to the isopropyledine di-epoxide, which in turn is converted to 3,4-*O*-isopropylidene-(3*S*,4*S*)-dihydroxy-(2*S*,5*S*)-hexane. The latter, (2.2g, 11.6mmol) and Et_2NH (4.9ml, 34.8mmol) in CH_2Cl_2 (30ml) is added dropwise to a solution of $MeSO_2Cl$ (2.0ml, 25.8mmol) in CH_2Cl_2 (10ml) at 0°, kept at 0° for 30 minutes, stirred at ~25° for 30 minutes, and treated with saturated aqueous NH_4Cl. The layers are separated, the aqueous phase is extracted with CH_2Cl_2, the combined organic phases are dried (Na_2SO_4), evapor-

ated and the residue is purified by flash chromatography on silica gel, eluting with CH_2Cl_2/Et_2O (9/1) to give ***3,4-O-isopropylidene-(3S,4S)-bis(mesyloxy)-(2S,5S)-hexane*** (3.85g, 96%) as a colourless oil. This is a useful intermediate for making a variety of phosphine ligands and has **$[\alpha]_D^{24}$ (-) 1.3 (c 1.04, $CHCl_3$)**; its ^{1}H NMR (360MHz, $CDCl_3$) has δ at 4.82-4.76 (m, 2H), 3.99-3.96 (m, 2H), 3.03 (s, 6H), 1.45 (d, *J* = 6.6, 6.0Hz), 1.37 (s, 6H); and and for ^{13}C NMR and EI-MS see references. The preceding dimesylate (1.04g, 3.0mmol) in THF (20ml) is added to the orange solution at -78° of Ph_2PLi [prepared under N_2, from Ph_2PH (1.15ml, 6.6mmol) in THF (50ml) to which is added *via* a syringe *n*-BuLi in hexane (4.0ml, 6.4mmol) at -78° during 5 minutes, warmed to ~25° while stirring for 1 hour, and cooling to -78° again] during 20 minutes. The orange solution is warmed to ~25°, stirred overnight, the resulting white suspension is hydrolysed with saturated aqueous NH_4Cl, the aqueous layer is extracted with CH_2Cl_2, the combined organic layers are dried (Na_2SO_2), filtered, evaporated and the residue is purified by flash chromatography on silica gel, eluting with hexane/Et_2OAc (95/5), or hexane/Et_2O (95/5) to give **(+)-*RSSR*-DIOP*** (1.06g, 67%) as a colourless oil or low melting white solid respectively. Its ^{1}H NMR (360MHz, $CDCl_3$) has δ at 7.56-7.52 (m, 8H), 7.38-7.33 (m, 12H), 3.78-3.76 (m, 2H), 2.50-2.46 (m, 2H), 1.14 (s, 6H), 0.91 (d, *J* = 7.0Hz, 3H), 0.87 (d, *J* = 6.9Hz, 3H); the ^{31}P NMR ($CDCl_3$) has δ at -6.3 (-5.42); and for ^{13}C NMR and HRMS see references. [Li & Zhang *J Org Chem* **65** 5871 *2000*, DOI: 10.1021/jo0004613; Yan & RajanBabu *Org Lett* **26** 4137 *2000*, DOI: 10.1021/ol006591f.]

Lithium tetrachloropalladate(II) hydrate (Li_2PdCl_4 xH_2O) *[123334-21-4]* **Li_2PdCl_4. xH_2O, M 262.1 (anhydrous).** It is commercially available as a powder or in chunks. A 0.5M solution of water-free Li_2PdCl_4 in dry MeOH for the preparation of Pd catalysts (e.g. see *Oxime Palladacycles* above) is made by stirring anhydrous LiCl (42.4g, 1 mole, dried at 130° to constant weight, several hours, see *[7447-41-8]*) and anhydrous $PdCl_2$ (88.6g, 0.5 mole, see *[7647-10-1]*) in dry MeOH (1L) until the solution is homogeneous. Store the solution under N_2 or argon. [Onue, Minami and Nakagawa *Bull Chem Soc Jpn* **43** 3480 *1970*, DOI: org/10.1246/bcsj.43.3480]

η^5-(*S*)-(*pR*)-2-(2'-(4'-Methylethyl)-oxazolinyl)cyclopentadienyl,1-*C*-3'-*N*)(η^4-tetraphenylcyclobutadiene) cobalt *[222400-02-4]* **$C_{39}H_{34}NOCo$, M 591.6, m 160-162°, $[\alpha]_D^{24}$ -55.2 (c 0.09, $CHCl_3$).** This cobalt complex is the key intermediate for the preparation of all the **c**obalt **o**xazoline **p**alladacycle (COP) catalysts described in Part 1. Although originally prepared in four distinct steps [Stevens & Richards *Organometallics* **18** 1346 *1999*, DOI: 10.1021/om980812s], the synthesis has been slightly modified and can be completed in two steps without purifying intermediates. ***Firstly,*** *η^5-(carbomethoxycyclopentadienyl)-(η^4-tetraphenylcyclo-butadiene)cobalt [182627-81-2]* is prepared (using Schlenk equipment flushed with argon) in a triple-necked flask with two rubber septa containing sodium cyclopentadienide (20ml, 2.0M in THF, 40mmol, *[4984-82-1]*, should be light red/orange in colour; discard if black or contains solid residues), anhydrous THF (20ml *via* a syringe, pre-filtered through activated Al_2O_3), then dimethyl carbonate (10.2ml, 120mmol, *via* a syringe), and the mixture is stirred and boiled under reflux for 4 hours before cooling to ~25°. [The intermediate can be isolated but this is not necessary.] To the cooled mixture is added dry toluene (160ml, *via* a syringe), followed by chlorotris(triphenylphosphine)cobalt(I) (30.8g, 34.8mmol, see above *[26305-75-9]*, preferably freshly prepared for higher yields) and diphenylacetylene (14.2g, 80mmol, recrystallised from EtOH), and heated at reflux for 5 hours, cooled to ~25° before transferring to a single-necked flask and evaporating to dryness *in vacuo*. The residue is suspended in hexanes (150ml), the solid is filtered off, washed with hexanes (~3.5L) until the filtrate is colourless. The dark mustard–coloured solid is dissolved from the filter by washing with CH_2Cl_2 until the filtrate is colourless (discard any insoluble black solid) and evaporate the combined filtrates *in vacuo* to give the *Cobalt-ester* (12.7g, 67%) as a mustard-coloured solid. It can be purified by column chromatography on Matrix silica 60 (35-70μm, eluting with 20% EtOAc/petroleum ether b 40-60°) to give the ***Cobalt-ester*** as an orange crystalline solid (**m 240-244°**, lit **m 246-248°,** Mabrouk & Rausch *J Organomet Chem* **523** 111 *1996*, DOI: 10.1016/S0022-328X(97)00368-9). Its ^{1}H NMR (500MHz, $CDCl_3$) has δ_H at 3.23 (s, 3H), 4.79 (t, *J* = 2.0Hz, 2H), 5.21 (t, *J* = 2.0Hz, 2H), 7.22-7.30 (m, 12H), 7.43-7.45 (m, 8H); and for IR and ^{13}C NMR see references. [Anderson, Overman, Richards, Watson and White *Org Synth* **84** 139 *2007*, DOI: 10.15227/orgsyn.084.0139.]
Secondly, η^5-(*S*)-(*pR*)-2-(2'-(4'-methylethyl)oxazolinyl)cyclopentadienyl,1-*C*-3'-*N*)(η^4-tetraphenylcyclobutadiene)cobalt is prepared by stirring under argon the above crude *Cobalt-ester* (10g, 18.6mmol), lithium iodide (4.96g, 37.2mmol, see *[10377-51-2]*) and 2,4,6-collidine (100ml, b **175-178°**/atm, see *[108-75-8]*), then boiling under reflux (air condenser) for ~16 hours until the *Cobalt-ester* (R_F 0.8, silica plate eluted with 20% EtOAc:hexanes) has completely reacted. The solution is cooled to ~25°, diluted with CH_2Cl_2, washed with 2N

aqueous HCl (4 x 150ml), dried (Na_2SO_4), filtered and evaporated *in vacuo* to give the solid orange coloured ***Cobalt-acid*** [^{1}H NMR (500MHz, $CDCl_3$) at δ_H: 4.84 (2d, *J* = 2.0Hz, 2H), 5.23 (2d, *J* = 2.0Hz, 2H), 7.20-7.24 (m, 12H), 7.42-7.44 (m, 8H)] which is used further. Under argon, with stirring, the preceding *cobalt-acid* in CH_2Cl_2 (124ml, pre-filtered through activated Al_2O_3), oxalyl chloride (3.25ml, 37.2mmol) followed by anhydrous DMF (3 drops sequentially, as evolution of gas occurs) are kept at ~25^o for 30 minutes, evaporated *in vacuo*, CH_2Cl_2 (100ml) is added to dissolve the residue, evaporated again *in vacuo* and the process is repeated three times to give dry ***Cobalt-acid chloride*** as a red-brown residue. A Schlenk flask with a rubber septum, flushed with argon *via* inlet and outlet needles, is loaded with *S*-valinol hydrochloride (3.6g, 26mmol, prepared from the free base, see *[2026-48-4]*, by treating with 2N HCl in Et_2O), then dry Et_3N (15.5ml, 112mmol) and CH_2Cl_2 (86ml) are added *via* the septum, followed, *via* a cannula, a solution of the preceding crude *Cobalt-acid chloride* in CH_2Cl_2 (100ml). The mixture is stirred at ~25^o for 2 hours and cooled to 0^o in an ice-bath. $MeSO_2Cl$ (3.6ml, 47mmol, *[124-63-0]*) is then added to the mixture in one portion *via* a syringe and allowed to warm to ~25^o. After 16 hours the mixture is washed with saturated aqueous $NaHCO_3$ (150ml), brine (150ml), the organic layer is dried (Na_2SO_4), filtered, and concentrated *in vacuo*. The residue is purified by dissolving it in the minimum volume of CH_2Cl_2 (~50ml), adding it to a silica gel column and eluting with hexanes/EtOAc (9:1) to give ***η^5-(S)-(pR)-2-(2'-(4'-methylethyl)-oxazolinyl)cyclopentadienyl,1-C-3'-N)(η^4-tetraphenylcyclobutadiene)cobalt*** (8.2g, 75%) as a yellow solid, which can be recrystallised to analytical purity from 10% EtOAc/petroleum ether to **m 160-162^o**. Its ^{1}H NMR (400MHz, $CDCl_3$) has δ_H at 0.77 (d, *J* = 6.7Hz, 6H, C*H*$_3$), 0.97 (d, *J* = 6.7Hz, 3H, C*H*$_3$), 1.40 (oct, *J* = 6.7Hz, 1H, C*H*$(CH_3)_2$), 3.41-3.56 (m, 3H, -C*H*-C*H*$_2$-), 4.62 (brs, 1H, Cp*H*), 4.80 (brs, 1H, Cp*H*), 5.09 (brs, 1H, Cp*H*), 5.20 (brs, 1H, Cp*H*), 7.17-7.27 (m, 12H, *m*+*p*-Ph*H*), 7.44-7.47 (m, 8H, *o*-Ph*H*); and for IR and ^{13}C NMR see references. The ***R-enantiomer*** is prepared in precisely the same way except that *R*-valinol hydrochloride is used instead, and it differs only in having optical rotation of opposite sign. [Stevens & Richards *Organometallics* **18** 1346 *1999*, DOI: 10.1021/om980812s; Anderson, Overman, Richards, Watson and White *Org Synth* **84** 139 *2007*, DOI: 10.15227/orgsyn.084.0139.]

N*-Methyliminodiacetic acid (MIDA)** *[4408-64-4]* **$CH_3N(CH_2CO_2H)_2$, M 147.1, m 220^o (dec), 223-225^o (dec), 226^o (dec), pKa** (thermodynamic) **acidic: 2.138 (0^o), 2.142 (10^o), 2.146 (20^o), 2.150 (30^o), 2.154 (50^o); basic: 10.474 (0^o), 10.287 (10^o), 10.088 (20^o), 9.920 (30^o), 9.730 (40^o).** It has been prepared from $MeNH_2$ and formaldehyde cyanohydrin followed by hydrolysis of the dinitrile formed [Eschweiler *Justus Liebigs Ann Chem* **279** 39 *1894*, DOI: 10.1002/jlac.18942790105], and in 63-71% yield from chloroacetic acid and $MeNH_2$ [Berchet *Org Synth* Coll Vol **2** 397 *1943*, DOI: 10.15227/orgsyn.018.0056]. However, a more convenient preparation is from iminodiacetic acid *[142-73-4]* (13.3g), formic acid (4.6g), aqueous formaldehyde (10ml, 36%) and H_2O (5ml) at 100^o until evolution of CO_2 ceases, and after 2 hours the mixture is refluxed for 10 minutes, diluted with excess EtOH, cooled and the precipitated acid is filtered off. Recrystallisation from aqueous EtOH (charcoal) provides **pure colourless *MIDA (14.7g, 90%). [Childs et al. *J Chem Soc* 2174 *1948*, DOI: 10.1039/JR9480002174]. It has been purified *via* the Ba salt [Berchet *Org Synth* Coll Vol **2** 397 *1943*, DOI: 10.15227/orgsyn.018.0056] and the stability constants of the complexes with Cu^{2+}, Mg^{2+}, Ca^{2+}, Sr^{2+}, Ba^{2+}, Zn^{2+}, Cd^{2+}, Hg^{2+}, and Ni^{2+} have been determined [Scwarzenbach et al. *Helv Chim Acta* **38** 1147 *1955*, DOI: 10.1002/hlca.19550380509]. The ***diethyl ester*** has **b 92-94^o/0.04mm** [Viscontini et al. *Helv Chim Acta* **35** 451 *1952*, DOI: 10.1002/hlca.19520350205], and the ***monoamide*** has **m 168^o** after crystallisation (needles) from aqueous EtOH [Eschweiler *Justus Liebigs Ann Chem* **279** 39 *1894*, DOI: 10.1002/jlac.18942790105]. ***MIDA*** **(m 215-216^o dec)** has been prepared on a ~100g scale by the method described by Childs et al. (above) with slight modification in 88% yield, and had IR (thin film) with ν_{max} at 2998, 2955, 1682 (C=N), 1477, 1380, 1328, 1223, 1172, 1126, 1065, 1018, 982, 958, 903, 886, 723 cm^{-1}; the ^{1}H NMR (400MHz, D_2O) has δ_H at 2.98 (s, 3H), 3.96 (s, 4H); the ^{13}C NMR (100MHz, 95:5 DMSO-d_6: D_2O, TMS) has δ_C at 170.0, 56.7, 41.7; the LRMS (ESI+) has *m/z* (relative intensity) 219.1 (24%), 148.1 (M^+, 100%), 102.1 (8%); and the HRMS (ESI+) for $C_5H_{10}NO_4$ [M+H$^+$] has calculated 148.0604, and found 148.0603. [Ballmer, Gillis and Burke *Org Synth* **86** 344 *2008,* DOI: 10.15227/orgsyn.086.0344]. [*Beilstein* **4** H 367, **4** II 800, **4** III 1177, **4** IV 2428].

MIDA boronic esters: MIDA is a very useful protecting group for boronic acids and forms stable (more stable that the free acid) ***boronates*** which are readily prepared from the boronic acid, MIDA in toluene-DMSO (2.5:1) under reflux using Dean-Stark conditions to eliminate H_2O requiring ~3 hours. When these boronic acid surrogates are suitably substituted on boron they can be made to undergo Suzuki-Miyaura, Stille, Heck, Sonogashira and Negishi coupling, as well as Miyaura borylations. The boronates are easy to handle, stable in

air, stable under cross-coupling conditions, surviving temperatures of up to 80°, and acidic reagents like trifluoromethanesulfonic, acetic acid and oxidising agents such as Jones reagent. The MIDA group can be ***easily hydrolysed*** by mild aqueous base (see below) thus also allowing the use of controlled ***iterative cross-coupling*** (ICC) of protected haloboronic acids. [Gillis & Burke *Aldrichimica Acta* **42** 17 *2009*]. A variety of MIDA boronate synthons are available commercially.

Hydrolysis of 4-(*p*-tolyl)phenylboronic acid MIDA ester (m 214-216°) to the boronic acid is given here as a typical example for the hydrolysis procedure. The MIDA ester (10.1g, 31.3mmol, 1 equivalent) in THF (220ml), and aqueous 1M NaOH (93.5ml, 93.5mmol, 2.99 equivalents) gives a biphasic mixture with a clear colourless lower layer and a milky white upper layer. The container is capped, and the mixture is stirred vigorously at ~25° for 10 minutes whereby the lower colourless layer becomes clear and the upper layer becomes clear yellow. A saturated aqueous solution of NH_4Cl (250ml) is added (to act as acidifier) and the mixture is stirred vigorously for 5 minutes, shaken with Et_2O (4 x 50ml), and the aqueous layer is extracted with freshly prepared THF/Et_2O (1:1, 400ml). The combined organic layers are dried (MgSO), filtered through Celite, and concentrated by rotary evaporation in a vacuum (40°/20mm), and residual solvent is removed by three azeotropic cycles with MeCN (3 x 50ml) in a rotary evaporator (40°/20mm), and then at higher vacuum (25°/1mm) for 12 hours to give the boronic acid as a fine off-white powder (6.24g, 94% yield, **m 136-138° dec**) with the expected IR, NMR and Mass spectra which indicate ~92% purity. [Ballmer, Gillis and Burke *Org Synth* **86** 344 *2008*, DOI: 10.15227/orgsyn.086.0344].

MIDA-disodium salt is prepared from MIDA (147g, 1 mol), which is dissolved (caution: exothermic) in NaOH (120g, 3 mol) in H_2O (300ml) to give a clear light yellow solution that is evaporated *in vacuo*. The residue is treated with MeOH (300ml), heated to reflux, filtered through a glass frit, heated to reflux and filtered again, and the process repeated once more. The filtrate is co-evaporated with MeCN (3 x) and lyophilised to give analytically pure **diNa salt** (173g, 91%) as a white powder with ^{1}H NMR (300MHz, CD_3OD, TMS) δ_H at 2.95 (s, 4H), 2.24 (s, 3H); and ^{13}C NMR (125MHz, CD_3OD, TMS) δ_C at 179.2, 63.7, 43.9. It is used for preparing MIDA-boronate esters [Uno et al. *Tetrahedron* **65** 3130 *2009*, DOI: 10.1016/j.tet.2008.11.010; cf. also Coombs & Margerum *Inorg Chem* **9** 1711 *1970*, DOI: 10.1021/ic50089a020; Davis & Richardson *Inorg Chem* **23** 184 *1984*, DOI: 10.1021/ic00170a014; Stringfield & Shepherd *Inorg Chim Acta* **309** 28 *2000*, DOI: 10.1016/S0020-1693(00)00238-3].

Norbornadiene (NBD, bicycle[2.2.1]hepta-2,5-diene) *[121-46-0]* **C_7H_8, M 92.1, m -19.1°, b 89.5-90°/atm, 90.3°/atm, d_4^{20} 0.9064, n_D^{25} 1.4684.** NBD is a versatile diene that coordinates with metals, helps in solubilising them in organic solvents, and is used for making a variety of ***pre-catalysts*** (see in this chapter under 'Homogeneous Catalysts' Part-1). It is prepared by a general method whereby ***cis-* or *trans- 1,2-bis(phenylsulfonyl)ethylene*** {0.22g, 0.714mmol; *trans [963-16-6]* M 308.4, **m 221-223°, 226.5-227°, 229.5°** from EtOH or AcOH; *cis-isomer* has **m 89.5-90°, 101-101.5°**, from EtOH, *Beilstein* **6** IV 1500, Truce & McManimie *J Am Chem Soc* **75** 1672 *1953*, DOI: 10.1021/ja01103a045} and freshly distilled cyclopentadiene (1.6g, 2.42mmol) in toluene (5ml) are heated at 130° for 24 hours, evaporated to dryness *in vacuo*, and the residue is recrystallised from *C_6H_6-EtOH (1:1) to give the Diels-Alder adduct ***3,6-methano-4,5-bis(phenylsulfonyl)cyclohex-1,2-ene***, **m 257-258°**, in good yield. Lower yields are obtained in *C_6H_6 (~25°/40 hours). Elimination of the β-disulfone groups is achieved by stirring a mixture of the *bis(diphenylsulfonyl)* compound (2.5mmol) and $NaH_2PO_4.2\ H_2O$ (5g) in MeOH (~40ml) at room temperature overnight with freshly prepared sodium amalgam (from *ca* 0.4g, 17mmol of Na, *[11110-52-4]*). The mixture is extracted with pentane (b 36°/atm) and the extract is fractionated at atmospheric pressure to give NBD in 65% yield. Store and stabilise with 0.50.25% of BHT under N_2. [De Lucchi & Modena *JCS Chem Commun* 914 *1982*, DOI: 10.1039/C39820000914; cf. Parham & Heberling *J Am Chem Soc* **77** 1175 *1955*, DOI: 10.1021/ja01610a027.] Industrially, it is prepared from cyclopentadiene and acetylene at 340°/6atm [Shell Devel. Co., USP 2 875256 *1953*].

NBD has UV with λ_{max} (logε) at 198.5 (3.78), 202infl (3.41), 213infl (3.24). 219infl (3.01), 227infl (2.41)nm (in EtOH), and 194.5 (3.53)nm (in cyclohexane) [Stich, Rotzler & Reichstein *Helv Chim Acta* **42** 1480 *1959*, DOI: 10.1002/hlca.19590420511]; its IR (thin film) has ν_{max} of the more intense bands at 2987, 1543, 1311, 1228, 875, 799, 727, 502 cm^{-1}, and in CS_2 and CCl_4 it has ν_{max} at 3080(s), 2960 (vs), 2880 (s), 1646 (m), 1452 (ms), 1335 (ms), 1310 (vs), 1271 (m), 1229 (s), 1206 (s), 1150 (s), 1105 (ms), 1063 (m), 1016 (m), 935 (s), 911 (s), 885 (sh), 870 (vs), 795 (sh), 715 (vs), 650 (s) cm^{-1} [Abel, Bennett and Wilkinson *J Chem Soc* 3178 *1959*,

DOI: 10.1039/JR9590003178.]; the ^{1}H NMR (60MHz, $CDCl_3$) has δ_H at 1.99 (s, 2H, CH_2). 3.56 (s, 2H, bridgehead H), 6.74 (s, 4H, olefin H) from TMS, and for ^{13}C NMR see references. The photoelectron spectrum shows intense bands at 8.69, 9.55, 11.26, 12.51—12.75, 14.24 and weak bands at 15.66—17.16 eV; and the interaction between the two non-conjugated π-bonds has been shown to be 0.85eV [Bischof et al. *Helv Chim, Acta* **52** 1745 *1969*, DOI: 10.1002/hlca.19690520631.]

NBD-silver nitrate complex is formed by shaking for 5 minutes a mixture of $AgNO_3$ (1.36g) in H_2O (10ml) and NBD (3ml). The white complex is collected and recrystallised from EtOH to give pure **NBD-$(AgNO_3)_2$** (0.95g) which decomposes in air, in H_2O, and on heating to give a strong odour of NBD. Store it cold and under N_2. It is soluble in warm MeOH, EtOH, CCl_4, $CHCl_3$, and $*C_6H_6$, but insoluble in Me_2CO, Et_2O and light petroleum. Its IR (Nujol and hexachlorobutadiene mulls) has ν_{max} at 3020 (w), 2960 (w), 2885 (w), 1470 (m), 1385 (v, brs), 1325 (s), 1310 (s), 1243 (m), 1189 (m), 1046 (m), 1014 (w), 969 (m), 950 (vw), 929 (m), 890 (w), 877 (w), 808 (m), 795 (w), 790 (w), 725 (ms) cm^{-1} [Abel, Bennett and Wilkinson *J Chem Soc* 3178 *1959*, DOI: 10.1039/JR9590003178.]

Similarly the **NBD-cuprous bromide** complex is formed by shaking for 5 minutes a mixture of anhydrous CuBr (2.6g) in EtOH (30ml) and NBD (5ml). The white crystalline complex is filtered off, and washed with EtOH (5ml) and Et_2O (5ml) to give **NBD-$(CuBr)_2$** as fine white crystals which slowly become green in air. The complex, which is insoluble in most organic solvents, releases CuBr under reduced pressure, and is decomposed by H_2O to give Cu_2O. Its IR (Nujol and hexachlorobutadiene mulls) has ν_{max} at 3027 (vw), 3000 (vw), 2930 (m), 2860 (w), 1471 (w), 1453 (m), 1310 (ms), 1265 (w), 1245 (vw), 1234 (w), 1180—1080 (br-w), 1050 (vw), 993 (m), 976 (m), 950 (w), 938 (w), 918 (ms), 889 (w), 867 (w), 777 (w), 765 (w), 739 (m), 719 (m) cm^{-1} [Abel, Bennett and Wilkinson *J Chem Soc* 3178 *1959*, DOI: 10.1039/JR9590003178.] [*Beilstein* **5** IV 879.]

For the ***bis(phenylsulfonyl)ethylenes*** see also Truce & McManimie *J Am Chem Soc* **76** 5745 *1954*, DOI: 10.1021/ja01651a036; Montaniari *Gazetta* **86** 429 *1956*, Parham & Heberling *J Am Chem Soc* **77** 1175 *1955*, DOI: 10.1021/ja01610a027; Modena & Montaniari *Gazetta* **86** 436 *1956*, Adams & Ferretti *J Am Chem Soc* **81** 4927 *1959*, DOI: 10.1021/ja01527a042; and for UV see Angeletti & Montaniari *Boll Scient Fac Chim Ind Univ Bologna* **15** 44, 45 *1957*; in EtOH the *cis-isomer* has λ_{max} at 241-243nm, and the *trans-isomer* λ_{max} at 246nm.

Pentaphenylferrocenyl(di-*tert*-butyl)phosphine [$P(C_5H_4FeC_5Ph_5)(t\text{-butyl})_2$, Q-Phos] *[312959-24-3]* **$[(C_6H_5)_5C_5]Fe[C_6H_4(P(C_6H_9)_2)_2]$, M 710.7, m 211-219°.** This catalyst ligand is prepared in two steps in high yield, and all reactions are performed in a drybox. ***Firstly*** *(di-*tert*-butylphosphino)ferrocene* is prepared by adding *t*-BuLi (31.6ml, 53.8mmol) in THF to a solution of Cp_2Fe (10.0g, 53.8mmol) in THF (25ml) during 5 minutes at 0°, stirring for 20 minutes and the solvent is removed *in vacuo*. The residue is dissolved in pentane (100ml) and THF (5ml), $(t\text{-Bu})_2PCl$ (5.33g, 29.5mmol) is added and the mixture is stirred for 3 hours after which time degassed MeOH (1ml) is added, and most of the solvents are removed *in vacuo*. The residue is filtered through a plug of silica gel under N_2 and unreacted Cp_2Fe is eluted with pentane first and then the phosphine is eluted all at once with Et_2O, the solvent is removed *in vacuo*, and the required *phosphine* is crystallised from pentane (yield 7.58g, 78%). In the ***second step*** this *phosphine* (1.00g, 3.03mmol), $Pd(OAc)_2$ (0.35g, 0.156mmol) and *t*-BuONa (2.93g, 30.5mmol) are dissolved in PhCl (34.10g, 303.0mmol) and heated at 110° for 18 hours. The mixture is filtered through Celite, the PhCl is removed *in vacuo*, and the residue is subjected to chromatography on Silica gel, and eluting with pentane/Et_2O (80:1), to ***give $P(C_5H_4FeC_5Ph_5)(t\text{-butyl})_2$*** (1.47g, 68%) as a pink-red solid. Its ^{1}H NMR (C_6D_6*) has resonances at δ: 1.07 (d, 11.0Hz, 18H, Me_3), 4.42 (t, 1.7Hz, 2H, C_5H_4), 4.67 (d, 1.0Hz, 2H, C_5H_4), 6.95-6.97 (m, 15H, *m,p*-C_6H_5), 7.44-7.48 (m, 10H, *o*-C_6H_5); the $^{31}P\{^1H\}$ NMR (C_6D_6*) has a resonance at δ 25.49 (s); and for ^{13}C NMR see references. Similarly prepared were ***$P[C_5H_4FeC_5(C_6H_4\text{-}p\text{-}CF_3)_5](t\text{-butyl})_2$*** (37.3% yield, from pentane), ***$P[C_5H_4FeC_5(C_6H_4\text{-}p\text{-}OMe)_5](t\text{-butyl})_2$*** (36% yield, from Et_2O at -30°), ***$P(C_5H_4FeC_5HPh_4)(t\text{-butyl})_2$*** (47.4% yield, orange crystals from pentane at -35°), and ***$P[C_5H_4FeC_5(3,5\text{-}Me_2C_6H_3)_5](t\text{-butyl})_2$*** (30% yield, red solid from pentane/Et_2O) by using *p*-trifluoromethylchlorobenzene, *p*-methoxychlorobenzene, a limited amount of PhCl and 5-bromo-*m*-xylene respectively. These are ***air-stable ferrocenyl dialkylphosphines*** for palladium-catalysed C-C, C-N and C-O bonding-forming cross-coupling reactions. The ligand $P(C_5H_4FeC_5Ph_5)(t\text{-butyl})_2$ exhibits turnovers of ~1000 for aminations with unactivated aryl bromides or chloride, it catalysed the formation of selected aryl ethers under mild conditions, it catalysed the aryl halides coupling with acyclic or cyclic secondary alkyl- and arylamines, and it catalysed coupling of the latter amines with aryl- and primary alkylboronic acids. The ligand is ***air stable*** in the solid state and in solution, and produces highly active Pd catalysts which are ***stable*** in the solid state and react only slowly with oxygen in solution. [Kataoka et al. *J Org Chem* **67** 5553 *2002*, DOI: 10.1021/jo025732j;

cf. also Shelby et al. *J Am Chem Soc* **122** 10718 *2000*, DOI: 10.1021/ja002543e.]

4-(3-Phenylpropyl)pyridine 1-oxide (P$_3$NO) *[34122-28-6]* **$C_{14}H_{15}NO$, M 213.3, m 58-65°, 60°, pK_{Est}~1.3.** The *N*-oxide is prepared by adding 4-(3-phenylpropyl)pyridine (12.5g, *[2057-49-0]*, in 'Heterocyclic Compounds' Chapter 3) during 5 minutes to a slurry of oxone (37.5g, *[70693-62-8]*), H_2O (63.5ml) and MeOH (125ml) (pH ~1.4) under N_2, and the stirred mixture is kept at pH 5.5 by addition of 5N aqueous NaOH while the temperature is kept at ≤ 35° (the temperature being controlled by external water cooling and by the rate of NaOH addition). The reaction is monitored by HPLC, and at completion, the salts are removed by filtration and the cake is washed with MeOH (50ml). The combined filtrate and washes are treated with 1M aqueous sodium metabisulfite solution (12ml), stirred for 0.5 hours and the pH is adjusted to 10.0 by addition of 5N aqueous NaOH, and set aside for 1 hour. The mixture is concentrated *in vacuo* (at 50°) to a final volume of ~75ml, cooled to 20°, the solid is filtered off, washed with H_2O (50ml), and dried under N_2 to give the desired ***1-oxide*** in 93% yield. *Alternatively*, it can be prepared by the oxidation of the *phenylpropylpyridine* with 30% H_2O_2/AcOH using the standard method of Ochiai [*J Org Chem* **18** 534 *1953*, DOI: 10.1021/jo01133a010; see also Boekelheide & Linn *J Am Chem Soc* **76** 1286 *1954*, DOI: 10.1021/ja01634a026]. Its ^{1}H NMR (300MHz, $CDCl_3$) has δ at 1.8-1.98 (m, 2H, 2'propyl-CH_2), 2.3-2.6 (m, 4H, ph-CH_2, py-CH_2), 7.05 (m, 2H, 3,5-pyridine), 7.12-7.30 (m, 5H, benzene H), 8.11 (m, 2H, 2,6-pyridine H). [Senanayake et al. *Tetrahedron Lett* **37** 3271 *1996*, DOI: 10.1016/0040-4039(96)00565-5.] This reagent stabilises and enhances Jacobsen Mn-salen catalysts and is more readily obtained in quantity than the commonly used 4-phenylpyridine 1-oxide [see Jacobsen et al. *J Am Chem Soc* **113** 7063 *1991*, DOI: 10.1021/ja00018a068].

Pinacolborane (4,4,5,5-tetramethyl-1,3,2-dioxaborolane) *[25015-63-8]* **$C_6H_{13}BO_2$, M 128.0, b 42-43°/50mm, d_4^{25} 0.882, n_D^{20} 1.396.** This borolane is prepared by stirring a cooled solution (at 0°) of pinacol (2.36g, 20mmol *[76-09-5]*) in CH_2Cl_2 (2ml) to which is added, dropwise, BH_3-SMe_2 (20mmol, 10.0M in SMe_2) whereby effervescence occurs (use efficient fume hood, and gases have a foul odour, are flammable, and should be absorbed through alkaline solution or oxidising solutions containing H_2O_2 or $KMnO_4$). After stirring for ~1 hour at 0°, the mixture is warmed to ~25°, when gas evolution ceases (*ca* another 1 hour) and is distilled to give the borolane as a clear oil (1.61g, 63% yield). Its IR (CH_2Cl_2) has ν_{max} at 3272s, 2980s, 1530m, 1482s, 1333s, 1143s, 983s, 851s cm^{-1}; and the ^{1}H NMR (300MHz, $CDCl_3$) has δ at 1.27 (s, 12H); the ^{13}C NMR (75.5MHz, $CDCl_3$) has δ at 83.1, 24.5; and the ^{11}B NMR (115.5MHz, $CDCl_3$) has δ at 28.07. It is a very ***efficient hydroboration reagent***, requires mild reaction conditions, has higher functional group tolerance, higher regio- and stereoselectivity, with excellent stability of the resulting pinacol boronic esters produced. [Tucker et al. *J Org Chem* **57** 3482 *1992*, DOI: 10.1021/jo00038a044.]

Rhodium(I) chloride 1,5-cyclooctadiene complex dimer {chloro(1,5-cyclooctadiene)rhodium dimer, di-μ,μ'-chlorobis[(1,2,5,6-η)-1,5-cyclooctadiene]dirhodium (I), $[Rh(COD)Cl]_2$} *[12092-47-6]* **$C_{16}H_{24}Cl_2Rh_2$, M 493.1, m ~243° (dec, see below).** The complex is prepared by refluxing a solution of $RhCl_3.3H_2O$ (1.93g, 7.3mmol), H_2O (3ml), EtOH (35ml) and COD (6ml, 48mmol) overnight. After cooling, the crude solid is collected, washed with a little H_2O, dried and recrystallised from CH_2Cl_2/hexane or acetic acid, then dried *in vacuo* to give 82% yield (1.5g) of dimer. On heating it darkens from about 220°, melts at **~256°** and decomposes with effervescence at 258°. **M** by ebullioscopy in 0.9% $CHCl_3$ is **~513** confirming the ***dimeric*** stucture. It is soluble in CH_2Cl_2 and THF, moderately in $CHCl_3$, AcOH and Me_2CO, slightly soluble in hexane, Et_2O, MeOH, EtOH, and *C_6H_6 but insoluble in H_2O. Its magnetic susceptibility χ, is -0.52 x 10^{-6} ±4% per g.
Alternatively, $NaBH_4$ (0.5g) in EtOH (100ml) is added, over 3 hours, to a stirred solution of $RhCl_3.3H_2O$ (5g) and COD (3ml) in EtOH (125ml) at 20°. The ***exothermic reaction*** deposits some Rh, and after 2 days the mixture is filtered, and the residue is extracted with CH_2Cl_2. The extract is evaporated to dryness and the orange residue is recrystallised form AcOH (yield 0.67g). The reaction mixture still contained much unreacted $RhCl_3$. [Chatt & Venanzi *J Chem Soc* 4735 *1957*, DOI: 10.1039/JR9570004735; Schenck et al. *Inorg Chem* **24** 2334 *1985*, DOI: 10.1021/ic00209a003; cf. Giordano et al. *Inorg Synth* **19** 218 *1979*, DOI: 10.1002/9780470132500.ch50.] The related ***bis-(Rhodium COD-μμ'-diacetato)*** complex **$[Rh(COD)OAc]_2$, M 540.1**, is obtained from an acetone solution of the preceding chloro complex (1g) and KOAc (1g) which is boiled under reflux for 2 hours. After filtration and evaporation of the filtrate to dryness, the residue is recrystallised from EtOAc to give ***pure diacetato*** complex as orange crystals, **m 197-198°** (yield 0.54g), M 540 (ebullioscopically in 1.4% *C_6H_6; M 587 in 1.5% *C_6H_6; M 554 in 0.9% *C_6H_6). A 10^{-3}M solution in $PhNO_2$ is non-conducting.

Rhodium(I) chloride norbornadiene complex dimer {bicyclo[2.2.1]hepta-2,5-diene-rhodium(I) chloride dimer, di-μμ'-chlorobis[2,5-norbornadiene]dirhodium(I), [Rh(NBD)Cl]$_2$} *[dimer 12257-42-0; polymer 42740-82-9]* **$C_{14}H_{16}Cl_2Rh_2$, M 460.99, m ~240° (dec).** The yellow dimer is obtained by shaking rhodium 'trichloride' (0.7g, $RhCl_3.3H_2O$) and norbornadiene (2ml) in aqueous EtOH (10ml) for 2 days. It is collected and recrystallised from hot $CHCl_3$/light petroleum to give analytically complex (0.62g). **M** by ebullioscopy in $*C_6H_6$ is 481 consistent with a ***dimeric*** structure. The fine yellow crystals are soluble in $CHCl_3$ and $*C_6H_6$, but almost insoluble in light petroleum and Et_2O. Its IR (CS_2) has ν_{max} at 3060(m), 3000(m), 2960(m), 2920(m), 2855(m), 1307(s), 1171(m), 1157(w), 1068(w), 1029(w), 995(w), 932(m), 882(m), 721(w), 680(s), 630(s) cm^{-1}. [Abel, Bennett & Wilkinson *J Chem Soc* 3178 *1959*, DOI: 10.1039/JR9590003178.]

Ruthenium(II)benzenedichloride dimer {di-μ-chloro-bis[(η-benzene)chlororuthenium(II)], $Ru_2(C_6H_6)_2Cl_4$, $[Ru(C_6H_6)Cl_2]_2$} *[37366-09-9]* **$Rh_2(C_6H_6)2Cl_2$, M 500.2, m 242°.** This ***versatile reagent*** is prepared by refluxing $RuCl_3.3H_2O$ (2.0g) in EtOH (100ml) with cyclohexadiene (10ml, of 1,3- or 1-4 prepared by reduction of *benzene with Na/Liquid NH_3) [Kaiser *Synthesis* 391 *1972*, DOI: 10.1055/s-1972-21889; Birch & Smith *Q Rev Chem Soc* **12** 17 *1958*, DOI: 10.1039/QR9581200017] for 4 hours. The brown precipitate is filtered off, washed with MeOH and dried *in vacuo* to give the ***complex*** (1.83g, 95%). The complex is diamagnetic, it is ***dimeric*** in freezing $CHBr_3$, and is sparingly soluble in organic solvents except Me_2SO with which it forms a red complex with the ***monomeric*** structure ***$RuCl_2(C_6H_6)(dmso)$***. It dissolves in pyridine, tertiary phosphines, phosphites, tertiary arsines (***L***) which cleave the chlorine bridges of the dimer to form orange or red air stable complexes ***$RuCl_2(C_6H_6)(L)$*** which are ***monomeric*** in $CHCl_3$. Large excess of the ligand ***L*** should be avoided in the reaction, otherwise the benzene rings may be displaced. Its IR has Ru—Cl stretching bands with ν_{max} at 295, 259 and 248sh cm^{-1}; and the ^1H NMR ($CDCl_3$, TMS) has a singlet at τ_H 4.02 which is *ca* 2.0 ppm upfield of the free benzene H resonance. It is a useful ***precursor*** for the preparation of Ru(II) complexes, some of which are good catalysts. [Bennett & Smith *JCS Dalton Trans* 233 *1974*, DOI: 10.1039/DT9740000233; Bennett et al. in *Comprehensive Organometallic Chemistry* Wilkinson ed, Vol 4 pp 748-750 Pergamon Press Oxford *1982*.]

The complex ***$Ru_2(C_6H_6)_2$*** has also been prepared by evaporating a coat of Ru powder (10-15%) in slow curing 'Araldite' cement on a 1mm tungsten wire heated to ~2400°. The Ru vapour thus produced is co-condensed with *benzene to form thermally unstable orange-yellow crystals of ***$Ru_2(C_6H_6)_2$*** which decompose below 0°. The ^1H NMR ($CFCl_3$) of the orange crystals show H resonances at τ 4.22 (2H), 4.84 (6H), 5.10 (2H) and 7.11(2H) consistent with the 1—4-η, 1—6-η formulation of the $Ru_2(C_6H_6)_2$ structure. [Timms & King *JCS Chem Commun* 898 *1978*, DOI: 10.1039/C39780000898.]

Ruthenium dichloride 1,5-cyclooctadiene complex [dichloro-μ-(η^4-cycloocta-1,5-diene)ruthenium(II), $RuCl_2(COD)_n$] *[50982-12-2]* **$[Rh(C_8H_{12})Cl_2]_n$, M 280.2 (monomer).** Analytically pure complex is obtained by heating a mixture of pure $RuCl_3.3H_2O$ (50.0g, 0.2mol) and cycloocta-1,5-diene (50ml, 0.4mol, use a fume hood) in absolute EtOH (400ml) under reflux for 24 hours whereby the brown complex precipitates. After cooling, the solid is filtered off, washed with Et_2O ((50ml) and dried *in vacuo* to give pure ***[$RuCl_2(COD)$]*** (~52g, ~90%). It is stable in air, only slightly soluble in organic solvents, reacts by halogen-bridge cleavage and is a useful synthetic ***precursor*** of ruthenium((II) complexes. [Ohta, Takaya and Noyori *Inorg Chem* **27** 566 *1988*, DOI: 10.1021/ic00276a025; Albers et al. *Inorg Synth* **26** 249 *1989*, DOI: 10.1002/9780470132579.ch44; Bennett et al. in *Comprehensive Organometallic Chemistry* Wilkinson ed., **Vol 4** pp 748-750 Pergamon Press Oxford *1982*.]

Tetrakis(acetonitrile)copper(I) hexafluorophosphate $[Cu(MeCN)_4^+ PF_6^-]$ *[64443-05-6]* **$[(CH_3CN)_4Cu]PF_6$, M 372.7, m 160°(dec).** In an efficient fume cupboard, 60-65% aqueous hexafluorophosphoric acid (10ml, ~113mmol, *[16940-81-1]*, M 146.0) is added in 2ml portions to a stirred suspension of Cu(I) oxide (4.0g, 28mmol) in MeCN (80ml) when a ***very exothermic*** reaction occurs (use a refux condenser), causing the solution to boil. After stirring for a further 3 minutes the solution is filtered (use a medium-porosity frit) from some black solid, and $Cu(MeCN)_4^+ PF_6^-$ may begin to crystallise out, and is complete on standing at -20°, or by adding an equal volume of dry Et_2O and cooling to 0°. (If some white solid separates with the black solid it should be washed off with MeCN and the MeCN solutions combined and cooled at -20°, or diluted with Et_2O.) The salt is collected by filtration, washed with Et_2O and immediately dissolved in MeCN (100ml), filter off any undissolved blue Cu^{2+} species, add Et_2O (100ml) and set aside at -20° for several hours to crystallise out. The

crystalline complex would need a second recrystallisation if it has a blue tinge. It may be recrystallised from MeCN (80ml) and Et_2O (80ml). The white complex salt is dried *in vacuo* for ~30 minutes immediately after washing with Et_2O to give the ***analytically pure salt*** (~12.5g, ~60% depending on crystallisation losses). It is a free-flowing white, microcrystalline powder that does not darken on long storage under N_2 or argon. On exposure to air for >1 hour minor surface oxidation occurs and it is ***slightly hygroscopic***. The MeCN ligands are not removed easily *in vacuo* at ~25º (but dissociation occurs at ~5 torr/80º and ~25 torr/110º). The IR (Nujol) has ν_{max} at 2277m and 2305m cm^{-1} (for MeCN), and 850vs and 557s cm^{-1} for PF_6^-. The related salt, ***$Cu(MeCN)_4^+ BF_4^-$,*** can be prepared similarly by using an equivalent amount of HBF_4 (as 48% aqueous acid *[16872-11-0]*, M 87.9) instead of HPF_6. These complexes are suited for the non-aqueous-media synthesis of Cu(I) complexes [see $(IPr)_2Cu^+ PF_6^-$ and $(IPr)_2Cu^+ BF_4^-$ above]; as well as for preparing other complexes such as $[Rh(C_2H_4)_3(MeCN)_2]^+$ + CuCl by reaction of $Cu(MeCN)_4^+$ with $[Rh(C_2H_4)_2Cl]_2$ and C_2H_4 in CH_2Cl_2 [Maspero et al. *J Organomet Chem* **38** C43 *1972*, DOI: 10.1016/S0022-328X(00)83316-1]. The X-ray structure of the ClO_4^- salt showed that the copper is almost ideally ***tetrahedral*** coordinated with nearly linear MeCN molecules [Csöregh et al. *Acta Cryst* **B31** 314 *1975*, DOI: 10.1107/S0567740875002634]. [Kubas et al. *Inorg Synth* **19** 90 *1979*, DOI: 10.1002/9780470132500.ch18; Kubas et al. *Inorg Synth* **28** 68 *1990*, DOI: 10.1002/9780470132593.ch15].

***cis-cis-cis*-1,2,3,4-Tetrakis(diphenylphosphinomethyl)cyclopentane [(1*R**,2*R**,3*S**,4*S**)-tetrakis-(diphenylphosphinomethyl)cyclopentane, Tedicyp]** *[333380-86-2]* **$C_{57}H_{54}P_4$, M 862.9, m 79º.** The intermediate cis-cis-cis-1*,2,3,4-tetrakis(boranatodiphenylphosphanylmethyl)cyclopentane* (white crystals **m 149º**, after chromatography on silica gel eluting with AcOEt/petroleum ether, 1:4) is obtained from Ph_2PLi (from Ph_2PCl see *[1079-66-9]* and Li) and *cis-cis-cis*-1,2,3,4-tetrakis(tosyloxymethyl)cyclopentane in THF under argon (~20º/5 hours), then borane in THF is added. This boranato intermediate formed is added to anhydrous Et_2NH, heated at 55-60º for 10 hours, evaporated to dryness, this process is repeated twice, and the residue is chromatographed on silica gel (eluted with Et_2O/petroleum ether, 1:4) to give white crystals of Tedicyp (98%) with **m 79º**. It is not very stable in air and must be stored under argon. It has ^1H NMR (400MHz, THF-d_8) with δ at 7.71-7.23 (40H, m), 2.91-2.52 (2H, m), 2.38-1.72 (10H, m), 1.25 (2H, m); the ^{31}P NMR (162MHz, THF-d_8) has δ at -16.3 and -17.7; and for ^{13}C NMR see references. It is used for preparing the Pd-Tedicyp catalyst with $[Pd(\eta^3\text{-}C_3H_5)Cl]_2$ (see above) for promoting allylic alkylations [Laurenti et al. *J Org Chem* **66** 1633 *2001*, DOI: 10.1021/jo001146j], cross coupling reactions, and catalysing Heck reactions of α- or β-substituted enol ethers with aryl bromides [Battace et al. *Eur J Org Chem* 3122 *2007*, DOI: 10.1002/ejoc.200700152] with high efficiency. [cf. for efficiency only see Wallow & Novak *J Org Chem* **59** 5034 *1994*, DOI: 10.1021/jo00096a056]

The tetra-phosphine oxide cis-cis-cis-1*,2,3,4-tetrakis(diphenylphosphinoylmethyl)cyclopentane*, **$C_{57}H_{54}O_4P_4$, M 926.29**, is obtained by oxidising Tedicyp in THF with excess H_2O_2 (~20º/4 days) then purified by chromatography on silica gel (eluting with MeOH/CH_2Cl_2, 5:95) to yield (66%) white crystals of the ***tetroxide*** with **m 165º**. It has ^1H NMR (400MHz, $CDCl_3$) with δ at 7.79-7.62 (16H, m), 7.32-7.28 (8H, m), 2.85 (2H, br t, *J* = 12.9Hz), 2.28 (4H, d, *J* = 11.9Hz), 2.26-2.15 (2H, m), 2.10-2.05 (2H, m), 1.88 (2H, br q, *J* = 12.9Hz), 1.60 (1H, dt, *J* = 13.8, 7.5Hz), 1.36 (1H, dt, *J* = 13.8, 10.2Hz); and for ^{13}C NMR see reference. [Laurenti et al. *J Org Chem* **66** 1633 *2001*, DOI: 10.1021/jo001146j.]

R*-(+)- and *S*-(-)- 2,2',6,6'-Tetramethoxy-4,4'-bis(diphenylphosphino)-3,3'-bipyridine (*R*-(+)- P-Phos and *S*-(-)- P-Phos)** *[R- 221012-82-4* and *S- 362524-23-0]* **$C_{38}H_{34}N_2O_4P_2$, M 644.6, m 261-265º, $[\alpha]_D^{20}$ +98 and -98 (c 1, $CHCl_3$).** This group of ligands have been prepared from (3-bromo-2,6-dimethoxypyrid-4-yl)(diphenyl)-phosphine oxide by an Ulmann reaction (Cu/DMF/140º) to give ***RS- 2,2',6,6'-tetramethoxy-3,3'-bipyridine-4,4'-diphenylphosphine dioxide (85%) which is resolved into the (+)- and (-)- enantiomers by HPLC on a preparative Diacel AD column (25m x 1.2m), eluting with 2-propanol/hexane (20:80) at a flow rate of 3.0ml/minute: t_R = 12.24 minutes, t_S = 25.06 minutes. The phosphine oxide groups are then each reduced by Cl_3SiH/Et_3N/toluene at 140º to give *R*-(+)- and *S*-(-)- R-Phos in 99% yields. *Alternatively*, the above *RS*-dioxide, which cannot be resolved easily, is converted into the ***5,5'dibromo derivative*** (Br_2/NaOAc/AcOH; 0º-60º, 97%) which can now be resolved *via* the (+) and (-)-di-*O*-benzoyl tartrate salts (in EtOAc/$CHCl_3$, 1/1) to provide the enantiomeric ***5,5'-dibromo-dioxides*** that are de-brominated, and reduced (Cl_3SiH/Et_3N/toluene during an extended period from 25º to 140º) to give ***R-(+)- and S-(-)- P-Phos*** in 91% yields. [Pai et al. *J Am Chem Soc* **122** 11513 *2000*, DOI: 10.1021/ja000163n.] This ligand is employed in transition-metal-catalysed

asymmetric reactions including hydrogenation, hydrosilylation and C—C bond formation [Wu & Chan *Acc Chem Res* **39** 711 *2006*, DOI: 10.1021/ar0680015.]

R*-(+)- and *S*-(-)- 2,2',6,6'-Tetramethoxy-4,4'-bis[di(3,5-xylyl)phosphino]-3,3'-bipyridine [*R*-(+)- Xylyl-P-Phos and *S*-(-)- Xylyl-P-Phos)** *[R- 442905-33-1* and *S- 443347-10-2]* **$C_{46}H_{50}N_2O_4P_2$, M 756.9, m (158-162°), 190-194°, $[\alpha]_D^{20}$ +125 and -125 (c 1, $CHCl_3$).** The Xylyl-P-Phos ligands are prepared in a slightly different way from the P-Phos ligands above. Thus *3-bromo-2,6-dimethoxypyridine* is converted into *(3-bromo-2,6-dimethoxypyrid-4-yl)di(3,5-dimethylphenyl)phosphine* [a*:** LDA/THF/-78°; ***b*:** (3,5-dimethylphenyl)$_2$PCl/-78°) in 56% yield, then oxidised (H_2O_2/Me_2CO/0°) to the *phosphine oxide* (99%), followed by an Ullmann reaction as above (Cu/DMF/140°) to give *RS- 2,2',6,6'-tetramethoxy-3,3'-bipyridine-4,4'-di(3,5-dimethylphenyl)phosphine dioxide* (85% yield) that is resolved *via* (-)- and (+)- di-*O*-benzoyl tartrate salts (***a*:** see above fractional crystallisation; ***b*:** 10% aqueous NaOH) to give the ***R-** (75%)* and ***S-** (88%)* ***Xylyl-P-Phos dioxides*** which are reduced (Cl_3SiH/Et_3N/toluene) to ***R*(+)-**and ***S- Xylyl-P-Phos*** in >90% yields. The absolute configuration *S*- was determined from the X-ray crystal stucture of the diastereoisometrically pure 1:1 salt of (-)-Xylyl-P-Phos and (+)-(2*S*,3*S*)-dibenzoyl-*O*-tartrate. The latter have ^{1}H NMR (500MHz, $CDCl_3$) with δ_H at 2.20 (s, 12H, PhC*H*$_3$), 2.25 (s, 12H, PhC*H*$_3$), 3.37 (s, 6H, O C*H*$_3$), 3.83 (s, 6H, O C*H*$_3$), 6.06 (d, *J* = 1.5Hz, 2H, Py*H*), 6.79-6.92 (m, 12H, Ph*H*); the ^{31}P NMR (200MHz, $CDCl_3$) with δ_P at -11.99; the C, H and N elemental analyses fit for the latter empirical formula; and for ^{13}C NMR and LSMS see reference. [Wu et al. *Tetrahedron Lett* **43** 1539 *2002*, DOI: 10.1016/S0040-4039(02)00062-X.] This ligand is employed in transition-metal-catalysed asymmetric reactions including hydrogenation, hydrosilylation and C—C bond formation [Wu & Chan *Acc Chem Res* **39** 711 *2006*, DOI: 10.1021/ar0680015.]

Tricyclohexylphosphine (PCy3) *[2622-14-2]* **$C_{18}H_{33}P$, M 280.4, m 76-78°, 77°, 82°, 82-83°, pK_{Est}~9.5.** It recrystallises from EtOH [Boere et al. *J Am Chem Soc* **109** 7781 *1987*, DOI: 10.1021/ja00259a029]. [*Beilstein* **16** IV 947.] Used in organometallic chemistry and characterised by its high basicity and large ligand cone angle. When applied with Ni it is a critical intermediate in forming cyclopentane compounds [Ogoshi et al. *J Am Chem Soc* **128** 5350 *2006*, DOI: 10.1021/ja060220y], when used with Pd it mediates coupling of malononitrile with aryl halides [Schnyder et al. *Synlett* 3167 *2006*, DOI: 10.1055/s-2006-944215], and when used with a Pd(0)-triolefinic macrocycle catalyst it allows Suzuki coupling of aryl bromides and chlorides [Moreno-Manas et al. *Synlett* 3001 *2006*, DOI: 10.1055/s-2006-948173].

6RS*(±)-*4*,4,6-Trimethyl-2-vinyl-1,3,2-dioxaborinane (vinylboronic acid 2-methyl-2,4-pentanediol ester)** *[4627-10-5]* **$C_8H_{15}BO_2$, M 154.0, b 50-55°/0.46mm, d ^{25} 0.893g/ml, n_D^{20} 1.429.** It is prepared by a modification of a published method [Hoffmann & Landmann *Chem Ber* **119** 2013 *1986*, DOI: 10.1002/cber.19861190622] where *n*-octanol is replaced by 2-methylpentane-2,4-diol (MPD). To a solution of $(MeO)_3B$ (30ml, 270mmol) in dry Et_2O (125ml) at -78° is added over 45 minutes a 2.1M solution of vinylmagnesium chloride (118ml, 248mmol) in THF with stirring, and allowing the temperature to rise to ~25°. The mixture is then acidified, under cooling, with aqueous HCl (concentrated, 21ml, 0.25mol in 62.5ml of H_2O), phenothiazine (0.1g, as stabiliser) is added, the phases are separated, the aqueous phase is extracted with MPD (3 x 50ml). The combined organic phases are evaporated *in vacuo* from a bath at 80° and the residual oil is distilled at high vacuum to give pure ***borinane in ~60% yield. [***Note*** that all the liquids in the reaction mixture distil at lower temperatures than the desired racemic vinyl-dioxaborinane.] It is *superior to vinylboronic pinacol ester* in preparation, storage, stability, and reactivity, providing improved selectivity for Heck *versus* Suzuki coupling with aryl and heteroaryl bromides and iodides [Lightfoot et al. *Tetrahedron Lett* **44** 7645 *2003*, DOI: 10.1016/j.tetlet.2003.08.032]. By adopting different reaction conditions with $Pd(PPh_3)_4$/*t*-BuOK, selective Suzuki-Miyaura coupling with a range of aryl and heteroaryl halides (Cl, Br and I) was achieved [Lightfoot et al. *Synlett* 529 *2005*, DOI: 10.1055/s-2005-862354; cf. Lightfoot et al. *Org Biomol Chem* **3** 3167 *2005*, DOI: 10.1039/B507900D].

Tri-*tert*-butylphosphonium tetrafluoroborate [(*tert*-Bu)$_3$PH$^+$ BF_4^-] *[131274-22-1]* **[$(CH_3)_3C]_3P$ HBF_4, M 290.1, m 261°(dec), pK^{25} 11.4 (phosphine).** The salt is prepared by adding HBF_4 (48% aqueous solution, 1.0ml, 7.6mmol) to a solution of pure (*t*-Bu)$_3$P (225mg, 1.11mmol, see above) in CH_2Cl_2 (15ml), stirring vigorously for 5 minutes, the organic layer is separated, dried ($MgSO_4$), filtered and evaporated to dryness to give **analytically pure *salt*** (302mg, 94%) as a white powder. Its^{1}H NMR (400MHz, $CDCl_3$) has δ_H at 6.07 (d,

$^1J_{PH}$ = 465Hz, 1H), 1.65 (d, $^3J_{PH}$ = 15.3Hz, 27H); the $^{31}P\{^1H\}$ NMR (121MHz, $CDCl_3$) has δ_P at 51.7; and for IR, and ^{13}C NMR see references. The salt is more ***air-stable*** than the free phosphine, and can be heated at 120° for 24 hours without decomposition (no change in NMR spectra), or loss of catalytic activity with transition metal complexes. It is ***not hygroscopic***. In the presence of $Pd_2(dba)_3$ in THF it catalyses Suzuki cross-coupling reactions between aryl halides and arylboronic acids, Stille cross-coupling reactions between aryl halides and tributylSn compounds, and Heck reactions between aryl halides and olefins [Netherton & Fu *Org Lett* **3** 4295 *2001*, DOI: 10.1021/ol016971g]. The salt has also been used successfully in the Heck coupling [with $PdCl_2(COD)$, LiCl, Cy_2NMe] of non-activated alkenyl tosylates and phosphates as substrates with electron-poor alkenes and styrene derivatives [Hansen et al. *Angew Chem Int Ed* **45** 3349 *2006*, DOI: 10.1002/anie.200600442]. This ligand is useful in the Pd-catalysed enantioselective α-arylation of *N*-BOC-pyrrolidine [Campos et al *J Am Chem Soc* **128** 3538 *2006*, DOI: 10.1021/ja0605265].

Vinyl MIDA boronate {vinylboronic acid MIDA ester, 6-methyl-2-vinyl-1,3,6,2-dioxazaborocane-4,8-dione, [*N*-[(carboxy-κ*O*)methyl]-*N*-methylglycinato(2-)-κ*N*,κ*O*]ethenyl boron } *[1104636-73-8]* **$C_7H_{10}BNO_4$, M 183.0, m 152-156°.** The boronate is prepared in Schlenk equipment by adding dropwise vinyltrimethylsilane (4.49ml, 31.5mmol, freshly distilled see *[754-05-2]*) to a stirred solution of BBr_3 (1.0M in CH_2Cl_2, 30mmol) at 0°, and maintained at this temperature for 20 minutes, then allowed to warm to ~ 25° with stirring for a further 2 hours. This mixture is added *via* a cannula to a stirred suspension of MIDA sodium salt (5.73g, 30.0mmol, see above) in MeCN (50ml) at 0°, at such a rate as to keep the temperature below 5°; then the temperature is allowed to warm to ~25° while stirring for 1 hour. The resulting white suspension is filtered through a pad of Celite and the filtrate cake is extracted 3 times with Me_2CO. Et_2O is added to the combined orange filtrates which allowed the colourless free flowing ***vinyl MIDA boronate*** (4.74g, 86%) to crystallise out. On TLC it has R_F 0.26 (Merck silica gel plate grade 9385, 60Å, 230-400 mesh, with EtOAc). Its ^1H NMR (500MHz, Me_2CO-d_6, δ = 2.04 centre line) has δ_H at 5.96 (dd, *J* = 19.0, 13.5Hz, 1H), 5.72-5.63 (m, 2H), 4.21 (d, *J* = 17.0Hz, 2H), 4.01 (d, *J* = 17.0Hz, 2H), 3.0 (s, 3H); and for IR, ^{13}C NMR and EI-MS see reference. Single crystal X-ray analysis confirmed the predicted structure as having a pyramidalised boron centre. The vinylboronate shows no signs of deterioration when kept on the benchtop in air for more than 3 months. It is a versatile reagent that can be prepared on a multigram scale. It readily reacts with $CH_2N_2/Pd(OAc)_2$ to provide ***cylopropyl MIDA boronate*** [Et_2O, 0-23°, 1 hour, 93%], and with *m*-CPBA it yields ***oxiranyl MIDA boronate*** [CH_2Cl_2, 0-23°, 18 hours, 74%] [Uno, Gillis and Burke *Tetrahedron* **65** 3130 *2009*, DOI:10.1016/j.tet.2008.11.010]; and can be used in Suzuki, Heck, Stille, Negishi and Sonogashira couplings and Miyaura borylations [Gillis & Burke *Aldrichimica Acta* **42** 17 *2009*].

Xantphos [4,5-Bis(diphenylphosphino)-9,9-dimethylxanthene] *[161265-03-8]* **$C_{39}H_{32}OP_2$, M 578.2, m 221-222°, 224-228°.** Xantphos is prepared, using Schlenck techniques under N_2, by adding *sec*-BuLi (13.6ml of 1.3M in 98/2 cyclohexane/hexane, 14.3mmol) dropwise to a stirred solution of 9,9-dimethylxanthene (1.0g, 4.76mmol, see *[19814-75-6]*) and TMEDA (2.3ml, 13.3mmol) in dry Et_2O (54ml), and stirring for 16 hours at ~25° to form the 4,5-dilithium derivative. To this mixture is added a solution of chlorodiphenylphosphine (2.8ml, 14.3mmol, see *[1079-66-9]*) in hexane (16ml) dropwise, and stirring is continued for 16 hours, then the solvent is removed *in vacuo*. The residual thick oil is dissolved in CH_2Cl_2, washed with H_2O, dried ($MgSO_4$), filtered, the solvent is removed *in vacuo*, the residue is washed with hexanes, and recrystallised from propan-1-ol to give ***xantphos*** (2.05g, 74.6%) as an air stable yellow-white powder. Its ^1H NMR (300MHz, $CDCl_3$) has δ at 7.4 (dd, 2H, *J* = 7.8, 1.0Hz, CPC*H*CH), 7.15-7.26 (aryl, 20H, $[P(C_6H_5)_2]_2$), 6.96 (t, 2H, *J* = 7.7Hz, CHC*H*CH), 6.54 (dd, 2H, *J* = 7.4, 1.4Hz, CHC*H*CC), 1.65 (s, 6H, CH_3); the $^{31}P\{^1H\}$NMR (121.5MHz, $CDCl_3$, referenced to external 85% H_3PO_4) has δ at -17.5; and for IR, ^{13}C NMR and HRMS see references. Out of several diphenylphosphino ligands studied, xantphos induced the ***highest selectivity*** in rhodium-catalysed hydroformylation of 1-alkenes to form linear aldehydes. The hydroformylation is carried out in a stainless steel bomb under pressure of ~10 bars of CO/H_2 (1:1) in toluene with phosphorus ligand and $Rh(acac)(CO)_2$ as metal source. [Kranenburg et al. *Organometallics* **14** 3081 *1995*, DOI: 10.1021/om00006a057.] The synthesis of heterocycles by C—N cross coupling of bromothiophenes with amino pyridines is achieved with this ligand by Pd catalysis [Begouib et al. *Synthesis* 2794 *2006*, DOI: 10.1055/s-2006-942510]. This ligand is also used in a ruthenium-catalysed alkylation of active methylene compounds with alcohols [Slatford et al. *Tetrahedron Lett* **47** 6787 *2006*, DOI: 10.1016/j.tetlet.2006.07.069], and as a metal chelating ligand for catalysis [Manley & Bilodeau *Org Lett* **6** 2433 *2004*, DOI: 10.1021/ol049165t; and Gao et al. *Org Lett* **6** 1837 *2004*, DOI: 10.1021/ol049440b].

CHIRAL AUXILIARIES

—These compounds are involved in reactions, which direct stereospecificity and are decomposed, e.g. by hydrolysis, reduction, to generate the desired chiral products and the remains of the original auxiliary which can be recycled. Unlike the case of catalysis, the auxiliary is involved stoichiometrically and is not recycled during the reaction. It is one of the products of the reaction and can, *via* other reactions if necessary, be used to regenerate the original auxiliary. These have been used for decades and are of necessity chiral molecules themselves. The auxiliaries have to be linked to the molecule that has a reactive group which can be operated on, e.g. carbonyl, to generate an asymmetric centre, i.e. a chiral alcohol. This section includes more recently available auxiliaries, although many useful ones such as cinchonine, cinchonidine, borneols, camphors, menthol derivatives, substituted sugars, substituted chiral heterocycles (e.g. pyrrolidines), sterols etc. will be found scattered in Chapters 3, 4 and 6. [see Evans *Aldrichimica Acta* **15** 23 *1982*, Ager et al. *Chem Rev* ***96*** 835 *1996*, DOI: 10.1021/cr9500038; Ager et al. *Aldrichimica Acta* **30** 3 *1997*, Mukaiyama *Aldrichimica Acta* **29** 59 *1996*, K. Rück-Braun and H. Kunz *Chiral Auxiliaries in Cycloaddition Reactions* Wiley-VCH, Weinheim *1999*, ISBN 3-527-29386-8.]

R*-(-)- and *S*-(+)- Acetyl-cyclopentadienyl-ironcarbonyl triphenylphosphine complex** *[R 36548-61-5 ; S 36548-60-4; RS 12101-02-9]* **(η^5-C_5H_5)Fe(CO)(CH_3CO) (PPh_3)] M 454.3, m 142° (for +), m 140° (for −), m 145° (for ±); *R*-$[\alpha]_{436}^{27}$ −288, $[\alpha]_{546}^{22}$ −288 (c 0.045, C_6H_6), *S*- $[\alpha]_{546}^{22}$ +288 (c 0.045, C_6H_6).** This racemic 'chiral' auxilliary can be made on a large scale from [η^5-(C_5H_5)Fe(CO)$_2$]$_2$ *[38117-54-3]* which is cleaved with Na/Hg to give the anion [η^5-(C_5H_5)Fe(CO)$_2^-$ (Na^+)] that is methylated to η^5-(C_5H_5)Fe(CO)COMe (m **78-82°**, caramel coloured waxy crystals from sublimation *in vacuo* onto an ice-cooled glass finger) with MeI [Piper & Wilkinson *J Inorg Nucl Chem* **3** 104 *1956*, DOI:10.1016/0022-1902(56)80073-0; Aktogu et al. *J Organomet Chem* **262** 49 *1984*, DOI:10.1016/S0022-328X(00)99122-8; King *Organometallic Synthesis Vol 1*, Academic Press, NY, p 145 *1965*]. This methyl complex provides the racemic title compound when treated with PPh_3. Thus (C_5H_5)Fe(CO)$_2$Me (1.0g, 5mmol) and PPh_3 (1.3g, 5mmol) in redistilled THF (10ml) are refluxed (65°) under N_2 until the Fe-Me band (IR: strong C-H deformation band at 1170 cm^{-1} in CS_2) disappears (~48 hours). The solution is filtered, the solvent is evaporated (to ~20mm), the residue is dissolved in pentane (10ml), passed through an Al_2O_3 column (5 x 20cm), and only one band (yellow orange to orange) is eluted with pentane which, on evaporation (to ~20mm), provides the analytically pure orange **(±)-η^5-C_5H_5)Fe(CO)(CH_3CO)(PPh_3), m 145°** in ~98% yield. This reaction is solvent dependent, i.e. no reaction occurs in boiling hexane (68°), and is only 50% complete in boiling Et_2O (34°) after 48 hours. The solid is ***stable in air, is soluble in organic solvents, e.g. pentane, hexane, Et_2O, THF, CH_2Cl_2, $CHCl_3$, and $*C_6H_6$, but is insoluble in MeOH or H_2O. Solutions in $CHCl_3$, and $*C_6H_6$ decompose rapidly in air to produce brown intractable solids. Hence these solutions should be prepared and used under N_2 or argon. Its IR ($CHCl_3$) has bands with ν_{max} at 1598 (s, MeC=O) and 1920 (vs, br, Fe carbonyl) cm^{-1}; and the ^1H NMR (60MHz, $CDCl_3$, external TMS) has δ_H at 7.59 (m, Ph, 15H), 4.69 (s, C_5H_5, 5H) and 2.52 (s, COMe, 3H). [Bibler & Wojcicki *Inorg Chem* **5** 889 *1966*, DOI: 10.1021/ic50039a037; Butler et al. *Inorg Chem* **6** 2074 *1967*, DOI: 10.1021/ic50057a032.]

The versatility of this acetyl auxiliary has prompted its **optical resolution** into the pure enantiomers which proved to be very good chiral auxiliaries for preparing a variety of optically active molecules where high stereo control is achieved. Two independent resolutions were achieved, both involving 1*R,2S,5R*-(–)-2-isopropyl-5-methylcyclohexan-1-ol (*R- l*-menthol). The ***first resolution*** is from the reaction of sodium *R*-menthylate ($NaOC_{10}H_{19}$, *R*-menthyl refers to the radical produced by loss of the hydroxyl group) and (±)-*(η^5-C_5H_5)Fe(CO)$_2$(PPh_3)$^+PF_6^-$* [see below recovered from hydrolysis, decomplexation, of derivatives of the racemic title compound Aktogu et al. *J Organomet Chem* **262** 49 *1984*, DOI:10.1016/S0022-328X(00)99122-8] to give a diastereoisomeric mixture of (+)-*(C_5H_5)Fe(CO)(PPh_3)-(–)$COOC_{10}H_{19}$* {$[\alpha]_{589}^{20}$ +30, $[\alpha]_{579}^{20}$ +35, $[\alpha]_{546}^{20}$ +70, $[\alpha]_{436}^{20}$ −1450 (in 10^{-3}M $*C_6H_6$)}, and (–)-*C_5H_5)Fe(CO)(PPh_3)-(–)$COOC_{10}H_{19}$* {$[\alpha]_{589}^{20}$ −75, $[\alpha]_{579}^{20}$ −80, $[\alpha]_{546}^{20}$ −120, $[\alpha]_{436}^{20}$ +1550 (in 10^{-3}M $*C_6H_6$)}, (together with $NaPF_6$) which were separated by recrystallisation from pentane, with the latter being more soluble. [Brunner & Schmidt *J Organomet Chem* **21** P53 *1970*, DOI: 10.1016/S0022-328X(00)83614-1] Then the ester with $[\alpha]_{546}^{20}$ −120 (560mg, 0.93mmol) in THF (20ml) at −30°, is treated dropwise with MeLi (1ml of 1.5M Et_2O solution), followed by stirring at –30°/1 hour, then at ~25°/1 hour. After quenching the reaction and evaporating, the brown residue is extracted into $*C_6H_6$, and purified through a column of Al_2O_3/3%H_2O and eluted with $*C_6H_6$. The greenish zone gives a menthol-free yellow solid, which on sublimation provides ***analytically pure orange* (+)-η^5-(C_5H_5)Fe(CO)(CH_3CO)(PPh_3)** (47mg, 11% yield), **m 142°**, $[\alpha]_{546}^{20}$ −228 (in 10^{-3}M $*C_6H_6$), found M 465 (osmometry in $*C_6H_6$). Similarly the menthyl

ester with $[\alpha]_{546}^{20}$ +70 gives ***pure* (–)-η^5-*(C$_5$H$_5$)Fe(CO)(CH$_3$CO)(PPh$_3$)*** (80mg, 30% yield), **m 140°**, $[\alpha]_{546}^{20}$ +227 (in 10^{-3}M *C$_6$H$_6$), found M 464 (osmometry in *C$_6$H$_6$). From the CD and ORD spectra it was concluded that these reactions occurred with ***inversion of configuation*** at the tetrahedral iron centre [Brunner & Schmidt *J Organomet Chem* **36** C18 *1972*, DOI: 10.1016/S0022-328X(00)85109-8].

In the ***second resolution*** *R-(–)-chloromethylmenthyl ether* (***R-*** *is the configuration at* 1-C-OH *of menthol*, see *[26127-08-2]*) was reacted with the lithium salt of (±)-η^5-*(C$_5$H$_5$)Fe(CO)(CH$_3$CO)(PPh$_3$)* (generated with *n*-BuLi) to give the diastereomeric ethers (–)-η^5-*(C$_5$H$_5$)Fe(CO) (PPh$_3$) (COCH$_2$CH$_2$O-(–)-C$_{10}$H$_{19}$* {$[\alpha]_D^{20}$ +65 (c 0.4, *C$_6$H$_6$)}, and (+)-η^5-*(C$_5$H$_5$)Fe(CO) (PPh$_3$) (COCH$_2$CH$_2$O-(–)-C$_{10}$H$_{19}$* {$[\alpha]_D^{20}$ –150 (c 0.4, *C$_6$H$_6$)} which are separable by chromatography and distinguishable by ^{1}H NMR (300MHz). Crystals of the latter diastereoisomer were subjected to x-ray crystallographic analysis which revealed that the absolute configuration at the tetrahedral **Fe centre** was ***R***, by virtue that the absolute configuration of the *R*-menthyl moiety had been established. Since the original formation of these ethers occurs with alteration in the configuration at the Fe centre, then the desired *S*-(+)- and *R*-(–)- configurations of (±)-η^5-*(C$_5$H$_5$)Fe(CO)(CH$_3$CO)(PPh$_3$)* are established. It was also shown that Brunner & Schmidt's reactions of the *R*-menthyl esters with *n*-BuLi to provide the title enantiomers occurred with ***complete inversion of configuration*** (as determined by 500MHz ^{1}H NMR spectroscopy). The enantiomers can be discriminated in solution (9mg in 700µl of $CDCl_3$) containing the chiral shift reagent Eu(tfc) {tris[3-(trifluouomethylhydroxymethylene)-(+)-camphorato] europium (III), see *[34834-11-0]*} (0.48mg in 8µl) where a clear separation of the methyl singlets in the 300MHz ^{1}H NMR spectra occurs: the *S*-(+)- enantiomer has δ at 2.66 and the *R*-(–)-enantiomer has δ at 2.58 (from TMS). [For absolute configuration and optical purity see Davies et al. *JCS Chem Commun* 607 *1986*, DOI: 10.1039/C39860000607.]

The chiral auxiliary properties of the complexes *η^5-C$_5$H$_5$)Fe(CO)(CH$_3$CO)(PPh$_3$)* are displayed by deprotonation with *n*-BuLi (isoPr$_2$NLi in THF has also been used) to give the blood-red enolate which undergoes a variety of reactions and sequences of reactions (homochiral synthesis) that are highly stereoselective. These include alkylation, homochiral succinylation, asymmetric aldol reactions, formation of α,β-unsaturated iron acyls and homochiral dienolates, asymmetric Michael addition reaction, asymmetric synthesis of β-amino acids and β-lactams, asymmetric synthesis of cyclopropanecarboxylic acids, asymmetric synthesis of chiral sulfoxides, and chirality recognition for homochiral synthesis. [Davies *Aldrichimica Acta* **23** 31 *1990*.] Decomplexation at the end of the reactions can be achieved by oxidative cleavage (Br/MeOH, H_2O or *n*-BuNH$_2$, NBS/EtOH) to provide the acid, amide or ester, also by alcoholysis (to provide different esters) from which the products can be isolated. From the aqueous solution *η^5-C$_5$H$_5$)Fe(CO)$_2$(PPh$_3$)$^+$PF$_6^-$* (evaporated to 20ml, from 1mmol of complex product) can be recovered by addition of NH_4PF_6 (0.6g, 3.7mmol), stirring for 1 hours, evaporating to dryness, and the residue is extracted with CH_2Cl_2 (3 x 10ml). The combined extracts are evaporated to 5ml and Et_2O is added to give pale yellow crystals of the complex salt (0.38g, 65%, **m 186°**). It can also be recrystallised from Me_2CO/Et_2O or Me_2CO/hexane. Its ^{1}H NMR (60MHz, Me_2CO, TMS) has δ_H at 5.62 (d, $J_{P,H}$ = 1.5Hz, C$_5$*H*$_5$) and 7.68 (m, Ph, 15H); and for IR see references. [Aktogu et al. *J Organomet Chem* **262** 49 *1984*, DOI: 10.1016/S0022-328X(00)99122-8; Treichel et al. *Inorg Chem* **5** 1177 *1966*, DOI: 10.1021/ic50041a022.]

1R,2S,5R*-(-)-Chloromethylmenthylether [*R-(-)-chloromethylmenthyl ether*]** *[26127-08-2]* **M 204.7, b 62°/0.1mm, 160-162°/13-16mm, d 0.9821, d^{25} 0.994, n_D^{20} 1.467, n_D^{27} 1.465, $[\alpha]_D^{24}$ -177.0 (c 1, CH_2Cl_2),** and ***1S,2R,5S*-(+)-chloromethylmenthyl-ether [*S-(+)-chloromethylmenthyl ether*]** *[103128-76-3]* **$C_{11}H_{21}ClO$, M 204.7, b 72°/0.4mm, d^{21} 0.994, n_D^{20} 1.467, $[\alpha]_D^{24}$ +181.0 (c 2, CH_2Cl_2).** The chloro methyl derivatives of *R-(l)-* and *S-(+)-* menthol respectively are useful chiral auxiliary resolving agents (see previous entry) as they can be readily removed by mild hydrolysis and the recovered menthol can be recycled. The *R*-(*l*)-enantiomer is prepared by melting *l*-menthol (100g, 0.64moles) on a water bath and stirring vigorously with 40% w/w aqueous formalin (50g, 0.67moles) while HCl gas is bubbled through. The mixture warms up at first and has to be cooled at 0° until no more gas dissolves. The clear mixture separates into two layers, the upper layer is removed and the lower layer is dried over Na_2SO_4. This is filtered and fractionated under reduced pressure from some unreacted menthol, formaldehyde trimer and HCl to give the ***chloromethyl ether (120-130g, 91-99%) as a slightly refracting oil which distils steadily at **160-162°/16mm** (and **62°/0.1mm**), but it decomposes at *ca* 230°/atm. The pure ether has **$[\alpha]_D^{21}$ -172.75 (c 6.78 $CHCl_3$).** On heating in EtOH/charcoal it forms the ***dimethylmethylal*** **$C_{10}H_{19}OCH_2OC_{10}H_{19}$** derivative which crystallises from aqueous EtOH in greasy looking scales or from Et_2O in colourless needles **m 57°** (**b 337°/atm**), with **$[\alpha]_D^{24}$ -77.94 (c 0.8 EtOH)**. The ***chloromethylmenthyl ethers*** hydrolyse in H_2O to menthol, HCHO and HCl so they should be stored in an inert atmosphere in the cold [Wedekind *Chem Ber* **34** 813 *1901*, DOI: 10.1002/cber.190103401142; Deutsches Reichspatent No. 119008,

D.R.P. 189331 *Chem Zentralblatt* **1** 184 *1908*]. [*Beilstein* **6** H 32, **6** I 21.]

4*R*-(+)-4-Isopropyl-5,5-dimethyl-2-oxazolidinone (4*R*-(+)-4-isopropyl-5,5-dimethyl-1,3-oxazolidin-2-one) *[223906-38-5]* **and 4*S*-(-)-4-isopropyl-5,5-dimethyl-2-oxazolidinone (4*S*-(-)-4-isopropyl-5,5-dimethyl-1,3-oxazolidin-2-one)** *[168297-86-7]* **$C_8H_{15}NO_2$, M 157.2, m 86-87°, $[\alpha]_D^{20}$ (+)** and **(-) 47 (c 1, H_2O)**. The starting chiral ethanolamine is prepared from the methyl esters of chiral α-aminoacids (*R*- or *S*- valine in this case) by reaction with MeMgI/Et_2O to give chiral 2,2-dimethylvalinol which is converted into the desired chiral 2-oxazolidinones with $(EtO)_2CO/K_2CO_3$ (as in the following entry), or by reaction with CCl_3COCl (in pyridine) or carbonyl-diimidazole (in CH_2Cl_2) as carbonyl equivalents. Similarly by using the esters of chiral alanine, norleucine or α-phenylglycine the respective optically active 5,5-dimethyl-2-oxazolidinones where the 4-isopropyl group is replaced by methyl, *n*-butyl and phenyl groups respectively can be prepared. These auxilliaries have been named '***second series Quat auxilliaries***', the first series being substituted 3,3-dimethyl-2-pyrrolidinones [Davies et al. *Tetrahedron Lett* **35** 2369 *1994*, DOI: 10.1016/0040-4039(94)85222-7; 2373 *1994*, DOI: 10.1016/0040-4039(94)85223-5]. The present 2-oxazolidinones can be *N*-acylated, (e.g. with BuLi, then RCH_2COCl or MeCH=CHCOCl), and the *N*-acyl moieties can be the targets for highly stereoselective enolate alkylation and conjugate addition reactions. The products can be hydrolysed (e.g. with LiOH, THF/H_2O 3:1, 0° at ~25°) to provide the respective chiral acids and regenerated oxazolidin-2-one. The *gem*-dimethyl groups enhance the face-stereoselective shielding of the attached *N*-acyl moeity leading to very high diastereomeric excess in the products. [Davies & Sanganee *Tetrahedron Asymm* **6** 671 *1995*, DOI: 10.1016/0957-4166(95)00057-V; cf. review by Mukaiyama *Aldrichimica Acta* **29** 59 *1996*.]

4*R*-(+)-4-Isopropyl-2-oxazolidinone (4*R*-(+)-4-isopropyl-1,3-oxazolidin-2-one) *[95530-58-8]* **and 4*S*-(-)-4-isopropyl-2-oxazolidinone (4*S*-(-)-4-isopropyl-1,3-oxazolidin-2-one)** *[17016-83-0]* **$C_6H_{11}NO_2$, M 129.2, m 70-71.5°, 70-72°, 71-72°, *R*- $[\alpha]_D^{20}$ +18, *S*- $[\alpha]_D^{20}$ -18, (c 6, EtOH)**. These compounds are ***Evans' type*** of chiral auxiliaries. The *S*-enantiomer was prepared by stirring 1mol of *S*-valinol, 1.1mol of diethyl carbonate and 1mol of anhydrous K_2CO_3 at 125-126° (internal temperature) until 2.0mols of EtOH had distilled off (4-6 hours). The cooled mixture (to 20°) is dissolved in Et_2O, filtered through a pad of Celite to remove the K_2CO_3, evaporated to a small volume and cooled slowly to 0° when the oxazolinone crystallises as white needles (**m 69-70°**, 85-95% yield). It is soluble in CH_2Cl_2 and recrystallises from hexanes/EtOAc (4:1, v/v) by allowing it to stand at 6° overnight. On TLC (0.25mm silica gel 60-F_{245} plates) it has R_F 0.19 (hexanes/EtOAc 6:4,v/v). It has $[\alpha]_{589}$ -16.6, $[\alpha]_{577}$ -17.3, $[\alpha]_{546}$ -20.2, $[\alpha]_{435}$ -37.3, $[\alpha]_{365}$ -63.7 (c 5.81, EtOH); the IR (CH_2Cl_2) has ν_{max} at 1240, 1400, 1760, 2980, 3060, 3240-3340, 3480 cm⁻; and the ^{1}H NMR (90MHz, $CDCl_3$) has δ at 6.7 (br s, 1H, NH), 4.42 (t, *J* = 8.6Hz, 1H, C_5-H), 4.07 (d of d, *J* = 8.5, 6.5Hz, 1H, C_5–H), 3.58 (d of t, *J* = 8.6, 6.5Hz, 1H, C_4–H), 1.9-1.6 (m, 1H, C_4–H), 0.95 (overlapping d's, *J* = 6.0Hz, 6H, $CH(CH_3)_2$). 4*R*-(+)-4-Isopropyl-2-oxazolidinethione [4*R*-(+)-4-isopropyl-1,3-oxazolidin-2-thione, (*4R*)-4-(1-methyl-ethyl)-2-oxazolidinethione) *[1217463-35-8]* **and 4*S*-(-)-4-isopropyl-2-oxazolidinethione (4*S*-(-)-4-isopropyl-1,3-oxazolidin-2-thione)** *[104499-08-3]* **$C_6H_{11}NOS$, M 1***2216-51-5***45.2, m 48-52°, 51-53°, *R*- $[\alpha]_D^{20}$ +23.2, *S*- $[\alpha]_D^{20}$ -23.2, (c 0.4, $CHCl_3$).** These compounds are ***Evans' type*** of chiral auxiliaries. The *S*-(-)-enantiomer is synthesised by adding CS_2 (0.9ml, 15mmol) to a solution of *S*-valinol (10mmol *[cf. 2026-48-4]*) in aqueous N Na_2CO_3 (20ml) and stirring at 100° (bath at 110° under efficient reflux and fume-cupboard) for 15 minutes, cooling to 20° and extracting with CH_2Cl_2 (2 x 50ml). The extract is dried (Na_2SO_4), filtered, evaporated to dryness and the residue is recrystallised from EtOAc/cyclohexane or EtOAc/hexane. It has UV (EtOH) with λ_{max} at 244 nm (ε 18,800); the IR has ν_{max} (KBr) at 3160 and 1515 cm⁻¹; and the ^{1}H NMR (300MHz, $CDCl_3$) has δ at 0.77 (d, 3H, *J* = 6.8Hz), 0.82 (d, 3H, *J* = 6.7Hz), 1.68 (m, 1H), 3.77 (d of t, 1H, *J* = 6.6 and 9.1Hz), 4.23 (d of d, 1H, *J* = 6.6 and 9.1Hz), 4.55 (t, 1H, *J* = 9.1Hz), 9.00 (br s, 1H); and the ^{13}C NMR (75.5MHz, $CDCl_3$) has δ at 189.54, 73.53, 62.52, 32.17, 18.04, 17.90. [Delaunay et al. *J Org Chem* **60** 6604 *1995*, DOI: 10.1021/

jo00125a059; Nagao et al. *JCS Perkin Trans I* 2361 *1985*, DOI: 10.1039/P19850002361.] They are selective and efficient chiral auxiliaries [Velàzquez & Olivo *Current Org Chem* **6** 303 *2002*, DOI: 10.2174/1385272024605023] which can be directly reduced by reductive cleavage with diisobutylaluminium hydride to their corresponding aldehydes and the chiral auxiliary. [Crimmins & Chaudhary *Org Lett* **2** 775 *2000*, DOI: 10.1021/ol9913901].

4*R*-(+)-4-Isopropyl-2-thiazolidinethione (4*R*-(+)-4-isopropyl-1,3-thiazolidin-2-thione) *[110199-16-1]* **and** 4*S*-(-)-4-isopropyl-2-thiazolidinethione **(4*S*-(-)-4-isopropyl-1,3-thiazolidin-2-thione)** *[76186-04-4]* **$C_6H_{11}NS_2$, M 161.3, m 66-67°, 67-68°, 69-71°, *R*- $[\alpha]_D^{20}$ +37, *S*- $[\alpha]_D^{20}$ -37 (c 1, $CDCl_3$).** These compounds are efficient ***Evans' type*** of chiral auxiliaries. The *S*-(-)-enantiomer was synthesised by adding CS_2 (3ml, 50mmol) to a solution of *S*-valinol (10mmol (see *[2026-48-4]*) in aqueous N KOH (50ml) and stirring at 100° (bath at 110° under reflux and efficient fume-cupboard) for 16 hours, cooling to 20° and extracting with CH_2Cl_2 (2 x 50ml). The extract is dried (Na_2SO_4), filtered, evaporated to dryness and the residue is recrystallised from CH_2Cl_2 (colourless needles) or Et_2O. ***Note*** that unlike the preparation of the 1,3-oxazolidine-2-thione above, the preparation of this 1,3-thiazolidine-2-thione required a larger excess of CS_2, stronger base and much longer heating time to replace the alcoholic O by S. It has ^1H NMR (300MHz, $CDCl_3$) with δ at 1.00 (d, 3H, *J* = 7.2Hz), 1.03 (d, 3H, *J* = 8.5Hz), 2.01 (m, 1H), 3.32 (d of d, 1H, *J* = 8.2 and 11.0Hz), 3.53 (d of d, 1H, *J* = 8.2 and 11.0Hz), 4.11 (m, 1H), 9.05 (br s, 1H); and the ^{13}C NMR (75.5MHz, $CDCl_3$) has δ at 200.78, 70.20, 35.73, 31.98, 18.78, 18.18. [Delaunay et al. *J Org Chem* **60** 6604 *1995*, DOI: 10.1021/jo00125a059; Nagao et al. *JCS Chem Commun* 1418 *1985*, DOI: 10.1039/C39850001418; Nagao et al. *J Org Chem* **51** 2391 *1986*, DOI: 10.1021/jo00362a047; McKennon & Meyer *J Org Chem* **58** 3568 *1993*, DOI: 10.1021/jo00065a020.] These are selective and efficient chiral auxiliaries [Velàzquez & Olivio *Current Org Chem* **6** 303 *2002*, DOI: 10.2174/1385272024605023], and the condensation products can be directly reduced to the corresponding aldehyde and the chiral auxiliary by reductive cleavage with diisobutylaluminium hydride [Crimmins & Chaudhary *Org Lett* **2** 775 *2000*, DOI: 10.1021/ol9913901].

1*R*(-)-Menthol [natural *l-(-)-*, 1*R*,2*S*,5*R*-(-)-1-hydroxy-2-*iso*propyl-5-methylcyclohexane] *[2216-51-5]* **M $C_{10}H_{20}O$, 156.3, m 42-45°, 43°, 44-46.5°, 89°/2mm, 100-101°/7mm, 212°/atm, d^{25} 0.89, n_D^{25} 1.458, n_D^{60} 1.446, $[\alpha]_D^{20}$ - 50 (c 10, EtOH), $[\alpha]_{546}^{18}$ - 58.7 (c 2, EtOH),** and **1*S*(+)-menthol [synthetic *d-(+)-*menthol, 1*S*,2*R*,5*S*-(+)-1-hydroxy-2-*iso*propyl-5-methylcyclohexane]** *[15356-60-2]* **m 43-44°, 103-104°/9mm, d^{25} 0.89, n_D^{25} 1.458, n_D^{60} 1.446, $[\alpha]_D^{23}$ + 48 (c 10, EtOH), $[\alpha]_{546}^{18}$ +58,6 (c 2, EtOH).** The natural *l*-isomer is present in peppermint oil and has a strong odour of peppermint, and is sometimes called *peppermint camphor*. Crystallise menthol from $CHCl_3$, petroleum ether or EtOH/water. It can be sublimed at 40° *in vacuo*, but distillation at 5-10mm is preferable with large quantities. It is best stored under N_2 in the dark. It is soluble in most organic solvents and is slightly soluble in H_2O. [Barrow & Atkinson *J Chem Soc* 638 *1939*, DOI: 10.1039/JR9390000638; *Beilstein* **6** III 133, **6** IV 150.] *l*-(-)-Menthol is a very useful resolving agent for acids [Brunel & Buono *J Org Chem* **58** 7313 *1993*, DOI: 10.1021/jo00077a072; see also resolution of the Fe-PPh_3 complex *[12101-02-9]* above], and has been used in crystallisation-induced asymmetric transformation of malonate esters [Ihara et al. *JCS Chem Commun* 9 *1988*, DOI: 10.1039/C39880000009]. It is a chiral auxiliary that can be recycled [Solladié et al. *Synthesis* 173 *1987*, DOI: 10.1055/s-1987-27877; Katagiri et al. *J Org Chem* **53** 226 *1988*, DOI: 10.1021/jo00236a057]. Similar purification and applications are applicable for ***non-natural d-(+)-menthol***, with the advantage of producing the optical enantiomers of the products. The ***racemic*** form ***1RS,2SR,5RS-(±)-1-hydroxy-2-isopropyl-5-methylcyclohexane (hexahydro-thymol)*** *[1490-04-6]* **$C_{10}H_{20}O$, M 156.3, m 28° and 38° (dimorphic), b 216.5°/atm, d^{30} 0.8911, n_D^{20} 1.4415, n_D^{60} 1.4461**, is obtained by catalytic hydrogenation of thymol *[89-83-8]* followed by distillation. [Waters & Beal *J Am Pharm Assoc* **34** 52 *1945*, DOI: 10.1002/jps.3030340208; Huggett *J Soc Chem Ind* **60** 67 *1941*; *Beilstein* **6** III 137, **6** IV 152.]

LEWIS AND BRØNSTED/LOWRY ACIDS AND BASES

A few words are warranted here because these terms are frequently used in current literature. The definition of acids (which produce H^+ ions) and bases (which produce HO^- ions) was adequate to explain reactions (e.g. salt formation) in aqueous solutions, and led to the concepts of pH (S.P.L. Sørensen *Biochem Z* **21** 131, 201 *1909*) and pK (ionisation, cf: Chapter 1, see report by ad-hoc committee of New York Academy of Sciences conference on *Acid-Base Terminology* in *The Lancet* **286** 1010-1012 *1965*, DOI: 10.1016/S0140-6736(65)92864-3). The definition becomes unsatisfactory when applied to studies of reactions in non-aqueous media, particularly in the

catalytic context. Independently, J.N. Brønsted [*Recl Trav Chim Pays-Bas* **42** 718 *1923*, DOI: 10.1002/recl.19230420815; *Chem Rev* **5** 231 *1928*, DOI: 10.1021/cr60019a001] and T.M. Lowry [*J Soc Chem Ind* (London) **42** 42 *1923*, DOI: 10.1002/jctb.5000420302] developed the view that an acid is a substance that has a tendency to lose a proton, and a base is one that has a tendency to gain a proton. This led to the understanding of ***conjugate*** species, e.g. R_3NH^+ as potential acids, and defining the equilibrium: *Base* + $H^+ \leftrightarrows$ H-*Base*$^+$. They pointed out that the differences in nett charge is not as important as the chemical behaviour on which their definition is based. Basicity and acidity do not bear a simple relationship to the nett respective charges, and both their properties depend much more on the complex electronic constitutions of the reagents. Later G. N. Lewis (1928 and later work) began with the classical concept of acids and bases, and progressed to a broader definition of an acid as a substance that is able to accept a pair of electrons, and a base as a substance capable of supplying a pair of electrons. This broader definition has been used extensively for reactions in non-aqueous solutions as well as in aqueous solutions. [***Note*** that these concepts originated from extensive studies of catalytic reactions, e.g. mutarotation, hydrolysis, etc]. Thus a **Lewis acid** is a substance that is electron deficient (e.g. BF_3), and a **Lewis base** is a substance that can donate electrons (e.g. amines, phosphines, boranes, ethers, sulfides etc) to form bonds or complexes with Lewis acids.

In the ***Brønsted/Lowry definition***, a base donates an electron pair to a proton to form a covalent B—H bond (a positive charge, if involved, will reside on B). In the ***Lewis definition***, a base donates a pair of electrons to an electron deficient atom (other than a proton). An acid does not donate a proton but accepts a base to form a new bond. An electron pair is required for forming a covalent or a dative bond.

In the broadest form, an acid is an *electrophile* whereas a base is a *nucleophile*. When these species are regenerated during reactions then they become catalytic. For general reading see Michael B. Smith *Organic Chemistry*: *An Acid-Base Approach* CRC Press *October 2010*, ISBN 10: 1420079204, 13: 978142007203.

CHAPTER 6

PURIFICATION OF BIOCHEMICALS

INTRODUCTION

Biochemicals are chemical substances produced by living organisms. They range widely in size, from simple molecules such as formic acid and glucose to macromolecules such as proteins and nucleic acids. Their *in vitro* chemical synthesis is often impossibly difficult, and in such cases they are available (if at all) only as commercial tissue extracts which have been subjected to purification procedures of widely varying stringency. The desired chemical may be, initially, only a minor constituent of the source tissue which may vary considerably in its composition and complexity. Recent advances in molecular biology have made it possible to produce substantial amounts of biological materials, which are present in nature in extremely small amounts, by recombinant DNA technology and expression in bacteria, yeast, insect and mammalian cells. The genes for these substances can be engineered such that the gene products, e.g. polypeptides or proteins, can be readily obtained in very high states of purity, and in large amounts if necessary. However, many such products, which are still obtained from the original natural sources, are available commercially and may require further purification.

As a preliminary step the tissue might be separated into phases [e.g. whole egg into white and yolk, blood into plasma (or serum) and red cells], and the desired phase may be homogenised. Subsequent treatment usually comprises filtration, solvent extraction, salt fractionation, ultracentrifugation, chromatographic purification, gel filtration and dialysis. Fractional precipitation with ammonium sulfate gives crude protein species. Purification is finally judged by the formation of a single band of macromolecule (e.g. protein, DNA) on electrophoresis and/or analytical ultracentrifugation. Although these generally provide good evidence of high purity, nonetheless it does not follow that one band under one set of experimental conditions is an absolute indication of homogeneity [D.S. Vodopich and R. Moore, *Biology Laboratory Manual*, McGraw-Hill, *2007*, ISBN 9780072995220].

During the past 20 or 30 years a wide range of methods for purifying substances of biological origin have become available. For small molecules (including many sugars and amino acids) reference should be made to Chapters 1 and 2. The more important methods used for large molecules, polypeptides and proteins in particular, comprise:

1. *Centrifugation*. In addition to centrifugation for sedimenting proteins after ammonium sulfate precipitation in dilute aqueous buffer, the technique has been used for fractionation of large molecules in a denser medium or a medium of varying density. By layering sugar solutions of increasing densities in a centrifuge tube, proteins can be separated in a sugar-density gradient by centrifugation. Smaller DNA molecules (e.g. plasmid DNA) can be separated from RNA or nuclear DNA by centrifugation in aqueous cesium chloride (*ca* 0.975g/ml of buffer) for a long time (e.g. 40 hours at 40,000 x g). The plasmid DNA band appears at about the middle of the centrifuge tube and is revealed by the fluorescent pink band formed by the binding of DNA to ethidium bromide which is added to the CsCl buffer. *Microfuges* are routinely used for centrifugation in Eppendorf tubes (1.2-2ml) and can run up to speeds of 12,000 x g or more. *Analytical centrifugation*, which is performed under specific conditions in an analytical ultracentrifuge is very useful for determining purity, aggregation of protein subunits and the molecular weights of macromolecules. [D. Rickwood, T.C. Ford and J. Steensgaard (Eds), *Centrifugation: Essential Data Series*, J Wiley & Sons, *1994*, ISBN 9780471942719; L.L. Regel and W.R. Wilcox, *Processing by Centrifugation*, Springer, *2001*, ISBN 9780306466546; J.M. Graham and D. Rickwood, *Biological Centrifugation*, Springer, *2001*, 9781859960370; A. Records and K. Sutherland, *Decanter Centrifugation Handbook*, Elsevier, *200I*, ISBN 1856173690].

Purification of Laboratory Chemicals.
http://dx.doi.org/10.1016/B978-0-12-805457-4.50006-9,

2. *Gel filtration* with polyacrylamide (mol wt exclusion limit from 3000 to 300,000) and agarose gel (mol wt exclusion limit 0.5 to 150 x 10^6) is useful for separating macromolecules. In this technique high-molecular-weight substances are too large to fit into the gel microapertures and pass rapidly through the matrix (with the void volume), whereas low-molecular-weight species enter these apertures and are held there for longer periods of time, being retarded by the column material in the equilibria, relative to the larger molecules. This method is also used for desalting solutions of macromolecules.
   *Dry gel*s and *crushed beads* are also useful in the gel filtration process. Selective retention of water and inorganic salts by the gels or beads (e.g. Sephadex G-25) results in increased concentration and purity of the protein fraction which moves with the void volume. (See also section on 'Gel filtration' in Chapter 1.)

3. *Ion-exchange matrices* are microreticular polymers containing carboxylic acid (e.g. Bio-Rad 70) or phosphoric acid (Pharmacia, Amersham Biosciences, Mono-P) exchange functional groups for weak acidic cation exchangers, sulfonic acid groups (Dowex 50W) for strong acidic cation exchangers, diethylaminoethyl (DEAE) groups for weakly basic anion exchangers and quaternary ammonium (QEAE) groups for strong anion exchangers. The old cellulose matrices for ion exchangers have been replaced by Sephadex, Sepharose or Fractogel which have more even particle sizes with faster and more reproducible flow rates. Some can be obtained in fine, medium or coarse grades depending on particle size. These have been used extensively for the fractionation of peptides, proteins and enzymes. The use of *p*H buffers control the strength with which the large molecules are bound to the support in the chromatographic process. Careful standardisation of experimental conditions and similarly the very uniform size distribution of Mono beads have led to high resolution in the purification of protein solutions. MonoQ is a useful strong anion exchanger, and MonoS is a useful strong cation exchanger, whereas MonoP is a weak cation exchanger (check with commercial sources, see Chapter 1). These have been successful with medium pressure column chromatography (HPLC, see below in 7). Chelex 100 binds strongly and removes metal ions from macromolecules. [See sections on 'HPLC', 'Ion-exchange Resins' and 'Ion-exchange Celluloses and Sephadex' in Chapter 1.]

4. *Hydroxylapatite (hydroxyapatite)* is used for the later stages of purification of enzymes. It consists essentially of hydrated calcium phosphate which has been precipitated in a specific manner. It combines the characteristics of gel and ionic chromatography. Crystalline hydroxylapatite is a structurally organised, highly polar material which, in aqueous solution (in buffers), strongly adsorbs macromolecules such as proteins and nucleic acids, permitting their separation by virtue of the interaction with charged phosphate groups and calcium ions, as well as by physical adsorption. The procedure therefore is not entirely ion-exchange in nature. Chromatographic separations of singly and doubly stranded DNA are readily achievable, whereas there is negligible adsorption of low-molecular-weight species. [Tiselius et al. *Arch Biochem Biophys* **65** 132 *1916*, DOI: 10.1016/0003-9861(56)90183-7; Siegelman et al. *Anal Biochem* **13** 402 *1965*, DOI: 10.1016/0003-2697(65)90332-5.]

5. *Affinity chromatography* is a chromatographic technique whereby the adsorbant has a particular and specific affinity for one of the components of the mixture to be purified. For example the adsorbant can be prepared by chemically binding an inhibitor of a specific enzyme (which is present in the crude complex mixture) to a matrix (e.g. Sepharose). When the mixture of impure enzyme is passed through the column containing the adsorbant, only the specific enzyme binds to the column. After adequate washing, the pure enzyme can be released from the column by either increasing the salt concentration (e.g. NaCl) in the eluting buffer or adding the inhibitor to the eluting buffer. The salt or inhibitor can then be removed by dialysis, gel filtration (above) or ultrafiltration (see below). [See W.H. Scouten, *Affinity Chromatography: Bioselective Adsorption on Inert Matrices*, J.Wiley & Sons, NY, *1981*, ISBN 0471026492; H. Schott, *Affinity Chromatography: Template Chromatography of Nucleic Acids and Proteins*, Marcel Dekker, NY, *1984*, ISBN 0824771117; P. Matejtschuk Ed. *Affinity Separations* Oxford University Press *1997* ISBN 0199635501 (paperback); M.A. Vijayalakshmi, *Biochromatography, Theory and Practice*, Taylor & Francis Publ, *2002*, ISBN 0415269032; and the section on 'Other Types of Chromatography' in Chapter 1.]

6. In the *Isoelectric focusing* of large charged molecules on polyacrylamide or agarose gels; slabs of these are prepared in buffer mixtures (e.g. ampholines) which have various pH ranges along the length of the gel. When a voltage is applied for some time, the buffers arrange themselves on the slabs in respective areas according to their pH ranges (prefocusing). Then the macromolecules are applied near the middle of the slab and allowed to migrate in the electric field until they reach the pH area similar to their isoelectric points and focus at that position. This technique can also be used in a chromatographic mode, *chromatofocusing*, whereby a gel in a column is run (also under HPLC conditions) in the presence of ampholines (narrow or wide pH ranges as required) and the macromolecules are then run through in a buffer. *Capillary electrophoresis* systems in which a current is applied to set the gradient are available in which the columns are fine capillaries and are used for qualitative and quantitative purposes [See R. Kuhn and S. Hoffstetter-Kuhn, *Capillary Electrophoresis*: Principles and Practice, Springer-Verlag Inc, NY, *1993*; P. Camilleri Ed. *Capillary Electrophoresis-Theory and*

Practice, CRC Press, Boca Raton, Florida, *1993*; D.R. Baker, *Capillary Electrophoresis*, J Wiley & Sons, NY, *1995*; P.G. Righetti, A. Stoyanov and M. Zhukov, *The Proteome Revisited, Isoelectric Focusing; J. Chromatography Library Vol* **63** *2001*, Elsevier, ISBN 0444505261, P. Schmitt-Kopplin, *Capillary Electrophoresis: Methods and Protocols,* Humana, *2007*, ISBN 9781588295392; J.P. Landers, *Handbook of Capillary & Microchip Electrophoresis and Associated Microtechniques*, CRC Press, Boca Raton, Florida, *2007*, ISBN 9780849333293, C. Henry, *Microchip Capillary Electrophoresis*, Humana, *2006*, ISBN 9781588292933.] The bands are eluted according to their isoelectric points. Isoelectric focusing standards are available which can be used in a preliminary run in order to calibrate the effluent from the column, or alternatively the pH of the effluent is recorded using a glass electrode designed for the purpose. Several types of efficient commercial equipment are available for separating proteins on a preparative and semi-preparative scale.

7. *High performance liquid chromatography* (HPLC) is liquid chromatography in which the eluting liquid is sent through the column containing the packing (materials as in paragraphs 2. to 6. above, which can withstand higher than atmospheric pressures) under pressure. On a routine basis this has been found useful for purifying proteins (including enzymes) and polypeptides after enzymic digestion of proteins or chemical cleavage (e.g. with CNBr) prior to sequencing (using reverse-phase columns such as μ-Bondapak C18). Moderate pressures (50-300psi) have been found most satisfactory for large molecules (FPLC). [See Scopes *Anal Biochem* **114** 8 *1981*, DOI: 10.1016/0003-2697(81)90443-7; B.A. Bidlingmeyer *Practical HPLC Methodology and Applications*, J Wiley & Sons, NY *1991*; L.R. Snyder, J.L. Glajch and J.J. Kirkland *Practical HPLC Method Development*, J Wiley & Sons, NY *1988*; ISBN 0471627828; R.W.A. Oliver, *HPLC of Macromolecules: A Practical Approach*, 2nd Edn, Oxford University Press, *1998*, T. Hanai, *HPLC: A Practical Guide*, Royal Society of Chemistry (UK), *1999*, ISBN 084045155; P. Millner *High Resolution Chromatography*, Oxford University Press, *1999* ISBN 0199636486; see also Chapter 1, Bibliography.]

8. *Ultrafiltration* (UF) using a filter (e.g. Millipore) can remove water and low-molecular-weight substances without the application of heat. Filters with a variety of molecular-weight exclusion limits not only allow the concentration of a particular macromolecule to be determined, but also the removal (by washing during filtration) of smaller molecular-weight contaminants (e.g. salts, inhibitors or cofactors). This procedure has been useful for changing the buffer in which the macromolecule is present (e.g. from Tris-Cl to ammonium carbonate), and for desalting. Ultrafiltration can be carried out in a stirrer cell (Amicon) in which the buffer containing the macromolecule (particularly protein) is pressed through the filter, with stirring, under argon or nitrogen gas pressure (e.g. 20-60psi). During this filtration process the buffer can be changed. This is rapid (e.g. 2L of solution can be concentrated to a few mls in 1 to 2 hours depending on pressure and filter). A similar application uses a filter in a specially designed tube (Centricon tubes, Amicon) and filtration occurs under centrifugal force in a centrifuge (4-6000rpm at 0º/40min). The macromolecule (usually DNA) then rests on the filter and can be washed on the filter also by centrifugation. The macromolecule is recovered by inverting the filter, placing a conical receiver tube on the same side where the macromolecule rests, filling the other side of the filter tube with eluting solution (usually a very small volume e.g. 100 μL), and during further centrifugation this solution passes through the filter and collects the macromolecule from the underside into the conical receiver tube. With the development of polymeric and ceramic nanofilters use can be made of nanofiltration (NF) in which particles or molecules of less than 2nm can be held back. This is to be compared with UF where the size limit is between 2nm and 0.1μm (see Chapter 7).

9. *Partial precipitation* of a protein in solution can often be achieved by controlled addition of a strong salt solution, e.g ammonium sulfate. This is commonly the first step in the purification process. Its simplicity is offset by possible denaturation of the desired protein and the (sometimes gross) contamination with other proteins. It should therefore be carried out by careful addition of small aliquots of the powdered salt or concentrated solution (below 4º, with gentle stirring) and allowing the salt to be evenly distributed in the solution before adding another small aliquot. Under carefully controlled conditions and using almost pure protein, it is sometimes possible to obtain the protein in crystalline form suitable for X-ray analysis (see below).

10. *Dialysis*. This is a process by which small molecules, e.g. ammonium sulfate, sodium chloride, are removed from a solution containing the protein or DNA using a membrane which is porous to small molecules. The solution (e.g. 10ml) is placed in a dialysis bag or tube tied at both ends, and stirred in a large excess of dialysing solution (e.g. 1.5 to 2 L), usually a weak buffer at *ca* 4º. The dialysing buffer is replaced with fresh buffer several times, e.g. four times in 24 hours. This procedure is similar to ultrafiltration (above) and allows the replacement of buffer in which the protein, or DNA, is dissolved. It is also possible to concentrate the solutions by placing the dialysis tube or bag in Sephadex G25 which allows the passage of water and salts from the inside of the bag thus concentrating the protein (or DNA) solution. Dialysis tubing is available from various distributors, but 'Spectra/por' tubing (from Spectrum Medical Industries, Inc, LA) is particularly effective because it retains macromolecules and allows small molecules to dialyse out very rapidly, thus reducing dialys-

sing time considerably. This procedure is used when the buffer has to be changed so as to be compatible with the next purification or storage step, e.g. when the protein (or DNA) needs to be stored frozen in a particular buffer over extended periods. UF and NF can also serve this purpose whereby the solvent can be completely replaced by washing with an alternative solvent.

11. *Gel Electrophoresis*. This is becoming a more commonly used procedure for purifying proteins, nucleic acids, nucleoproteins, polysaccharides and carbohydrates. The gels can be 'electroblotted' onto membranes, and the modern procedures of identifying, sequencing (proteins and nucleic acids) and amplifying (nucleic acids) on sub-micro scales have made this technique of separation a very important one. See below for polyacrylamide gel electrophoresis (PAGE), [D. Patel *Gel Electrophoresis*, J.Wiley-Liss, Inc., *1994*; P. Jones and D. Rickwood, *Gel Electrophoresis: Nucleic Acids*, J. Wiley and Sons, NY *1999* (paperback) ISBN 0471960438; D.M. Gersten and D. Gersten, *Gel Electrophoresis: Proteins*, J. Wiley and Sons, NY, *1996*, ISBN 0471962651; R. Westermeier *Electrophoresis in Practice*, 4th Edn, Wiley-VCH Publishing, *2004* ISBN 9783527311811].

12. *Crystallisation*. The ultimate in purification of proteins or nucleic acids is crystallisation. This involves very specialised procedures and techniques and is best left to the experts in the field of X-ray crystallography who can provide a complete picture of the structure of these large molecules. [A. Ducruix and R. Giegé Eds, *Crystallisation of Nucleic Acids and Proteins: A Practical Approach*, 2nd Edition, *2000*, Oxford University Press, ISBN 0199636788 (paperback); T.L. Blundell and L.N. Johnson *Protein Crystallisation*, Academic Press, NY, *1976*; A. McPherson *Preparation and Analysis of Protein Crystals*, J.Wiley & Sons, NY, *1982*; A. McPherson, *Crystallisation of Biological Macromolecules*, Cold Spring Harbour Laboratory Press, *2001* ISBN 0879696176, see also Bibliography in Chapter 1.]

Other details of the above can be found in Chapters 1 and 2 which also contain relevant references.

Several illustrations of the usefulness of the above methods are given in the *Methods Enzymol* series (Academic Press) in which 1000-fold purifications or more have been readily achieved. In applying these sensitive methods to macromolecules, reagent purity is essential. It is disconcerting, therefore, to find that some commercial samples of the widely used affinity chromatography ligand Cibacron Blue F3GA contained this dye only as a minor constituent. The major component appeared to be the dichlorotriazinyl precursor of this dye. Commercial samples of Procion Blue and Procion Blue MX-R were also highly heterogeneous [Hanggi and Carr, *Anal Biochem* **149** 91 *1985*, DOI: 10.1016/0003-2697(85)90480-4]. Variations in composition of sample dyes can well account for differences in results reported by different workers. The purity of substances of biological origin should therefore be checked by one or more of the methods given above. Water of high purity should be used in all operations. Double glass distilled water or water purified by a MilliQ filtration system (see Chapter 2) is most satisfactory.

Brief general procedures for the purification of polypeptides and proteins.

Polypeptides of molecular weights up to *ca* 1-2000 (10-20 amino acid residues) are best purified by reverse phase HPLC. The desired fractions that are collected are either precipitated from solution with EtOH or lyophilised. The purity can be checked by HPLC and identified by microsequencing (1-30 picomoles required) to ascertain that the correct polypeptide is in hand. Polypeptides larger than these are sometimes classified as proteins and are purified by one or more of the procedures described above. The purification of enzymes and functional proteins which can be identified by specific interactions is generally easier to follow because enzyme activities or specific protein interactions can be checked (by assaying) after each purification step. The commonly used procedures for purifying soluble proteins involve the isolation of an aqueous extract from homogenised tissues or extracts from ruptured cells from microorganisms or specifically cultured cells, for example, by sonication, freeze shocking or passage through a small orifice under pressure. Contaminating nucleic acids are removed by precipitation with a basic protein, e.g. protamine sulfate. The soluble supernatant is then subjected to fractionation with increasing concentrations of ammonium sulfate. The required fractions are then further purified by the procedures described in sections 2-9 above. If an affinity adsorbant has been identified, then affinity chromatography can provide an almost pure protein in one step sometimes even from the crude extract. The rule of thumb is that a solution with a protein concentration of 1mg/ml has an absorbance A_{1cm} at 280nm of 1.0 absorbance unit. Membrane-bound proteins are usually insoluble in water or dilute aqueous buffer and are obtained from the insoluble fractions, e.g. the microsomal fractions from the >100,000 x g ultracentrifugation supernatant. These are solubilised in appropriate detergents, e.g. Mega-10 (nonionic), Triton X-100 (ionic) detergents, and purified by methods 2 to 8 (previous section) in the presence of detergent

in the buffer used. They are assayed also in the presence of detergent or membrane lipids.
The purity of proteins is best checked by *polyacrylamide gel electrophoresis* (PAGE). The gels are either made or purchased as pre-cast gels and can be with uniform or gradient gel composition. Proteins are applied onto the gels *via* wells set into the gels or by means of a comb, and travel along the gel surface by means of the current applied to the gel. When the buffer used contains sodium dodecylsulfate (SDS), the proteins are denatured and the denatured proteins (e.g. as protein subunits) separate on the gels mainly according to their molecular sizes. These can be identified by running marker proteins, with a range of molecular weights, simultaneously on a track alongside the proteins under study. The protein bands are visualised by fixing the gel (20% acetic acid) and staining with Coomassie blue followed by silver staining if higher sensitivity is required. Commercial 'Phast Gel Electrophoresis' apparatus, or related equipment, is very useful for rapid analysis of proteins. It uses small pre-cast polyacrylamide gels (two gels can be run simultaneously) with various uniform or gradient polyacrylamide concentrations as well as gels for isoelectric focusing. The gels are usually run for 0.5-1.5 hours and can be stained and developed (1-1.5 hours) in the same apparatus. The equipment can be used to 'electroblot' the protein bands onto a membrane from which the proteins can be isolated and sequenced or subjected to antibody or other identification procedures. It should be noted that all purification procedures are almost always carried out at *ca* 4º in order to avoid denaturation or inactivation of the protein being investigated.

There has been considerable necessity for, and interest in, the study of **Proteomics.** This involves the identification, quantitation and isolation of all the proteins produced by a cell or organism at a particular point in time. It provides information on the expression of **all** the proteins produced by particular cells at a desired stage of the cell's development, maturity, activation or condition. A sophisticated apparatus for this purpose is a flat bed polyacrylamide gel which is run electrophoretically in one direction according to the extent of polymerisation of the acrylamide, and then run at right angles along a pH gradient (isoelectric focusing). Hundreds of polypeptides and proteins are thus separated, collected and identified by various other techniques such as LC-MS-MS, capillary electrophoresis etc (T. Palzkill, *Proteomics*, Springer, *2001*, ISBN 0792375653; T.D. Veenstra and R.D. Smith *Proteome Characterization and Proteomics*, Academic Press, *2003*, ISBN 978079237565; R. Westermeier, T. Naven and H-R. Höpker, *Proteomics in Practice: A Guide to Successful Experimental Design*. J.Wiley & Sons, NY *2008*, ISBN 9783527319411; J.M. Walker (ed) *The Proteomics Protocols Handbook* Springer, *2005*, ISBN: 978-1-58829-343-5 Print, 978-1-59259-890-8 Online; the *Journal of Proteomics (ISSN: 1874-3919)*, which is the official journal of *The European Proteomics Association* that is published by Elsevier, and has been running for several years, is but one of the many journals on Proteomics and Bioinformatics that are avaliable and can be viewed on the internet; see also Bibliography in Chapter 1).
Another rapidly developing field is **metabolomics** where metabolites are screened and identified in the normal and diseased cell at specfic time intervals. These can be identified from studies of *genomics*, *transcriptomics* or *proteomics*. Such studies are now possible because of the highly improved power of HPLC, GC, MS, NMR and the interfacing of these instruments with each other, and with labtop computers which may drive them, store the data and compare it built-in libraries of substances. Thus *metabolones* can be mapped for various biological systems (plant and animal). Publications that are avaiable include the *Metabolomics Journal* published by SpringerLink and started in 2005, and *Journal of Metabolomics and Systems Biology (JMSB)*, published by Academic Journals which started in 2011. They publish original papers, reviews and conference reports.

The point should be made that advances in liquid chromatograpy (HPLC, coupled or uncoupled to MS or MS-MS) are ever increasing. This is not only in the improvements of the hardware but also in the variety of column materials that can now be purchased. Thus after the first precipitations of proteins, the rest of the purification can be carried out by HPLC equipment. Also in the syntheses of polypeptides, small proteins, RNAs and DNAs the final purifications are invariably done using HPLC procedures.

Considerable advances have been made in recent years with the rapid development and applications of the **microchip**. This in a sense is a **laboratory on a chip** (refer to sections on *Advances in Physical Techniques used in Purification* and *Advances in Chemical Techniques Used in Purification* at the ends of Chapters 1 and 2 respectively for applictions.) To mention one example, complete sequencing of DNA can be performed using microchips no larger 15-30mm square. Throughput of fluids (reagents, solvents etc) is considerably faster and uses very small volumes, hence the synonym ***microfluidics***. No wonder that complete sequencing of genomes can be performed in a matter of a few days. These procedures require purification at various stages; all being carried out on the same or accompanying microchips. The use of very small volumes and amounts of reagents and nucleic acid materials, results in shorter turnover times and rapid and quite accurate results. The downside is that very expensive equipment is required. However, once this cost is overcome, which can be recuperated in a short period, the running costs are not high considering the value of the results.

Protein Function

A very brief description of the function of proteins is made here. Proteins, which are chains of assorted amino acids perform a variety of functions. Depending of their amino acids and the sequences in which they are linked, they invariably, but not always, fold in specific ways as they are synthesised from the messenger RNA. The folding process is sometimes assisted by other specific proteins or polypeptides called *chaperones*. The folding tends to dictate the function of the protein. The folding is usually complex. The process not only folds segments of the amino acid sequences to produce α-helices and/or β-sheets which run parrallel or anti-parrallel to each other, but can also allow folds that cause the monomeric protein to form dimers, trimers, tetramers etc. Thus, if the folding is such that many charged amino acids (e.g. lysine, histidines for basic residues, and aspartate and glutamate for acidic residues) are on the exposed surfaces of the protein then the protein is water soluble depending on the pH of the solution. At pH values which cause the positive charges of the exposed acid residues to neutralise the exposed basic residues, e.g. at the PI (isoelectric point), the protein may precipitate out of solution. On the other hand if hydrophobic residues e.g. phenylalanine, leucine, valine, are on the exposed surface of the protein then its solubility in H_2O would be limited or extremely poor, and the protein would confine itself in a lipid bilayer and become membrane bound. Proteins capable of catalysing chemical reactions are called ***enzymes***, others which are embedded in a cellular membrane may function as ***pores*** which allow ions or small molecules to flow into or out of a cell. These may or may not be ***gated***, i.e. controlling the movement of particles in or out of the cell, as in ***neurons*** (nerve cells). Other lipid bound proteins function in ***signalling*** and are generally associated with protein ***receptors***. Among the smaller polypeptides are the ***activators***, ***inhibitors***, ***hormones***, and ***immunopeptides***.

Enzymes: These proteins are folded in such a specific manner that a ***pocket*** is formed. This pocket is flanked by residues (basic, acidic or hydrophobic) which would assist catalysis. Unlike the catalytic process of chemical reactions (which following first, second or higher order kinetics), enzymic reactions follow **Michaelis-Menten kinetics**, also known as ***saturation kinetics***. The reactive pocket is generally known as the *Active Site* and may or may not bind a small molecule (***cofactor***) or two to assist the enzyme in the catalytic process by entering into the reaction. This may be involved in reversible chemical bond formation or electron movement between the enzyme substrate(s) or product(s). Enzymic reactions are very highly stereospecific reactions with very careful steric control. Stereospecificity is not surprising considering that all the amino acids, including those at the active sites, are pure chiral entities. The enzyme can be activated or deactivated, e.g. by the binding of another molecule at a site away from the active pocket which alters the conformation

at the pocket so as to assist or desist the reaction rate. This site of binding is called the ***allosteric site***. A plethora of enzymes and enzymic reactions are known with a great spectrum of reactions and mechanisms. Hydrophilic enzymes are easier to study, as this can be carried out in aqueous buffers. Hydrophobic enzymes are more difficult to study because they are generally active in the presence of the lipid membrane in which they are embedded. The kinetics are therefore studied in the presence of detergents (otherwise they many not be active or be dissolved in the aqueous medium), which may not mimic the natural state of the enzyme. A very rough measurement of activity is $\mathbf{C}_{50}$ which is the concentration of substrate that causes the enzyme to reach 50% activity. However, thorough kinetic studies are usually made, and two enzyme parameters are determined and are as charcteristic of individual enzymes/substrates as are the melting and boiling points of organic compounds. These parameters are the Michaelis Constant ($\mathbf{K_m}$) and the maximum velocity $\mathbf{V_{max}}$ of the particular enzyme with a stated substrate under specified conditions (i.e. temperature, buffer pH, ionic strength, etc.). The K_m is vaguely associated with the reversible binding of the substrate at the active site, and the V_{max} is the ultimate steady state velocity when the active site is saturated with the substrate. V_{max} also depends on the concentration of the enzyme used. A better parameter than V_{max} is the ***turnover number*** or $\boldsymbol{k_{cat}}$ which is related to the maximum velocity but takes into account the molecular mass of the enzyme in which case the enzyme needs to be in a high state of purity. $\boldsymbol{k_{cat}}$ has the dimension of min^{-1} (or sec^{-1}) and is the number of catalytic events taking place per min (or sec), the number of μmoles of substrate converted to product(s) in (μmol enzyme) $^{-1}min^{-1}$. The activities of enzymes are known to be inhibited, and these too can be simple or complex. $\mathbf{IC_{50}}$ **values**, the concentration of inhibitor which will reduce the maximum activity to 50%, is a very rough guide, but it says little about the type of inhibition. Various types of inhibition are known, such as ***competitive inhibition***, ***uncompetitive inhibition*** or ***non-competitive inhibition*** depending on how the inhibitor molecule competes with the substrate at the active site. Similarly with ***activator***, as well as the possiblity that as the concentration of products increases they can reach values when the products can inhibit enzyme activity. Most of these interactions are ***reversible***. On the other hand, the inhibitor can also be designed such that it possess a reactive chemical group which will react ***irreversibly*** with amino acid residues at the active site and ***kill*** the enzyme. Such inhibition is known as ***suicide inhibition***.

It was found necessary to identify enzymes, in a similar way that the Chemical Abstract Service identifies chemical compounds by their CASRegistry Numbers (see information at the beginning of this book, and the CASRNumber Index). The International Enzyme Commission has thus identified enzymes by EC numbers which consist of four numbers each separated by a full stop e.g. **EC 1.6.99.7**. [See section on 'Proteins, Enzymes, RNA and DNA' in this Chapter, and in the General Index]. This particular EC number is for ***Dihydropteridine Reductase*** where **1.** refers to the **Group number** which is for ***oxidoreductase*** enzymes, **6.** refers to the cofactor being NADH-NAD^+ acceptor, **99.** refers to a second acceptor — *quinonoid*-dihydrobiopterin in this case, and **7.** is for it being the seventh enzyme classified in this group. The Groups are: EC 1 for ***Oxidoreductases***, EC 2 for ***Transferases***, EC 3 for ***Hydrolases***, EC 4 for ***Lyases***, EC 5 for ***Isomerases***, and EC 6 for ***Ligases*** [See the comprehensive list in https://en.wikipedia.org/wiki/Enzyme Commission number, www.chem.qmul.ac.uk/iubmb/enzyme, and for details of, and references for, enzymes see M. Dixon & E.C. Webb [assisted by C.J.R. Thorne & K.F. Tipton *The Enzymes* (3rd Edn) Longman Group, London *1979*, ISBN: 0-12-218358-4, https://www.researchgate.net/publication/247011955; and references above]. It should be noted that this classification is for ***enzyme function***, i.e. enzymes with similar function which could have different sequences, or come from different sources, would have the same EC number, except perhaps the last digit(s). [Bibliography: A. Fersht *Enzyme Structure and Mechanism* (2nd edn) Freeman & Co *1985*, ASIN: B010WF331A; A. Fersht *Structure and mechanism in protein science: a guide to enzyme catalysis and protein folding* W.H. Freeman San Francisco: *1999*. ISBN 0-7167-3268-8; K.G. Scrimgeour *Chemistry and Control of Enzyme Reactions* Academic Press *1977*, ISBN: 0126341508; J. Tze-Fei Wong *Kinetics of Enzyme Mechanisms* Academic Press *1975*, ISBN: 012762250; https:// en.wikipedia.org/wiki/Enzyme_kinetics].

Transport Proteins: These are at least of two types. Those that bind to and assist molecules, e.g. small molecules, proteins, lipids or carbohydrates, to enter or leave the cell; and those that are embedded in the cell membrane and allow the desired ***molecular traffic*** to occur. They also include ***pore proteins*** which are embedded in the cell wall and allow, in a gated or non-gated process, for ions such as Na^+, K^+ and Ca^{2+} to move in and out of cells that require this. They are plentiful in the ***synapses*** of neurons which allow movement of ions, and small molecules, across them, causing electrical conductance. Special ***pore proteins*** in synapses may also cause small excitatory and inhibitory molecules to move across them (e.g. ***neurotransmitters*** like γ–aminobutyic acid GABA), or cause disturbances between synapses.

Receptor Proteins: These are lipophilic proteins that embed themselves into the lipid membranes of cells. Their sequences dictate their folding and dictate their specific action. They commonly have a small protein ***anchor***, or a series of smaller proteins which are activated when a molecule (e.g. a drug, a hormone, a ***cytokine***) binds to the outer surface of the receptor protein. The binding transfers a signal to the ***anchor proteins*** beneath (e.g. G-proteins, phosphorylating ***tyrosine kinases***, Jak's) that are bound to the inner side (cell lumen) of the receptor. The signal can activate mechanisms further inside of the cell which carry out the intended function of the drug, cytokine etc. Among these mechanisms, for example, the signal molecule such as a phosphorylated protein at a tyrosine residue, can now enter the cell nucleus and alter gene production. These ***receptor proteins*** can be very complicated e.g. the string of their amino acids can traverse the lipid bilayer membrane several times, and occasionally can form a protein crown. In some cases the receptor proteins in the lipid bilayer are caused to come together (e.g. dimerise) under the influence of a bound ***cytokine*** before activating the signalling of the anchor proteins inside the cell. As in the above case with enzymes, the agonistic or antagonistic effects of the binding drug (*cytokine*, hormone etc) can be roughly quantitated by IC_{50} values, the concentrations that cause 50% of the desired physiological effects. [https://en.wikipedia.org/wiki/Receptor_(biochemistry); https://en.wikipedia.org/wiki/Cell_surface_receptor; https://www.ibiblio.org/virtualcell/textbook/chapter3/cmf3.htm.]

Brief general procedures for purifying DNA.
Oligo-deoxyribonucleotides (up to *ca* 60-mers) are conveniently purified by HPLC (e.g. using a Bio-Rad MA7Q anion exchange column and a Rainin Instrument Co, Madison, Dynamax-300A C_8 matrix column) and used for a variety of molecular biology experiments. Plasmid and chromosomal DNA can be isolated by centrifugation in **cesium chloride** buffer (see paragraphy 1. *centrifugation* above), and then re-precipitated with 70% ethanol at -70^o (18 hours), collected by centrifugation (microfuge) and dried in air before dissolving in TE (10mM TrisHCl, 1mM EDTA pH 8.0). The DNA is identified on an Agarose gel slab (0.5 to 1.0% DNA grade in 45mM Tris-borate + 1mM EDTA or 40mM Tris-acetate + 1mM EDTA pH 8.0 buffers) containing ethidium bromide which binds to the DNA and under UV light causes it to be visualised as pink fluorescent bands. Marker DNA (from λ phage DNA cut with the restriction enzymes Hind III and/or EcoRI) with bands running from 72 to 353 base-pairs (bp) are run in a parallel track in order to estimate the size of the unknown DNA. Various other DNA markers are commercially available such as the step ladder ranging from 50bp to 800bp with bands at 50bp intervals, and the step ladder with bands ranging from 100bp to 4000bp with bands at 200bp intervals. The DNA can be isolated from the bands on the gel by transfer onto nitro-acetate paper (e.g. NA 45) electrophoretically, by binding to silica or an ion-exchange resin, then extracted from the adsorbent paper and precipitated with ethanol. The DNA pellet is then dissolved in TE buffer and its concentration determined. A solution of duplex DNA (or RNA) of 50μg/ml gives an absorbance of 1.0 unit at 260nm/1cm cuvette (single-stranded DNA or RNA gives a value of 1.3 absorbance units). DNA obtained in this way is suitable for molecular cloning.
Recombinant and chemically synthesised DNA and RNA are now routinely separated and purified by HPLC, and their structures are confirmed by sequencing an aliquot. A variety of commercially available HPLC systems are now available, and a desired system can be selected from them.
Brief mention must be made of the tremendous advances that have been made in recent years in the fields of DNA, RNA gene sequencing and synthesis. The development of instrumentation and analysers by the Illumina –Company [www.illumina.com/) and the ***'Ion torrent'*** semiconductor sequencing of DNA and RNA, using an ion PGM (personal genome machine) sequencer (see; http://lifetech-it.hosted.jivesoftware.com/index.jspa) have made it possible to sequence complete genomes in a matter of weeks or less.

This chapter lists some representative examples of biochemicals and their origins, a brief indication of key techniques used in their purification, and literature references where further details may be found. Simpler low-molecular-weight organic compounds, particularly those that may have been prepared by chemical syntheses, e.g. phenylacetic acid, will be found in Chapter 3. Only a small number of enzymes and proteins are included because of space limitations. The purification of the ones that have been included has been described only briefly. The reader is referred to comprehensive texts such as the *Methods in Enzymology* (E-Book Series) series which currently runs to Vol **597** *2017*, ISBN 9780128114698, Electronic ISBN: 9780128114704; and *The Enzymes* (3rd Edn, Academic Press) which ran to more than 28 volumes in 2010, for methods of preparation and purification of proteins and enzymes. Leading references on proteins will be found in *Advances in Protein Chemistry* which was incorporated with *Advances in Structural Biology* (84 volumes (2011), Elsevier Inc), and enzymes will be found in *Advances in Enzymology* which then became *Advances in Enzymology and Related Areas of Molecular Biology,* J Wiley & Sons, NY (up to volume 78 in 2011). The *Annual Reviews of Biochemistry* (Annual Reviews Inc. Patlo Alto California) also are an excellent source of key references to the up-to-date information on known and new natural compounds, from small molecules, e.g. enzyme cofactors, to proteins and nucleic acids. See also the *Springer Handbook of Enzymes* cited above.

Abbreviations of titles of periodical are generally defined as in the Chemical Abstracts Service Source Index (CASSI) but without punctuation. References to Fieser & Fieser's *Reagents for Organic Synthesis* will be shortened to Fieser throughout, e.g. Fieser **2** 254, **11** 88, etc. All temperatures are in degrees Centigrade unless otherwise stated. Other abbreviations are self evident.

Ionisation constants of ionisable compounds are given as **pK** values (published from the literature) and refer to the **pKa** values at room temperature (~ 15ºC to 25ºC). The values at other temperatures are given as superscripts, e.g. $\mathbf{pK}^{25}$ for 25ºC. Estimated values are entered as $\mathbf{pK_{Est(1)}}$ **~** (see section on 'Ionisation Constants' in Chapter 1 for further information).

Benzene, which has been used as a solvent successfully and extensively in the past for reactions and purification by chromatography and crystallisation is now considered a **very dangerous substance**, so it has to be used with extreme care. It is important that an alternative solvent to benzene (e.g. toluene, toluene-petroleum ether, or a petroleum ether to name a few) should be used first. However, if benzene has to be used then all operations have to be performed in well-ventilated fumehoods and precautions taken to avoid inhalation and contact with skin and eyes. Whenever benzene is mentioned in the text, an asterisk e.g. *C_6H_6 or *benzene, is inserted to remind the user that special precaution should be adopted.

Selected Amino acids and peptides, Proteins, Enzymes DNA and RNA, Carotenoids, Carbohydrates, Steroids, and Physiologically Active Compounds* (*including miscellaneous low-molecular-weight bioactive substances, drugs, antibiotics, coenzymes, vitamins, lipids, phospholipids, nucleosides, nucleotides, polynucleotides and useful reagents*) *are collected in the following separate respective sections of this chapter.

AMINO ACIDS and PEPTIDES

This section includes amino acid derivatives and related compounds.

N*-Acetyl-L-alaninamide** *[15962-47-7]* **$C_5H_{10}N_2O_2$, M 130.2, m 162°.** Crystallise the amide repeatedly from EtOH/diethyl ether. The **(±)-*isomer crystallises from H_2O and has **m 157-158°**. [Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, **Vol 3** p 1838 *1961*, de Jong *Recl Trav Chim Pays-Bas* **19** 288 *1900*, DOI: 10.1002/recl.19000190902; *Beilstein* **4** H 295.]

***N*-Acetyl-ß-alanine** *[3025-95-4]* **$C_5H_9NO_3$, M 127.2, m 78.3-80.3°, pK^{25} 4.45.** The β-alanine crystallises from acetone. [King & King *J Am Chem Soc* **78** 1089 *1956*, DOI: 10.1021/ja01587a005; *Beilstein* **4** IV 2526, 2548.]

***N*-Acetyl-L-alanyl-L-alaninamide** *[30802-37-0]* **$C_8H_{15}N_3O_3$, M 201.2, m 250-251°.** Crystallise the dipeptide derivative repeatedly from EtOH/diethyl ether. [Puliti & Mattia *Acta Cryst Section C* **2** 51 *1995*, DOI: 10.1107/S0108270194008577.]

***N*-Acetyl-L-alanyl-L-alanyl-L-alaninamide** *[29428-34-0]* **$C_{11}H_{20}N_4O_4$, M 272.3, m 295-300°.** Crystallise the tripeptide derivative from MeOH/diethyl ether.

***N*-Acetyl-L-alanylglycinamide** *[76571-64-7]* **$C_7H_{13}N_3O_3$, M 187.2, m 148-149°, d ^{25} 1.191g/cm^3.** Crystallise the dipeptide derivative repeatedly from EtOH/diethyl ether.

Acetyl-α-amino-*n*-butyric acid *[34271-24-4]* **$C_6H_{11}NO_3$, M 145.2**, **pK^{25} 3.72.** Crystallise the acid twice from water (charcoal) and dry it in air [King & King *J Am Chem Soc* **78** 1089 *1956*, DOI: 10.1021/ja01587a005; Gördes et al. *Adv Synth & Catalysis* **345** 510 *2003*, DOI: 10.1002/adsc.200390059].

O*-Acetylcarnitine chloride (2-acetoxy-3-carboxy-*N,N,N*-trimethylpropanamine HCl)** *[S(*D+*)- 5080-50-2*, *R(*L*-)- 5061-35-8*, *RS 2504-11-2]* **$C_9H_{17}NO_4$. HCl, M 239.7, m 181°, 187°(corr, dec), 197°(dec), $[\alpha]_D^{25}$ -28 (c 2, H_2O) for *S*-isomer, pK^{25} 3.6.** Recrystallise the chloride from isopropanol. Dry it over P_2O_5 under high vacuum. The ***S-betaine crystallises from EtOH/Et_2O with **m 145°(dec)** and is ***hygroscopic***; it has $[\alpha]_D^{20}$ -19.5 (c 6, H_2O). It is an endogenous mitochondrial metabolite that transports acetyl groups across the mitochondrial membrane. [Poorthuis *et al* 'Determination of acylcarnitines in urine of patients with inborn errors of metabolism using HPLC after derivatisation with 4'-bromophenacyl bromide' *Clin Chim Acta* **216** 53 *1993*, DOI:10.1016/0009-8981(93)90138-T, PMID: 8222273; Krimberg & Wittandt *Biochem Z* **251** 231 *1932*, Strack et al. *Z Physiol Chem* **238** 191 *1936*, *Beilstein* **4** III 1630, 1632.]

R*-(-)-*N*-Acetyl-L-cysteine methyl ester** *[7652-46-2]* **$C_6H_{11}NO_3S_6$, M 177.2, m 71-78°, 80°, $[\alpha]_D^{20}$ -24.0 (c 1, MeOH).** The ester is purified by converting into the cuprous mercaptide which is decomposed by dilute H_2SO_4, extracted into Et_2O, dried (Na_2SO_4), filtered, evaporated and the residue is recrystallised from H_2O containing a little AcOH. The crystals are dried in a vacuum. These operations should be carried out in an inert atmosphere (N_2 or argon) to avoid oxidation to the disulfide cystin ester. ***Note that the cuprous salt is only stable when it is dry, but is readily oxidised when wet. It has been used as a sulfur transfer agent [Gilman & Spero *Tetrahedron Lett* **34** 1751 *1993*, DOI:10.1016/S0040-4039(00)60769-4]. [Pirie *Biochem J* **25** 614 *1931*, DOI: 10.1042/bj0250614; *Beilstein* **4** III 1607.]

***N*-Acetylglutamic acid** *[1188-37-0]* **$C_7H_{11}NO_5$, M 189.2, m 185° (*RS*), 201° (*S*), $[\alpha]_D^{25}$ -16.6 (in H_2O), $[\alpha]_D^{25}$ -15.6 (c 4, MeOH) for *S-enantiomer*, $pK_{Est\,(1)}$ ~3.4, $pK_{Est(2)}$ ~4.3.** A likely impurity is glutamic acid. Crystallise it from boiling water. It inhibits *N*-acetyl-L-glutamate synthase. [Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, **Vol 3** p 1948 *1961*, Shigesada & Tatibana *Eur J Biochem* **84** 285 *1978*, DOI: 10.1111/j.1432-1033.1978.tb12167.x; Coudé et al. *Biochem Biophys Res Commun* **102** 1016 *1981*, DOI: 10.1016/0006-291X(81)91639-9; *Beilstein* **4** IV 3047.]

***N*-Acetylglycinamide** *[2620-63-5]* **$C_4H_8N_2O_2$, M 116.1, m 139-139.5°.** Crystallise the amide repeatedly from EtOH/Et_2O. Dry it in a vacuum desiccator over KOH. [Davis & Levy *J Chem Soc* 3479 *1951*, DOI: 10.1039/JR9510003479; Fischer & Otto *Chem Ber* **36** 2106 *1903*, DOI: 10.1002/cber.190303602128; *Beilstein* **4** IV 2401.]

***N*-Acetylglycine (Aceturic acid)** *[543-24-8]* **$C_4H_7NO_3$, M 117.1, m 206-208°, 207-209°, pK_1^{25} -1.92, pK_2^{25} 3.69.** *N*-Acetylglycine is treated with acid-washed charcoal and recrystallised three times from water or EtOH/Et_2O and is dried *in vacuo* over KOH [King & King *J Am Chem Soc* **78** 1089 *1956*, DOI: 10.1021/ja01587a005]. [*Beilstein* **4** IV 2399.]

***N*-Acetylglycyl-L-alaninamide** *[34017-20-4]* **$C_7H_{13}N_3O_3$, M 187.2.** Crystallise the dipeptide derivative repeatedly from EtOH/Et_2O. Dry it in a vacuum desiccator over KOH. [Hedwig et al. *JCS Faraday Trans* **87** 1751 *1991*, DOI: 10.1039/FT9918701751.]

***N*-Acetylglycylglycinamide** *[27440-00-2]* **$C_6H_{11}N_3O_3$, M 173.2, m 207-208°.** Crystallise the dipeptide derivative repeatedly from EtOH/Et_2O. Dry it in a vacuum desiccator over KOH. [Hedwig et al. *JCS Faraday Trans* **87** 1751 *1991*, DOI: 10.1039/FT9918701751.]

***N*-Acetylglycylglycylglycinamide** *[35455-24-4]* **$C_8H_{14}N_4O_4$, M 230.2, m 253-255°.** Crystallise the tripeptide derivative repeatedly from EtOH/Et_2O. Dry it in a vacuum desiccator over KOH.

***N*-Acetylhistidine (H_2O)** *[39145-52-3]* **$C_8H_{11}N_3O_2$, M 181.2, m 148° (*RS*), 169° (*S*), $[\alpha]_D^{25}$ +46.8 (c 1, H_2O) for *S-enantiomer*.** A likely impurity is histidine. Crystallise it from water, then 4:1 acetone/water. [For Co complexing see Marshall et al. *J Am Chem Soc* **78** 4636 *1956*, DOI: 10.1021/ja01599a030; Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, **Vol 3** p 1990 *1961*, *Beilstein* **25** IV 4359.]

***N*-Acetyl-*RS*-homocysteine thiolactone (Citiolone)** *[1195-16-0] [17896-21-8 for ±]* **$C_6H_9NO_2S$, M 159.2, m 110°, 109-111°, 111.5-112.5°**. Dry Citiolone in a vacuum desiccator. It recrystallises from toluene as needles. It is a ninhydrin -ve substance which gives a 'slow' nitroprusside test. It has λ_{max} at 238nm (ε 4,400 $M^{-1}cm^{-1}$); and ν_{max} (nujol) 1789*s* and 851*ms* cm^{-1}. [Benesch & Benesch *J Am Chem Soc* **78** 1597 *1956*, DOI: 10.1021/ja01589a025; cf. Laliberté et al. *J Chem Soc* 2756 *1963*, DOI: 10.1039/JR9630002756.]

***N*-Acetyl-L-leucinamide (2-acetamido-4-methylvaleramide)** *[30130-37-1, 28529-34-2]* **$C_8H_{16}N_2O_2$, M 172.2, m 202°.** Recrystallise it from aqueous EtOH or $CHCl_3$/petroleum ether (b 40-60°). [Gränacher *Helv Chim Acta* **8** 216 *1925*, DOI: 10.1002/hlca.19250080135; *Beilstein* **4** II 864, for L, and Bergmann et al. *Justus Liebigs Ann Chem* **449** 301 *1926*, DOI: 10.1002/jlac.19264490116; *Beilstein* **4** II 877 for DL.]

***N*-Acetyl-L-methionine** *[65-82-7]* **$C_7H_{13}NO_3S$, M 191.3, m 103.5-104.5°, 104°, $[\alpha]_{546}$ -24.5 (c 1, in H_2O), pK_{Est} ~3.4.** Crystallise *N*-acetyl-L-methionine from Me_2CO, H_2O or EtOAc. Dry it in a vacuum over P_2O_5. Its solubility at 25° in H_2O is 30.7%, and in Me_2CO it is 29.5%. [Mitzi & Schueter *Biochim Biophys Acta* **27** 168 *1958*, DOI: 10.1016/0006-3002(58)90305-6; Birnbaum et al. *J Biol Chem* **194** 455 *1952*, www.jbc.org/content/194/1/455; *Beilstein* **4** IV 3206.]

Acetylmethionine nitrile *[538-14-7]* **$C_7H_{12}N_2OS$, M 174.3, m 44-46°**. Crystallise the nitrile from diethyl ether. [Catch et al. *J Chem Soc* 1609 *1947*, DOI: 10.1039/JR9470001609; *Beilstein* **4** III 1654.]

***N*-Acetyl-*N*'-methyl-L-alaninamide** *[19701-83-8]* **$C_6H_{12}N_2O_2$, M 144.2, m 181.2-182° (sealed tube), $[\alpha]_D^{25}$ -51.1 (c 2, EtOH).** Crystallise the amide from EtOAc/Et_2O, then from EtOH and Et_2O. Also recrystallise it twice by dissolving ~2.5g in hot 200ml of toluene and cooling. It sublimes at ~170° , so its **m** is measured in a sealed tube. [Applewhite & Niemann *J Am Chem Soc* **81** 2208 *1959*, DOI: 10.1021/ja01518a050; *Beilstein* **4** IV 2500.]

***N*-Acetyl-*N*'-methylglycinamide** *[7606-79-3]* **$C_5H_{10}N_2O_2$, M 130.2, m 157.5-158°.** Recrystallise the amide from EtOH/Et_2O mixture. Also recrystallise it twice from EtOAc/EtOH (16:1) and once from EtOAc. [Applewhite & Niemann *J Am Chem Soc* **81** 2208 *1959*, DOI: 10.1021/ja01518a050.]

***N*-Acetyl-*N*'-methyl-L-leucine amide** *[32483-15-1]* **$C_9H_{18}N_2O_2$, M 186.3, m 165.3-166.8° (sealed tube), $[\alpha]_D^{25}$ -33.9 (c 1, H_2O).** Recrystallise the amide from EtOAc, EtOH/hexane mixture or toluene/hexane mixture. It sublimes above ~160°. [Applewhite & Niemann *J Am Chem Soc* **81** 2208 *1959*, DOI: 10.1021/ja01518a050.]

N*-Acetyl-L-phenylalanine** *[2018-61-3]* **$C_{11}H_{13}NO_3$, M 207.2, m 170-171°, 174-175°, $[\alpha]_D^{25}$ +47.5 (c 4, EtOH), +52.5 (c 2, EtOH), (DL) m 152.5-153°, pK_{Est} ~3.5.** *N*-Acetyl-L-phenylalanine is recrystallised from H_2O, 20% MeOH/H_2O, or $CHCl_3$; dry and store it at 4°. The ***(DL)-mixture crystallises from H_2O, Me_2CO, EtOAc, or $CHCl_3$ with **m 152-154°** and the solubilities in w% at 25° are 0.73 (H_2O), 4.3 (Me_2CO), 0.79 (EtOAc) and 0.34 ($CHCl_3$) [Kerr & Niemann *J Org Chem* **23** 893 *1958* DOI: 10.1021/jo01100a601, Overby & Ingersoll *J Am Chem Soc* **73** 3363 *1951*, DOI: 10.1021/ja01151a110; L-form: Fu et al. *J Am Chem Soc* **76** 6054 *1954*, DOI: 10.1021/ja01652a057; Bender & Glasson *J Am Chem Soc* **81** 1590 *1959*, DOI: 10.1021/ja01516a020]. [*Beilstein* **14** I 238, **14** IV 1575.]

***N*-Acetyl-L-phenylalanine ethyl ester** *[2361-96-8]* **$C_{11}H_{17}NO_3$, M 235.3, m 93-94°.** Crystallise the ester from aqueous EtOH or H_2O. [Izumiya & Fruton *J Biol Chem* **218** 59 *1956*, http://www.jbc.org/content/218/1/59, PMID: 13278315.]

***N*-Acetyltryptophan** *[87-32-1]* **$C_{13}H_{14}N_2O_3$, M 246.3, m 206°, 207-208° (*RS*), pK_{Est} ~3.8,** *[1218-34-4]* **m 188°, 189.5-190.5° (*S*), $[\alpha]_D^{25}$ +30.1 (aqueous NaOH), +71.5° (dioxane/aqueous HCl).** A likely impurity is tryptophan. Crystallise it from EtOH by adding water. [Cowgill *Biochim Biophys Acta* **200** 18 *1970,* DOI: 10.1016/0005-2795(70)90038-3, DL: Berg *J Biol Chem* **100** 79 *1933*, http://www.jbc.org/content/100/1/79; *Beilstein* **22/14** V 40-50.]

***N*-Acetyl-L-valine amide** *[37933-88-3]* **$C_7H_{14}N_2O_2$, M 158.3, m 275°.** Recrystallise the amide from CH_3OH/Et_2O. [den Tweel, Harder & Buitelaar *Stability and Stabilization of Enzymes* Elsevier Sci Publ, Amsterdam *1993*, ISBN: 0444893725.]

α-Alanine (*RS*) *[302-72-7]* **$C_3H_7NO_2$, M 89.1, m 295-296°, (*S*)** *[56-41-7]* **m 297°(dec), $[\alpha]_D^{15}$ +14.7 (in 1M HCl), (*R*)** *[338-69-2]* **m 289-291°(dec), $[\alpha]_D^{15}$ -14.1 (c 0.9, 1M HCl), pK_1^{25} 2.34, pK_2^{25} 9.87.** Crystallise alanine from H_2O or aqueous EtOH, i.e. crystallise it from 25% EtOH in water, or recrystallise it from 62.5% EtOH, wash it with EtOH and dry it to constant weight *in vacuo* over P_2O_5. ***RS*-α-alanineamide** *[20108-77-4]* has **m 62°** (from $CHCl_3$)**, pKa 8.02**, the ***hydrochloride*** *[80222-96-4]* has **m 173°** (from EtOH) and the ***acetate salt*** has **m 136-137°.** ***S*-α-alanine methyl ester hydrochloride** *[2491-20-5]* has **m 109-111°**, $[\alpha]_D^{15}$ +8.0 (c 1.6, MeOH), and ***S*-α-alanine N-methylamide** *[7324-05-2]* has **m 78°** (hygroscopic, also **m 72°** reported, from $CHCl_3$). [Gutter & Kegeles *J Am Chem Soc* **75** 3893 *1953*, DOI: 10.1021/ja01112a006; Minireview: Walsh *J Biol Chem* **264** 2393 *1989*, www.jbc.org/content/264/5/2393.full.pdf.] ***2,2'-Iminodipropionic acid*** is a likely impurity. L-Allothreonine has $[\alpha]_D^{25}$ +9.8 (c 4 H_2O) [Elliot *J Chem Soc* 62 *1950*, DOI: 10.1039/JR9500000062; Birnbaum et al. *J Biol Chem* **194** 455 *1952*, http://www.jbc.org/content/194/1/455, PMID: 14927637; IR: Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, **Vol 3** *1961*, *Beilstein* **4** IV 3170.]

RS*-α-Allylglycine (2-aminopent-4-enoic acid)** *[7685-44-1]* **$C_5H_9NO_2$, M 115.1, m 250-255°(dec), 258-260°(dec), $pK_{Est(1)}$ ~2.3, $pK_{Est(2)}$ ~9.6.** Dissolve it in absolute EtOH and precipitate it with pyridine, then recrystallise it from aqueous EtOH [R_F on paper in BuOH/EtOH/NH_3/H_2O (4:4:1:1:) is 0.37]. Store at -20°. The ***hydrobromide has **m 136-140°** (from EtOAc) and the ***phenylureido derivative*** has **m 159-161°**. [Schögl *Monatsh Chem* **89** 377 *1958*, DOI: 10.1007/BF00898759; *Beilstein* **4** IV 2852.]

Aminoacetic acid see **Glycine** below.

α-Amino acids. All the α-amino acids with the '***natural***' configuration [*S* (L), except for cysteine which is *R*(L)] at the α- carbon atom are available commercially in a very high state of purity. Many of the '***non-natural***' α-amino acids with the [*R*(D)] configuration as well as racemic mixtures are also available, and generally none require further purification before use unless they are of '***Technical Grade***' or were stored for a very long period. The *R* or *S* enantiomers are optically active except for glycine which has two hydrogen atoms on the α- carbon atom, but these are *pro*-chiral and enzymes or proteins ***do*** distinguish between them, e.g. serine hydroxymethyltransferase successfully replaces the *pro*-α- hydrogen atom of glycine with CH_2OH (from formaldehyde) to make *S*-serine. The twenty common natural α-amino acids are: **amino acid**, three-letter abbreviation, **one-letter abbreviation**, pK (-COOH) and pK ($-NH_3^+$): **Alanine**, Ala, **A**, 2.34, 9.69; **Arginine**, Arg, **R**, 2.17, 9.04; **Asparagine**, Asn, **N**, 2.01, 8.80; **Aspartic acid**, Asp, **D**, 1.89, 9.60; **Cysteine**, Cys, **C**, 1.96, 8.18; **Glutamine**, Gln, **Q**, 2.17, 9.13; **Glutamic acid**, Glu, **E**, 2.19, 9.67; **Glycine**, Gly, **G**, 2.34, 9.60; **Histidine**, His, **H**, 1.8, 9.17; **Isoleucine**, Ile, **I**, 2.35, 9.68; **Leucine**, Leu, **L**, 2.36, 9.60; **Lysine**, Lys, **K**, 2.18, 8.95; **Methionine**, Met, **M**, 2.28, 9.20; **Phenylalanine**, Phe, **F**, 1.83, 9.12; **Proline**, Pro, **P**, 1.99, 10.96; **Serine**, Ser, **S**, 2.21, 9.15; **Threonine**, Thr, **T**, 2.11, 9.62; **Tryptophan**, Trp, **W**, 2.38, 9.39; **Tyrosine**, Tyr, **Y**, 2.2, 9.11, **Valine**, Val, **V**, 2.32, 9.61, respectively. Technical grade amino acids can be purified on ion-exchange resins (e.g. Dowex 50W and eluting with a gradient of HCl or AcOH), and the purity can be checked by TLC in two dimensions and stained with ninhydrin. [J.P.Greenstein & M.Winitz, *Chemistry of the Amino Acids* (3 Volumes), J.Wiley & Sons, NY, 1961; C.Cooper, N.Packer and K.Williams, *Amino Acid Analysis Protocols*, Humana Press, 2001, ISBN 0896036561.] Recently codons for a further two amino acids have been discovered which are involved in ribosome-mediated protein synthesis giving proteins containing these amino acids. The amino acids are *R*(L)-selenocysteine [Stadtman *Ann Rev Biochem* **65** 83 *1996*, PMID: 8811175] and pyrrolysine [(4*R*, 5*R*)-4-substituted (with Me, NH_2 or OH) pyrroline-5-carboxylic acid] [Srinivasan, James & Krzychi *Science* **296** 1459 *2002*, PMID: 12029131.] They are, however, rare at present and only found in a few microorganisms.

dl*-α-Aminoadipic acid (hydrate) (2-aminohexane-1,6-dioic acid)** *[542-32-5]* **$C_6H_{11}NO_4$, M 161.2, m 196-198°, 204°, 205-206°, $pK_{Est(1)}$ ~2.0, $pK_{Est(2)}$ ~4.5, $pK_{Est(3)}$ ~9.8.** Crystallise the acid from H_2O. *Alternatively*, purify it by precipitating the Cu salt and decomposing the Cu salt suspended in H_2O by bubbling H_2S, filtering off the CuS, evaporating, and recrystallising the residue from H_2O. Note that prolonged refluxing of an aqueous solution converts the acid to the lactone: ***piperid-2-one-6-carboxylic acid which has **m 177-178°**. [Linstead & Wang *J Chem Soc* 810, 811 *1937*, DOI: 10.1039/JR9370000807; Waalkes et al. *J Am Chem Soc* **72** 5760 *1950*,

Wiley, **Vol 3** p. 2408 *1961*, *Beilstein* **4** III 1555, **4** IV 3070.] It is found in rat retina and is a biomarker for diabetes in humans [Wang et al. *J Clin Invest* **123** 4309 *2013*, DOI:10.1172/JCI64801, PMID: 24091325].

***N*-(*p*-Aminobenzoyl)-L-glutamic acid** *[4271-30-1]* **$C_{12}H_{14}N_2O_5$, M 266.3, m 173°, 174-175° (L-form), $[\alpha]_{546}$ -17.5 (c 2, 0.1m HCl); 197° (DL), pK_1^{25} 2.61, pK_2^{25} 3.76, pK_3^{25} 4.83**. Crystallise the acid from H_2O. Also purify it by dissolving 2.7g in H_2O (130ml), adding aqueous NaOH to pH 5.5 and adding portionwise a solution of 0.5M $CuSO_4$ to complete precipitation of the Cu salt. This salt is filtered off, suspended in H_2O and H_2S is bubbled through to precipitate CuS, filter, evaporate and recrystallise the residue from H_2O. It has λ_{max} (H_2O) at 273nm. [Backer & Houtman *Recl Trav Chim Pays-Bas* **70** 738 *1951*, DOI: 10.1002/recl.19510700902; *Beilstein* **14** IV 1153.]

***RS*-2-Aminobutyric acid** *[2835-81-6]* **$C_4H_9NO_2$, M 103.1, m 283-285°(dec), 287-288°(dec), 291°(dec), 303°(dec), 303°(dec, sealed tube), pK_1^{25} 2.29, pK_2^{25} 9.83.** Crystallise the acid from water. [Stiles & Finkbeiner *J Am Chem Soc* **81** 505 *1959*, DOI: 10.1021/ja01511a067; Fe complexing: Perrin *J Chem* Soc 3125 *1958*, DOI: 10.1039/JR9580003125; *Beilstein* **4** IV 2584.]

S*-2−Aminobutyric acid (Butyrine)** *[1492-24-6]* **$C_4H_9NO_2$, M 103.1, m 292°(dec), $[\alpha]_D^{25}$ + 20.6 (c 2, 2.5N HCl), pK_1^{25} 2.55, pK_2^{25} 9.60**. Crystallise butyrine from aqueous EtOH, and the melting point depends on heating rate but has **m 303°** in a sealed tube. ***R*-2−Aminobutyric acid (D-)** *[2623-91-8]* **$C_4H_9NO_2$, M 103.1, m 292°(dec),** is the ***enantiomer and has **$[\alpha]_D^{25}$ - 20.6 (c 2, 2.5N HCl), $[\alpha]_D^{20}$ -7.94 (c 4, H_2O).** [Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, **Vol 3** p 2399 IR: 2401 *1961*, *Beilstein* **4** III 1294, **4** IV 2584.]

***RS*-3-Aminobutyric acid (BABA)** *[541-48-0, 2835-82-7]* **$C_4H_9NO_2$, M 103.1, m 193-194°, $pK_{Est(1)}$ ~3.5, $pK_{Est(2)}$ ~10.3.** Crystallise the acid from aqueous EtOH or MeOH/Et_2O. Also crystallise it by heating a slightly diluted EtOH solution and adding Me_2CO. It gives a purple spot with R_F 0.89 on paper chromatography using 80% aqueous phenol (the α-amino acid has R_F 0.74). [Zukha & Rivlin *J Org Chem* **23** 94 *1958*, DOI: 10.1021/jo01095a604; Bruylants *Bull Soc Chim Belg* **32** 259 *1923*, *Beilstein* **4** IV 2595.] It induces plant disease resistance, and increases resistance to abiotic stress [Cohen *Plant Disease* **86** 448 *2002*, DOI:10.1094/PDIS.2002.86.5.448].

S*-3-Aminobutyric acid** *[3775-72-2]* **$C_4H_9NO_2$, M 103.1, m 212°, 210-212°, $[\alpha]_D^{18}$ + 38.8 (c 0.5, H_2O).** Purify the acid by recrystallisation from absolute EtOH. It has also been crystallised from MeOH or MeOH/Et_2O and dried in a vacuum. [Synthesis from *S*-alanine: Balenovic et al. *J Chem Soc* 3316 *1952*, DOI: 10.1039/JR9520003313; Bruylants *Bull Soc Chim Belg* **32** 259 *1923*.] ***Optical resolution of the ***(±)-methylester*** was achieved *via* recrystallisation of the *d*-camphorsulfonic acid salts which, after decomposition of the salts and hydrolysis of the methyl esters gave pure *R- and S- 3-aminobutyric acids* [Fischer & Scheibler *Justus Liebigs Ann Chem* **383** 337 *1911*, DOI: 10.1002/jlac.19113830206; *Beilstein* **4** IV 2595.]

4-Aminobutyric acid (GABA) *[56-12-2]* **$C_4H_9NO_2$, M 103.1, m 202°(dec), 203°(dec), pK_1^{25} 4.14, pK_2^{25} 10.55.** Crystallise GABA from aqueous EtOH or MeOH/Et_2O. Also crystallise it by dissolving it in the least volume of H_2O and adding 5-7 volumes of absolute EtOH. It is a neurotransmitter. [Sherman *Biochemical Preparations* **4** 91 *1955*; de Witt *Org Synth* Coll Vol **2** 25 *1943*, DOI: 10.15227/orgsyn.017.0004; *Beilstein* **4** III 1316, **4** IV 2600.]

1-Amino-1-cyclopentanecarboxylic acid (cycloleucine) *[52-52-8]* **$C_6H_{11}NO_2$, M 129.2, m 328-335°(dec), 328-329°, 330°(dec), pK_1^{20} 2.4, pK_2^{20} 10.3.** Any Cl^- or other anions are removed by stirring with a strong cation exchange resin (Amberlite IR-120), filtering, and washing with distilled H_2O until the filtrate is free from the anion. The resin is then stirred overnight with 6N NH_4OH, filtered, the filtrate is decolourised (charcoal) and evaporated to dryness in a vacuum. The residue is recrystallised from H_2O/EtOH. Also crystallise it from aqueous EtOH. The ***hydrochloride*** has **m 222-224°(dec)**. [Neelakantan & Hartung *J Org Chem* **23** 964 *1958*, DOI: 10.1021/jo01101a007; Connors & Ross *J Chem Soc* 2119 *1960*, DOI: 10.1039/JR9600002119; O'Donnell et al. *Synthesis* 127 *1984*, DOI: 10.1055/s-1984-30749; *Beilstein* **14** IV 974.]

***trans*-(1*RS*,4*RS*)-4-Aminoethylcyclohexane-1-carboxylic acid (*t*-AMCHA, Tranexamic acid, Tranex, Transamin, Trasamlon, Ugurol, Frenolyse, Hexapromin, Abvitoff among other names)** *[1197-18-8]* **$C_6H_{11}NO_2$, M 157.2, m 386-392° (dec), and *cis*-(1*RS*,4*SR*)-4-aminoethylcyclohexane-1-carboxylic acid** *[1197-17-7]* **M 157.2, m 236-238° (dec); *cis*- and *trans*- acids have the same pK_1^{25} 4.51 (CO_2H), pK_2^{25} 10.72 (NH_2).** A mixture of *cis*- and *trans*- acids (2:1) is obtained by catalytic reduction of 4-acetamidomethylbenzoic acid (3.9g, 20mmol, from acetylation of 4-aminomethylbenzoic acid see *[56-91-7]*) in aqueous NaOH (0.8g, 20mmol in 15ml of H_2O) in the presence of Raney Ni (3ml of aqueous suspension) are shaken with H_2 in a bomb (100ml) at 170° and 82atm/cm^2 (1205psi). Reduction is complete after 2 hours, the catalyst is filtered off, the filtrate is acidified with 4N H_2SO_4 and evaporated to dryness *in vacuo*; the residue is extracted with Me_2CO, filtered and evaporated to dryness *in vacuo* to give crude 4-acetamidomethylcyclohexane-1-carboxylic acid (~3.9g). The acid is then refluxed with 20% HCl (20ml) for 3 hours (in an oil bath at 150°), evaporated to dryness *in vacuo*; the residue is dissolved in H_2O (20ml) and freed from HCl by passage throught a column of 'Amberlite IR-4B' (15ml, in OH^- form) and eluted with H_2O. Evaporation of the eluate *in vacuo* and crystallisation of the residue from aqueous Me_2CO gives a **2:1** mixture of ***cis*-and *trans*- 4-aminomethylcyclohexane-1-carboxylic acid** (2.24g, ~71%, **m ~232-236°, dec)**. Both acids are symmetrical, i.e. mirror images are superimposable.

The mixture (10g, 64mmol) is ***separated*** by refluxing with $Cu(CO_3)_2$ (9.15g, 38mmol) in H_2O (100ml) for 1 hour (turning deep blue in colour), cooled and the blue precipitate is filtered off, dissolved into 8% aqueous NH_3 (100ml), filtered from a little solid, and passed through a column of 'Diaion SK#1 (NH_4^+ form)' and washed with H_2O. The eluted solution is then passed through an 'Amberlite IR-4B' (OH^- form)' column and the effluent is evaporated to dryness. The residue (6.75g, **m ~221-223°, dec**.) is repeatedly recrystallised from H_2O-Me_2CO to give the pure ***cis*-amino acid** with **m 236-238°, dec**, and IR (KBr) peaks at ν_{max} 2940, 2660, 1639 (*1640*), 1560 (*1563*), 1509 (*1515*), 1408 (*1403*), 1305 (*1308*), 930 and 904 cm^{-1}, value in ***italics*** are from Meyer see below). The combined filtrates from the recrystallisation are evaporated, the residue is dissolved in H_2O and similarly de-ionised through the same columns. The final residue is recrystallised from H_2O-Me_2CO to give the pure ***trans*-4-aminoethylcyclohexane-1-carboxylic acid** (3.37g) with **m 286-292°, dec**, and IR (KBr) peaks at ν_{max} 2940, 2610, 1637, 1535 (*1528*), 1383 (*1381*) (*1325*) and 920 cm^{-1}, value in ***italics*** are from Meyer see below). On TLC (Silica gel G, eluted with ascending *n*-PrOH/H_2O, 65:35) the R_F of the *cis*-isomer was always 1.2 times larger than that of the *trans*- isomer. [***Note*** that the melting points of the isomers measured in the usual way vary somewhat, and by using a Du Pont Model 900 differential thermal analyzer the ***cis-acid*** had **m 252°**, and the ***trans-acid*** had **m 295-300°** as endotherms, Meyer *J Med Chem* **9** 641 *1966*, DOI: 10.1021/jm00322a059].

The ***cis-hydrochloride*** has **m 195-197°, dec** (prisms from H_2O-Me_2CO), the ***trans-hydrochloride*** has **m 238-241.5°, dec** (needles from H_2O-Me_2CO); the ***cis-hydrobromide*** has **m 205-208°, dec** (plates from Me_2CO), the ***trans-hydrobromide*** has **m 227-229°, dec** (plates from H_2O); the ***cis-p-toluenesulfonic acid salt*** has **m 177-178°** (plates from *n*-PrOH-Et_2O), the ***trans-p-toluenesulfonic acid salt*** has **m 262-264°** (plates from H_2O), the ***cis-HCl-$AuCl_3$ salt*** has **m 178-180°, dec** (yellow needles from H_2O), the ***trans-HCl-$AuCl_3$ salt*** has **m 205-206°, dec** (yellow prisms from H_2O), the ***cis-HCl-$PtCl_4$ salt*** has **m 233°, dec** (yellow needles from H_2O), the ***trans-HCl-$PtCl_4$ salt*** has **m 254-255°, dec** (yellow-orange plates from H_2O); the ***cis-N-acetamide*** has **m 189-190°** (prisms from EtOH), the ***trans-N-acetamide*** has **m 154-155°** (prisms from Me_2CO); the ***cis-N-benzamide*** has **m 157-158°** (plates from EtOH/*C_6H_6) and the ***trans-N-benzamide*** has **m 177-178°** (needles from EtOH/H_2O).

The *cis*- and *trans*- acids are also readily separated from the mixture by recrystallisation of their ***p-toluenesulfonic acid salts*** which have very different solubility properties. ***Isomerisation:*** When a solution of the ***cis-acid*** (2g) in 0.5N NaOH (26ml) is heated in a silver vessel in an autoclave at 200° for 6 hours, and the cooled solution is passed through an 'Amberlite IR-120' (NH_4^+ form)' column and washed with H_2O, evaporation of the eluate *in vacuo* and four recrystallisations from aqueous MeOH gave the *trans-acid* (0.8g, 40%), **m 384-390° dec**. [Naito et al. *Chem Pharm Bull Jpn* **16** 728 *1968*, Daiichi Seiyak *Dutch Pat* 6,414,942 *1965*, *Chem Abstr* **64** 3379 *1966*.] The width-at-half height of the peaks from the cyclohexane protons in the ^{1}H NMR spectra are larger from the *trans*-acid than for the corresponding peaks from the *cis*-acid. The structure of the ***cis-acid*** was confirmed by conversion to a cyclic ***lactam*** on fusion. It has **m 104°** after recrystallisation from hexane followed by sublimation at 100°/2.5 x 10^{-2}mm. [***Note*** *that this melting point was recorded at the point where, under crossed Nichol prisms, birefringence was lost. The crystal form, however, was only slowly lost thereafter over a wide range of temperatures*]. The ***lactam*** has IR (KBr) peaks at ν_{max} 1661 (amide I),

1421, 1325 and 1205 cm^{-1} [Meyer *J Med Chem* **9** 641 *1966*, DOI: 10.1021/jm00322a059].
These amino acids are haemostatic with antiplasmic activity. The ***trans***-acid has potent antiplasmic activity (inhibiting the fibrinolytic enzyme system), being 50 times more active than the ***cis***-acid, and 5-7 times more potent than ε-aminocaproic acid [Naito et al. *Chem Pharm Bull Jpn* **16** 357 and 728 *1968*.] The antifibrolytic activity is due to blocking of the lysine binding sites of plasminogen. *t*-AMCHA has been used as a lysine analogue to characterise binding sites in plasminogens. [Brockway & Castellino *Arch Biochem Biophys* **151** 194 *1972*, DOI:10.1016/0003-9861(72)90488-2; Hoover at al. *Biochemistry* **32** 10936 *1993*, DOI: 10.1021/bi00092a002; Marshall et al. *Biochemistry* **33** 3599 *1994*, DOI: 10.1021/bi00178a017.]

α-Amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid hydrate (AMPA) *[R(+)- 83654-131*; *RS*(±)-*74341-63-2*; *S*(-)- *83643-88-3]* **$C_7H_{10}N_2O_4$, M 204.2 (H_2O), *RS* m 252°(dec).** AMPA is an analogue of glutamic acid designed and studied by Hansen and Krogsgaard-Larsen [*JCS Perkin Trans 1* 1829 *1980*, DOI: 10.1039/P19800001826; Lauridsen et al. *J Med Chem* **28** 668 *1985*, DOI: 10.1021/ jm50001a022] as a possible agonist for the ***AMPA* subgroup of ionotropic glutamate receptors**. The ***racemic*** amino acid has been synthesised in four steps from ethyl 3-methoxy-5-methylisoxazol-4-carboxylate → 4-hydroxymethyl-3-methoxy-5-methylisoxazole → 4-chloromethyl-3-methoxy-5-methylisoxazole → diethyl acetamido-(3-methoxy-5-methylisoxazol-4-ylmethyl)malonate which was deprotected [de-acetylated, 3-MeO- → 3-HO, $(=COOEt)_2$ → $(=COOH)_2$ → -COOH] to give *RS*(±)-AMPA. The last step was achieved by treating the diethyl N-Ac-OMe-AMPA with 48% aqueous HBr under a blanket of N_2 and refluxed (oil bath at 140°) for 15-20 minutes, cooled rapidly, evaporated *in vacuo*, dissolved in H_2O and re-evaporated. The residue was dried *in vacuo* over KOH and P_2O_5, and recrystallised twice from *iso*PrOH/Et_2O (**m 206-209° dec**; 80% yield), and finally from iso-PrOH to give an analytical sample of the ***hydrobromide*** (**m 218-220° dec**): IR (KBr) had ν_{max} at 3000br, 1740, 1660m, 1535, 1500, 1255 and 1215 cm^{-1}, and ^1H NMR (D_2O with MeCN internal standard at 2.02) with δ at 2.25(s, 3H), 2.95(d, 2H) and 4.25(t, 1H). The ***free RS-amino acid*** (±)-AMPA *[77521-29-0]* was obtained by neutralising the ***hydrobromide*** in EtOH with Me_3N and recrystallising from H_2O to provide pure ***amino acid monohydrate*** (86% yield) with (**m 252° dec**) and IR with ν_{max} at 3550—2450(several bands), 1655, 1625, 1585, 1535, 1515, 1400, 1335 and 1255 cm^{-1}. [Hansen and Krogsgaard-Larsen *JCS Chem Commun* 87 *1979*, DOI: 10.1039/C39790000087.]
The enzyme used for the ***Enzymic optical resolution*** was a gel-bound aminoacylase (Enzygel aminoacylase available from Boehringer) well known to hydrolyse N-acetyl *S*-amino acids at a rate of *ca* 10,000 times faster than the enantiomeric N-acetyl *R*-amino acids. This also established the absolute configuration of the products. It was found that ***RS*-N-Ac-3-OMe-AMPA** was a better substrate to use than *RS*-N-Ac-AMPA, and was prepared as follows: The above diethyl acetamido-(3-methoxy-5-methylisoxazol-4-ylmethyl)malonate was hydrolysed and monodecarboxylated without demethylating the 3-OMe group by refluxing with 1M aqueous

HCl for 8 hours, evaporating to dryness, twice dissolving in H_2O and re-evaporating; and to the residue was added H_2O (1part), Et_3N (1.0 mol) in EtOH (3parts) until the pH was ~6. The precipitated ***RS*-3-OMe-AMPA** *[83643-90-7]* had **m 224-225°(dec)**, IR (KBr) had ν_{max} at 2950br, 1660, 1510, 1475, 1405 and 1345 cm^{-1}, and ^1H NMR (D_2O-CF_3COOD) with δ at 2.29(s, 3H), 3.01(d, 2H), 3.97(s, 3H) and 4.28(t, 1H). This product (0.5mmol) was acetylated with Ac_2O (9.8mmol) in AcOH by refluxing for 70 minutes, adding H_2O, evaporating to dryness *in vacuo*, dissolving in toluene, re-evaporating twice, and finally the residue was recrystallised from EtOAc to give ***RS*-N-Ac-3-OMe-AMPA** *[84751-72-4]* (45% yield) which had **m 161°** and IR (KBr) with ν_{max} at 3370, 2300—2950(several bands), 1725, 1610, 1520, 1465, 1410, 1345, 1230, 1200 and 1135 cm^{-1}, and ^1H NMR (CD_3OD; also as internal standard at δ 3.36) with δ at 1.19(s, 3H), 2.31(s, 3H), 2.84(m, 2H), 3.99(s, 3H) and 4.63(dd, 1H).

Enzymic optical resolution: A solution of **RS-*N-Ac-3-OMe-AMPA*** (28.6mg, 0.118mmol) in H_2O (19.7ml) containing Enzygel aminoacylase (212mgm ~40 IU) adjusted to pH 7.1, by dropwise addition of aqueous LiOH solution, was stirred gently to keep the enzyme gel in suspension at 30° and covered with Parafilm to 186 hours avoid evaporation, and sampled at time intervals to estimate the amount of deacetylated amino acid. After 50% of deacetylated amino acid was formed. The Enzygel was removed by centrifugation and washed with H_2O (3 x 10ml) also by centrifugation. The combined original supernatant and washings was placed on an column (~0.7 x 10cm) of Amberlite IR-120 (~4ml, in H^+ form) and eluted with H_2O (30ml at ~0.5ml/min) to give a weakly acidic eluate followed by a neutral eluate. The column was then eluted with 0.1M aqueous NH_3 to give a basic eluate followed by a neutral eluate. **(a)** The combined first weakly acidic and neutral eluates were evaporated *in vacuo*, suspended in MeOH, filtered and the filtrate evaporated *in vacuo*, to give an oil which was extracted with hot EtOAc (3 x 5ml), filtered again an evaporated to provide pure (by TLC on silica gel 60 F_{264}, EtOAc-MeOH 9:1 + 1% HCOOH; visualised with I_2) unhydrolysed ***R*-N-Ac-3-OMe-AMPA** *[84799-53-1]* as an oil (11.7mg, >82% yield of 50% of *RS-material*) with **$[\alpha]_D^{20}$ -25.2 (c 1.17, EtOH), $[\alpha]_{436}^{20}$ -56 (c 1.17, EtOH)**. **(b)** The combined basic and following neutral eluates were evaporated to dryness *in vacuo*, twice dissolved in H_2O and evaporated *in vacuo*, to give a white crystalline residue which was recrystallised from H_2O/EtOH to afford ***pure*** (by TLC on silica gel 60 F_{264}, EtOH/25% aqueous NH_3 7:3; visualised with ninhydrin spray) ***S*-3-OMe-AMPA** *[84799-54-2]* (9.3mg, >79% yield of *RS-material*) with **$[\alpha]_D^{20}$ -8.6 (c 0.47, H_2O), $[\alpha]_{436}^{20}$ -14.5 (c 0.47, H_2O)**. The Enzygel can still be reused efficiently after washing by centrifugation. The preceding ***R*-N-Ac-3-OMe-AMPA** (19.1mg 0.079mmol from two combined preparations) was deacetylated and demethylated by heating (oil bath temperature 140°), under reflux and a blanket of N_2 with 48% aqueous HBr (5ml) for 23 minutes (see above for *RS*-compound), cooled, evaporated *in vacuo*, washed with H_2O twice and re-evaporated *in vacuo*, dried also *in vacuo* over KOH and P_2O_5 and recrystallised from EtOH-petroleum ether (b 40-60°) to give ***R*-AMPA.HBr** *[84799-50-8]* (14.1g, 67% yield) with **$[\alpha]_D^{25}$ -14.2 (c 0.71, EtOH), $[\alpha]_{436}^{25}$ -31.6 (c 0.71, EtOH)**. When this salt was dissolved in EtOH (0.3ml) and treated with 10v/v% of Et_2N in EtOH to pH 5-6 the amino acid precipitated; which upon recrystallisation from H_2O-EtOH gave pure (by TLC) ***R*-AMPA** *[83654-13-1 anhydrous*; *84799-49-5 monohyrate]* (9.3mg), that **melted with gradual dec > ~200°,** and had elemental analysis for the ***monohydrate*** with **$[\alpha]_D^{27}$ +19 (c 0.18, H_2O)**, and IR (KBr) broad bands with ν_{max} at 3420, 3000, 1625, 1490, 1400, 1335, 1245 and 1200 cm^{-1}, and ^1H NMR (D_2O, MeCN internal standard at δ 2.02) with δ at 2.21(s, 3H), 2.83(d, 2H) and 2.88(t, 1H). The above ***S*-3-OMe-AMPA** (14.8mg, 0.074mmol, pooled from two enzymic reactions) was demethylated by reaction with 43% HBr in AcOH (5ml) at 22° and was complete after 77 hours (as shown by TLC). After evaporation *in vacuo*, treatment with H_2O twice (charcoal) and re-evaporation, the residue was dried (KOH and P_2O_5 *in vacuo*) and recrystallisation from EtOH-petroleum ether (b 40-60°) provided pure ***S*-AMPA.HBr** *[84799-52-0]* (12.3mg, 62%) with **$[\alpha]_D^{25}$ +14.6 (c 0.62, EtOH)**, **$[\alpha]_{436}^{25}$ -31.5 (c 0.62, EtOH)**. When this salt was dissolved in EtOH (0.3ml) and treated with 10v/v% of Et_2N in EtOH to pH 5-6 the ***enantiomeric*** amino acid precipitated out. Recrystallisation of this enantiomer from H_2O-EtOH gave **pure** (by TLC) ***S*-AMPA** *[83643-88-3 anhydrous*; *84799-51-9 monohydrate]* (7.8mg), which had identical physical and spectral properties as its *R-enantiomer* except for the optical rotation which was **$[\alpha]_D^{28}$ -21 (c 0.19, H_2O)**.

Receptor binding studies in rat brain membranes showed that ***S*- AMPA** was the active isomer. The following IC_{50} values were determined: *RS*-AMPA = 0.8±0.3 μM; *RS*-5-OMe-AMPA = >100 μM; ***S*-AMPA = 0.4±0.1 μM**; *R*-AMPA = 4.8±0.8 μM; *S*-Glu = 1.3±0.6 and *R*-Glu = ~100 μM. 5-Aminolaevulinic acid hydrochloride (ALA-HCl, δ-aminolaevulinic acid HCl) *[5451-09-2]* **$C_5H_9NO_3$. HCl, M 167.6, m 148°(dec), 150-151°(dec), 156-158°(dec), pK_1^{22} 4.05, pK_2^{22} 8.90.** Dry ALA-HCl in a vacuum desiccator over P_2O_5 overnight, then crystallise it by dissolving it in cold EtOH and adding dry Et_2O. Also crystallise it by dissolving in the minimum volume of MeOH, and placing in a desiccator containing dry Et_2O (clamp the desiccator). During several days the Et_2O slowly distils into the MeOH causing the hydrochloride to separate as long needles. Filter them off and dry them in a Fischer pistol. [Neuberger & Scott *J Chem Soc* 1820, 1924 *1954*, DOI: 10.1039/JR9540001820; Wynn & Corwin *J Org Chem* **15** 203, 207 *1950*, DOI: 10.1021/jo01147a031; *Beilstein* **4** IV 3265.] It is a photosensitiser and is antineoplastic [Peng et al. *Cancer* **79** 2282 *1997*, DOI: 10.1002/(SICI)1097-0142(19970615)79:12<2282].

4-Aminomethylbenzoic acid (α-amino-*p*-toluic acid) *[56-91-7]* **$C_8H_9NO_2$, M 151.2, m 273-274°, 294-295°, >300°, 345°(dec, sealed tube), 347-350° (sealed tube), pK_1^{20} 3.59 (CO_2H), pK_2^{20} 9.64 (NH_2).** This acid has been prepared in two different ways from *p*-cyanobenzoic acid [Levine & Sedlecky *J Org Chem* **24** 115 *1959*, DOI: 10.1021/jo01083a608; Albert & Magrath *J Chem Soc* 678 *1944*, DOI: 10.1039/JR9440000677], and by reduction of *p*-carboxybenzaldehyde oxime [Nair & Baugh *J Org Chem* **38** 2185 *1973*, DOI: 10.1021/jo00952a016]. A mixture of *p*-cyanobenzoic acid (14g, *619-65-8*), Raney cobalt (2g, W-6 or W-7), 28% aqueous NH_3 (40ml) and H_2O (150ml) are shaken in a Parr hydrogenator at 3 atm (initial pressure) and 25° for ~3 hours when the theoretical volume of H_2 is absorbed. The catalyst is filtered off, the filtrate is boiled to remove NH_3 and the solid that separated is collected, and recrystallised from 18 parts of boiling H_2O (charcoal) to give the amino acid (m 347-350°) in 80% yield. It is soluble in 70 parts of H_2O. *Alternatively*, the oxime of *p*-carboxybenzaldehyde (1g, *619-66-9*) in 95% EtOH (100ml) containing 5% Pd/C (100mg) is shaken with H_2 at 30 psi for 18 hours at 25°. The catalyst is filtered off and washed with hot glacial AcOH (2 x 20ml); the combined washings and filtrate are evaporated to dryness and the residue is recrystallised from H_2O (charcoal) to give the white crystalline amino acid (850mg, m 294-295°). *The melting point appears to vary with heating rate*. Its UV has λ_{max} at 234nm (H_2O), and the ^{1}H NMR [TFA] has δ at 4.15 (q, *J* = 6Hz, benzylic H), 7.3 (d, *J* = 8Hz, two protons adjacent to H_2NCH_2-) and 7.9 (d, *J* = 8Hz, two protons adjacent to CO_2H). The ***N-acetyl derivative*** crystallises from a large volume of xylene and has **m 199-200°** (lit: Levine & Sedlecky state **m 199-120°**). [For pKa see Goldacre *Nature* **154** 796 *1944*, DOI: 10.1038/154796b0; *Beilstein* **14** H 487, **14** III 1212, **14** IV 1362.]

***S*-2-Amino-3-methyl-1-butanol (*S*-valinol)** *[2026-48-4]* **$C_5H_{13}NO$, M 103.2, m 31-32°, 35-36°, b 81°/8mm, 88°/11mm, d ^{25} 0.926g/ml, $[\alpha]_{546}$ + 16.5 (c 6.32, *l* = 2 H_2O), $[\alpha]_D$ + 15.6 (EtOH), pK_{Est} ~10.4.** Purify *S*-valinol by vacuum distillation using a short Vigreux column. *Alternatively*, it is purified by steam distillation. The steam distillate is acidified with HCl; the aqueous layer is collected and evaporated. The residue is dissolv-

ed in butan-1-ol, filtered and dry Et_2O added to crystallise the hydrochloride salt (*hygroscopic*), **m 113°**. The ***free base*** can be obtained by suspending the salt in Et_2O and adding small volumes of saturated aqueous K_2CO_3 until effervescence is complete and the mixture is distinctly alkaline. At this stage the aqueous layer should appear as a white sludge. The mixture is heated to boiling and refluxed for 30 minutes (more Et_2O is added if necessary). The Et_2O layer is decanted off from the white sludge, the sludge is extracted twice with Et_2O (by boiling for a few minutes), the combined organic layers are dried (KOH pellets), evaporated and the residue is distilled in a vacuum. The ***R*-(-)-*enantiomer*** has *[4276-09-9]* $[\alpha]_D^{20}$ -16 (c 10, EtOH); and the ***racemate*** *RS-valinol [16369-05-4]* has **b 75-77°/8mm, d ^{25} 0.936g/ml, n $_D^{20}$ 1.4543.** [Nagao et al. *J Org Chem* **55** 1148 *1990*, DOI: 10.1021/jo00291a012; *Beilstein* **4** III 805, Fieser **12** 563, **13** 341, **16** 380.]

Anserine [*N*,β−alanyl-1-methyl-*S*-histidine] *[584-85-0]* **$C_{10}H_{16}N_4O_3$, M 240.3, m 238-239°, $[\alpha]_D^{23}$ +12.3 (c 5,H_2O), pK_1^{25} 2.64, pK_2^{25} 7.04, pK_3^{25} 9.49.** Crystallise anserine from aqueous EtOH. It is ***hygroscopic*** and is best stored as the nitrate salt (see below). Purify it by shaking the nitrate salt with Dowex 3 (x4 free base) and washing with H_2O, evaporating the filtrate and removing H_2O by 3 distillations with 10ml of propan-2-ol. Dissolve the crystals in MeOH and add H_2O dropwise until one phase is obtained and cool. Dry the crystals at 60° over P_2O_5 in a vacuum. The ***picrate*** has **m 145°** (from H_2O). [Rinderknecht et al. *J Org Chem* **29** 1968 *1964*, DOI: 10.1021/jo01030a075; *Beilstein* **25** II 408, **25** IV 4383.] This dipeptide occurs in vertebrate skeletal muscle as in birds and other animals, but apparently not in dog, cow, horse and man (see carnosine below).

***S*-Anserine nitrate** *[5937-77-9]* **$C_{10}H_{16}N_4O_3$. HNO_3, M 303.3, m 225°(dec), 226-228°(dec), $[\alpha]_D^{30}$ +12.2.** Likely impurities are 1-methylimidazole-5-alanine and histidine. Crystallise the nitrate from aqueous MeOH or EtOH (needles). Also dissolve ~20g in 25ml of MeOH, add 2-propanol (150-200ml) and store the mixture at 5°

overnight to give shiny needles. Recrystallise it by heating 12g of the nitrate in MeOH (300ml) and adding H_2O (50-60ml) until one phase is obtained and refrigerating overnight. Filter and dry it at 60°/P_2O_5 in a vacuum. [Rinderknecht et al. *J Org Chem* **29** 1968 *1964*, DOI: 10.1021/jo01030a075; Behrens & duVigneaud *J Biol Chem* **120** 517 *1937*, http://www. jbc.org/ content/120/2/517.]

S*-Arginine (*S*-2-amino-5-guanidinopentanoic acid)** *[74-79-3]* **$C_6H_{14}N_4O_2$, M 174.2, m 205°(dec, anhydrous), 207°(dec, 2 H_2O), $[\alpha]_D$ +26.5 (c 5, in 5M HCl), $[\alpha]_{546}$ +32 (c 5, in 5M HCl), pK_1^{25} 2.18, pK_2^{25} 9.36, pK_3^{25} 11.5.** *S*-Arginine crystallises from H_2O as the ***dihydrate and as plates from EtOH. It also crystallises from 66% EtOH. Its solubility in H_2O is 15% at 21°. Its isoelectric point is at pH 10.76. The ***racemate*** *[7200-25-1]* has **m 228-233° (dec)**. [Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, **Vol 3** p 1841 *1961*, *Beilstein* **4** IV 817.] Natural precursor substrate for nitric oxide synthase which converts it to citrulline and NO. This induces the release of insulin by a nitric oxide dependent mechanism which also has other important physiological effects [Andrew & Mayer 'Enzymatic function of nitric oxide synthases' (review), *Cardiovascular Research* **43** (3) 521 *1999*, DOI: 10.1016/S0008-6363(99)00115-7].

***S*-Arginine hydrochloride** *[1119-34-2]* **$C_6H_{14}N_4O_2$. HCl, M 210.7, m 217°(dec), 222°(dec), $[\alpha]_D^{20}$ +26.9 (c 6, M HCl).** A likely impurity is ornithine. Crystallise the salt from H_2O at pH 5-7, by adding EtOH to 80% (v/v). [Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, **Vol 3** p 1841 *1961*, *Beilstein* **4** IV 2649.]

S*-Argininosuccinic acid {*N*-(4*S*-4-amino-4-carboxybutylamino)iminomethyl-*S*-aspartic acid}** *[2387-71-5]* **$C_{10}H_{18}N_4O_6$, M 290.3, $[\alpha]_D^{24}$ +16.4 (H_2O).** A likely impurity is fumaric acid. In neutral or alkaline solution it readily undergoes ring closure to the ***'anhydride' (see below). Crystallise it from water by adding 1.5 volumes of EtOH. The barium salt is stable at 0-5° if dry. [Westfall *Biochem J* **77** 135 *1960*, DOI: 10.1042/bj0770135; Ratner & Kunkemueller *Biochemistry* **5** 1821 *1966*, DOI: 10.1021/bi00870a007.]

S*-Argininosuccinic anhydride** *[28643-94-9]* **$C_{10}H_{16}N_4O_5$, M 272.3, $[\alpha]_D^{23}$ -10 (H_2O for anhydride formed at neutral pH).** Crystallise the anhydride from H_2O by adding two volumes of EtOH. An ***isomeric anhydride is formed if the free acid is allowed to stand at acid pH. In solution, the mixture of anhydride and free acid is formed [see above entry, Ratner & Kunkemueller *Biochemistry* **5** 1821 *1966*, DOI: 10.1021/bi00870a007; Kowalsky & Ratner *Biochemistry* **8** 899 *1969*, DOI: 10.1021/bi00831a020].

***S*-Asparagine (2-aminosuccinic acid 4-amide)** *[70-47-3]* **$C_4H_8N_2O_3$, M 132.1, m 234-235° (monohydrate)** *[5794-13-8]* **$[\alpha]_D$ +32.6 (0.1M HCl), pK_1^{25} 1.98, pK_2^{25} 8.84.** Likely impurities are aspartic acid and tyrosine. Crystallise it from H_2O or aqueous EtOH. It slowly effloresces in dry air. The ***R*(-)-enantiomer** has *[2058-58-4]* and optical rotation of opposite sign. [Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, **Vol 3** p 1856 *1961*, *Beilstein* **4** IV 3005.]

Aspartic acid (2-aminosuccinic acid) $C_4H_7NO_4$, M 133.1, m 338-339° (*RS*, *[617-45-8]*), m 271° (*S*, requires heating in a sealed tube *[56-84-8]*), **$[\alpha]_D^{25}$ +25.4 (3M HCl), pK_1^{25} 1.99, pK_2^{25} 3.90.** Likely impurities are glutamic acid, cystine and asparagine. Crystallise the acid from water by adding 4 volumes of EtOH and dry it at 110°. [Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, **Vol 3** p 1856 *1961*, *Beilstein* **4** IV 2998, 3000.]

L-Aspartic acid ß-methyl ester hydrochloride *[16856-13-6]* **$C_5H_{10}ClNO_4$, M 183.6, m 191-193°, 194°, pK^{25} 8.62.** Recrystallise it from MeOH by adding anhydrous Et_2O [Bach et al. *Biochemical Preparations* **13** 20 *1971*].

DL-Aspartic acid dimethyl ester hydrochloride *[RS- 14358-33-9, S- 32213-95-9]* **$C_6H_{12}ClNO_4$, M 197.7, 116-117°.** Crystallise it from absolute MeOH. [Kovach et al. *J Am Chem Soc* **107** 7360 *1985*, DOI: 10.1021/ja00311a024.] The ***diethyl ester*** has **pK^{25} 6.4.**

Azaserine (*O*-diazoacetyl-*S*-serine) *[115-02-6]* **$C_5H_7N_3O_4$, M 173.1, m 146-162°(dec), $[\alpha]_D^{27.5}$ -0.5 (c 8.5, H_2O, pH 5.2), $pK_{Est(1)}$ ~4.53, $pK_{Est(2)}$ ~5.40.** Crystallise azaserine from 90% EtOH. Also dissolve it in H_2O,

filter it through Supercel and add EtOH to give azaserine as pale yellow crystals. [Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, **Vol 1** pp 75-76 *1961*, Curphey & Daniel *J Org Chem* **43** 4666 *1978*, DOI: 10.1021/jo00418a033; *Beilstein* **4** IV 3124.] This antibiotic from *Streptomyces* sp, or by synthesis, has antifungal activity, and because it retards growth it is antineoplastic.

Benzoyl glycine (hippuric acid) *[495-69-2]* **$C_9H_9NO_3$, M 179.2, m 188°, pK^{20} 3.81, 3.59. pK^{40} 3.59.** Crystallise the acid from boiling H_2O. Dry it over P_2O_5. Also purify it by dissolving 135-140g in 2L of boiling H_2O, filtering through a steam-heated funnel and allowing to crystallise at ~20° (yield 115-122g first crop, **m 186-187°**). [Ingersoll & Babcock *Org Synth* Coll Vol **2** 328 *1943*, DOI: 10.15227/orgsyn.012.0040; *Beilstein* **9** 225, I 100.]

***N*-Benzyloxycarbonylglycyl-L-alaninamide** *[17331-79-2]* **$C_{13}H_{17}N_3O_4$, M 279.3, m dec >200°.** Recrystallise the dipeptide derivative from EtOH/Et_2O.

***N*-Benzyloxycarbonyl-*N*'-methyl-L-alaninamide** *[33628-84-1]* **$C_{12}H_{16}N_2O_3$, M 236.3, m dec >200°.** Recrystallise the amide from EtOAc.

Betaine (1-carboxymethyl-*N,N,N*-trimethylammonium zwitterion) *[107-43-7 (anhydrous), 590-47-6, 17146-86-0 (monohydrate)]* **$C_5H_{11}NO_2$, M 117.1, m 294-294°(dec) (monohydrate?) 301-305°(dec) (anhydrous), ~319°(dec), pK^{25} 1.83.** Crystallise betaine from aqueous EtOH or EtOH/Et_2O. The *monohydrate* loses H_2O above 100°. Betaine undergoes internal alkylation to methyl dimethylaminoacetate above its melting point. It is also prepared by treating the hydrochloride (below) with silver oxide and recrystallising from EtOH/Et_2O. [Raman spectra: Edsall *J Am Chem Soc* **65** 1767 *1943*, DOI: 10.1021/ja01249a029; IR: Leifer & Lippincott *J Am Chem Soc* **79** 5098 *1957*, DOI: 10.1021/ja01576a006; for pK see Grob et al. *Chem Ind (London)* 1222 *1955*, *Beilstein* **4** III 1127, **4** IV 2369.]

Betaine hydrochloride *[590-46-5]* **$C_5H_{12}ClNO_2$, M153.6, m 227-228°(dec), 232°(dec), 241-242°, 246-247°(dec).** Recrystallise the salt from EtOH. Its solubility at 25° is 65% in H_2O, and 5% in EtOH. [Edsall *J Am Chem Soc* **66** 1767 *1943*, DOI: 10.1021/ja01249a029; Kuhn & Ruelius *Chem Ber* **83** 420 *1950*, DOI: 10.1002/cber.19500830504; *Beilstein* **4** III 1127, IV 2369.]

Bis-*N-tert*-butyloxycarbonyl-L-cystine *[10389-65-8]* **$C_{16}H_{28}N_2O_8S_2$, M 440.5, m 144.5-145°, $[\alpha]_D^{20}$ -133.2 (c 1, MeOH), $[\alpha]_D^{20}$ -120 (c 2, AcOH), pK_{Est} ~2.9.** Crystallise the cystine derivative from EtOAc by adding hexane [Ferraro *Biochemical Preparations* **13** 39 *1971*].

Bombesin (2-L-glutamine-3,6-L-asparaginealytesin, a tetradecapeptide) *[31362-50-2]* **$C_{71}H_{110}N_{24}O_{18}S$, M 1619.9.** Purify Bombesin by gel filtration on a small column of Sephadex G-10 and elute with 0.01 M AcOH. This procedure removes lower molecular weight contaminants which are retarded on the column. The procedure should be repeated twice, and the material should now be homogeneous on electrophoresis; and on chromatography it gives a single active spot which is negative to ninhydrin but positive to Cl_2 and iodoplatinate reagents. R_F on paper chromatography (*n*-BuOH/pyridine/AcOH/H_2O :: 37.5: 25: 7.5: 30) is 0.55 for Bombesin and 0.65 for Alytin. [Bernardi et al. *Experientia* **Part 1 27** 166 *1971*, Anastasi et al. **Part 2 27** 873 *1971*.] The ***hydrochloride*** has **m 185°(dec)** (from EtOH) $[\alpha]_D^{24}$ -20.6 [c 0.65, $Me_2NCHO/(Me_2N)_3PO$ (8:2)]. [For the stimulation of inositol phosphate see Lloyd et al. *Biochem J* **260** 813 *1989*, DOI: 10.1042/bj2600813.] This polypeptide was first isolated from the skin of the European fire-bellied toad (*Bombina bombina*) and has two known homologues in mammals known to cause the release of gastric secretions from G cells. [Gonzalez et al. 'Bombesin-related peptides and their receptors: recent advances in their role in physiology and disease states' *Current Opinion in Endocrinology, Diabetes and Obesity* **15** 58 *2008*, DOI:10.1097/ MED.0b013e3282f3709b, PMID: 18185064.]

Bradykinin [ArgProProGlyPheSerProPheArg] *[5979-11-3]* **$C_{50}H_{73}N_{15}O_{11}$, M_r 1,060.2.** Purify Bradykinin by ion-exchange chromatography on CMC (*O*-carboxymethyl cellulose) and partition chromatography on Sephadex G-25. The purity is checked by paper chromatography using BuOH/AcOH/H_2O

(4:1:5) as eluent. [Park et al. *Can J Biochem* **56** 92 1978, DOI: 10.1139/o78-015; ORD and CD: Bodanszky et al. *Experientia* **26** 948 *1970*, activity: Regoli & Barabé *Pharmacol Rev* **32** 1 *1980*, *Beilstein* **22** III/IV 91.] Bradykinin is an inflammatory peptide modulator which dilates blood vessels and causes blood pressure to decrease. [Dendorfer et al. 'Pathways of bradykinin degradation in blood and plasma of normotensive and hypertensive rats' *Am J Physiol Heart Circ Physiol* **280** H2182 *2001*, PMID: 11299220.]

***S*-Canavanine [2-amino-4-(guanidinooxy)butyric acid]** *[543-38-4]* **M 176.2, m 184°, $[\alpha]_D^{17}$ +19.4 (c 2, H_2O), $[\alpha]_D^{20}$ +7.9 (c 3.2, EtOH), 184°, d ^{25} 1.61g/cm^3, pK_1^{25} 2.43, pK_2^{25} 6.60, pK_3^{25} 9.25.** Crystallise *S*-canavanine from absolute EtOH or aqueous EtOH. [Tomiyama *J Biol Chem* **111** 45 *1935*, http://www.jbc.org/content/111/1/45, gave pK_1^{25} 9.25 (pK_a COOH), pK_2^{25} 7.40 (pK_b guanidinium), pK_3^{25} 11.50 (pK_b NH_4^+), Gulland & Morris *J Chem Soc* 763 1935, DOI: 10.1039/JR9350000763; (±) Frankel et al. *J Chem Soc* 3127 *1963*, DOI: 10.1039/JR9630003127; Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, **Vol 3** pp 2622-2628 *1961*, *Beilstein* **4** III 1636, **4** IV 3188.] It is a plant amino acid which can mimic *S*-arginine and be incorporated into proteins with unusual properties; and differs from arginine in having a CH_2 replaced by O. [Rosenthal et al. 'Aberrant, canavanyl protein formation and the ability to tolerate or utilize L-canavanine'. *Experientia* **43** (5) 558 *1987*, DOI: 10.1007/BF02143585. PMID: 3582574.]

***S*-Canavanine sulfate (from jackbean, *O*-guanidino-L-homoserine)** *[2219-31-0]* **$C_5H_{12}N_4O_3 \cdot H_2SO_4$, M 274.3, m 160-165°(dec), 172°(dec), $[\alpha]_D^{18.5}$ +19.8 (c 7, H_2O), pK_1^{25} 2.50 (CO_2H), pK_2^{25} 6.60 (α-NH_2), pK_3^{25} 9.25 (guanidinoxy).** Recrystallise the sulfate by dissolving (~1g) in H_2O (10ml), and adding with stirring 0.5 to 1.0 volumes of 95% EtOH whereby crystals separate. These are collected, washed with Me_2CO/EtOH (1:1) and dried over P_2O_5 in a vacuum. [Hunt & Thompson *Biochemical Preparations* **13** 416 *1971*, Fearon & Bell *Biochem J* **59** 221 *1955*, DOI: 10.1042/bj0590221; *Beilstein* **4** III 1636, **4** IV 3188.]

N*-Carbamoylglycine (hydantoic acid, *N*-carboxymethylurea, ureidoacetic acid)** *[462-60-2]* **$C_3H_6N_2O_3$, M 118.0, m 169-170°(dec), m 173-175°(dec), 178-180°(dec), pKa (H_2O) 3.91 (5°), 3.80 (20.3°), 3.87 (32.1°) and 3.89 (50°).** ***Hydantoic acid is prepared by reaction of potassium cyanate (KNCO) with glycine in H_2O, and is recrystallised from H_2O or EtOH. [Dakin *J Chem Soc* **107** 434 *1915*, DOI: 10.1039/CT9150700434; King *J Am Chem Soc* **78** 6020 *1956*, DOI: 10.1021/ja01604a017; Inouye &Watanabe *JCS Perkin Trans I* 1911 *1977*, DOI: 10.1039/P19770001911.] It has UV with λ_{max} (ε) at 215 (2800) and 240 (165)nm (neutral species: EtOH); 215 (2600) and 240 (105)nm (cation: EtOH + H^+); 215 (2400) and 240 (80)nm (anion: EtOH + OH^-) [Crombie & Hooper *J Chem Soc* 3010 *1955*, DOI: 10.1039/JR9550003010]. The ***ethyl ester*** *[6293-20-5]* **M 146.0,** crystallises from H_2O as needles with **m 135°**; and the ***amide*** *[3530-79-8]* **M 117.1,** crystallises from H_2O as prisms with **m 204°** (**180°** has also been reported). [*Beilstein* **4** H 359, **4** I 477, **4** II 792, **4** III 1163, **4** 1V 2411.]

Carnitine see **Vitamin B_7** in 'Physiologically Active….' compounds in this Chapter.

L-Carnosine (β-alanyl-L-histidine) *[305-84-0]* **$C_9H_{14}N_4O_3$, M 226.2, m 253°(dec), 258-260°(dec), 260°(capillary tube), 262°(dec), $[\alpha]_D^{25}$ +20.5 (c 1.5, H_2O), pK_1^{25} 2.64, pK_2^{25} 6.83, pK_3^{25} 9.51.** Likely impurities are histidine and β-alanine. Crystallise L-carnosine from water by adding EtOH in excess. Recrystallise it from aqueous EtOH by slow addition of EtOH to a strong aqueous solution of the dipeptide. Its solubility in H_2O is 33.3% at 25°. [Vinick & Jung *J Org Chem* **48** 392 *1983*, DOI: 10.1021/jo00151a026; Turner *J Am Chem Soc* **75** 2388 *1953*, DOI: 10.1021/ja01106a032; *Beilstein* **25** H 516, **25** I 717, **25** II 408, **25** IV 4381.]

***S*-Citrulline (2-amino-5-ureidopentanoic acid)** *[372-75-8]* **$C_6H_{13}N_3O_3$, M 175.2, m 222°, $[\alpha]_D^{20}$ +24.2 (in 5M HCl), pK_1^{25} 2.43, pK_2^{25} 9.41.** Likely impurities are arginine and ornithine. Crystallise *S*-citrulline from water by adding 5 volumes of EtOH. Also crystallise it from water by addition of MeOH. [Ellenbogen *J Am Chem Soc* **74** 5198 *1952*, DOI: 10.1021/ja01140a065; Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, **Vol 3** pp 2491-2494 *1961*, *Beilstein* **4** IV 2647.] Intermediate in the urea cycle and in a pathway by which mammals excrete ammonia.

Corticotropin *[92307-52-3]* **polypeptide from bovine hypothalamus M_r ~4697**. The extract is purified by

ion-exchange on CM-cellulose, desalted, evaporated and lyophilised. Then separated from impurities by gel filtration through Sephadex G-50. [Lande et al. *Biochemical Preparations* **13** 45 *1971*, Esch et al. *Biochem Biophys Res Commun* **122** 899 *1984*, DOI:10.1016/0006-291X(84)91175-6].

Creatine (*N*-guanidino-*N*-methylglycine) *[6020-87-7 (monohydrate), 57-00-1 (anhydrous)]* **$C_4H_9N_3O_2$, M 131.1 (anhydrous), 149,1 (hydrate) m 303°, pK_1^{25} 2.63, pK_2^{25} 14.3.** Likely impurities are creatinine and other guanidino compounds. It crystallises from the minimum volume of boiling H_2O as the ***monohydrate***. The ***hydrate*** is also obtained by dissolving in H_2O and adding Me_2CO. Drying under vacuum over P_2O_5 or drying at 100° gives the ***anhydrous*** base. The ***anhydrous base*** can be obtained also by dissolving the hydrate in H_2O, seeding with the anhydrous base and cooling in ice. A **m** of **258-268°(dec)** was reported. The ***picrate*** crystallises from 17 parts of H_2O with **m** of **218-220°(dec)**. [King *J Chem Soc* 2377 *1930*, DOI: 10.1039/JR9300002374; anhydrous: Huffman et al. *J Am Chem Soc* **58** 1728 *1936*, DOI: 10.1021/ja01300a066; Mendel & Hodgkin *Acta Cryst* **7** 443 *1954*, DOI: 10.1107/S0365110X54001326; Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, **Vol 3** p 2750 *1961*, *Beilstein* **4** III 1170, **4** IV 2425.]

Creatine phosphate di Na, $4H_2O$ salt (phosphocreatine) *[922-32-7]* **M 327.1, pK_1^{27} 2.7, pK_2^{27} 4.58, pK_3^{27} ~12.** To 3-4g of the salt in H_2O (220ml) is added 4 volumes of EtOH with thorough stirring and allowing to stand at 20° for 12 hours (this temperature is critical as crystals do not readily form at 23° or 25°). The salt first appears as oily droplets which slowly settle and crystallise. After 12 hours the supernatant is clear. Stirring and scratching the flask containing the filtrate brings out additional crystals (0.3-1g) if the salt is kept at 20° for 12 hours. Filter it off at room temperature, wash with 3 x 5ml of ice-cold 90% EtOH, then 5ml of absolute EtOH and dry it in a vacuum desiccator (Drierite or $CaCl_2$) for 16-30 hours. The ***hexahydrate*** (plates) is converted to the ***tetrahydrate*** salt (needles) in a vacuum at -10°. [Ennor & Stocken *Biochemical Preparations* **5** 9 *1957*, *Biochem J* **43** 190 *1948*, DOI: 10.1042/bj0430190; *Beilstein* **4** III 1170, **4** IV 2425.]

Creatinine [2-amino-1-methylimidazolidin-4-one, 2-imino-1-methyl-4(3*H*)-oxoimidazolidine] *[60-27-5]* **$C_4H_7N_3O$, M 113.1, m 295°(dec), ~305°(dec), pK_1^{25} 4.80, pK_2^{25} 9.2.** Likely impurities are creatine and ammonium chloride. Dissolve it in dilute HCl, then neutralise with ammonia. Recrystallise it from H_2O by adding excess of Me_2CO. The ***picrate*** crystallises from 23 volumes of boiling H_2O and has **m 220-221°(dec)**. [King *J Chem Soc* 2377 *1930*, DOI: 10.1039/JR9300002374; *Beilstein* **25** III/IV 3543; see p 1007.]

Cycloserine [2-amino-3-isoxazolidone; D-(*R-natural*) and L-(*S*-non-natural)] *[R- 68-41-7 and S- 339-72-0]* **$C_3H_6N_2O_2$, M 102.1, m 145-150° (dec), 154-155°, 155-156° (dec), 156° (dec), $[\alpha]_D^{25}$ (+) and (-) 137 (c 5, 2N NaOH), pK_1^{10} 4.5, pK_2^{10} 7.74, pK_1^{25} 4.50, pK_2^{25} 7.43, pK_1^{50} 4.44, pK_2^{50} 7.20.** Purify cycloserine by recrystallisation from aqueous EtOH or MeOH or aqueous NH_3/EtOH or isoPrOH. Also recrystallise it from aqueous ammoniacal solution at pH 10.5 (100mg/ml) by diluting with 5 volumes of isopropanol and then adjusting to pH 6 with acetic acid. An aqueous solution, buffered to pH 10 with Na_2CO_3, can be stored in a refrigerator for 1week without decomposition. Its UV has λ_{max} at 226nm ($A_{1cm}^{1\%}$ 4.02). The ***tartrate salt*** has **m 165-166° (dec)**, **166-168° (dec)**, and $[\alpha]_D^{24}$ -41 (c 0.7, H_2O). [Stammer et al. *J Am Chem Soc* **79** 3236 *1957*, DOI: 10.1021/ja01569a065; UV: Kuehl *J Am Chem Soc* **77** 2344 *1955*, DOI: 10.1021/ja01613a105; *Beilstein* **27** III/IV 5549.] The ***R-isomer*** interferes with D-Ala transport and D-ala to L-Ala bond formation and interconversion of these, hence its bacteriostatic action; and is an antibiotic for Gram-positive bacteria. The ***S-isomer*** inhibits ketosphinganine synthase and blocks sphingosine biosynthesis.

Cystamine dihydrochloride [2,2'-diaminodiethylene disulfide dihydrochloride, 2,3'-dithio-bis(ethylamine) dihydrochloride] *[56-17-7]* **$C_4H_{12}N_2S_2$. 2HCl, M 225.2, m 217-220°(dec), 219-220°(dec), pK_1^{30} 8.82, pK_2^{30} 9.58.** Recrystallise the salt by dissolving in EtOH containing a few drops of dry EtOH/HCl, filtering and adding dry Et_2O. The solid is dried in a vacuum and stored in a dry and dark atmosphere. It has been recrystallised from EtOH (solubility: 1g in 60ml of boiling EtOH) or MeOH (plates). The ***free base*** has **b 90-100°/0.001mm**, **106-108°/5mm** and **135-136°/760mm**, d_4^{20} 1.1559, n_D^{20} 1.5720. [Verly & Koch *Biochem J* **58** 663 *1954*, DOI: 10.1042/bj0580663; Gonick et al. *J Am Chem Soc* **76** 4671 *1954*, DOI: 10.1021/ja01647a055; Jackson & Block *J Biol Chem* **113** 135 *1936*, http://www.jbc.org/content/113/1/135.] The ***dihydrobromide*** has **m 238-239°** (from EtOH/Et_2O) [Viscontini *Helv Chim Acta* **36** 835 *1953*, DOI: 10.1002/hlca.19530360412]. [*Beilstein* **4** H 287, **4** IV 1578.] It is an –SH modifying reagent and a ***heparin*** antagonist.

S,S*-(L,L)-Cystathionine (*S*-2-amino-2-carboxyethyl-L-homocysteine, L-2-amino-4[(2-amino-2-carboxyethyl)thio]butyric acid)** *[56-88-2]* **$C_7H_{14}N_2OS_2$, M 222.3, m >300°, dec at 312° with darkening at 270°, $[\alpha]_D^{20}$ +23.9 (c 1, M HCl).** *S,S*-Cystathionine is purified by converting it to the ***HCl salt in 20% HCl and carefully basifying with aqueous NH_3 until separation is complete. Filter it off and dry it in a vacuum. It forms prisms from H_2O. The ***dibenzoyl*** derivative has **m 229°** (from EtOH). [IR: Greenstein & Winitz *Chemistry of the Amino Acids (J Wiley)* **Vol 3** p2690 *1961* and Tallan et al. *J Biol Chem* **230** 707 *1958*, http://www.jbc.org/content/230/2/707, PMID: 13525388; Synthesis: du Vigneaud et al. *J Biol Chem* **143** 59 *1942*, http://www.jbc.org/content/143/1/59; Anslow et al. *J Biol Chem* **166** 35 *1946*, http://www.jbc.org/content/166/1/35, PMID: 20273671.] [Prepn: Weiss & Stekol *J Am Chem Soc* **73** 2497 *1951*, DOI: 10.1021/ja01150a026; see also Greenberg *Methods Enzymol* **5** 936 *1962*, DOI: 10.1016/S0076-6879(62)05339-2; *Beilstein* **4** IV 3197.]

Cysteamine (2-aminoethanethiol, 2-mercaptoethylamine) *[60-23-1]* **C_2H_7NOS, M 77.2, m 97-98.5°, 98-99°, 99-100°, pK_1^0 9.15, pK_2^0 11.93, pK_1^{30} 8.42, pK_2^{30} 10.83.** It is soluble in H_2O giving an alkaline reaction, and it has a disagreeable odour. A likely impurity is the disulfide ***cystamine*** which is not soluble in alkaline solution. Under a N_2 atmosphere dissolve it in EtOH, evaporate to dryness and wash the white residue with dry petroleum ether, then sublime it at 0.1mm and store it under N_2 at 0-10° in the dark. Its ***$HgCl_2$ (2:3) complex*** has **m 181-182°** (from H_2O), and its ***picrate*** has **m 125-126°**. Cysteamine hydrochloride *[156-57-0]* **C_2H_7NOS. HCl, M 113.6, m 70.2-70.7°, 70-72°**. Purify the salt by recrystallisation from EtOH. It is freely soluble in H_2O and should be stored in a dry atmosphere. [Mills & Bogert *J Am Chem Soc* **62** 1173 *1940*, DOI: 10.1021/ja01862a053.] The ***picrate*** has **m 125-126°**; see previous entry for *free base*. [*Beilstein* **4** IV 1570.]

(±)-Cysteic acid (3-sulfoalanine, 1-amino-3-sulfopropionic acid) *[RS-13100-82-8, 3024-83-7, R(*L*)- 498-40-8]* **$C_3H_7NO_5S$, M 169.2, m 245°(± form, dec), 260°(+ form, dec)**. Likely impurities are cystine and oxides of cysteine. Crystallise the acid from water by adding 2 volumes of EtOH. It crystallises from H_2O as the ***monohydrate***. The ***anhydrous*** acid has **m ~260°(dec)**. [Chapeville & Formageot *Biochim Biophys Acta* **26** 538 *1957*, DOI: 10.1016/0006-3002(57)90102-6; Gortner & Hoffman *J Biol Chem* **72** 433 *1927*, http://www.jbc.org/content/72/1/433; Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, **Vol 3** p1908 *1961*.]

R*(L)-Cysteic acid (H_2O)** (*R*-abs config) *[498-40-8, 23537-25-9]* **$C_3H_7NO_5S$, M 187.2, m 275-280°(dec), 289°, L-Cysteic acid $[\alpha]_D^{20}$ +8.66 (c 7.4, H_2O, pH 1) and +1.54 (H_2O, pH 13), pK_1^{25} 1.89 (SO_3H), pK_2^{25} 8.7 (CO_2H), pK_3^{25} 12.7 (?NH_2).** Likely impurities are cystine and oxides of cysteine. Crystallise it from water by adding 2 volumes of EtOH. When recrystallised from aqueous MeOH it has **m 264-266°**, and the ***anhydrous acid has **m ~260°(dec)**. [Chapeville & Formageot *Biochim Biophys Acta* **26** 538 *1957*, DOI: 10.1016/0006-3002(57)90102-6; Riordan & Giese *Methods Enzymol* **47** 31 *1977*, DOI: 10.1016/0076-6879(77)47005-8; *Beilstein* **4** IV 3296.] It is a precursor of ***taurine***.

D-(*S*)- and L-(*R* *natural enantiomer*)- Cysteine (*S*- and *R*-2-amino-3-mercaptopropionoic acid) *[S(+) 921-01-7 , R(-) 52-90-4]* **$C_3H_7NO_2S$, M 121.2, m 230°, 240° (dec), $[\alpha]_D^{20}$ + and -7.6 (c 2, M HCl), + and -10.1 (c 2, H_2O, pH 10), pK_1^{25} 1.92 (CO_2), pK_2^{25} 8.35 (NH_2), pK_3^{25} 10.46 (SH).** Purify it by recrystallisation from H_2O (free from metal ions) and dry it in a vacuum. It is soluble in H_2O, EtOH, Me_2CO, EtOAc, AcOH, $*C_6H_6$ and CS_2. Acidic solutions can be stored under N_2 for a few days without deterioration. [For synthesis and spectra see Greenstein & Winitz *Chemistry of the Amino Acids (J. Wiley)* **Vol 3** p1879 *1961*, *Beilstein* **4** III 1618, **4** IV 3144.]

L-Cysteine hydrochloride (H_2O) *[52-89-1 (anhydrous), 7048-04-6 (monohydrate)]* **$C_3H_7NO_2S$. HCl, M**

175.6, m 175-178° (dec), $[\alpha]_D^{25}$ +6.53 (5M HCl). Likely impurities are cystine and tyrosine. Crystallise the salt from MeOH by adding diethyl ether, or from hot 20% HCl. Dry it under vacuum over P_2O_5. ***Hygroscopic***. [*Beilstein* **4** III 1580, 1600.] It is an NMDA (*N-methyl*-D-*aspartate*) glutamatergic receptor agonist.

(±)-Cysteine hydrochloride *[10318-18-0 (anhydrous), 116797-51-5 (monohydrate)]* **$C_3H_7NO_2S$. HCl, M 157.6, m 140-141.5° (dec), pK_2^{20} 8.36 (NH_2), pK_2^{20} 10.28 (SH).** Crystallise the salt from hot 20% HCl and dry it under vacuum over P_2O_5. It also crystallises from EtOH with **m 175°** (hydrate?). When crystallised from absolute EtOH or EtOH/Et_2O, it has **m 140-141.5°** (anhydrous?). [Turner & Voitle *J Am Chem Soc* **72** 628 *1950*, DOI: 10.1021/ja01157a510; cf. Albert *Biochem J* **50** 690 *1952*, DOI: 10.1042/bj0500690; *Beilstein* **4** IV 3145.]

L-(*R,R*-)Cystine *[56-89-3]* **$C_6H_{12}N_2O_4S_2$, M 240.3, $[\alpha]_D^{18.5}$ -229 (c 0.92 in M HCl), pK_1^{25} 1.04 (1.65), pK_2^{25} 2.05 (2.76), pK_3^{25} 8.00 (7.85), pK_4^{25} 10.25 (8.7, 9.85).** Cystine disulfoxide impurity is removed by treating an aqueous suspension with H_2S. The cystine is filtered off, washed with distilled water and dried at 100° under a vacuum over P_2O_5. Crystallise it by dissolving in 1.5M HCl, then adjusting to neutral pH with ammonia. Likely impurities are D-cystine, meso-cystine and tyrosine. Also purify it by dissolving it in 10% NH_3 and adding gradually dilute AcOH until the point of precipitation and cooling slowly [Oughton & Harrison *Acta Cryst* **12** 396 *1959*, DOI: 10.1107/S0365110X59001177]. Alternatively dissolve it in 6N NH_4OH and evaporate it at room temperature for crystallisation to occur. [Chaney & Steinrauf *Acta Cryst* B**30** 711 *1974*, DOI: 10.1107/S0567740874003566; *Beilstein* **4** IV 3155.]

***meso*-2,6-Diaminopimelic acid (2*R*,6*S*)** *[583-93-7]* **$C_7H_{14}N_2O_4$, M 190.2, m 295°(dec), 313-315°(dec), pK_1^{25} 1.04 (1.65, 1.8), pK_2^{25} 2.05 (2.2, 2.76), pK_3^{25} 8.00 (7.85, 8.8), pK_4^{25} 10.25 (8.7, 9.85, 9.9), pI ~5.5.** Crystallise the acid from H_2O or aqueous EtOH. Also purify it by dissolving it in hot H_2O and adding 5 volumes of EtOH, filter after 12 hours at -10°. The acid has been recrystallised from 35% aqueous EtOH. The preparation and separation of *meso-* from *dl-* 2,6-diaminopimelic acid and the enzymic resolution of the latter and some of its derivatives as well as IR spectra were described by Greenstein and coworkers [Izumiya et al. *J Am Chem Soc* **79** 648, 651 *1957*, DOI: 10.1021/ja01560a038]. [*Beilstein* **4** IV 3081.] Present in the cell wall of some bacteria.

L(*S*)-2,3-Diaminopropionic acid monohydrochloride (3-amino-L-alanine hydrochloride) *[1482-97-9]* **$C_3H_8N_2O_2$. HCl, M 140.6, m 132-133°(dec), 237°(dec), $[\alpha]_D^{25}$ +26.1 (c 5.8, M HCl), pK_1^{25} 1.30, pK_2^{25} 6.79, pK_3^{25} 9.51.** It forms needles from H_2O and can be recrystallised from aqueous EtOH. [IR: Koegel et al. *J Am Chem Soc* **77** 5708 *1977*, DOI: 10.1021/ja01626a073; Bisht et al, *J Biol Chem* **287** 20369 *2012*, DOI: 10.1074/jbc.M112.351809; *Beilstein* **4** IV 2501.] The *laevo* **D(*R*-)-*enantiomer*** has *[6018-56-0]*, and the ***racemic salt*** has *[54897-59-5]* and **m 232°(dec)** (see above)

meso*-2,3-Diaminosuccinic acid** *[23220-52-2, 921-52-8]* **$C_4H_8N_2O_4$, M 148.1, m 305-306°(dec, and sublimes), $pK_{Est(1)}$ ~3.6, $pK_{Est(2)}$ ~9.8.** Crystallise the acid from water. Also, dissolve it in dilute NaOH and add AcOH to pH 5-6 and allow it to crystallise (**m 304° dec**). *Alternatively*, dissolve the acid in aqueous NH_3 and boil; when the NH_3 has evaporated, the acid separates, filter it off and dry it at room temperature in a vacuum. In another procedure 1g of acid is dissolved in 10ml of concentrated HCl + 15ml of H_2O at 80°, filter immediately, dilute with 20ml of H_2O and allow to stand for 24 hours. When the ***monohydrochloride (0.7g, **m 175-156° dec**) crystallises out, filter and dry it. It has also been purified by dissolving it in the minimum volume of 10% HCl, filtering, and diluting with 5 volumes of H_2O when the crystals separate slowly on standing. The acid is filtered off after 24 hours and dried (**m 306-306° dec**). Similar procedures were used for the ***dl-isomer***. [Wenner *J Org Chem* **13** 28 *1948*, DOI: 10.1021/jo01159a004; McKennis & Yard *J Org Chem* **23** 980 *1958*, DOI: 10.1021/jo01101a010; *Beilstein* **4** III 1528, **4** IV 3025.]

6-Diazo-5-oxo-L-norleucine *[157-03-9]* **$C_6H_9N_3O_3$, M 171.2, m 140-150°(dec), 145-155°(dec), $[\alpha]_D^{20}$ +21 (c 5, EtOH), pK_1 2.1, pK_2 8.95.** Crystallise it from EtOH, H_2O/EtOH, MeOH, 95% aqueous MeOH or H_2O/Me_2CO. Its UV has λ_{max} at 274nm (E1%1cm: 683) and 244nm (E1%1cm: 276) at pH 7 in phosphate buffer. It is a tumour inhibitor. [DeWald & Moor *J Am Chem Soc* **80** 3941 *1958*, DOI: 10.1021/ja01548a036;

Dion et al. *J Am Chem Soc* **78** 3075 *1956*, DOI: 10.1021/ja01594a036; *Beilstein* **4** IV 3278.]

Diglycyl glycine (triglycine) *[556-33-2]* **$C_6H_{11}N_3O_4$, M 189.2, m 246°(dec), pK_1^{25} 3.30, pK_2^{25} 7.96.** Crystallise triglycine from H_2O or H_2O/EtOH and dry it at 110°. *Alternatively*, crystallise the tripeptide (103mg) by dissolving it in H_2O (0.4ml) and adding absolute EtOH (0.4ml) to give 64mg (68%) of Glyglygly which can be converted to ***N-o-nitrophenoxyacetylGlyglygly*** with **m 212-217°**. [Yakel & Hughes *Acta Cryst* **5** 847 *1952*, DOI: 10.1107/S0365110X52002318; Hughes & Moore *Acta Cryst* **3** 313 *1952*, DOI: 10.1107/S0365110X50000793; Holley & Holley *J Am Chem Soc* **74** 3069 *1952*, DOI: 10.1021/ja01132a035; *Beilstein* **4** III 1198, **4** IV 2469.]

***N,N*-Di-(2-hydroxyethyl)glycine (BICINE, *N,N*-bis-(2-hydroxyethyl)glycine)** *[150-25-4]* **$C_6H_{13}NO_4$, M 163.2, m 193°(dec), 193-195°(dec), pK_1^{25} 2.50, pK_2^{25} 8.11.** Dissolve bicine in a small volume of hot water and precipitate it with EtOH, twice. Repeat once more but treat the aqueous solution with charcoal and filter before adding EtOH. Also crystallise it from concentrated aqueous solutions. [Torn & Kolthoff *J Am Chem Soc* **77** 2061 *1955*, DOI: 10.1021/ja01613a008; Chaberek et al. *J Am Chem Soc* **75** 2185 *1953*, DOI: 10.1021/ja01105a049; *Beilstein* **4** IV 2390.] It is a useful buffer and a spacer on Sephadex for plasma protein fractionation.

3-(3,4-Dihydroxyphenyl)-L-alanine (DOPA, LEVODOPA, EUODOPA) *[*L- *59-92-7, 5796-17-8;* DL- *63-84-3]* **$C_9H_{11}NO_4$, M 197.2, m 275°(dec), 267-268°(dec), 284-286°(dec), ~295°(dec), $[\alpha]_D^{13}$ -13.1° (c 5.12, N HCl), pK_1^{25} 2.32 (CO_2H), pK_2^{25} 8.72 (NH_2), pK_3^{25} 9.96 (OH), pK_4^{25} 11.79 (OH).** Likely impurities are vanillin, hippuric acid, 3-methoxytyrosine and 3-aminotyrosine. DOPA recrystallises from large volumes of H_2O forming colourless white needles; its solubility in H_2O is 0.165%, but it is insoluble in EtOH, $*C_6H_6$, $CHCl_3$, and EtOAc. Also crystallise it by dissolving it in dilute HCl and adding dilute ammonia to give pH 5, under N_2. *Alternatively*, crystallise it from dilute aqueous EtOH. It is rapidly oxidised in air when moist, and darkens, particularly in alkaline solution. Dry it *in vacuo* at 70° in the dark, and store it in a dark container preferably under N_2. It has λ_{max} at 220.5nm (log ε 3.79) and 280nm (log ε 3.42) in 0.001N HCl. [Yamada et al. *Chem Pharm Bull Jpn* **10** 693 *1962*, Bretschneider et al. *Helv Chim Acta* **56** 2857 *1973*, DOI: 10.1002/hlca.19730560821; NMR: Jardetzky & Jardetzky *J Biol Chem* **233** 383 *1958*, http://www.jbc.org/content/233/2/383; *Beilstein* **4** IV 2492, 2493.]

3-(3,4-Dihydroxyphenyl)-2-methyl-L-alanine [methyldopa, 2-amino-3-(3,4-dihydroxy-phenyl)-2-methylpropionic acid] *[555-30-6, 41372-08-1 (sesquihydrate)]* **$C_{10}H_{13}NO_4$, M 211.2(anhydr), m >300°, 300-301°(dec), pK_1^{25} 2.2, pK_2^{25} 9.2, pK_3^{25} 10.6, pK_4^{25} 12.0.** Recrystallise methyldopa from H_2O. [Reinhold et al. *J Org Chem* **33** 1209 *1968*, DOI: 10.1021/jo01267a059.] The **L-*isomer*** forms a ***sesquihydrate*** from H_2O **m 302-304° (dec)**, and the ***anhydrous*** crystals are ***hygroscopic***, $[\alpha]_D^{23}$ -4.0 (c 1, 0.1N HCl), $[\alpha]_{546}$ +154.5 (c 5, $CuSO_4$ solution). It has λ_{max} at 281nm (ε 2780). Its solubility in H_2O at 25° is ~10mg/ml and the pH of an aqueous solution is ~5.0. It is insoluble in most organic solvents. The ***3-methoxy-racemate*** has *[15073-80-8],* separates when an ammoniacal solution of it is adjusted to pH 6.0, the aminoacid is then filtered off, washed with H_2O, dried *in vacuo*, and has **m 218-220°(dec)**. [Stein et al. *J Am Chem Soc* **77** 700 *1955*, DOI: 10.1021/ja01608a046; *Beilstein* **4** IV 2505.]

3,5-Diiodo-L-thyronine (3,5-diiodo-4-[4-hydroxyphenoxy]-1-phenylalanine) *[1041-01-6]* **$C_{15}H_{13}I_2NO_4$, M 525.1, m 255°(dec), 255-257°(dec), $[\alpha]_D^{22}$ +26 [2N HCl-EtOH (1:2)], pK_1^{20} 3.25, pK_2^{20} 5.32, pK_3^{20} 9.48.** The amino-acid is purified by dissolving in EtOH containing a little concentrated HCl, decolorising the solution with charcoal, diluting with H_2O, and precipitating it by adding boiling NaOAc solution. If the solution is slightly violet in colour due to some free iodine, aqueous sodium metabisulfite solution should be added dropwise until the colour is discharged as the free iodine is reduced to iodide ions. Collect the solid, wash well with cold H_2O, dry *in vacuo* (over H_2SO_4) and store it dry in the dark. Also, it can be recrystallise from EtOH after decolorising. [Chambers et al. *J Chem Soc* 3424 *1949*, DOI: 10.1039/JR9490003424; *Beilstein* **14** III 1565, **14** IV 2372.]

3,5-Diiodo-L-tyrosine dihydrate *[300-39-0, 18835-59-0]* **$C_9H_9I_2NO_3$. $2H_2O$, M 469.0, m 199-210°, 202°(dec), 204°(dec), $[\alpha]_D^{20}$ +2.89 (c 4.9, 4% HCl), pK_1^{25} 2.12, pK_2^{25} 6.48, pK_3^{25} 7.82.** It forms crystals from

H_2O [solubility (g/L): 0.204 at 0°, 1.86 at 50°, 5.6 at 75° and 17.0 at 100°]. Also recrystallise it from 50% or 70% EtOH. When boiled in EtOH the crystals swell, and on further boiling a gelatinous precipitate is formed [Harrington *Biochem J* **22** 1429 *1928*, DOI: 10.1042/bj0221436; Jurd *J Am Chem Soc* **77** 5747 *1955*, DOI: 10.1021/ja01626a091]. It also crystallises from cold dilute ammonia on adding acetic acid to pH 6. Dry under a vacuum. [*Beilstein* **14** IV 2370.] It is a substrate for assaying thyroid hormone aminotransferase, and an intermediate in an alternative biosynthetic pathways of metabolism of thyroid hormones.

dl*-4-Dimethylamino-2,2-diphenylvaleramide (Dimevamide, Aminopentamide)** *[60-46-8]* **$C_{19}H_{24}N_2O$, M 296.4, m 183-184°, pK_{Est} ~9.8.** Crystallise dimevamide from aqueous EtOH. The ***hydrochloride forms leaflets from EtOH/Et_2O with **m 190-191°** and is ***deliquescent***. The ***picrate*** has **m 210-211°**. It is an antispasmotic. [Moffett et al. *J Am Chem Soc* **79** 4451 *1957*, DOI: 10.1021/ja01573a056; Beckett & Casy *J Chem Soc* 3076 *1957*, DOI: 10.1021/ja01573a056, *Beilstein* **14** III 1363, **14** IV 1865.]

(-)-L-4-Dimethylamino-2,2-diphenylvaleramide *[6078-64-4]* **$C_{19}H_{24}N_2O$, M 296.4, m 134.5-135.5°, 136.5-137.5°, $[\alpha]_D^{20}$ -112 (c 0.87, EtOH), -84.1 (c 0.9, 0.04N HCl), $pK_{Est(1)}$ 8.3.** Crystallise the amide from petroleum ether, EtOH or as needles from aqueous EtOH. It is an analgesic. [Beckett & Casy *J Chem Soc* 3076 *1957*, DOI: 10.1021/ja01573a056.]

N,N*-Dimethylglycinehydrazide hydrochloride** *[539-64-0]* **$C_4H_{12}ClN_3O$, M 153.6, m 181°.** Crystallise the salt by adding EtOH to a concentrated aqueous solution. [Viscontini & Meier *Helv Chim Acta* **33** 1773 *1950*, DOI: 10.1002/hlca.19500330646; *Beilstein* **4** III 1127, **4** IV 2368.] The ***dihydrochloride, **$C_4H_{11}N_3O$. 2HCl, M 190.1,** has **m 214.5°**, and is used as a reagent for aldehydes and ketones.

Djenkolic acid (S,S'-methylene-bis-L-cysteine) *[498-59-9]* **$C_7H_{14}N_2O_4S_2$, M 254.3, m 300-350°(dec), $[\alpha]_D^{20}$ -65 (c 2, HCl) [See pK of S-methyl-L-cysteine].** Crystallise djenkolic acid from a large volume of water (solubility is 1g/L at 30°). [du Vigneaud & Patterson *J Biol Chem* **114** 533 *1936*, http://www.jbc.org/content/114/2/533; Armstrong & du Vigneaud V *J Biol Chem* **168** 373 *1947*, PMID: 20291097; Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, **Vol 3** pp 2682, 2687 *1961*, *Beilstein* **4** III 1591.] The ***N,N'-dibenzoyl derivative*** crystallises with $1H_2O$ from aqueous EtOH with **m 87.5-89°** [*Beilstein* **9** III 1171.] The acid is nephrotoxic to humans.

S-Ethionine

(*S*-Ethyl-L-homocysteine, *S*-2-amino-4-ethylsulfanylbutyric acid) *[13073-35-3]* **$C_6H_{13}NO_2S$, M 163.2, m 282°(dec), $[\alpha]_D^{25}$ +23.7 (in 5M HCl), pK^{25} 9.02 (for *RS*).** Likely impurities are *N*-acetyl-(*R* and *S*)-ethionine, *S*-methionine, and *R*-ethionine. Crystallise it from water by adding 4 volumes of EtOH or 85% aqueous EtOH. It sublimes at 196-216°/0.3mm with 99.1% recovery and ***unracemised*** [Gross & Grodsky *J Am Chem Soc* **77** 1678 *1955*, DOI: 10.1021/ja01611a085]. [Stekol et al. *J Am Chem Soc* **72** 2309 *1950*, DOI: 10.1021/ja01161a540; Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, **Vol 3** pp 2658, 2659 *1961*, *Beilstein* **4** IV 3194.] It is an antimetabolite and methionine antagonist, highly toxic and a potent carcinogen [Shivapurkar et al. *Carcinogenesis* **5** 989 *1984*, DOI: 10.1093/carcin/5.8.989, PMID: 6744518].

Ethylene *N,N'*-bis[(*o*-hydroxyphenyl)glycine] (EHPG) *[1170-02-1, 6021-71-2]* **$C_{18}H_{20}N_2O_6$, M 360.4, m 249°(dec), $pK_{Est(1)}$ ~1.8, $pK_{Est(2)}$ ~4.8, $pK_{Est(3)}$ ~9.0.** Purify it by extensive Soxhlet extraction with acetone. Commercial sample is a 1:1 mixture or *R,R/S,S* pair and the *meso-RS* form. [Vanadium complexes: Bonadies & Carrano *J Am Chem Soc* **108** 4088 *1986*, DOI: 10.1021/ja00274a038; pKa Schroder & Sheik *Talanta* **21** 250 *1974*, DOI: 10.1016/0039-9140(74)80119-0; for metal chelation tendencies see Freedman et al. *Nature* **179** 1020 *1957*, DOI: 10.1038/1791020b0].

2-Fluorophenylalanine

[R(+) 97731-02-7, S(-) 19883-78-4, RS(±) 2629-55-2] **$C_9H_{10}FNO_2$, M 183.2, m 226-232°, 231-234°, $[\alpha]_D^{25}$ (+) and (-) 15 (c 2, H_2O pH 5.5), pK_1^{24} 2.12, pK_2^{24} 9.01.** Recrystallise 2-fluorophenylalanine from aqueous EtOH. The ***hydrochloride*** has **m 226-231°(dec)**, and the ***N-acetyl derivative*** has **m 147-149°** (aqueous EtOH). [Bennett & Nieman *J Am Chem Soc* **72** 1800 *1950*, DOI: 10.1021/

ja01160a110; *Beilstein* **14** III 1268, **14** IV 1671.]

4-Fluorophenylalanine *[R(+) 18125-46-7, S(-) 1132-68-9, RS(±) 51-65-0]* **$C_9H_{10}FNO_2$, M 183.2, m 227-232°, $[\alpha]_D^{25}$ + and -24 (c 2, H_2O), pK_1^{24} 2.13, pK_2^{24} 9.05.** It is recrystallised from aqueous EtOH. The ***(R)-N-acetyl derivative*** has **m 142-145°**, $[\alpha]_D^{25}$ -38.6 (c 8, EtOH). The ***(R)-hydrochloride*** *[122839-52-5]* M 219.6, has **m 245-251°(dec)**, $[\alpha]_D^{25}$ +11 (c 1, H_2O); the ***(S)-hydrochloride*** *[64231-54-5]* has same M and **m** but opposite optical rotation. [Bennett & Nieman *J Am Chem Soc* **72** 1800 *1950*, DOI: 10.1021/ja01160a110; *Beilstein* **14** III 1268.]

L-5-Fluorotryptophan monohydrate *[16626-02-1; 154-08-5]* **$C_{11}H_{11}FN_2O_2$, M 240.2(H_2O), m reported for the L-enantiomer 158-163°(dec), (±)-isomer >250°(dec), 264-265°(also 238-239° dec reported), $[\alpha]_D^{20}$ +5.5 (c 1, 0.1N HCl), $pK_{Est(1)}$~ 2.5 (CO_2H), $pK_{Est(2)}$~ 9.4 (NH_2), $pK_{Est(3)}$~16 (indole-NH).** Recrystallise it from EtOH, aqueous EtOH or AcOH. Also, purify it by passage through a Dowex AG1x2 (acetate form) column and recrystallise the L-enantiomer (from enzymic enrichment) from H_2O/EtOH, **m 158-163°(dec)**, $[\alpha]_D^{23}$ -8.3 (c 2.5, N NaOH). [Coy et al. *Biochemistry* **13** 3550 *1974*, DOI: 10.1021/bi00714a022; *Beilstein* **22/14** V 116.] It can be incorporated in place of Trp into proteins, and can sometimes lead to enhanced enzyme activity as in glutathione transferase [see Parsons et al. *Biochemistry* **37** 6286 *1998*, DOI: 10.1021/bi980219e, PMID: 9572843].

L(*S*)-Glutamic acid *[56-86-0]* **$C_5H_9NO_4$, M 147.1, m 205°(dec), 224-225°(dec), $[\alpha]_D^{25}$ +31.4 (c 5, 5M HCl), pK_1^{20} 2.06, p K_2^{20} 4.35, pK_3^{20} 9.85.** Crystallise L-glutamic acid from H_2O acidified to pH 3.2 by adding 4 volumes of EtOH, and drying at 110°. Likely impurities are aspartic acid and cysteine. It sublimes at 170-175°/10mm. It melts at **160°** with cyclisation to **L-*pyrrolidone carboxylic acid***. [King & Kidd *J Chem Soc* 3315 *1949*, DOI: 10.1039/JR9490003315; Parikh et al. *J Am Chem Soc* **80** 953 *1958*, DOI: 10.1021/ja01537a052; Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, **Vol 3** pp 1929-1952 *1961*, *Beilstein* **4** III 1530, **4** IV 3028.] The ***S-enantiomer*** is an excitatory neurotransmitter and an agonist to all subtypes of glutamate receptors. The non-natural ***R-enantiomer*** *[6893-26-1]* has similar properties except for opposite optical rotation. The racemic ***RS-glutamic acid*** *[617-65-2, 19285-83-7 (H_2O)]*, which has physiological activity due to it *S* component, crystallises from H_2O [solubility is 1.2%(25°), 5%(50°), (25°), 12%(75°) and 28%(100°)], and has **m 225-227°(dec) [199°(dec)** and **201°(open tube)** also reported]**, b 94-95°/3mm**.

L-Glutamic acid-γ-benzyl ester *[1676-73-9]* **$C_{12}H_{15}NO_4$, M 237.3, m 179-181°, 181-182°, $[\alpha]_{589}^{20}$ +19.3 (c 1, AcOH), pK_1^{25} 2.17, pK_2^{25} 9.00.** Recrystallise the ester from H_2O and store it at 0°. [Estrin *Biochemical Preparations* **13** 25 *1971*, *Beilstein* **6** IV 2538.]

L-Glutamine *[56-85-9]* **$C_{12}H_{15}NO_4$, M 146.2, m 184-185°, 187°, $[\alpha]_D^{25}$ +31.8 (M HCl), $[\alpha]_D^{22}$ +5.6 (H_2O), pK_1^{25} 2.17, pK_2^{25} 9.13.** Likely impurities are glutamic acid, ammonium pyroglutamate, tyrosine, asparagine, isoglutamine, arginine. Crystallise it from water [solubility is 1.2%(0°), 2.6%(50°), (18°), 4.8%(30°)] or aqueous EtOH. [Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, **Vol 3** pp 1929-1925 *1961*, *Beilstein* **4** IV 3038.] The ***racemic (RS)-glutamine*** *[585-21-7]* crystallises in prisms from aqueous Me_2CO and has **m 173-173.5°** [Kline & Cox *J Org Chem* **26** 1854 *1861*, DOI: 10.1021/jo01065a040] and glistening prisims from H_2O/Me_2CO with reported **m 185-186°** [King & Kidd *J Chem Soc* 3315 *1949*, DOI: 10.1039/JR9490003315].

L-Glutathione (GSH, reduced form, γ-L-glutamyl-L-cysteinyl-glycine) *[70-18-8]* **$C_{10}H_{17}N_3O_6S$, M 307.3, m 188-190°(dec), 195°(dec), $[\alpha]_D^{20}$ -20.1 (c 1, H_2O), pK_1^{25} 2.12 (CO_2H), pK_2^{25} 3.59 (CO_2H), pK_3^{25} 8.75 (NH_2), pK_4^{25} 9.65 (10.0, SH).** Crystallise L-glutathione from 50% aqueous EtOH, dry it in a vacuum and store it below 5°. *Alternatively*, recrystallise it from aqueous EtOH under N_2, and store it dry in a sealed container below 4°. It is freely soluble in H_2O. It has been isolated *via* its Zn Hg or Cu complexes. [Weygand & Geiger *Chem Ber* **90** 634 *1957*, DOI: 10.1002/cber.19570900428; Zn complex: Li et al. *J Am Chem Soc* **76** 225 *1954*, DOI: 10.1021/ja01630a058; Martin & Edsall *Bull Soc Chim Fr* **40** 1763 *1958*; Berse et al. *Can J Chem* **37** 1733

1959, DOI: 10.1139/v59-251; du Vigneaud & Miller *Biochemical Preparations* **2** 87 *1952*, Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, **Vol 2** p 1523 *1961*, *Beilstein* **4** IV 3165.] A 5-10mM solution will elute glutathione S-transferase (GST) from a glutathione agarose affinity column.

L-Glutathione (oxidised) *[27025-41-8]* **$C_{20}H_{32}N_6O_{12}S_2$, M 612.6, m 175-195°, 195°, $[\alpha]_D^{20}$ -98 (c 2, H_2O), pK_1 3.15, pK_2 4.03, pK_3 8.75.** Purify it by recrystallisation from 50% aqueous EtOH. Its solubility in H_2O is 5%. Store it at 4°. [Zn complex: Li et al. *J Am Chem Soc* **76** 225 *1954*, DOI: 10.1021/ja01630a058; Berse et al. *Can J Chem* **37** 1733 *1959*, DOI: 10.1139/v59-251; *Beilstein* **4** IV 3168.]

Glycinamide hydrochloride *[1668-10-6]* **$C_2H_6N_2O_2$. HCl, M 110.5, m 186-189°, 203-205°, 207-208°, pK_1^{25} -6.10, pK_2^{25} -1.78, pK_3^{25} 7.95.** Crystallise the salt from EtOH, EtOH/H_2O or MeOH. *Generally* dissolve the salt in the minimum volume of H_2O, add a three-fold volume of EtOH (or MeOH) and allow to crystallise over 3 days at -5° (yield >85%). [Karmas & Spoerri *J Am Chem Soc* **74** 1580 *1952*, DOI: 10.1021/ja01126a070; *Beilstein* **4** IV 2358,] Useful buffer at pH ~7, and for synthesising pyrazine.

Glycine (aminoacetic acid, glycocol) *[56-40-6]* **$C_2H_5NO_2$, M 75.1, m 262° (dec, goes brown at 226°, sublimes at 200°/0.1mm), d^{25} 1.1607g/ml, pK_1^{25} 2.35 (CO_2H), pK_2^{25} 9.78 (α-NH_2).** Crystallise glycine from distilled water by dissolving at 90-95°, filtering, cooling to about -5°, and draining the crystals centrifugally. *Alternatively*, crystallise it from distilled water by addition of MeOH or EtOH (e.g. 50g dissolved in 100ml of warm water, and 400ml of MeOH is added). The crystals are washed with MeOH or EtOH, then with diethyl ether and dried *in vacuo*. Likely impurities are ammonium glycinate, iminodiacetic acid, nitrilotriacetic acid or/and ammonium chloride. It is ***polymorphic*** — has three forms. It solubility in H_2O (g/100ml) is 25 (25°), 54.4 (75°) and 67 (100°); it is almost insoluble in EtOH (0.06%), and has some solubility in pyridine (0.61% w/v). [Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, **Vol 3** p 1955 *1961*, *Beilstein* **4** IV 2349; Fieser **1** 412.] Glycine tastes sweet and is an essential amino acid of proteins. It is an inhibitory neurotransmitter in the spinal chord, and is an allosteric regulator of NMDA (*N-methyl*-D-*aspartate*) receptors [Betz & Harvey *Glycine as a Neurotransmitter* eLS (Encyclopedia of Life Sciences), Wiley & Sons, *2001*, DOI: 10.1038/npg.els.0000140.]

Tetraglycine Hydroperiodide *[7097-60-1]* **$C_{16}H_{42}I_7N_8O_{16}$,** with the composition of **[$(H_2NCH_2COOH)_4$. HI. 5/4I_2], M 1490.9, decomposes between 162°** and **167°.** When ***diglycine monohydroiodide*** (cf. the corresponding hydrochloride below) (139g) in H_2O (1L) is placed in a wide-mouthed glass-stoppered flask with glycine (225g) and I_2 (80g), and stirred vigorous at 70°, a dark brown precipitate separates within a few minutes. After slow cooling, filtering and drying at ~25° (or slightly above to sublime any free elemental I_2), large flat needle (or blade) shaped crystals having a brassy-bronze metallic lustre in reflected light are obtained. They should be stored in the dark. [Frost & Eddy *J Am Chem Soc* **74** 1346 *1952*, DOI: 10.1021/ja01125a509]. It is soluble in H_2O (38g/100ml at ~25°). It is sold as tablets (20mg hyperiodide, 90mg disodium dihydrogen pyrophosphate, 5mg talc) which will dissolve in less than 1minute in 1L of H_2O at ~25°, for disinfecting drinking H_2O by liberating 8mg of I_2. The water is palpable and if the tablets are packaged properly they should be stable under adverse climatic conditions for extended periods. [Morris et al. *Ind Eng Chem* **45** 1013 *1053*, DOI: 10.1021/ie50521a043.] It is also used for the treatment of hyperthyroidism and exposure to radiation.

Glycine anhydride (2,5-diketopiperazine) *[106-57-0]* **$C_4H_6N_2O_2$, M 114.1, m 309-310°, 311-312°(dec), ~315°(dec), pK_1 -4.45, pK_2 -2.16 (pK_2 -1.94 in AcOH).** Recrystallise glycine anhydride from H_2O (plates), and it can be sublimed (slowly) at 260° or at 140-170°/0.5mm. The ***dihydrochloride*** has **m 129-130°** and is prepared by dissolving it in concentrated HCl and adding EtOH to crystallisation point; dry it in a vacuum. The ***bis-1-naphthylurethane*** has **m 232°(dec)**, and the ***diperchlorate*** has **m 117°** (***hygroscopic***). [MS: Johnstone *JCS Perkin Trans 1* 1297 *1975*, DOI: 10.1039/P19750001297; NMR: Bláha & Samek *Coll Czech Chem Commun* **32** 3780 *1967*, http://dx.doi.org/10.1135/cccc19673780; X-ray Cryst: Corey *J Am Chem Soc* **60** 1599 *1938*, DOI: 10.1021/ja01274a023; *Beilstein* **24** IV 1070.]

Glycine ethyl ester hydrochloride *[623-33-6]* **$C_4H_9NO_2$. HCl, M 136.9, m 145-146°, pK^{25} 7.69.** Crystallise it from absolute EtOH or EtOH/Et_2O. [Marvel *Org Synth* Coll Vol **2** 310 *1943*, DOI: 10.15227/orgsyn.014.0046; *Beilstein* **4** II 780, **4** III 3 75.]

Glycine *tert*-butyl ester (glycine 1,1-methylethyl ester) *[6456-74-2]* **$C_6H_{13}NO_2$, M 131.2, b 29-31°/2mm, 65-67°/20mm, d_D^{20} 1.4237, n_D^{25} 1,424, pK_{Est} ~7.6.** The ester, prepared from *tert*-butyl azidoacetate by catalytic reduction (5% Pd/C and H_2), has been purified *via* the phosphite salt. To the ester (23.6g, 0.18mole) in MeOH (150ml) is added phosphorous acid (15g, 0.18mole), the mixture is gently warmed to dissolve the latter and after cooling to 25°, Et_2O (150ml) is added slowly and the stirred mixture is cooled at 0° for 12 hours. The ***phosphite salt*** is collected, filtered off, washed with Et_2O and dried in an oven at 70° (32g, 82%, m 144-147° **dec**). After recrystallisation from MeOH-isopropyl ether, the phosphite salt has **m 154-157° (dec)**. The phosphite salt (32g, 0.15mole) is added with stirring into aqueous 6N-sodium hydroxide solution (50ml) until all the solid has dissolved. The mixture is extracted with Et_2O (2 x 20ml), the extract is dried (Na_2SO_4), filtered, evaporated and the residue is distilled under vacuum to give the ***tert-butyl ester*** as an oil (14g, 72%). The versatile *tert*-butyl group is labile under acidic conditions which do not affect a blocked amino grouping. ***Glycine tert-butyl ester hydrochloride*** *[27532-96-3]* **M 167.6**, has **m 143°** (EtOH/Et_2O). [Vollmar & Dunn *J Org Chem* **25** 387 *1960*, DOI: 10.1021/jo01073a020; More and Rydon *Org Synth* Coll Vol **5** 586 *1973*, DOI: 10.15227/orgsyn.045.0047; *Beilstein* **6** IV 2489.]

Glycine hydrochloride *[6000-43-7]* **$C_2H_5NO_2$. HCl, M 111.5, m 176-178°, 185°, 187°.** Crystallise the salt from absolute EtOH or 80% EtOH. ***Monoglycine hydrochloride*** has **m 176-177°**, but ***diglycine monohydrochloride*** has **m 187°**. Thus when using equivalent quantities of glycine and HCl in H_2O, the former salt is formed, but when ***glycine monohydrochloride*** (22.3g) and glycine (15g) are dissolved in H_2O (30ml) and heated to almost boiling, colourless crystals (24g after drying) of ***diglycine monohydrochloride*** (**m 186-187°**) separate on cooling. [Frost *J Am Chem Soc* **64** 1286 *1942*, DOI: 10.1021/ja01258a014; *Beilstein* **4** III 1111, **4** IV 2353.]

Glycine methyl ester hydrochloride *[5680-79-5]* **$C_3H_8NO_2$. HCl, M 125.6, m 174°(dec), 177°(corrected), pK^{25} 7.66.** Crystallise the ester salt from MeOH. [Werbin & Spoerri *J Am Chem Soc* **69** 1682 *1947*, DOI: 10.1021/ja01199a034; *Beilstein* **4** H 340, **4** III 1116.]

Glycine *p*-nitrophenyl ester hydrobromide *[7413-60-7]* **$C_8H_8N_2O_4$. HBr, M 277.1, m 214° (dec)**. Recrystallise the ester salt from MeOH by adding diethyl ether. [Alners et al. *Biochemical Preparations* **13** 22 *1971*].

Glycocyamine (*N*-guanylglycine) *[352-97-6]* **$C_3H_7N_3O_2$, M 117.1, m 280-284°(dec), >300°, pK^{25} 2.86 (NH_3^+)**. Recrystallise it from 15 parts of hot H_2O, or by dissolving it in slightly more than the calculated amount of 2N HCl and precipitating it by adding an equivalent of 2N NaOH, filtering, washing with cold H_2O and drying first *in vacuo*, then at 60° *in vacuo*. The ***hydrochloride*** has **m 200°(dec)** after recrystallisation from aqueous HCl as plates. The ***picrate*** forms needles from hot H_2O with **m 210°(dec)**. [Brand & Brand *Org Synth* Coll Vol **3** 440 *1955*, DOI: 10.15227/orgsyn.022.0059; Failey & Brand *J Biol Chem* **102** 768 *1933*, http://www.jbc.org/ content/102/2/767; King *J Chem Soc* 2374 *1930*, DOI: 10.1039/JR9300002374; *Beilstein* **4** H 359, **4** I 477, **4** II 793, **4** III 1165.]

N*-Glycylanilide** *[555-48-6]* **$C_8H_{10}N_2O$, M 150.2, m 62°, pK_{Est}~8.0.** *N*-Glycylanilide crystallises from water as needles (dihydrate***) and is soluble in Et_2O. [Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, **Vol 3** pp1915-1970 *1961*, *Beilstein* **4** H 343.]

Glycylglycine *[556-50-3]* **$C_4H_8N_2O_3$, M 132.1, m 260-262°(dec), pK^{20} 8.40, pK^{30} 8.04, pK_1^{15} 3.19, pK_2^{15} 8.40.** Crystallise glycylglycine from aqueous 50% EtOH or water at 50-60° by addition of EtOH. Its solubility in H_2O is 13.2 w/v% at 20°. Dry it at 110°. It sublimes at 190-200°/0.3mm with 30% recovery [Gross & Gradsky *J Am Chem Soc* **77** 1678 *1955*, DOI: 10.1021/ja01611a085; King *J Am Chem Soc* **79** 6153 *1957*, DOI: 10.1021/ja01580a013]. [*Beilstein* **4** IV 2459.]

Glycylglycine hydrochloride *[13059-60-4, 23273-91-8]* **$C_4H_8N_2O_3$. HCl, M 168.6, m 215-220°, 235-236°, 260-262°, pK_1^{25} 3.12, pK_2^{25} 8.17.** Crystallise the salt twice from 95% EtOH. Single crystals are formed by slow evaporation of an aqueous solution. [Mellon & Hoover *J Am Chem Soc* **73** 3879 *1951*, DOI: 10.1021/ja01152a095; for Raman spectrum see Garfinkel & Edsall *J Am Chem Soc* **80** 3818 *1958*, DOI:

10.1021/ ja01548a003; *Beilstein* **4** IV 2469.]

Glycyl-L-proline *[704-15-4]* **$C_7H_{12}N_2O_3$, M 172.2, m 184°(dec), 185°, 204°, pK_1^{25} 2.81, pK_2^{25} 8.65.** Crystallise glycyl-L-proline from water at 50-60° by addition of EtOH. [UV: Saidel *J Am Chem Soc* **77** 3892 *1955*, DOI: 10.1021/ja01619a063; Bergmann et al. *Z Physiol Chem* **212** 79 *1932*, *Beilstein* **22** IV 49.] Exhibits anti-ischemic effects on neuroactive amino acids.

***dl*−Glycylserine** *[687-38-7]* **$C_5H_{10}N_2O_4$, M 162.2, m 197-199°(dec, sealed tube), 207°(dec), pK_1^{25} 2.92, pK_2^{25} 8.10.** Crystallise it from H_2O (charcoal) by addition of EtOH. [Fölsch *Acta Chem Scand* **12** 561 *1958*, DOI: 10.3891/acta.chem.scand.12-0561; NSR: Bovey & Tiers *J Am Chem Soc* **81** 2870 *1959*, DOI: 10.1021/ja01520a063; *Beilstein* **4** III 1572, **4** IV 3140.]

Gramicidin A (a linear pentadecapeptide from *Bacillus brevis*) *[11029-61-1]* **m ~229-230°(dec)**. Purify gramicidin A by countercurrent distribution from *C_6H_6/$CHCl_3$, MeOH/H_2O (15:15:23:7) with 5000 tubes. Fractions are examined by UV (280nm) of small aliquots. Separation from gramicidin C and other material occurred after 999 transfers. Collectively called *Gramicidin D [1405-97-6]* **$C_{99}H_{140}N_{20}O_{17}$, M 1882.3**. [Gramicidin A, B and C, prep: Gross & Witkop *Biochemistry* **4** 2495 *1965*, DOI: 10.1021/bi00887a032; synth: Bauer et al. *Biochemistry* **11** 3266 *1972*, DOI: 10.1021/bi00767a022.] Purify it finally by recrystallisation from EtOH/H_2O and dry it at 100°/10^{-2}mm over KOH. It forms platelets **m** 229-230°. It is almost insoluble in H_2O (0.6%) but soluble in lower alcohols, dry Me_2CO, dioxane, acetic acid and pyridine. The commercial material is more difficult to crystallise than the synthetic compound. [*seco*-Gramicidin: Sarges & Witkop *J Am Chem Soc* **86** 1861 *1964*, DOI: 10.1021/ja01063a048; Gramincidin A, structure: **87** 2011 *1965*, DOI: 10.1021/ja01087a027; Gramincidin A, synth: **87** 2020 *1965*, DOI: 10.1021/ja01087a028; Gramincidin B, structure: **87** 2027 *1965*, DOI: 10.1021/ja01087a029] It has characteristic $[\alpha]_D^{20}$ +27.3 (c 1.3, MeOH) and UV with λ_{max} at 282nm (ε 22,100). The ***N-carbamoyldeformyl gramicidine A*** precipitates from EtOAc/petroleum ether (b 40-60°). [*Beilstein* **26** III/IV 4273.] The difference between A, B, and C is in residue 11 which is Trp, Phe and Tyr respectively.

Gramicidin C (a linear pentadecapeptide from *Bacillus brevis*) *[9062-61-7]***.** Purify as for Gramicidin A since they are isolated together and separated. [Structure: Sarges & Witkop *Biochemistry* **4** 2491 *1965*, DOI: 10.1021/bi00887a031; Hunter & Schwartz 'Gramicidins' in *Antibiotics I* (Gotlieb and Shaw Eds) Springer-Verlag, NY, p.642 *1967*, as well as references above for Gramicidin A.]

Gramicidin S *[113-73-5]* **$C_{60}H_{92}N_{12}O_{10}$, M 1120.0, m 268-270°, $[\alpha]_D^{25}$ -290 (c 0.5, EtOH + 30mM aqueous HCl {7:3}).** Gramicidin S crystallises from EtOH. The ***di-HCl*** *[15207-30-4]* crystallises from EtOH (+ few drops of HCl) with **m 277-278°** (see below). [^{13}C NMR in MeOH and in Me_2SO: Gibbons et al. *Nature* **227** 840 *1970*, DOI:10.1038/227840a0; *Beilstein* **26** III/IV 4273.] Unlike Gramicidins A, B and C, this antibiotic is a cyclic decapeptide with two ornithine residues which have free amino groups, hence it forms salts readily (see below). Potentially harmful, protect eyes.

Gramicidin S 2HCl (from *Bacillus brevis* Nagano) *[15207-30-4]* **$C_{60}H_{92}N_{12}O_{10}$. 2HCl, M 1192.9, m 277-278°(dec), $[\alpha]_D^{24}$ -289 (c 0.4, 70% H_2O+EtOH).** It crystallises in prisms from EtOH+aqueous HCl.

N*-Guanyltyramine hydrochloride** *[60-20-8]* **$C_9H_{13}N_3O$. HCl, M 215.7, m 218°, pK_1 10.2 (phenolic OH), pK_2 12.4 (guanidino N)**. Purify the salt on a phosphocellulose column and elute with a gradient of aqueous NH_3 (0-10%). The second major peak has the characteristic tryptamine spectrum and is collected, and lyophilised to give white crystals of the ***dihydrate which dehydrate at 100°. It has UV with λ_{max} at 274.5nm (ε 1,310) in 0.1N NaOH, and 274.5nm (ε 1,330) at pH 7.0. Excitation λ_{max} is at 280nm and emission λ_{max} is at 330nm. [For use of ^{125}I *N*-guanyltyramine in assaying ADP-ribosyltransferase activity in cholera toxin see Mekalanos et al. *J Biol Chem* **254** 5849 *1979*, http://www.jbc.org/content/254/13/5849, PMID: 447682.]

***S*-Histidine** *[71-00-1]* **$C_6H_9N_3O_2$, M 155.2, m 287°(dec), $[\alpha]_D^{25}$ -39.7 (c 1, H_2O), +13.0 (6M HCl), pK_1^{25} 1.96, pK_2^{25} 6.12, pK_3^{25} 9.17.** A likely impurity is arginine. *S*-Histidine is adsorbed from aqueous solution onto

a Dowex 50-H^+ ion-exchange resin, washed with 1.5M HCl (to remove other amino acids), then eluted with 4M HCl as the ***dihydrochloride***. This purified ***dihydrochloride*** (see below) is finally dissolved in water, the pH adjusted to 7.0, and the ***free zwitterionic base*** crystallises out on addition of EtOH. Its solubility in H_2O is 4.2% at 25°. ***RS-Histidine*** *[4998-57-6]* has **m 273°(dec).** [Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, **Vol 3** pp 1971-1993 *1961*, *Beilstein* **25** III/IV 4346-4348.]

S*-Histidine dihydrochloride** *[1007-42-7]* **$C_6H_9N_3O_2$. 2HCl, M 242.1, m 245°, $[\alpha]_D^{20}$ +47.5 (c 2, H_2O).** The dihydrochloride crystallises from water or aqueous EtOH and is washed with acetone, then diethyl ether. *Alternatively*, convert it to the histidine ***di-(3,4-dichlorobenzenesulfonate) salt by dissolving 3,4-dichlorobenzenesulfonic acid (1.5g/10ml) in the aqueous histidine solution with warming, and then the solution is cooled in ice. The resulting crystals (**m 280° dec**) can be recrystallised from 5% aqueous 3,4-dichlorobenzenesulfonic acid, then dried over $CaCl_2$ under vacuum, and washed with diethyl ether to remove excess reagent. The dihydrochloride can be regenerated by passing the solution through a Dowex-1 (Cl^- form) ion-exchange column. The solid is obtained by evaporating the solution on a steam bath or better in a vacuum. [Greenstein & Winitz, The Amino Acids **Vol 3** p 1976 *1961*, *Beilstein* **25/16** V 366.]

***S*-Histidine monohydrochloride (H_2O)** *[5934-29-2 (H_2O), 7048-02-4]* **$C_6H_9N_3O_2$. HCl, M 209.6(H_2O), m 80° monohydrate, 254°(dec, anhydrous), $[\alpha]_D^{25}$ +13.0 (6M HCl).** Crystallise the mono-hydrochloride from aqueous EtOH or 60% aqueous EtOH (**m** 259°dec). *Alternatively*, dissolve 10g in 50ml of H_2O, decolourise with Norite, filter, evaporate it in a vacuum to a syrup, cool to room temperature, add 95% EtOH with stirring until slightly turbid, scratch the sides of the vessel until crystals form, then add slowly 40ml of EtOH and keep at 0° overnight, filter the solid off, wash it several times with EtOH and dry it in a vacuum. [Rose & Cox *J Biol Chem* **68** 217 *1926*, http://www.jbc.org/content/68/1/217; Cox et al. *J Biol Chem* **81** 755 *1929*, http://www.jbc.org/content/81/3/755; Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, **Vol 3** pp 1972, 2098 *1961*, *Beilstein* **25** II 407, **25** III/IV 4346.]

L-Homocysteine (2-amino-4-mercaptobutyric acid) *[6027-13-0]* **$C_4H_9NO_2S$, M 135.2, m 232-233°, $[\alpha]_D^{25}$ +153 (c 13, 5N HCl), pK_1^{25} 2.22 (CO_2H), pK_2^{25} 8.87 (NH_3^+), pK_3^{25} 10.86 (SH).** Crystallise L-homocysteine from aqueous EtOH. All operations should be carried out under N_2 as the thiol readily oxidises in air. The acid (3g) is dissolved in freshly boiled H_2O (30ml) under N_2 cooled under N_2 (all operations should be under N_2), add absolute EtOH (100ml), the acid is filtered off, and a second crop is obtained by diluting the filtrate to 500ml with absolute EtOH, keeping overnight in a refrigerator, filtering, washing with EtOH and drying in a vacuum. Store it under N_2 or argon. The S-***benzyl derivative*** is repeatedly crystallised from H_2O, or by dissolving it in HCl followed by slow addition of ammonia. It has **m 240-241°**, $[\alpha]_D^{25}$ +27 (c 13, 5N HCl). [Riedel & du Vigneaud *J Biol Chem* **112** 149 *1935*, http://www.jbc.org/content/112/1/149; du Vigneaud & Patterson *J Biol Chem* **109** 97 *1935*, http://www.jbc.org/content/109/1/97; du Vigneaud et al. *J Biol Chem* **126** 217 *1938*, http://www.jbc.org/content/126/1/217; du Vigneaud & Brown *Biochemical Preparations* **5** 93, 95 *1975*, Greenstein & Winitz *The Chemistry of the Amino Acids* J. Crystallise the hydrochloride from water by adding 2-9 volumes of EtOH stepwise. [Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, **Vol 3** p 2000-2009 *1961*.]

DL-*erythro*-3-Hydroxynorvaline (2-amino-3-hydroxypentanoic acid) *[34042-00-7]* **M 133.2, m 257-259°(dec), 263°(dec), pK_1^{20} 2.32, pK_2^{20} 9.12.** Prepared by amination of α-bromo-β-hydroxy-*n*-valeric acid Purify it by recrystallisation from aqueous EtOH. The ***Cu salt*** has **m 255-256°** (**dec**), the ***benzoyl*** derivative has **m 181°**, the ***N-phenylcarbamoyl*** derivative has **m 164°**, and the ***N-naphthylcarbamoyl*** derivative has **m 179°**, [Buston et al. *J Biol Chem* **204** 665 *1953*, http://www.jbc.org/content/204/2/665, PMID: 13117840; *Beilstein* **4** IV 3220.]

***N*-(*p*-Hydroxyphenyl)glycine** *[122-87-2]* **$C_8H_9NO_3$, M 167.2, m 244°(dec).** Purify by recrystallising from a large volume of H_2O. It is sparingly soluble in most organic solvents but is soluble in aqueous acid or alkali. It

is used in photography (developing agent) and as an acid indicator in bacteriology. With $FeCl_3$ it produces a methylene blue olour (oxidation to the *p*-quinone-imine?). [Galatis *Helv Chim Acta* **4** 574 *1921*, DOI: 10.1002/hlca.19210040162; *Beilstein* **13** IV 1210.]

***p*-Hydroxy-D-phenylglycine [D-2-(4-hydroxyphenyl)glycine]** *[22818-40-2]* **$C_8H_9NO_3$, M 167.2, m >240°(dec), $[\alpha]_D^{20}$ -156 (c 1, M HCl), $pK_{Est(1)}$~2, $pK_{Est(2)}$~4.5, $pK_{Est(3)}$~10.3.** Crystallise it from water and dry it *in vacuo*. ***p*-Hydroxy-L-phenylglycine** *[32462-30-9]* has **$[\alpha]_D^{20}$ +158 (c 1, M HCl)**. [*Beilstein* **14** I 659.]

trans*-L-4-Hydroxyproline (2*S*,4*R*-4-hydroxypyrrolidine-2-carboxylic acid)** *[51-35-4]* **$C_5H_9NO_3$, M 131.1, m 273°(dec), 274°, $[\alpha]_D^{20}$ -76.0 (c 5, H_2O), pK_1^{25} 1.86, pK_2^{25} 9.79.** Crystallise it from MeOH/EtOH (1:1). Separation from normal ***allo*-**isomer can be achieved by crystallisation of the copper salts [see Levine *Biochemical Preparations* **8** 114 *1961*]. Separation from proline is achieved *via* the crystalline ***picrate, ***$CdCl_2$***, or ***acid ammonium rhodanate*** salts [see Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, **Vol 3** p 2182 *1961*]. [*Beilstein* **22/5** V 7.]

5-Hydroxy-L-tryptophan *[4350-09-8]* **$C_{11}H_{12}N_2O_3$, M 220.2, m 270°(dec), 273°(dec), $[\alpha]_D^{22}$ -32.5, $[\alpha]_{546}^{20}$ -73.5 (c 1, H_2O), $pK_{Est(1)}$~2.4, $pK_{Est(2)}$~9.0, $pK_{Est(3)}$~9.4, $pK_{Est(4)}$ 16 (NH).** Likely impurities are 5-hydroxy-D-tryptophan and 5-benzyloxytryptophan. Crystallise 5-hydroxy-L-tryptophan under nitrogen from water by adding EtOH. Store it under nitrogen. Also dissolve it in the minimum volume of hot H_2O (~0.7g in 4ml) under nitrogen (charcoal) and allow it to crystallise at 5°. The ***picrolonate*** crystallises from H_2O with **m 184-186°(dec)**. [Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, **Vol 3** p 2732-2737 *1961*, Morris & Armstrong *J Org Chem* **22** 306 *1957*, DOI: 10.1021/jo01354a022; *Beilstein* **22/14** V 278.]

(±)-Ibotenic acid monohydrate (α-[3-hydroxy-5-isoxazolyl]-glycine, α-amino-3-hydroxy-5-isoxazoleacetic acid) *[2552-55-8]* **$C_5H_6N_2O_4$, M 176.1, m 144-146° (monohydrate), 151-152° (anhydrous), 148-151°, pK_1 2, pK_2 5.1, pK_3 8.2.** It has been converted to the ammonium salt (**m 121-123° dec**) dissolved in H_2O, passed through an Amberlite IR 120 resin (H^+ form) and eluted with H_2O. The acidic fractions are collected, evaporated to dryness and the residue recrystallises from H_2O as the ***monohydrate*** (**m 144-146°**). The ***anhydrous acid*** is obtained by making a slurry with MeOH, decanting and evaporating to dryness, and repeating the process twice more (**m 151-152°**). Recrystallisation from H_2O gives back the ***monohydrate***. [Improved synth: Nakamura *Chem Pharm Bull Jpn* **19** 46 *1971*, DOI: 10.1248/cpb.19.46.] The ***ethyl ester*** forms needles when recrystallised from a small volume of Et_2O and has **m 78-79°**, and IR ($CHCl_3$) with ν_{max} at 3500−2300 (OH), 1742 (ester C=O), 1628, 1528cm^{-1}, and UV with λ_{max} at (EtOH) at 206nm (ε 7,080). The ***hydrazide*** has **m 174-175°** (from MeOH) with IR (KBr) 1656 (C=O)cm^{-1}. It occurs in muscarinic mushrooms, is hallucinogenic and is poisonous [Becker et al. *Psychopharmacology* **144** 333 *1999*, DOI:10.1007/s002130051015. PMID: 10435405].

Iminodiacetic acid *[142-73-4]* **$C_4H_7NO_4$, M 133.1, m 225°(dec), 240°(dec), 247.5°(dec), b 126-127°/14mm, pK_1^{25} 2.50, pK_2^{25} 9.40.** Crystallise the acid several times from water. The ***N*-Methyl** derivative **m 215°** is purified by dissolving it in an equal weight of warm H_2O and adding 3 volumes of MeOH [Kiematsu et al. *Org Synth* Coll Vol **2** 397 *1943*]. [Chaberek & Martell *J Am Chem Soc* **74** 5052 *1952*, DOI: 10.1021/ja01140a018; *Beilstein* **4** III 2428, **4** IV 1176.]

3-Iodo-L-tyrosine *[70-78-0]* **$C_9H_{10}NO_3$, M 307.1, m 205-208°(dec), 210°(dec), $[\alpha]_D^{25}$ -4.4 (c 5, 1M HCl), $pK_{Est(2)}$~2.1, $pK_{Est(3)}$~6.4, pK_4^{25} 8.7.** Likely impurities are tyrosine, diiodotyrosine and iodide. Crystallise it by dissolving it in concentrated ammonia (~200mg in ~20ml), evaporating to ~5ml, and NH_4Cl is added to pH 4.5—5.0. After a few hours at 0°, the amino acid crystallises in needles. It is filtered off, washed with a little ice-cold H_2O and dried in a vacuum. *Alternatively*, dissolve it in dilute ammonia at room temperature, then add dilute acetic acid to pH 6. Store it at 0°. Recrystallisation of ~250mg from H_2O (~5ml) removes any diiodotyrosine. It is an inhibitor of tyrosine hydroxylase with a Ki of ~500nM. [Harrington & Rivers *Biochem J* **38** 320 *1944*, DOI: 10.1042/bj0380320; Rivers *Chem Ind (London)* 21 *1956*, *Beilstein* **14** III 1562, **14** IV 1562, **14** IV 2369.]

L-Isoleucine *[73-32-5]* **$C_6H_{13}NO_2$, M 131.2, m 285-286°(dec), $[\alpha]_D^{20}$ +40.6 (6M HCl) pK_1^{25} 2.66, pK_2^{25} 9.69.** Crystallise L-isoleucine from H_2O by addition of 4 volumes of EtOH or from aqueous MeOH. It sublimes at 170-181°/0.3mm with 99.7% recovery, unracemised [Gross & Gradsky *J Am Chem Soc* **77** 1678 *1955*, DOI: 10.1021/ja01611a085]. [Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, **Vol 1** p 183-191, **Vol 3** pp 2043-2073 *1961*, Huffman & Ingersoll *J Am Chem Soc* **73** 3366 *1951*, DOI: 10.1021/ja01151a111; *Beilstein* **4** IV 2775.]

DL-Isoserine (±-3-amino-2-hydroxypropionic acid) *[565-71-9, 632-12-2]* **$C_3H_7NO_3$, M 105.1, m 235°(dec), 237°(dec), 245°(dec), 250-252°(dec), pK_1^{25} 2.78 (acidic), pK_2^{25} 9.27 (basic).** Recrystallise it from H_2O or 50% aqueous EtOH. It has an isoelectric pH of 6.02. [Rinderknecht & Niemann *J Am Chem Soc* **75** 6322 *1953*, DOI: 10.1021/ja01120a523; Gundermann & Holtmann *Chem Ber* **91** 160 *1958*, DOI: 10.1002/cber.19580910128; dissociation constants: Emerson et al. *J Biol Chem* **92** 451 *1931*, http://www.jbc.org/content/92/2/449.] The ***hydrobromide*** has **m 128-130°** (from aqueous HBr) [Schöberl & Braun *Justus Liebigs Ann Chem* **542** 288 *1939*, DOI: 10.1002/jlac.19395420120]. [*Beilstein* **4** H 503, **4** IV 3116.]

L-Isovaline (2-amino-2-methylbutyric acid) *[595-40-4]* **$C_5H_{11}NO_2$, M 117.2, m** *ca* **300° (sublimes in vac), $[\alpha]_D^{25}$ +113.1 (c 5, H_2O), $[\alpha]_D^{25}$ +10 (5M HCl), $pK_{Est(1)}$~2.4, $pK_{Est(2)}$~9.7.** Crystallise it from aqueous Me_2CO, or better dissolve in H_2O and add excess Me_2CO. [Baker et al. *J Am Chem Soc* **74** 4701 *1952*, DOI: 10.1021/ja01138a502; Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, **Vol 3** p 2573-2577 *1961*.]

L(*S*)-Leucine *[61-90-5]* **$C_6H_{13}NO_2$, M 131.2, m 293-295°(dec), $[\alpha]_D^{25}$ +15.6 (5M HCl), pK_1^{25} 2.33, pK_2^{25} 9.74.** Likely impurities are isoleucine, valine, and methionine. Crystallise L-leucine from water by adding 4 volumes of EtOH. It sublimes at 180-188°/0.3mm with 99.1% recovery, and ***unracemised*** [Gross & Gradsky *J Am Chem Soc* **77** 1678 *1955*, DOI: 10.1021/ja01611a085]. [Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, **Vol 3** p 2075-2094 *1961*, Kameda et al. *J Pharm Soc Jpn* **78** 763 *1958*, *Beilstein* **4** IV 2738.]

L-Lysine *[56-87-1]* **M 146.2,** *[39665-12-8 monohydrate]* **$C_5H_{14}N_2O_2$, M 164.2, m >210°(dec), $[\alpha]_D^{20}$ +25 (c 2, 6M HCl), pK_1 2.18, pK_2 8.95, pK_3 10.53.** Crystallise this basic amino acid from aqueous EtOH. [Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, **Vol 3** pp 2097-2122 *1961*, Kearley & Ingersoll *J Am Chem Soc* **73** 5783 *1951*, DOI: 10.1021/ja01156a089; *Beilstein* **4** IV 2717.]

L-Lysine dihydrochloride *[657-26-1]* **$C_5H_{14}N_2O_2$. 2HCl, M 219.1, m 193°, 199-201°, 203-204°, $[\alpha]_D^{25}$ +25.9 (5M HCl).** Crystallise it from MeOH, in the presence of excess HCl, by adding diethyl ether. [Yoneya *J Biochem(Tokyo)* **38** 343 *1951*, Kearley & Ingersoll *J Am Chem Soc* **73** 5783 *1951*, DOI: 10.1021/ ja01156a089; *Beilstein* **4** IV 2717.]

L-Lysine monohydrochloride *[657-27-2]* **$C_5H_{14}N_2O_2$. HCl, M 182.7, m 256°(dec), $[\alpha]_D^{25}$ +20.5 (c 5, 5M HCl).** Likely impurities are arginine, D-lysine, 2,6-diaminoheptanedioic acid and glutamic acid. Crystallise the mono-hydrochloride from water at pH 4-6 by adding 4 volumes of EtOH. At above 60% relative humidity it forms a ***dihydrate***. [Birhbaum et al. *J Biol Chem* **194** 455 *1952*, http://www.jbc.org/content/194/1/455, PMID: 14927637; Kearley & Ingersoll *J Am Chem Soc* **73** 5783 *1951*, DOI: 10.1021/ja01156a089; *Beilstein* **4** IV 2717.]

α-Melanotropin *[581-05-5]* **(a tridecapeptide, α-MSH, melanocyte stimulating hormone), $C_{77}H_{109}N_{21}O_{19}S$, M 1664.9, $[\alpha]_D^{25}$ -58.5 (c 0.4, 10% aqueous AcOH).** Its solubility in H_2O is 1mg/ml. It is separated from the extract by ion-exchange on carboxymethyl cellulose, desalted, evaporated and lyophilised, then chromatographed on Sephadex G-25. [Lande et al. *Biochemical Preparations* **13** 45 *1971*.] α-MSH is a melanocyte-stimulating hormone [Varga et al. *J Mol Neurosci* **50** 558 *2013*, DOI: 10.1007/s12031-013-9998-3. PMID: 23504281].

ß-Melanotropin *[9034-42-8]* **(octadeca to docosa peptides), amorphous.** An extract of β-melanotropin is

purified by ion-exchange on carboxymethyl cellulose, desalted, evaporated and lyophilised, then chromatographed on Sephadex G-25. [Lande et al. *Biochemical Preparations* **13** 45 *1971*.] Increased plasma ß-melanotropin (ß-MSH) leads to hyperpigmentation [Sawin et al. *Arch Intern Med* **125** 708 *1970*, DOI:10.1001/archinte.1970.00310040132018].

Melphalan (4-[bis-{2-chloroethyl}amino]-L-phenylalanine, L-sarcolysine) *[148-82-3]* **$C_{13}H_{18}Cl_2N_2O_2$, M 305.2, m 182-183° (dec), 183-185°, $[\alpha]_D^{25}$ +7.5 (c 1.33, 1.0 N HCl), $[\alpha]_D^{20}$ -28 (-31.5) (c 0.8, MeOH), pK_{Est} ~6.4.** Purify melphalan by recrystallisation from MeOH (colourless needles), and its solubility is 5% in 95% EtOH containing one drop of 6N HCl. It is soluble in EtOH and propylene glycol but is almost insoluble in H_2O. The ***R-form*** crystallises from MeOH (needles) with **m 181.5-182°** and $[\alpha]_D^{21}$ -7.5 (c 1.26, 1.0 N HCl). The ***RS-form*** has **m 180-181°** (very small needles from MeOH). [Bergel & Stock *J Chem Soc* 2409 *1954*, DOI: 10.1039/JR9540002409; *Beilstein* **14** IV 1689.] This *nitrogen mustard* is antineoplastic and a **CARCINOGEN**.

***dl*-Methionine (*RS*-2-amino-4-methylthiobutyric acid)** *[59-51-8]* **$C_5H_{11}NO_2S$, M 149.2, m 281°(dec), pK_1^{25} 2.28, pK_2^{25} 9.21.** Crystallise it from hot water [solubility in H_2O (g/100ml) is 1.8 (0°), 3.4 (25°), 10.5 (75°) and 17.6 (100°)] or EtOH. Also purify it by dissolving it in H_2O and passing through an Amberlite IR-120 resin (NH_4^+ form). The eluate is concentrated and then passed through Amberlite IR-4B resin, and this eluate is evaporated to dryness. The residue is washed with EtOH, then Me_2CO, dried and recrystallised from aqueous EtOH (colourless plates) [Baddiley & Jamieson *J Chem Soc* 4280 *1954*, DOI: 10.1039/JR9540004280]. [Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, **Vol 3** p 2125 *1961*, *Beilstein* **4** IV 3190.]

L-Methionine *[63-68-3]* **$C_5H_{11}NO_2S$, M 149.2, m 277-279°(dec), 283°(dec), $[\alpha]_D^{25}$ -8.1 (c 0.8, H_2O), $[\alpha]_D^{25}$ +21.2 (0.2M HCl), $[\alpha]_D^{25}$ +23.1 (c 1, M HCl), [note signs of rotation], pK_1^{25} 2.13, pK_2^{25} 9.73.** Crystallise L-methionine from aqueous EtOH. Also purify it by dissolving ~0.5g of amino acid in ~10ml of hot H_2O, filtering, adjusting the pH to 5.8 with 5N HCl, and collecting the solid after additing ~20ml of EtOH. It is recrystallised by dissolving in H_2O and adding EtOH. It sublimes at 197-208°/0.3mm with 99.8% recovery and ***unracemised*** [Gross & Gradsky *J Am Chem Soc* 77 1678 *1955*, DOI: 10.1021/ja01611a085]. [Baddiley & Jamieson *J Chem soc* 1085 *1955*, DOI: 10.1039/JR9550001085; Milne & Peng *J Am Chem Soc* **79** 645 *1957*, DOI: 10.1021/ja01560a037;Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, **Vol 3** pp 2125-2152 *1961*, *Beilstein* **4** IV 3189.] Methionine is a kidney acidifier, protects kidneys, and is used as an antidote in acetaminophen poisoning.

dl*-Methionine sulfoxide** *[454-41-1, 62697-73-8]* **$C_5H_{11}NO_3S$, M 165.2, m >240°(dec), 241-242°(dec).** Likely impurities are *dl*-methionine sulfone and *dl*-methionine. Crystallise the sulfoxide by dissolving it in hot H_2O and adding excess EtOH. [Lepp & Dunn *Biochemical Preparations* **4** 80 *1955*, Micheel & Schmitz *Chem Ber* **72** 518 *1939*, DOI: 10.1002/cber.19390720310; *Beilstein* **4** III 1650, **4** IV 3192.] ***dl-Methionine sulfone *[820-10-0]* **$C_5H_{11}NO_4S$, M 181.2**, has **m ~250°(dec)**, and is excreted in the urine of rats when the *sulfoxide* is injected intraperitoneally [Wingo et al. *Arch Biochem Biophys* **47** 307 *1953*, DOI: 10.1016/0003-9861(53)90468-8 [*Beilstein* **4** IV 3193.]

S-Methyl-L-cysteine *[1187-84-4]* **$C_4H_9NO_2S$, M 135.2, m 207-211°, ~240°(dec), 267-270°, $[\alpha]_D^{26}$ -32.0 (-34.5) (c 5, H_2O), pK_1^{25} 1.94 (COOH), pK_2^{25} 8.73 (NH_2, 8.97).** Likely impurities are cysteine and S-methyl-*dl*-cysteine. Crystallise it from H_2O by adding 4 volumes of EtOH. It also crystallises from MeOH with **m 234-236°(dec)**, but after sublimation it has **m 267-270°** and $[\alpha]_D^{27}$ -31.6 (c 1, H_2O). [Rinderknecht et al. *Helv Chim Acta* **41** 1 *1958*, DOI: 10.1002/hlca.660410102; Theodoropoulos *Acta Chem Scand* **13** 383 *1959*, DOI: 10.3891/acta.chem.scand.13-0383; Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, **Vol 3** p 1904 *1961*, *Beilstein* **4** IV 3145.]

α-Methylmethionine *[562-48-1]* **$C_6H_{13}N_2OS$, M 163.0, m 283-284°, $pK_{Est(1)}$ ~ 2.1, pK^{30} 9.45.** Crystallise α-methylmethionine from aqueous EtOH or H_2O. Pfister et al. stated '**m 283-284°**' when crystallised from aqueous EtOH which gave ***α-methylmethioninemethylsulfonium iodide*** with MeI, and upon recrystallisation from 50%aqueous EtOH/absolute EtOH had **m 95°(dec)**. Potts stated 'white needles' from H_2O with **m** 134°'. [Pfister et al. *J Am Chem Soc* **77** 697 *1955,* DOI: 10.1021/ja01608a045; Potts *J Chem Soc* (in Notes starting on p 1626) 1632 *1955*, DOI: 10.1039/JR9550001626; Greenstein & Winitz *The Chemistry of the Amino Acids* J.

Wiley, **Vol 3** p 2566 *1961*.]

S-Methyl-L-methionine chloride See Vitamin U in 'Physiologically Active…', this chapter.

N*-Methyltryptophan (L-abrine)** *[526-31-8]* **$C_{12}H_{14}N_2O_2$, M 218.3, m 295°(dec with darkening and sintering), $[\alpha]_D^{21}$ +44.4 (c 2.8, 0.5M HCl), $[\alpha]_D^{20}$ +65 (c 1, 0.5N NaOH), pI 10.10, $pK_{Est(1)}$~2.3, $pK_{Est(2)}$~9.7.** Crystallise L-abrine from H_2O or EtOH/H_2O mixture. Its solubility in MeOH is 1w/v% at ~25°. Dry it for 2 days at 60° in high vacuum; it has **m** 275-290°(dec with browning at 230°) and $[\alpha]_D^{21}$ +47.2 (c 2, 0.5N HCl) [Peter et al. *Helv Chim Acta* **46** 577 *1963*, DOI: 10.1002/hlca.19630460217]. The ***acetyl derivative, **$C_{14}H_{14}N_2O_3$**, has **m 176°** and $[\alpha]_D^{25}$ -148 (c 0.86, N NaOH). [Gregory & Morley *J Chem Soc C* 910 *1968*, DOI: 10.1039/J39680000910; for configuration and racemisation see Cahill & Jackson *J Biol Chem* **126** 29 *1938*, http://www.jbc.org/content/126/1/29; *Beilstein* **22/14** V 40.]

dl*-5-Methyltryptophan** *[951-55-3]* **$C_{12}H_{14}N_2O_2$, M 218.3, m 275°(dec), 284-288° [pK see tryptophan].** Crystallise *dl*-5-methyltryptophan from aqueous EtOH after dissolving it in aqueous NaOH, precipitating with AcOH, filtering the solid off and drying for 24 hours at 50°. The purity can be determined by titrating an NaOH solution with perchloric acid [Jackman & Archer *J Am Chem Soc* **68** 2105 *1946*, DOI: 10.1021/ja01214a507; *Beilstein* **22** IV 6815.] The ***picrate crystallises from MeOH with **m 202°(dec)**. The ***N-phenylcarbamoyl derivative*** crystallises from aqueous MeOH with **m 202°**. [Gordon & Jackson *J Biol Chem* **110** 151 *1935*, http://www.jbc.org/content/110/1/151.]

Nisin *[1414-45-5]* **$C_{143}H_{230}N_{42}O_{37}S_7$, M 3354.2.** This polypeptide from *S. lactis* is purified by crystallisation from 80% (v/v) EtOH and by countercurrent distribution. The synthetic polypeptide antibiotic can also be purified by preparative HPLC and assayed by HPLC on a Nucleosil 3007C_{18} (6 x 250mm) column using a MeCN—0.01M HCl gradient (30-50%), at 2%/minute, and flow rate of 1.5ml/minute to give a retention time of 8.1 minutes; or MeCN—0.3M guanidine-HCl gradient (30-50%), at 2%/minute, and flow rate of 1.5ml/minute to give a retention time of 10.9 minutes. FAB-MS gave the *pseudo*molecular ion m/z at 3352.7 $(M + H)^+$. It is soluble in dilute acid and is stable even on boiling. [Berridge et al. *Biochem J* **52** 529 *1952*, DOI: 10.1042/bj0520529; synthesis by Fukase et al. *Tetrahedron Lett* **29** 795 *1988*, DOI: 10.1016/S0040-4039(00)80212-9.] This polypeptide has 34 amino acids, 8 of which are unusual, having 5 sulfide bridges but no Trp residues [Gross & Morell *J Am Chem Soc* **93** 4634 *1971*, DOI: 10.1021/ja00747a073]. Nisin is used as a food preservative.

Norleucine (α-amino-*n*-caproic acid) *[R(+) 327-56-0, S(-) 327-57-1]* **$C_6H_{13}NO_2$, M 131.2, m 301°(some dec), $[\alpha]_{546}^{20}$ (+) and (-) 28 (c 5, 5M HCl), (+) and (-) 6.26 (c 0.7, H_2O),** *[RS: 616-06-8]* **m 297-300° (sublimes partially at ~280°), pK_1^{25} 2.39** and **pK_2^{25} 9.76 (for *RS*).** Crystallise norleucine from water or aqueous MeOH. ***Note*** that the crystals (shiny leaflets from H_2O) of the **(+)-form are sweet**, whereas those of the **(-)-form are bitter**. The ***(RS)-racemate*** also crystallises as shiny leaflets from H_2O [solubility in (g/100ml) is 1.1 (25°), 2.9 (75°) and 5.2 (100°)], and is slightly soluble in EtOH (0.42 w/w% at 25°). [Huffman & Ingersoll *J Am Chem Soc* **73** 3366 *1951*, DOI: 10.1021/ja01151a111; *Beilstein* **4** III 1386, **4** IV 2628.]

Norvaline (α-amino-*n*-valeric acid, 2-aminopentanoic acid) *[unnatural* D *(R-) 2031-12-9*, *natural* L *(S+) 6600-40-4]* **$C_5H_{11}NO_2$, M 117.2, m 305°(dec), $[\alpha]_{546}^{20}$ (+) and (-) 25 (c 10, 5M HCl), pI 6.04, pK_1^{25} 2.36, pK_2^{25} 9.87 (9.72).** Crystallise *R*- or *S*+ norvaline from aqueous EtOH or water. Crystallise the *RS-racemate* from hot H_2O [solubility at 18° is 1g/10ml] in which it is freely soluble, but is insoluble in most organic solvents. It sublimes unchanged. [Finkbeiner & Stiles *J Am Chem Soc* **85** 616 *1963*, DOI: 10.1021/ja00888a031; Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, **Vol 3** pp 2390-2399 *1961*, *Beilstein* **4** III 1331-1333, **4** IV 128, 2629.]

L-Ornithine (2,5-diaminopentanoic acid) *[70-26-8]* **$C_5H_{12}N_2O_2$, M 132.2, m 140°, $[\alpha]_D^{25}$ +16 (c 0.5, H_2O), pK_1^{20} 2.11, pK_2^{20} 8.39, pK_3^{25} 10.59.** Crystallise L-ornithine from water containing 1mM EDTA (to remove metal ions). An aqueous solution is alkaline since ornithine has an alkylamino chain which is strongly

basic. It is used in the treatment of hyperammonemia. [Perrin *J Chem Soc* 3125 *1958*, DOI: 10.1039/JR9580003125; Rivard *Biochemical Preparations* **3** 97 *1955*, Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, **Vol 3** pp 2477-2491 *1961*, *Beilstein* **4** III 1346, **4** IV 2644.] The ***racemate*** *[616-07-9]* can be purified by dissolving in H_2O, and adding EtOH; its ***monohydrochloride*** *[1069-31-4]* has **m ~233°(dec)** (from MeOH/Et_2O).

L-Ornithine monohydrochloride *[3184-13-2]* **$C_5H_{12}N_2O_2$. HCl, M 168.6, m 230-232°(dec), 233°(dec), 236.5-237.5°(dec), $[\alpha]_D^{25}$ +28.3 (5M HCl).** Likely impurities are citrulline, arginine and D-ornithine. Crystallise the monohydrochloride from water by adding 4 volumes of EtOH and dry it in a vacuum desiccator over fused $CaCl_2$. [Rivard *Biochemical Preparations* **3** 98 *1955*.] The ***dihydrochloride*** *[6211-16-1]* has **m 202-203°** and $[\alpha]_D^{20}$ +18.4 (c 2.3, 6N HCl) after recrystallisation from MeOH/Et_2O [Zaoral & Rudinger *Coll Czech Chem Commun* **24** 1993 *1959*, DOI: org/10.1135/cccc19591993]. [*Beilstein* **4** IV 2644.]

Oxytocin *[50-56-6]* **$C_{43}H_{66}N_{12}O_{12}S_2$, M 1007.2, m dec on heating, $[\alpha]_D^{22}$ -26.2° (c 0.53, N AcOH).** It is a cyclic nonapeptide which is purified by countercurrent distribution between solvent and buffer. It is soluble in H_2O, *n*-BuOH and isoBuOH. [Bodanszky & du Vigneaud *J Am Chem Soc* **81** 2504 *1959*, DOI: 10.1021/ja01519a053; Sakakibara et al. *Bull Chem Soc Jpn* **38** 120 *1965*, DOI: 10.1246/bcsj.38.120; for solid phase synthesis see Bayer & Hagenmyer *Tetrahedron Lett* **9** 2037 *1968*, DOI: 10.1016/S0040-4039(00)89739-7.] It was also synthesised on a solid phase matrix and finally purified as follows: A Sephadex G-25 column is equilibrated with the aqueous phase of a mixture of 3.5% AcOH (containing 1.5% of pyridine)/*n*-BuOH/*C_6H_6 (2:1:1) and then the organic phase of this mixture is run through. A solution of oxytocin (100mg) in H_2O (2ml) is applied to the column which is then eluted with the organic layer of the above mixture. The fractions containing the major peak [as determined by the Folin-Lowry protein assay: Fryer et al. *Anal Biochem* **153** 262 *1986*, DOI: 10.1016/0003-2697(86)90090-4] are pooled, diluted with twice their volume of H_2O, evaporated to a small volume and lyophilised to give oxytocin as a pure white powder (20mg, 508 U/mg). [Ives *Can J Chem* **46** 2318 *1968*, DOI: 10.1139/v68-378; *Beilstein* **22** III/IV 82.] It is a pituitary hormone which is the main stimulant for uterine contraction in pregnancy and for lactation. This hormone elicits affectionate feelings.

***dl*-Phenylalanine** *[150-30-1]* **$C_9H_{11}NO_2$, M 165.2, m 265-266°(capillary, dec), 271-273°(dec), 282-284°(dec), pK_1^{25} 2.58, pK_2^{25} 9.24.** *dl*-Phenylalanine crystallises from H_2O or H_2O/EtOH in large plates and is dried under vacuum over P_2O_5. [Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, **Vol 3** pp 2156-2175 *1961*, *Beilstein* **14** III 1229, **14** IV 1553.]

L(*S*)-Phenylalanine *[63-91-2]* **$C_9H_{11}NO_2$, M 165.2, m 280°(dec), 281-183°(dec), $[\alpha]_D^{25}$ -34.0 (c 2, H_2O).** Likely impurities are leucine, valine, methionine and tyrosine. Crystallise L-phenylalanine from water by adding 4 volumes of EtOH. Dry it *in vacuo* over P_2O_5. Also crystallise it from saturated refluxing aqueous solutions at neutral pH, or 1:1 (v/v) EtOH/water solution, or concentrated HCl. It sublimes at 176-184°/0.3mm with 98.7% recovery and ***unracemised*** [Gross & Grodsky *J Am Chem Soc* **77** 1678 *1955*, DOI: 10.1021/ja01611a085]. ***S*-Phenylalanine ethyl ester hydrochloride** *[3182-93-2]* has **m 156-158°** and $[\alpha]_D^{20}$ -7.8 (c 2, H_2O) after crystallisation from EtOH/Et_2O [Billimoria & Cook *J Chem Soc* 2323 *1949*, DOI: 10.1039/JR9490002323; *Beilstein* **14** IV 1556]. [Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, **Vol 3** pp 2156-2175 *1961*, *Beilstein* **14** IV 1552.]

L(*S*)-α-Phenylglycine *[2935-35-5]* **$C_8H_9NO_2$, M 151.2, m 305-310°, 305-308°(capillary, dec), $[\alpha]_D^{20}$ +157 (c 1, N HCl), $[\alpha]_{546}^{25}$ +188 (c 1, M HCl), pK_1^{25} 1.83, pK_2^{25} 4.39 (for *dl*).** Crystallise it from EtOH. [Kaneko *J Chem Soc Jpn* **60** 538 *1939*, Rudman et al. *J Am Chem Soc* **74** 551 *1952*, DOI: 10.1021/ja01122a083; Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, **Vol 3** pp 2694-2697 *1961*, *Beilstein* **14** III 1187, **14** IV 1317; Fieser **17** 278.] The **D(*R*)-*enantiomer*** *[875-74-1]* has similar properties but a negative optical rotation. The ***racemate*** *[69-91-0]* sublimes at ~255° without melting. [Steiger *Org Synth* Coll Vol **3** 84 *1955*, DOI: 10.15227/orgsyn.022.0023.]

Phenylglycine-*o*-carboxylic acid [*N*-(2-carboxyphenyl)glycine] *[612-42-0, 64241-57-2 Me Ester, 67990-19-6 mono-Na Salt, 71807-57-3 di-Na Salt]* **$C_9H_9NO_4$, M 195.2, m 206°, 208°, 218°(dec), 220°, pK_1^{20} 5.44**

(CO_2H), pK_2^{20} 6.96 (CO_2H) (in 50% aqueous dioxane). It is prepared by boiling under reflux a solution containing anthranlic acid (14g), chloroacetic acid (10g) and anhydrous Na_2CO_3 (20g) in H_2O (200ml) for 3 hours, then adjusted to pH~2 with concentrated HCl, and set aside overnight. The acid which precipitates is filtered off, washed well with cold H_2O, dried in air, recrystallised from hot H_2O (charcoal) and dried at 100° (yield 12g, m 208°) Crystallise the acid further from hot water (charcoal) if necessary. It forms complexes with Cu^{2+}, Zn^{2+}, Cd^{2+}, Co^{2+} and Ni^{2+} in aqueous dioxane. [Vogel's Textbook of Practical Organic Chemistry, Third edition, 1961, p. 980; Roileanu et al. *Rev Roumaine Chim* **12** 105 *1967*, Krause et al. D-Pipecolinic acid (*R*-piperidine-2-carboxylic acid) *[1723-00-8]* **$C_6H_{11}NO_2$, M 129.2, m 264°(dec), 267°(dec), ~280°(dec), $[\alpha]_D^{19}$ +26.2 (c 2, H_2O), $[\alpha]_D^{25}$ +35.7 (H_2O), pK_1^{20} 2.29 (CO_2H), pK_2^{20} 10.77 (NH^+).** D-Pipecolinic acid recrystallises as platelets from EtOH and is soluble in H_2O. The ***hydrochloride*** has **m 256-257°(dec)** from H_2O and $[\alpha]_D^{25}$ +10.8 (c 2, H_2O). [Lukés et al. *Coll Czech Chem Commun* **22** 286 *1957*, DOI: org/10.1135/cccc19570286; Bayerman *Recl Trav Chim Pays-Bas* **78** 134 *1959*, DOI: 10.1002/recl.19590780209; Asher et al. *Tetrahedron Lett* **22** 141 *1981*, DOI: 10.1016/0040-4039(81)80170-0; *Beilstein* **22/1** V 220.]

L-Pipecolinic acid (*S*-piperidine-2-carboxylic acid, L-homoproline) *[3105-95-1, 535-75-1 (RS)]* **$C_6H_{11}NO_2$, M 129.2, m 268°(dec), 271°(dec), ~280°(dec), $[\alpha]_D^{20}$ -26 (c 4, H_2O), $[\alpha]_D^{25}$ -34.9 (H_2O).** Recrystallise L-pipecolinic acid from aqueous EtOH, and it sublimes as needles in a vacuum. It is sparingly soluble in absolute EtOH, Me_2CO or $CHCl_3$ but insoluble in Et_2O. The ***hydrochloride*** has **m 258-259(dec**, cryst from MeOH) and $[\alpha]_D^{25}$ -10.8 (c 10, H_2O). [Synthesis from L-lysine: Fuji & Myoshi *Bull Chem Soc Jpn* **48** 1341 *1975*, DOI: 10.1246/bcsj.48.1341; synthesis of racemate: Shuman *J Org Chem* **55** 738 *1990*, DOI: 10.1021/jo00289a058; *Beilstein* **22/1** V 220.] This is a metabolite of lysine and is observed in pipecolic acidemia, a cerebro-hepato-renal syndrome in the onset of neonatal adrenoleukodystrophy which is an infantile Refsum disease (build-up of phytanic acid causing ataxia, scaly skin, difficulty in hearing and eye problems).

Piperidine-4-carboxylic acid (isonipecotic acid) *[498-94-2]* **$C_6H_{11}NO_2$, M 129.2, m 336°(dec, darkens at ~300°), p$K_{Est(1)}$~ 4.3 (CO_2H), p$K_{Est(2)}$~ 10.6 (NH^+).** It crystallises from H_2O or EtOH as needles. The ***hydrochloride*** crystallises from H_2O or aqueous HCl with **m 293°dec** (also **298°dec, 300°dec**). The ***amide*** *[39546-32-2]* **$C_6H_{11}N_2O$, M 128.2**, has **m 145-148°**. [Wibaut *Recl Trav Chim Pays-Bas* **63** 141 *1944*, DOI: 10.1002/recl.19440630704; IR: Zacharius et al. *J Am Chem Soc* **76** 2908 *1954*, DOI: 10.1021/ja01640a015; *Beilstein* **22/1** V 244.]

Polypeptides. These are strings of α-amino acids usually with the ***natural*** *S*(L) [L-cysteine is an exception and has the *R* absolute configuration, because of the *sequence rule*] or sometimes '***unnatural***' *R*(D) configuration (much less common) at the α-carbon atom. They generally have less than ~100 amino acid residues. They can be naturally occurring or, because of their small size, can be synthesised chemically from the desired amino acids. Their properties can be very similar to those of small proteins. Many are commercially available, and can be custom made commercially or locally with a peptide synthesiser. They are purified by HPLC and can be used without further purification. Their purity can be checked as described under proteins (Introduction).

L-Proline *[147-85-3]* **$C_5H_9NO_2$, M 115.1, m 215-220°(dec) (D-isomer), 220-222°(dec) (L-form), 205°(dec)(DL-isomer), $[\alpha]_D^{20}$ -53 (c 0.6, 0.5N HCl), -93 (c 2.4, 6N KOH) for L-isomer), pI 6.3, pK_1^{25} 1.95, pK_2^{25} 10.64.** A likely impurity is hydroxyproline. Purify L-proline *via* its ***picrate*** which is crystallised twice from water, then decomposed with 40% H_2SO_4. The picric acid is extracted with diethyl ether, the H_2SO_4 in solution is precipitated with $Ba(OH)_2$, and the filtrate is evaporated. The residue is then recrystallised from hot absolute EtOH [Mellon & Hoover *J Am Chem Soc* **73** 3879 *1951*, DOI: 10.1021/ja01152a095] or EtOH/Et_2O. Its solubility in H_2O is >100%. It sublimes at 182-187°/0.3mm with 99.4% recovery and ***unracemised*** [Gross & Gradsky *J Am Chem Soc* **77** 1678 *1955*, DOI: 10.1021/ja01611a085]. It is ***hygroscopic*** and is stored in a desiccator. [Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, **Vol 3** pp 2178-2199 *1961*, *Beilstein* **22** III/IV 8, **22/1** V 31.]

L-Prolylglycine *[2578-57-6]* **$C_7H_{12}N_2O_3$, M 172.2, m 236°, $[\alpha]_D^{20}$ +21.1 (c 4, H_2O), pK_1^{25} 3.19, pK_2^{25} 8.97.** Recrystallise L-prolylglycine from water at 50-60° by addition of EtOH. [Appel et al. *Chem Ber* **108** 2680 *1975*, DOI: 10.1002/cber.19751080825; Rydon & Smith *J Chem Soc* 3642 *1956*, DOI: 10.1039/JR9560003642.]

L-Propargylglycine (*S*-2-aminopent-4-ynoic acid) *[23235-01-0]* **$C_5H_7NO_2$, M 113.1, m 230°(dec starting at 210°), $[\alpha]_D^{20}$ -35 (c 1, H_2O), -4° (c 5, 5N HCl), $pK_{Est(1)}$~ 2.3 (CO_2H), $pK_{Est(2)}$~ 9.8 (NH_2).** The acid crystallises readily when ~4g in 50ml H_2O are treated with absolute EtOH at 4°/3 hours, and is collected, washed with cold absolute EtOH and Et_2O and dried in a vacuum. Also, it recrystallises from aqueous Me_2CO, R_F on SiO_2 TLC plates with *n*-BuOH/H_2O/AcOH (4:1:1) is 0.26. The ***racemate*** has **m 238-240°**. [Leukart et al. *Helv Chim Acta* **59** 2181 *1976*, DOI: 10.1002/hlca.19760590629; Eberle & Zeller *Helv Chim Acta* **68** 1880 *1985*, DOI: 10.1002/hlca.19850680711; Jansen et al. *Recl Trav Chim Pays-Bas* **88** 819 *1969*, DOI: 10.1002/recl.19690880707.] It is a suicide inhibitor of γ-cystathionase and other enzymes [Washtien & Abeles *Biochemistry* **16** 2485 *1977*, DOI: 10.1021/bi00630a026; Shinozjika et al. *Eur J Biochem* **124** 377 *1982*, DOI: 10.1111/j.1432-1033.1982.tb06603.x].

***R*-Pyroglutamic acid (5-oxo-D-proline, *R*-2-pyrrolidone-5-carboxylic acid)** *[4042-36-8]* **$C_5H_7NO_3$, M 129.1, m 156-158°, $[\alpha]_D^{20}$ +11.2 (c 1, H_2O).** Purify *R*-pyroglutamic acid by dissolving it in H_2O, filtering, passing the filtrate through Dowex 50 (H^+ form), washing with H_2O, pooling washings, evaporating, removing H_2O azeotropically with Me_2CO and $*C_6H_6$, washing the residue with Et_2O and recrystallising from EtOH/petroleum ether. [Pradeles et al. *Coll Czech Chem Commun* **42** 79 *1977*, DOI: org/10.1135/cccc19770079; *Beilstein* **22/6** V 7.]

S*-Pyroglutamic acid (5-oxo-L-proline)** *[98-79-3]* **$C_5H_7NO_3$, M 129.1, m 156-158°, 162-164°, $[\alpha]_{546}^{20}$ -11 (c 5, H_2O), pK^{25} 12.7 (by electron spin resonance).** Crystallise *S*-pyroglutamic acid by dissolving it in boiling EtOH (20g in 100ml), cooling and after a few minutes adding petroleum ether (b 40-60°, 120ml), then after 5 minutes adding a further 120ml, and cooling to room temperature with 90% recovery. This has **m 155.5-157.5°** and $[\alpha]_D^{20}$ -11.4 (c 4.4, H_2O) [Hardy *Synthesis* 290 *1978*, DOI: 10.1055/s-1978-24726; Pellegata et al. *Synthesis* 614 *1978*, DOI: 10.1055/s-1978-24834]. The *NH_4* salt has **m 184-186°** (from EtOH). [*Beilstein* **22/6** V 7.] The ***racemate *[149-87-1]*, purified in the same way, has **m 183-185°**.

Quisqualic acid (Quis, 3-[3,5-dioxo-1,2,4-oxadiazolin-2-yl]-L-alanine) *[52809-07-1]* **$C_5H_7N_3O_5$, M 189.1, m 190-191°, $[\alpha]_D^{20}$ +17 (c 2, 6M HCl), $pK_{Est(1)}$~ 2.1 (CO_2H), $pK_{Est(2)}$~ 8.9 (NH_2).** It has been purified by ion-exchange chromatography on Dowex 50W (x 8, H^+ form); the desired fractions are lyophilised and recrystallised from H_2O/EtOH. It has IR (KBr) with ν_{max} at 3400—2750br, 1830s, 1775s, 1745s and 1605s cm^{-1}; and ^1H NMR (NaOD/D_2O, pH 13) δ: 3.55-3.57 (1H m, X of ABX, H-2), 3.72-3.85 (2H, AB of ABX, H-3), ^{13}C NMR (D_2O) δ: 50.1(t), 53.4(d), 154.8(s), 159.7(s) and 171.3(s). [Baldwin et al. *JCS Chem Commun* 256 *1985*, DOI: 10.1039/C39850000256.] It is an excitatory amino acid agonist for the quisqualate receptor [Joels et al. *Proc Natl Acad Sci USA* **86** 3404 *1989*, PubMed ID2470102], acts on **AMPA** receptors and group I metabotrophic glutamate receptors [Porter et al. *Br J Pharmacol* **106** 509 *1992*, PMCID: PMC1907545]; and sensitises neurons in the hippocampus (CA-1 pyramidal neurons) to depolarisation by L-AP6 (L-2-amino-6-phosphonohexanoic acid), the so called ***'quis'*** effect [Schulte et al. *Brain Res* **649** 203 *1994*, DOI:10.1016/0006-8993(94)91065-0; Littman et al. *Neuropharmacology* **34** 829 *1995*, DOI:10.1016/0028-3908(95)00070-M].

Sarcosine (N-methylglycine) *[107-97-1]* **$C_3H_7NO_2$, M 89.1, m 2 12-213°(dec), pK_1^{20} 2.12, pK_2^{20} 10.19.** Crystallise sarcosine from absolute EtOH, 95% EtOH or H_2O. It sublimes at 180-185°/0.3mm with 99.1% recovery [Gross & Gradsky *J Am Chem Soc* **77** 1678 *1955*, DOI: 10.1021/ja01611a085]. [Cocker & Harris *J Chem Soc* 1290 *1940*, DOI: 10.1039/JR9400001290; Cocker & Lapworth *J Chem Soc* 1897 *1931*, DOI: 10.1039/JR9310001894; Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, **Vol 3** p 2750 *1961*, *Beilstein* **4** III 1121, **4** IV 2363.]

Sarcosine anhydride (1,4-dimethylpiperazin-2,5-dione) *[5076-82-4]* **$C_6H_7N_2O_2$, M 142.2, m 146-147°,**

148°, $pK_{Est(1)}$ ~ -4.2, $pK_{Est(2)}$~-1.9. Crystallise the anhydride from H_2O, EtOH or EtOAc. Dry it in a vacuum at room temperature. [Karrer et al. *Helv Chim Acta* **5** 140 *1922*, DOI: 10.1002/hlca.19220050115; *Beilstein* **24** II 144, **24** IV 1072.]

Seleno-DL-methionine (±2-amino-4-methylselanylbutyric acid) *[1464-42-2, 2578-28-1 (±)]* **$C_5H_{11}NO_2Se$, M 196.1, m 265°(dec), 267-269°(dec), 270° (see pKs of methionine).** It crystallises in hexagonal plates from MeOH and H_2O. [Klosterman & Painter *J Am Chem Soc* **69** 2009 *1949*, DOI: 10.1021/ja01200a054.] The ***L-isomer*** *[3211-76-5]* is purified by dissolving it in H_2O, adjusting the pH to 5.5 with aqueous NH_3, evaporating to near-dryness, and the residue is washed several times with absolute EtOH till a solid is formed and then recrystallise from Me_2CO. It has **m 266-268°(dec)** [also **275°(dec)**], and $[\alpha]_D^{25}$ +18.1(c 1, N HCl), $[\alpha]_D^{22}$ +21.6 (c 0.5, 2N HCl). [Pande et al. *J Org Chem* **35** 1440 *1970*, DOI: 10.1021/jo00830a040; *Beilstein* **4** IV 3216.]

L(*S*)-Serine *[56-45-1]* **$C_3H_7NO_3$, M 105.1, m 228°(dec), 233-235°(dec), $[\alpha]_D^{25}$ +14.5 (1M HCl), $[\alpha]_{546}^{20}$ +16 (c 5, 5M HCl), pK_1^{25} 2.15, pK_2^{25} 9.21.** It is biologically formed from glycine and formaldehyde by the enzyme serinehydroxymethyl transferase. A likely impurity is glycine. Crystallise L-serine from H_2O by adding 4 volumes of EtOH. Dry and store it in a desiccator. It sublimes at 160-170°/0.3mm with 99.7% recovery, and ***unracemised*** [Gross & Gradsky *J Am Chem Soc* **77** 1678 *1955*, DOI: 10.1021/ja01611a085]. [Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, **Vol 3** pp 2202-2235 *1961*, *Beilstein* **4** IV 3118; Fieser **12** 430. **14** 282.] ***D(R)-Serine*** *[312-84-5]* is physiologically active as a mimic at the strychnine-intensive glycine binding site associated with the NMDA (*N-methyl*-D-*aspartate*) receptor site and the inhibitory post-synaptic glycine receptor.

Somatostatin *[38916-34-6]* **$C_{76}H_{104}N_{18}O_{19}S_2$, M 1637.9, $[\alpha]_D^{25}$ -36 (c 0.57, 1% AcOH).** Somatostatin is a tetradecapeptide which is purified by gel filtration on Sephadex G-25, eluting with 2N AcOH, and then by liquid partition chromatography on Sephadex G-25 using *n*-BuOH/AcOH/H_2O (4:1:5) and has R_F = 0.4. It is a brain growth hormone releasing-inhibiting factor which has also been synthesised. [Burgus et al. *Proc Natl Acad Sci USA* **70** 684 *1973*, DOI: 10.1073/pnas.70.3.684; Sarantakis & McKinley *Biochem Biophys Res Commun* **54** 234 *1973*, DOI: 10.1016/0006-291X(73)90913-3; Hartrodt et al. *Pharmazie* **37** 403 *1982*, PMID: 6126893.]

L-Threonine (2*S*,3*R*-2-amino-3-hydroxybutyric acid) *[72-19-5]* **$C_4H_9NO_3$, M 119.1, m 251-253°, 254°(dec), 262-263°(dec), $[\alpha]_D^{26}$ -28.4 (H_2O), pK_1^{25} 2.17, pK_2^{25} 9.00.** Likely impurities are *allo*-threonine and glycine. Crystallise L-threonine from H_2O by adding 4 volumes of EtOH. Dry and store it in a desiccator. It also crystallises from 80% EtOH to give hexagonal plates **m 262-263°(dec)**. It sublimes at 200-226°/0.3mm with 99.6% recovery and ***unracemised*** [Gross & Gradsky *J Am Chem Soc* **77** 1678 *1955*, DOI: 10.1021/ja01611a085]. [Elliot *J Chem Soc* 62 *1950*, Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, **Vol 1** pp 176-183, **Vol 3** pp 2238-2257 *1961*, *Beilstein* **4** IV 3171.] ***D-Threonine* (2*R*,3*S*-2-amino-3-hydroxybutyric acid)** *[632-20-2]* has the same properties but with opposite rotation, and the ***racemate*** *[80-68-2]* has a lower melting point, **m 244°(dec)**; whereas ***L-allo-threonine* (2*S*,3*S*-2-amino-3-hydroxybutyric acid)** *[28954-12-3]* has **m 277°(dec)** and is optically active with $[\alpha]_D^{22}$ +9 (c 2, H_2O). [*Beilstein* **4** IV 3170.]

L-Thyroxine sodium salt ($5H_2O$) *[6106-07-6]* **$C_{15}H_{10}I_4NO_4$ Na. $5H_2O$, M 888.9, $[\alpha]_{546}^{20}$ +20 (c 2, 1M HCl + EtOH, 1:4).** Crystallise the sodium salt from absolute EtOH and dry it for 8 hours at 30°/1mm. [Joel & Canepa *Acta Cryst* **4** 283 *1951*, DOI: 10.1107/S0365110X51000921; *Beilstein* **14** II 378, **14** III 1566, **14** IV 2374.]

D-Thyroxine {*O*-[3,5-diiodo-4-oxyphenyl]-3,5-diiodo-D-(-)-tyrosine, 3,3',5,5'-tetraiodo-D-thyronine} *[51-49-0]* **$C_{15}H_{11}I_4NO_4$, M 776.9, m 235°(dec), 235-236°(dec), 340°(dec), $[\alpha]_D^{20}$ +4.5 (c 3, aqueous 0.2N NaOH in 70% EtOH), $[\alpha]_D^{20}$ -17 (c 2, aqueous N HCl + EtOH 1:4), pK_1^{25} 2.2 (CO_2H), pK_2^{25} 8.40 (OH), pK_3^{25} 10,1 (NH_2).** Recrystallise D-thyroxine from H_2O (needles) or from an ammonical solution by dilution with H_2O, MeOH or Me_2CO. It has also been purified by dissolving ~6.5 g in a mixture of MeOH (200ml) and 2N HCl (20ml), adding charcoal, filtering then adding NaOAc solution to pH 6. On standing the thyroxine separates, it is filtered off, washed with MeOH then Me_2CO and dried *in vacuo*. ***N-Formyl-D-thyroxine*** has

m 210° and $[\alpha]_{546}^{21}$ -26.9 (c 5, EtOH). ***(±)-Thyroxine*** *[300-30-1]* has **m 256°** (**231-233°** also reported) and is purified in the same way. [Siedel & Siedel *Chem Ber* **96** 1 *1963*, DOI: 10.1002/cber.19630960102; Harington & Salter *Biochem J* **24** 456 *1930*, DOI: 10.1042/bj0240456; *Beilstein* **14** I 671, **14** II 384, **14** III 1566, **14** IV 2374.]

L-Thyroxine (*O*-[3,5-diiodo-4-oxyphenyl]-3,5-diiodo-L-(+)-tyrosine, 3,3',5,5'-tetraiodo-L-thyronine, T_4) *[51-48-9]* **$C_{15}H_{11}I_4NO_4$, M 776.9, m 229-230°(dec), ~235°(dec), 237°(dec), $[\alpha]_D^{22}$ -5.1 (c 2, aqueous N NaOH + EtOH 1:2), $[\alpha]_D^{22}$ +15 (c 5, aqueous N HCl in 95% EtOH 1:2), $[\alpha]_D^{22}$ +26 (EtOH/1M aqueous HCl, 1:1) (pK^{25} 6.6).** Purification of this **natural L-*enantiomer*** is the same as for the D-isomer above. Likely impurities are tyrosine, iodotyrosine, iodothyroxines and iodide. Dissolve it in dilute ammonia at room temperature, then crystallise it by adding dilute acetic acid to pH 6. ***N*-Formyl-L-thyroxine** has **m 214°(dec)** and $[\alpha]_{546}^{21}$ +27.8 (c 5, EtOH). [Harington & Pitt Rivers *Biochem J* **39** 157 *1945*, DOI: 10.1042/bj0390157; Siedel & Siedel *Chem Ber* **96** 1 *1963*, DOI: 10.1002/cber.19630960102; Reineke & Turner *J Biol Chem* **161** 613 *1945*, http://www.jbc.org/content/161/2/613, PMID: 21006943; Chalmers et al. *J Chem Soc* 3424 *1949*, DOI: 10.1039/ JR9490003424; *Beilstein* **14** II 378, **14** III 1566, **14** IV 2373.] This **tetra-iodo**-containing hormone T_4, and the related **tri-iodo**-containing hormone T_3, are produced from ***thyroglobin*** in the thyroid follicular cells. The regulation of growth and development, and the metabolic rate of these hormones seems to be due to their effects on DNA transcription, consequently on protein synthesis.

N*-Tosyl-L-lysine chloromethyl ketone HCl (TLCK, 3*S*-1-chloro-3-tosylamino-7-amino-2-heptanone HCl)** *[4272-74-6]* **$C_{14}H_{21}ClN_2O_3S$. HCl, M 369.3, m 150-153°(dec), 156-158°(dec), ~165°(dec), $[\alpha]_D^{20}$ -7.3 (c 2, H_2O), pK_{Est} ~ 10.6 (7-NH_2).** The hydrochloride slowly crystallises from a concentrated solution in absolute EtOH, thinned with EtOH/Et_2O for collection and dried *in vacuo*. TLCK is soluble in H_2O, and a 10mM stock solution is prepared in 1mM HCl, pH 3.0, or in a buffer at pH 6.0 (solutions are unstable above this pH at 25°, thus 48% will decompose in ~5 minutes at pH 9.0). Solutions should be prepared freshly, and effective concentrations are 10-100μM. Solutions of 5mg/100ml in EtOH, and 5mM in Me_2SO, can also be prepared. It is a ***suicide enzyme inhibitor of serine proteases, e.g. trypsin and clostripain. [Matsuda et al. *Chem Pharm Bull Jpn* **30** 2512 *1982*, DOI: org/10.1248/cpb.30.2512; Shaw et al. *Biochemistry* **4** 2219 *1965*, DOI: 10.1021/bi00886a039; improved prep: Shaw & Glover *Arch Biochem Biophys* **139** 298 *1970*, DOI: 10.1016/0003-9861(70)90481-9].

Triglycyl glycine (tetraglycine) *[637-84-3]* **$C_8H_{14}N_4O_5$, M 246.2, m 270-275°(dec), pK_1^{25} 3.21(CO_2H), pK_2^{25} 7.94 (NH_3^+).** Crystallise it from H_2O (optionally, by the addition of EtOH). [Li et al. *J Am Chem Soc* **79** 5859 *1957*, DOI: 10.1021/ja01579a006; Rising et al. *J Am Chem Soc* **56** 1178 *1934*, DOI: 10.1021/ ja01320a057; *Beilstein* **4** II 807, **4** III 1201, **4** IV 2472.]

Trigonellamide chloride (1-methylnicotinamide chloride) *[1005-24-9]* **$C_7H_9ClN_2O$, M 172.6, m 240°(dec).** It crystallises from MeOH, and is dried *in vacuo*. It is prepared from nicotinamide and MeI in refluxing MeOH then shaking with AgCl [Karrer et al. *Helv Chim Acta* **19** 826 *1936*, DOI: 10.1002/hlca.193601901112]. It is soluble in organic solvents but moderately in H_2O. It is a metabolite of nicotinic acid in man, and was isolated from urine [Huff & Perlzweig *J Biol Chem* **150** 395 *1943*, http://www.jbc.org/content/150/2/395]. With ketones in aqueous alkali, it produces a green-blue fluorescence which turns blue on acidification and intensifies on heating. [*Beilstein* **22** III/IV 468, **22/2** V 80.]

3,3',5-Triiodo-*S*-thyronine *[6893-02-3]* **$C_{15}H_{12}I_3NO_4$, M 651.0, m 234-238°, 236-237°(dec), $[\alpha]_D^{29.5}$ +21.5 (+23.0) (EtOH/1M aqueous HCl, 2:1, EtOH or 0.1H HCl), pK_1^{25} 6.48, pK_2^{25} 7.62, pK_3^{25} 7.82.** Likely impurities are as in *thyroxine*. Purify it by dissolving in dilute NH_3 at ~20°, then crystallise it by addition of dilute acetic acid to pH 6. *Alternatively*, 35g are purified by dissolving it in a mixture of EtOH (250ml) and 2N NaOH (100ml), then hot 2N HCl is added to the boiling solution until the pH is 4-5. After cooling for a few hours, the solid is filtered off and dried in a vacuum [**m 233-235°(dec)**]. [Chambers et al. *J Chem Soc* 2424 *1949*, DOI: 10.1039/JR9490003424; *Beilstein* **14** III 1566, **14** IV 2373.]

***N,N,N*-Trimethyl glycinehydrazide chloride (Girard Reagent T, 2-hydrazino-*N,N,N*-trimethyl-2-oxo-ethanaminium chloride)** *[123-46-6]* **$C_5H_{14}ClN_3O$, M 167.6, m 188-192°(dec), 192°.** It is prepared by

reacting ethyl chloroacetate with Me_3N to form $(Me_3NCH_2CO_2Et)^+ Cl^-$ followed by reaction with hydrazine. It is purified by crystallisation from absolute EtOH (slight decomposition) until it has only a slight odour. Store it in well-stoppered containers because it is very ***hygroscopic***. It is very soluble in H_2O, AcOH and glycerol but slightly soluble in EtOH (0.66%). It forms water-soluble hydrazones with carbonyl compounds, and is used to purify them by allowing impurities in the aqueous solution to be extracted out. The carbonyl compounds are then recovered from the hydrazones. By replacing Me_3N by pyridine, the pyridine analogue *Girard P* is obtained which works in the same way. [*Beilstein* **4** III 1133; Fieser **1** 410.]

***N*-Tris-(hydroxymethyl)methylglycine (TRICINE)** *[5704-04-1]* **$C_6H_{13}NO_5$, M 179.2, m 186-188°(dec), pK_1^{20} ~2.3, pK_2^{20} 8.15.** Crystallise Tricine from EtOH and water. It is a good buffer in the pH range 7.4—8.8. [Good et al. *Methods Enzymol* **24B** 53 *1968*, McGlothlin & Jordan *Analyt Lett* **9** 245 *1976*, DOI: 10.1080/ 00032717608059100; *Beilstein* **18** III/IV 3454.]

L(*S*)-Tryptophan *[73-22-3]* **$C_{11}H_{12}N_2O_2$, M 204.3, m 278°, 281-282°, 290°, $[\alpha]_D^{20}$ -33.4 (EtOH), $[\alpha]_{546}^{20}$ -36 (c 1, H_2O), $[\alpha]_D^{28}$ +28 (c 2.1, 10% HCl), pK_1^{25} -6.23 (aqueous H_2SO_4), pK_2^{25} 2.46, pK_3^{25} 9.41, pK_4^{25} 14.82 (acidic NH, in aqueous NaOH).** Crystallise L-tryptophan from H_2O/EtOH, wash it with anhydrous diethyl ether and dry it at room temperature in a vacuum over P_2O_5. It sublimes at 220-230°/0.03mm with 99% recovery and ***unracemised*** [Gross & Gradsky *J Am Chem Soc* **77** 1678 *1955*, DOI: 10.1021/ja01611a085]. [Cox & King *Org Synth* Coll Vol **2** 612 *1943*, DOI: 10.1227/orgsyn.010.0100; Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, **Vol 3** pp 2368-2377*1961*, *Beilstein* **4** IV 2659.] The ***racemate*** sublimes without melting, but decomposes at ~298°(very rapid heating in a sealed capillary), and has similar solubilities as the optically active isomers.

PROTEINS, ENZYMES, DNA and RNA

Abrin A and C (agglutinins from *Abrus seeds*) *[1393-62-0]* **M_r 63,000-67,000.** These are toxic lectins (proteins) from seeds of *Abras precatorius*. The yellow-white powder is purified by successive chromatography on DEAE-Sephadex A-50, carboxymethylcellulose, and DEAE-cellulose. Abrin A is more positively charged on the DEAE-cellulose column and has been crystallised from $(NH_4)_2SO_4$ by the free interface diffusion technique. Its molecular weight (by sedimentation equilibrium) is 60,000, whereas Abrin C has molecular weight of 63,800. Treatment of A with mercaptoethanol at 100º/2 hours followed by SDSPAGE gave a main band with M_r 32,000 and two very weak bands, whereas C (which is more toxic) gave two intense bands with M_r 28,000 and 33,000. [Wei et al. *J Biol Chem* **249** 3061 *1974*, PMID: 4830236.] Abrin C has been crystallised for X-ray analysis by the free interface diffusion technique described by Salemme [*Arch Biochem Biophys* **151** 533 *1972*, DOI: 10.1016/0003-9861(72)90530-9]. The crystals were grown at 37º in Pyrex tubes (5 x 30 cm) by layering 50µl of protein solution (22mg/ml) over 100µl of unbuffered 70% saturated $(NH_4)_2SO_4$ [Wei & Einstein *J Biol Chem* **249** 2985 *1974*, PMID: 4828333.] [UV and CD: Herrmann & Behnke *Biochim Biophys Acta* **621** 43 *1980*, DOI: 10.1016/0005-2795(80)90060-4; for physical and chemical properties see Herrmann & Behnke *Biochim Biophys Acta* **667** 397 *1981*, DOI: 10.1016/0005-2795(81)90206-3; for the crystal structure of Arbin-A see Tahirov et al. *J Mol Biol* **250(3)** 354 *1995*, DOI: 10.1006/jmbi.1995.0382, PMID: 7608980; *Beilstein* **22** III/IV 6776.] The median toxic dose for humans is in the range 10 to 1000 µg/Kg [Johnson et al. *J Analyt Toxicol* **33** 77 *2009*, http://jat.oxfordjournals.org/content/33/2/77.full.pdf; Gill *Microbiological Reviews* **46** (1): 86–94 *1982*, PMC 373212, PMID: 6806598].

Acetoin dehydrogenase [from beef liver, acetoin NAD oxidoreductase] *[9028-49-3]* **M_r 76000, [EC 1.1.1.5].** Purify it *via* the acetone cake, then Ca-phosphate gel filtration (unabsorbed), lyophilised and then fractionated through a DEAE-22 cellulose column. The Km for ***diacetyl*** is 40µM, and for ***NADH*** it is 100µM in phosphate buffer at pH 6.1. [Burgos & Martin *Biochim Biophys Acta* **268** 261 *1972*, DOI: 10.1016/0005-2744(72)90321-X; **289** 13 *1972*, DOI: 10.1016/0005-2744(72)90102-7.]

β-D-*N*-Acetylglucosaminidase [from *M sexta* insects] *[9012-33-3]* **M_r ~61,000 [EC 3.2.1.52].** Purify it by chromatography on DEAD-Biogel, hydroxylapatite chromatography and gel filtration through Sephacryl S200. Two isoforms: a ***hexosaminidase*** EI with Km 177µM (V_{max} 328 sec^{-1}) and EII a ***chitinase*** with Km 160µM (V_{max} 103 sec^{-1}) with 4-nitrophenyl-β-acetylglucosamine as substrate. [Dziadik-Turner et al. *Arch Biochem Biophys* **212** 546 *1981*, DOI: 10.1016/0003-9861(81)90398-2.]

β-D-*N*-Acetylhexosaminidase A and B (from human placenta) *[9012-33-3]* **M_r ~61,000, [EC 3.2.1.52].** Purify it by Sephadex G-200 filtration and DEAE-cellulose column chromatography. The hexosaminidase A is further purified by DEAE-cellulose column chromatography, followed by an ECTEOLA-cellulose column, Sephadex-200 filtration, electrofocusing and Sephadex G-200 filtration. Hexosaminidase B is purified by a CM-cellulose column, electrofocusing and Sephadex G-200 filtration. [Srivastava et al. *J Biol Chem* **249** purification 2043, http://www.jbc.org/content/249/7/2043, PMID: 4818822; for kinetics see p2049, http://www.jbc.org/content/249/7/2049, PMID: 4818822; for biochemical genetics see p2054 http://www.jbc.org/content/249/7/2054, PMID: 4206549; *1974*.]

***N*-Acetyl neuraminic acid aldolase [from *Clostridium perfringens, N*-acetylneuraminic acid pyruvate lyase]** *[9027-60-5]* **M_r 32,000 [EC 4.1.3.3].** Purify the aldolase by extraction with H_2O, protamine precipitation, $(NH_4)_2SO_4$ fractionation, Me_2CO precipitation, acid treatment at pH 5.7 and precipitation at pH 4.5. The equilibrium constant for pyruvate + *n*-acetyl-D-mannosamine $\rightleftharpoons$ *N*-acetylneuraminidate at 37º is 0.64. The Km for *N*-acetylneuraminic acid is 3.9mM in phosphate at pH 7.2 and 37º. [Comb & Roseman *Methods Enzymol* **5** 391 *1962*, DOI: 10.1016/S0076-6879(62)05246-5.] The enzyme from hog kidney (cortex) has been purified 1700-fold by extraction with H_2O, protamine sulfate precipitation, $(NH_4)_2SO_4$ fractionation, heating between 60-80º, a second $(NH_4)_2SO_4$ fractionation and starch gel electrophoresis. The Km for *N*-acetylneuraminic acid is 1.5mM. [Brunetti et al. *J Biol Chem* **237** 2447 *1962*, http://www.jbc.org/content/237/8/2447, PMID: 13874013.]

Acyl-coenzyme A Synthase [from beef liver] *[9013-18-7]* **M_r 57,000 [EC 6.2.1.2].** Purify the synthase by extraction with sucrose/HCO_3 buffer, protamine sulfate precipitation, $(NH_4)_2SO_4$ (66-65%) fractionation (pH 4.35) and a second $(NH_4)_2SO_4$ (35-60%) fractionation (pH 4.35). It has Km 0.15mM (V_{rel} 1.0) for octanoate and 0.41mM (V_{rel} 2.37) for heptanoate. The Km for ATP is 0.5mM, all at pH 9.0 in ethylene glycol buffer at 38º. [Mahler et al. *J Biol Chem* **204** 453 *1953*, http://www.jbc.org/content/204/1/453, PMID: 13874013; Jencks *Methods Enzymol* **5** 467 *1962*, DOI: 10.1016/S0076-6879(62)05259-3.]

Acyl-coenzyme A Synthase (from yeast) *[9012-31-1]* **M_r ~151,000 [EC 6.2.1.1].** This enzyme has been purified by extraction into phosphate buffer pH 6.8-7.0 containing 2-mercaptoethanol and EDTA, protamine sulfate precipitation, polyethylene glycol fractionation, Alumina γ gel filtration, concentration by $(NH_4)_2SO_4$ precipitation, Bio-Gel A-0.5m chromatography and DEAE-cellulose gradient chromatography. It has Km (apparent) 0.24mM (for acetate) and 0.035mM (for CoA); 1.2 mM for ATP and Mg^{2+} 4.0mM. [Frenkel & Kitchens *Methods Enzymol* **71** 317 *1981*. DOI: 10.1016/0076-6879(81)71040-1]

ADP-Ribosyl transferase (adenylyl transferase, polynucleotide, from human placenta) *[9026-30-6]* **M_r~115,000 [EC 2.4.2.30].** Purify the transferase by making an affinity absorbent for ADP-ribosyltransferase by coupling 3-aminobenzamide to Sepharose 4B. [Burtscher et al. *Anal Biochem* **152** 285 *1986*, DOI: 10.1016/0003-2697(86)90410-0]

Agglutinin (from peanuts) [*Arachis hypogaea*] *[1393-62-0]* **M_r 134,900 (tetramer).** Agglutinin is purified by affinity chromatography on Sepharose-ζ-aminocaproyl-ß-D-galactopyranosylamine. [Lotan et al. *J Biol Chem* **250** 8518 *1975*, http://www.jbc.org/content/250/21/8518, PMID: 811657.]

Albumin (bovine and human serum) *[9048-46-8 (bovine), 70024-90-7 (human)]* **M_r ~67,000 (bovine), 69 000 (human), UV: $A^{1\%}_{280nm}$ 6.6 (bovine) and 5.3 (human) in H_2O, $[\alpha]^{25}_{546}$ -78.2º (H_2O).** Albumin is purified by dissolving it in conductivity water and passage at 2-4º through two ion-exchange columns, each containing a 2:1 mixture of anionic and cationic resins (Amberlite IR-120, H-form, Amberlite IRA-400, OH^-form). This treatment removes ions and lipid impurities. Care is taken to exclude CO_2, and the solution is stored at -15º. [Möller et al. *Trans Faraday Soc* **57** 312 *1961*, DOI: 10.1039/TF9615700312.] More complete lipid removal is achieved by lyophilising the de-ionised solution, covering the dried albumin (human serum) with a mixture of 5% glacial acetic acid (v/v) in iso-octane (previously dried with Na_2SO_4) and allowing it to stand at 0º (without agitation) for upwards of 6 hours before decanting and discarding the extraction mixture, washing with iso-octane, re-extracting, and finally washing twice with iso-octane. The purified albumin is dried under vacuum for several hours, then dialyzed against water for 12-24 hours at room temperature, lyophilised, and stored at -10ºC [Goodman *Science* **125** 1296 *1957*, DOI: 10.1126/science.125.3261.1296]. It has been recrystallised in high (35%) and in low (22%) EtOH solutions from Cohn's Fraction V.

The **high EtOH recrystallisation** is as follows: To 1kg of Fraction V albumin paste at -5º is added 300ml of 0.4 M pH (pH 5.5) acetate buffer in 35% EtOH pre-cooled to -10º and 430 ml of 0.1 M NaOAc in 25% EtOH also at -10º. Best results are obtained by adding all of the buffer and about half of the NaOAc and stirring slowly for 1 hour. The rest of the NaOAc is added when all the lumps have disintegrated. The mixture is set aside at -5º for several days to crystallise. 35% EtOH (1 L) is then added to dilute the crystalline suspension and lower the ionic strength prior to centrifugation at -5º (yield 80%). The crystals are further dissolved in 1.5 volumes of 15% EtOH/0.02M NaCl at -5º and clarified by filtration through washed, calcined diatomaceous earth. This solution may be recrystallised by re-adjusting to the conditions in the first crystallisation, or it may be recrystallised at 22% EtOH with the aid of a very small amount of decanol (enough to give a final concentration of 0.02%). ***Note*** that crystallisation from lower EtOH concentration gave better purification (i.e. by removing globulins and carbohydrates) and producing a more stable product.

The **low EtOH recrystallisation** is as follows: To 1kg of Fraction V at -10º to -15º is added 500ml of 15% EtOH at -5º, stirred slowly until a uniform suspension is formed. To the 15% EtOH (500ml) is added sufficient 0.2M $NaHCO_3$ solution (125-150ml) at 0º to bring the pH (1:10 dilution) to 5.3. Some temperature rise occurs, and care must be taken to keep the temperature < -5º. If the albumin is incompletely dissolved a small amount of H_2O is added (100ml at a time at 0º, allowing 15 minutes between additions). Undissolved albumin can be easily distinguished from small amounts of undissolved globulins, or as the last albumin dissolves, the appearance of the solution changes from milky white to hazy grey-green in colour. Keep the solution at -5º for

12 hours and filter by suspending in 15g of washed fine calcined diatomaceous earth, and filtering using a Büchner funnel precoated with coarser diatomaceous earth. The filtrate may require two or more similar filtrations to give a clear solution. To crystallise the filtrate, add through a capillary pipette, and with careful stirring, 1/100volume of a solution containing 10% decanol and 60% EtOH (at -10º), and seed with the needle-like albumin crystals. After 2-3 days, crystallisation is complete. The crystals are centrifuged off. These are suspended with gentle mechanical stirring in one-third their weight of 0.005 M NaCl pre-cooled to 0º. With careful stirring, H_2O (at 0º) is added slowly in an amount equal to 1.7 times the weight of the crystals. At this stage there is about 7% EtOH, and the temperature cannot be made lower than -2.5º to -1º. Clarify, and collect as above. [Cohn et al. *J Am Chem Soc* **69** 1753 *1947*, DOI: 10.1021/ja01199a051.]
Human serum albumin has been purified similarly with 25% EtOH and 0.2% decanol. The isoelectric points of bovine and human serum albumins are 5.1 and 4.9, respectively.

Alamethicin (peptide antibiotic from *Tricoderma viridae*) *[27061-78-5]* **$C_{92}H_{150}N_{22}O_{25}$, M 1964.3, m 259-260º, 275-270º, $[\alpha]_D^{22}$ -45 (c 1.2, EtOH), pK^{25} 6.04 (aqueous EtOH).** Recrystallise alamethicin from MeOH. [MS, ^{13}C NMR and GC on optically active substrate confirms all L- amino acids: Panday et al. *J Am Chem Soc* **99** 8469 *1977*, DOI: 10.1021/ja00468a016.] The ***acetate*** *[64918-47-4]* **$C_{94}H_{152}N_{22}O_{26}$, M 2004,** has **m 195-180º** from MeOH/Et_2O, the ***methyl ester*** has **m 175-176º** (**240-242º**) from $CHCl_3$/Et_2O, and the ***acetate-methyl ester*** *[64936-53-4]* has **m 145-140º** from aqueous MeOH/Et_2O. [Martin & Williams *Biochem J* **153 (2)** 181 *1976*, DOI: 10.1042/bj1530181.]

Angiotensin (from rat brain) *[70937-97-2]* **M_r ~1524.8.** Angiotensin is purified using extraction, affinity chromatography and HPLC [Hermann et al. *Anal Biochem* **159** 295 *1986*, DOI: 10.1016/0003-2697(86)90346-5.]. It is obtained by the action of the '*converting enzyme*' on **angiotensinogen** (see below). The following structures have been identified: ***Angiotensin* I** as Asp-Arg-Val-Tyr-Ile-His-Pro-Phe-His-Lue; ***Angiotensin* II** as Asp-Arg-Val-Tyr-Ile-His-Pro-Phe, and ***Angiotensin* III** as Arg-Val-Tyr-Ile-His-Pro-Phe [Ehlers & Riordan *Biochemistry* **28** 5311 *1989*, DOI: 10.1021/bi00439a001; history of discovery: Basso & Terragno *Hypertension* **38(6)** 1246 *2001*, DOI: 10.1161/hy1201.101214, PMID: 11751697].

Angiotensin-converting enzyme (ACE, *angiotensinase*, peptidyl peptide hydrolase) (from rabbit lung) *[9015-82-1]* **M 129,000 Dal (equilibrium sedimentation), M_r ~140,000 (SDS-PAGE) [EC 3.14.15.1].** Purify ACE by fractionation on DEAE-cellulose, Ca phosphate gel chromatography, elution from Sephadex G-200 and lectin affinity chromatography. The MW varied with glycosidation and is higher by gel filtration. It contains one atom of Zn/mol of protein and has Km values for hydrolysis of hippurylhistidinylleucine and angiotensin I of 2.3 and 0.07 mM, and turnover of 15,430 and 792 mol/min/mol (min^{-1}) at 37º, respectively. The activity is inhibited by EDTA and increased amounts of Ca ions but required Ca ions. [Das & Soffer *J Biol Chem* **250** 6762 *1975*, http://www.jbc.org/content/250/17/6762, PMID: 169257; Reviewed by Ehlers & Riordan *Biochemistry* **28** 5311 *1989*, DOI: 10.1021/bi00439a001.]

Angiotensinogen (from porcine plasma) *[64315-16-8]* **M_r 59,400, 60,000, 62,600, 63,600 depending on sialic acid content.** This rennin substrate is purified 390-fold from the serum by chromatography on Blue Sepharose, phenyl sepharose, hydroxyapatite and finally by affinity chromatography on 5-hydroxytryptamine (5-HT)-sepharose to which it specifically binds to the 5-HT. It is applied to the latter column in 50mM sodium phosphate at pH 7 and after washing, it is eluted by increasing the ionic strength with 100mM sodium phosphate buffer containing 250mM NaCl. The multiple forms (with a tetradecapeptide having various degrees of glycosyltion) are separated by SDSPAGE and have pI 4.40-4.82. [Campbell et al. *Biochem J* **243** 121 *1987*, DOI: 10.1042/bj2430121; *Beilstein* **25** III/IV 4390 *for angiotensin*.]

Avidin (from egg white) *[1405-69-2]* **M_r ~70,000.** Avidin is purified by chromatography of an ammonium acetate solution on CM-cellulose [Green *Biochem J* **101** 774 *1966*, DOI: 10.1042/bj1010774]. It is also purified by affinity chromatography on 2-iminobiotin-6-aminohexyl-Sepharose 4B [Orr *J Biol Chem* **256** 761 *1981*, PMID: 6161128]. It is a biotin-binding protein.

Azurin (from *Pseudomonas aeruginosa*) *[12284-43-4]* **M_r 30,000.** Azurin with $A_{625/280}$ = 0.56 is purified by gel chromatography on G-25 Sephadex with 5mM phosphate pH 7 buffer as eluent [Cho et al. *J Phys Chem* **91**

3690 *1987*, DOI: 10.1021/j100297a046]. It is a blue Cu protein used in biological electron transport, and its reduced form is obtained by adding a slight excess of $Na_2S_2O_4$. [See *Structure and Bonding* Springer Verlag, Berlin **23** 1 *1975*; for blue copper proteins see Rienzo et al. *Protein Sci* **9(8)** 1439 *2000*, DOI: 10.1110/ps.9.8.1439, PMID: 10975566.]

Bromelain (anti-inflammatory Ananase from pineapple) *[37189-34-7]* **M_r ~33,000, [EC 3.4.33.4].** This protease has been purified *via* the acetone powder, G-75 Sephadex gel filtration and Bio-Rex 70 ion-exchange chromatography, and has $A^{1\%}_{1cm}$ 20.1 at 280nm. The protease from pineapple hydrolyses benzoyl glycine ethyl ester with a Km (app) of 210mM and k_{cat} of 0.36 sec^{-1}. [Murachi *Methods Enzymol* **19** 273 *1970*, DOI: 10.1016/0076-6879(70)19021-5; Balls et al. *Ind Eng Chem* **33** 950 *1941*, DOI: 10.1021/ie50379a028.]

Carbonic anhydrase (carbonate hydrolase) *[9001-03-0]* **M_r 31,000 [EC 4.2.1.1].** Purify carbonic anhydrase by hydroxylapatite and DEAE-cellulose chromatography [Tiselius et al. *Arch Biochem Biophys* **65** 132 *1956*, DOI: 10.1016/0003-9861(56)90183-7; Lindskog *Biochim Biophys Acta* **39** 218 *1960*, DOI: 10.1016/0006-3002(60)90156-6], and is then dialysed for crystallisation. A 0.5 to 1% solution of the enzyme in 0.05 M Tris-HCl pH 8.5 is dialysed against 1.75M solution of $(NH_4)_2SO_4$ in the same buffer, and this solution is slowly increased in salt concentration by periodic removal of small amounts of dialysate and replacing with an equal volume of 3.5M $(NH_4)_2SO_4$. The final salt concentration, in which the DEAE-cellulose fractions give beautiful birefringent suspensions of crystals, ranged from 2.4 to 2.7M and appeared first as fine crystals, then underwent transition to thin fragile plates. Carbonic anhydrase is a Zn enzyme which exists as several isoenzymes of varying degrees of activity [Funakoshi & Deutsch *J Biol Chem* **243** 6474 *1968*, PMID: 4973232; for crystal structure see Liljas et al. *Nature, New Biology* **235** 131 *1972*, DOI: 10.1038/newbio235131a0; see also P.D. Boyer Ed. *The Enzymes* Academic Press NY, pp 587-665 *1971*].

Carboxypeptidase A (from bovine pancreas, peptidyl-L-aminoacid lyase) *[11075-17-5]* **M_r 34,600 [EC 3.4.17.1]**. Carboxypeptidase A is purified by DEAE-cellulose chromatography, activation with trypsin and dialysed against 0.1M NaCl, yielding crystals. It is recrystallised by dissolving in 20 ml of M NaCl and dialysed for 24 hours each against the following salts present in 500ml of 0.02M sodium veronal pH 8.0, 0.5M NaCl, 0.2M NaCl and 0.15M NaCl. The last dialysate usually induces crystallisation. If it does not crystallise, then dialyse the last solution against 0.02M sodium veronal containing 0.10M NaCl. Only 2 or 3 recrystallisations are required to attain maximum activity. [Cox et al. *Biochemistry* **3** 44 *1964*, DOI: 10.1021/bi00889a008.] Enzyme activity is measured by hydrolysing hippuryl-L-phenylalanine (or phenylacetic acid) and observing the rate of change of optical density at 254nm (reaction extinction coefficient is ~0.592 cm^2/μmole at pH 7.5) [Bergmeyer *Methods in Enzymatic Analysis* (Academic Press) **1** 436 *1974*, ISBN 10: 0120913011 ISBN 13: 9780120913015].

Cathepsin B (from human liver) *[9047-22-7]* **M_r 27,500 [EC 3.4.22.1].** Cathepsin B is purified by affinity chromatography on the semicarbazone of Gly-Phe-glycinal-linked to Sepharose 4B, with elution by 2,2'-dipyridyl disulfide [Rich et al. *Biochem J* **235** 731 *1986*, DOI: 10.1042/bj2350731; Barrett & Kirschke *Methods Enzymol* **80** 535 *1981,* DOI: 10.1016/S0076-6879(81)80043-2].

Cathepsin D (from bovine spleen) *[9025-26-7]* **M_r 56,000 [EC 3.4.23.5].** Cathepsin D is purified on a CM column after $(NH_4)_2SO_4$ fractionation and dialysis, then starch-gel electrophoresis and by ultracentrifugal analysis. Finally chromatograph on a DEAE column [Press et al. *Biochem J* **74** 501 *1960*, DOI: 10.1042/bj0740501].

Ceruloplasmin (from human blood plasma) *[9031-37-2]* **M_r 134,000.** This blue protein is the principal Cu transporter (up to 90% of circulating Cu) and is purified by precipitation with polyethylene glycol 4000, batchwise adsorption and elution from QAE-Sephadex, and gradient elution from DEAE-Sepharose CL-6B. Ceruloplasmin is thus purified 1640-fold and is homogeneous on anionic polyacrylamide gel electrophoresis

(PAGE), SDS-PAGE, isoelectric focusing and low-speed equilibrium centrifugation. It has λ_{max} at 280, 260nm ($A^{1\%}_{1cm}$ 14.9, 0.68). [Oosthuizen *Anal Biochem* **146** 1 *1985*, DOI: 10.1016/0003-2697(85)90386-0; Cohn et al. *J Am Chem Soc* **68** 459 *1946*, DOI: 10.1021/ja01207a034.]

Chemokines. These are small proteins formed from longer precursors and are chemo-attractants for lymphocytes and lymphoid organs. They are characterised by having cysteine groups in specific relative positions. The two largest families are the α and β families that have four cysteine residues arranged (C-X-C) and (C-C) respectively. The mature chemokines have ~70 amino acids with internal cys S-S bonds and attract myeloid type cells *in vitro*. The γ-family (Lymphotactin) has only two cys residues. The δ-family (Neurotactin, Fractalkine) has the C-C-X-X-X-C sequence (*ca* 387 amino acids), binds to membrane and promotes adhesion of lymphocytes. It is the soluble domain of human Fractalkine 'chemo-attract' monocytes and T cells. Several chemokines are available commercially (some prepared by recombinant DNA techniques), including 6Ckine/exodus/SLC which belongs to the β-family with 6 cysteines (110 amino acids, mature protein), as the name implies (C-C-C-C-X.....X-C-C) and homes lymphocytes to secondary lymphoid organs with lymphocyte adhesion antitumor properties. Other chemokines available are C10 (βCC) and Biotaxin. Several chemokine receptors and antibodies are available commercially and can generally be used without further purification. [Murphy 'Molecular biology of lymphocyte chemo-attractant receptors' in *Ann Rev Immunol* **12** 593 *1994*, DOI: 10.1146/annurev.iy.12.040194.003113.]

Chirazymes. These are commercially available enzymes, e.g. lipases, esterases, that can be used for the preparation of a variety of optically active carboxylic acids, alcohols and amines. They can cause regio and stereospecific hydrolysis and do not require cofactors. Some can be used also for esterification or trans-esterification in neat organic solvents. The proteases, amidases and oxidases are obtained from bacteria or fungi, whereas esterases are from pig liver and thermophilic bacteria. For preparative work the enzymes are covalently bound to a carrier and do not therefore contaminate the reaction products. Chirazymes are available from Roche Molecular Biochemicals or similar biochemicals suppliers, and are used without further purification.

α-Chymotrypsin *[9004-07-3]* **M_r ~25000 [EC 3.4.21.1].** α-Chymotrypsin is crystallised twice from four-tenths saturated ammonium sulfate solution, then dissolved in 1mM HCl and dialysed against 1mM HCl at 2-4°. The solution is stored at 2° [Lang et al. *J Am Chem Soc* **80** 4923 *1958*, DOI: 10.1021/ja01551a041].

Citric acid cycle components (from rat heart mitochondria). These are resolved by anion-exchange chromatography [LaNoue et al. *J Biol Chem* **245** 102 *1970*, PMID: 4312474].

Clostripain *[9028-00-6]* **M_r ~55,000, [EC 3.4.22.8].** Clostripain is isolated from *Clostridium histolyticum* callogenase by extraction in pH 6.7 buffer, followed by hydroxylapatite chromatography with a 0.1-0.2 M phosphate gradient, then Sephadex G-75 gel filtration with 0.05M phosphate pH 6.7, dialysis and a second hydroxylapatite chromatography (gradient elution with 0.1M → 0.3M phosphate, pH 6.7) purification. It has proteinase and esterase activity and is assayed by hydrolysing *N*-benzoyl-L-arginine methyl ester. [Mitchell & Harrington *J Biol Chem* **243** 4683 *1968*, PMID: 4971659; *Methods Enzymol* **19** 635 *1970*, DOI: 10.1016/0076-6879(70)19050-1.]

Colicin E1 (from *E.coli*) *[11032-88-5]* **M_r 56,000, pI 9.5.** Colicin E1 is purified (8.6-fold to Specific Activity of 1.5 x 10^5 units/mg) from *E.coli* JC411 by salt extraction of extracellular-bound colicin followed by $(NH_4)_2SO_4$ (40-60% saturation) fractionation and ion-exchange chromatography on a DEAE-Sephadex A 50 column, and then by CM-Sephadex column chromatography [Schwartz & Helinski *J Biol Chem* **246** 6318 *1971*, PMID: 5001789].

Collagenase (from human polymorphonuclear leukocytes) *[9001-12-1]* **M_r 68,000-125,000 [EC 3.4.24.3].** Collagenase is purified by using *N*-ethylmaleimide to activate the enzyme, and wheat germ agglutinin-agarose affinity chromatography [Callaway et al. *Biochemistry* **25** 4757 *1986*, DOI: 10.1021/bi00365a006].

Copper-zinc-superoxide dismutase (from blood cell haemolysis) *[9054-89-1]* **M_r ~32,000 [EC 1.15.1.1].**

The dismutase is purified by DEAE-Sepharose and copper chelate affinity chromatography. The preparation so achieved is homogeneous by SDS-PAGE, by analytical gel filtration chromatography and by isoelectric focusing [Weselake et al. *Anal Biochem* **155** 193 *1986*, DOI: 10.1016/0003-2697(86)90246-0; McCord & Fridovich *J Biol Chem* **244** 6049 *1969*, PMID: 5389100].

Cytochrome c_1 (from horse, beef or fishes' heart, or pigeon breast muscle) *[9007-43-6]* **M_r ~ 13,000.** Cytochrome c_1 is purified by chromatography on CM-cellulose (CM-52 Whatman) [Brautigan et al. *Methods Enzymol* **53** 128 *1978*, DOI: 10.1016/S0076-6879(78)53021-8]. It has a high PI (isoelectric point) and has been purified further by adsorption onto an acidic cation exchanger, e.g. Amberlite IRC-50 (polycarboxylic) or in ground form Amberlite XE-40 (100-200 mesh) or Decalso-F (aluminium silicate), where the non-cytochrome protein is not adsorbed and is readily removed. The cytochrome is eluted using a solution containing 0.25g ions/L of a univalent cation at pH 4.7 adsorbed onto the NH_4^+ salt of Amberlite IRC-50 at pH 7, washed with H_2O and then with 0.12M NH_4OAc to remove non-cytochrome protein. When the cytochrome begins to appear in the eluate, then the NH_4OAc concentration is increased to 0.25 M. The fractions with *ca* Fe = 0.465—0.467 are collected, dialysed against H_2O and adsorbed onto a small IRC-50 column and eluted with 0.5M NH_3, then dialysed and lyophilised. (A second fraction II can be eluted from the first resin with 0.5M NH_3 but is discarded). [Keilin & Hartree *Biochemical Preparations* **1** 1 *1952*, Margoliash *Biochemical Preparations* **8** 33 *1957*.]

Cytochrome c has been recrystallised as follows: The above eluate (*ca* 100ml) is dialysed against H_2O (10 vols) at 4° for 24 hours (no more), then passed through an XE-40 column (2 x 1 cm above) which is equilibrated with 0.1M NH_4OAc pH 7.0. The column is washed with 0.1% $(NH_4)_2SO_4$ pH 8.0, and the dark red resin in the upper part of the column is collected and in 0.1% $(NH_4)_2SO_4$ pH 8.0 is transferred to another column (7mm diameter) and the cytochrome c is eluted with 5% $(NH_4)_2SO_4$ pH 8.0. More than 98% of the red colour is collected in a volume of *ca* 4ml in a weighed centrifuge tube. Add a drop of octanol and 0.43g of $(NH_4)_2SO_4$/g of solution. When the salt has dissolved, ascorbic acid (5mg) is added as well as a few drops of 30% aqueous NH_3, and it is kept at 10° for 10 minutes (turns lighter colour due to reduction). Then add finely powdered $(NH_4)_2SO_4$ in small portions (stir with a glass rod) until the solution becomes turbid. Stopper the tube tightly, and set aside at 15-25° for 2 days while the cytochrome c separates as fine needles or rosettes. Further $(NH_4)_2SO_4$ (20mg) are added per ml of suspension and kept in the cold for a few days to complete the crystallisation. The crystals are collected by centrifugation (5000xg), suspended in saturated $(NH_4)_2SO_4$ (pH 8.0 at 10°), then centrifuged again. For recrystallisation the crystals are dissolved in the least volume of H_2O, one drop of ammonia and 1 mg of ascorbic acid are added and the above process is repeated. The yield of twice recrystallised cytochrome c from 2Kg of muscle is *ca* 200 mg, but this varies with the source and freshness of the muscle used. The crystals are stored as a solid after dialysis against 0.08M NaCl or 0.1M sodium buffer and lyophilising, or as a suspension in saturated $(NH_4)_2SO_4$ at 0°. [Hagihara et al. *Biochemical Preparations* **6** 1 *1958*.]

Purity of cytochrome c: This is checked by the ratio of the absorbance at 500nm (reduced form) to 280nm (oxidised form), i.e. $\varepsilon_{500}/\varepsilon_{280}$ should be between 1.1 and 1.28, although values of up to 1.4 have been obtained for pure preparations.

For the preparation of the ***reduced form*** see Margoliash *Biochemical Preparations* **5** 33 *1957* and Yonetani *Biochemical Preparations* **11** 19 *1966*.

Cytochrome from *Rhodospirillum rubrum* ($\varepsilon_{270}/\varepsilon_{551}$ 0.967) is purified by chromatography on a column of CM-Whatman cellulose [Paleus & Tuppy *Acta Chem Scand* **13** 641 *1959*, DOI: 10.3891/acta.chem.scand.13-0641].

Cytochrome c oxidase (from bovine heart mitochondria) *[9001-16-5]* **M_r 100,000/haeme [EC 1.9.3.1].** This oxidase is purified by selective solubilisation with Triton X-100 and subsequently with lauryl maltoside, and finally by sucrose gradient centrifugation [Li et al. *Biochem J* **242** 417 *1987*, DOI: 10.1042/bj2420417].

It has also been purified by extraction into 0.02 M phosphate buffer (pH 7.4) containing 2% of cholic acid (an inhibitor which stabilises as well as solubilises the enzyme) and fractionated with $(NH_4)_2SO_4$, collecting the 26-33% saturation cut and refractionating again and collecting the 26-33% saturation fraction. The pellet collected at 10,000xg appears as an oily paste. **The cholate needs to be removed to activate the enzyme as follows**: The precipitate is dissolved in 10ml of 0.1M phosphate buffer pH 7.4, containing 1% of Tween-80 and dialysed against 1L of 0.01 M PO_4 buffer (pH 7.4) containing 1% of Tween-80 for 10 hours at 0° and aliquoted. The enzyme is stable at 0° for 2 weeks and at -15° for several months. It is assayed for purity (see reference) by oxidation of reduced cytochrome c (Km 10μM). [Yonetani *Biochemical Preparations* **11** 14 *1966*, *J Biol Chem*

236 1680 *1961*, PMID: 13787373.]

Cytokines See chemokines, interferons, interleukins.

Deoxyribonucleic acid (from plasmids). These are purified by two buoyant density ultracentrifugations using ethidium bromide-CsCl. The ethidium bromide is extracted with Et_2O, and the DNA is dialysed against buffered EDTA and lyophilised. [Marmur & Doty *J Mol Biol* **5** 109 *1962*, DOI: 10.1016/S0022-2836(62)80066-7; Guerry et al. *J Bacteriol* **116** 1064 *1973*, PMID: 4583233.] See 'Introduction' in this chapter.

Dermatan sulfate (condroitin sulfate B from pig skin) M_r 20,000-36,000 *[54328-33-5 (Na salt)]***.** Dermatan sulfate is purified by digestion with papain and hyaluronidase, and fractionation using aqueous EtOH. [Gifonelli & Roden *Biochemical Preparations* **12** 1 *1968*.]

Dihydrofolate reductase (from *Mycobacterium phlei*) *[9002-03-3]* **M_r ~18,000 [EC 1.5.1.3].** Dihydrofolate reductase is purified by $(NH_4)_2SO_4$ precipitation, then fractionation on a Sephadex G-75 column, applied to a Blue Sepharose column and eluted with 1mM dihydrofolate. [Al- Rubeai & Dale *Biochem J* **235** 301 *1986*, DOI: 10.1042/bj2350301.]

Dihydropteridine reductase (from sheep liver) *[9074-11-7]* **M_r 52,000 [EC 1.6.99.7].** Dihydropteridine reductase is purified by fractionation with ammonium sulfate, dialysed against Tris buffer, adsorbed and eluted from hydroxylapatite gel. It is then run through a DEAE-cellulose column and also subjected to Sephadex G-100 filtration. [Craine et al. *J Biol Chem* **247** 6082 *1972*, PMID: 4405600.]

Dihydropteridine reductase (from human liver) *[9074-11-7]* **M_r 52,000 [EC 1.6.99.7].** Dihydropteridine reductase is purified to homogeneity on a naphthoquinone affinity adsorbent, followed by DEAE-Sephadex and CM-Sephadex chromatography. [Firgaira, Cotton and Danks, *Biochem J* **197** 31 *1981*, DOI: 10.1042/bj1970031.] [For other dihydropteridine reductases see Armarego et al. *Med Res Rev* **4**(3) 267 *1984*, DOI: 10.1002/med.2610040302.]

3,4-Dihydroxyphenylalanine-containing proteins. Boronate affinity chromatography is used in the selective binding of proteins containing 3,4-dihydroxyphenylalanine to a *m*-phenylboronate agarose column and eluted with 1M NH_4OAc at pH 10. [Hawkins et al. *Anal Biochem* **159** 187 *1986*, DOI: 10.1016/0003-2697(86)90326-X.]

Dipeptidyl aminopeptidase (dipeptidyl peptidase IV, from rat brain) *[9031-94-1, 54249-88-6]* **M_r 87,500 (monomer SDS-PAGE), (88,107 from nucleotide sequence), up to 4000,000 [EC 3.4.14.5].** The aminopeptidase is purified about 2000-fold by column chromatography on CM-cellulose, hydroxylapatite and Gly-Pro AH-Sepharose. [Imai et al. *J Biochem (Tokyo)* **93** 431 *1983*, PMID: 6341372; Schomburg & Schomburg *Springer Handbook of Enzymes* 2nd Edn **vol 6** p 286 *2002*.]

DNA (deoxyribonucleic acids). The essential structures of chromosomes are DNA and contain the genetic 'blueprint' in the form of separate genes. They are made up of the four deoxyribonucleic acids (nucleotides): adenylic acid, guanylic acid, cytidylic acid and thymidylic acid (designated A, G, C, T respectively) linked together by their phosphate groups in ester bonds between the 3' and 5' hydroxy groups of the 2'-deoxy-D-ribose moiety of the nucleotides. The chains form a double-stranded spiral (helix) in which the two identical nucleotide sequences run antiparallel with the heterocyclic bases hydrogen bonded (A….T, G….C) forming the 'ladder' between the strands. Short sequences of DNA are available commercially, are commercially custom made or synthesised in a DNA synthesiser and purified by HPLC. Their purity can be checked by restriction enzyme cleavage followed by gel electophoresis, or directly by gel electrophoresis or analytical HPLC. Commercial DNAs are usually pure enough for direct use but can be further purified using commercially available kits involving binding to silica or other matrices and eluting with Tris buffers. There are now rapid 'throughput' techniques for sequencing DNA which are very accurate.

Dopamine-β-hydroxylase (from bovine adrenal medulla) *[9013-38-1]* **M_r ~290,000 [EC 1.14.17.1].** The Cu-containing glycoprotein enzyme has been isolated by two procedures. The **first** is an elaborate method requiring extraction, two $(NH_4)_2SO_4$ fractionations, calcium phosphate gel filtration, EtOH fractionation, DEAE-cellulose chromatography followed by two Sephadex-G200 gel filtrations giving enzyme with a specific activity of 65 Units/mg. [Friedman & Kaufman *J Biol Chem* **240** 4763 *1965*, PMID: 5846992; Rush et al. *Biochem Biophys Res Commun* **61** 38 *1974*, DOI: 10.1016/0006-291X(74)90530-0.] The **second** procedure is much gentler and provides good quality enzyme. Sedimented chromaffin vesicles are lysed in 10 volumes of 5mM K-phosphate buffer pH 6.5 using a loosely fitting Teflon-glass homogeniser. The mixture is centrifuged at 40,000xg/0.5 hours, and the supernatant is diluted with an equal volume of 100mM phosphate buffer (pH 6.5) containing 0.4M NaCl. This lysate is applied to a concanavelin A-Sepharose column (4 x 0.7cm) which has been equilibrated with 50 mM of phosphate buffer (pH 6.5 + 0.2M NaCl) with a flow rate of ~ 0.3 ml/minute. The column is washed thoroughly with the buffer until OD_{280nm} is 0.005. The enzyme is then eluted with the same buffer containing 10% α-methyl-D-mannoside (flow rate 0.1 ml/minute), and the enzyme is collected in 20-column volumes. The pooled eluate is concentrated by ultrafiltration in an Amicon Diaflo stirrer cell using an XM100A membrane. The concentrated enzyme is dialysed against 50mM phosphate buffer (pH 6.5) containing 0.1% NaCl. The enzyme gives one band (+ two very weak bands) on disc gel electrophoresis indicating better than 93% purity (67% fold purification) and has a specific activity of 5.4 Units/mg. [Rush et al. *Biochem Biophys Res Commun* **57** 1301 *1974*, DOI: 10.1016/0006-291X(74)90837-7; Stewart & Klinman *Ann Rev Biochem* **57** 551 *1988,* DOI: 10.1146/annurev.bi.57.070188.003003.]

Exonucleases. Like the endonucleases they are restriction enzymes which act at the 3' or 5' ends of linear DNA by hydrolysing off the nucleotides. Although they are highly specific for hydrolysing nucleotides at the 3' or 5' ends of linear DNA, the number of nucleotides cleaved is time dependent and usually has to be estimated from the time allocated for cleavage. Commercially available exonucleases are used without further purification.

Ferritin (from human placenta) *[9007-73-2]* **M_r ~445,000 (Fe free protein).** The purification of this major iron-binding protein is achieved by homogenisation in water and precipitation with ammonium sulfate, repeating the cycle of ultracentrifugation, and molecular sieve chromatography through a Sephadex 4B column. Isoelectric focusing reveals a broad spectrum of impurities which can be separated by ion-exchange chromatography on Sephadex A-25 and stepwise elution. [Konijn et al. *Anal Biochem* **144** 423 *1985*, DOI: 10.1016/0003-2697(85)90135-6.]

Fibrinogen (from human plasma) *[9001-32-5]* **M_r 341,000.** This protein is made up of 2Aα, 2Bβ and 2γ subunits connected by disulfide bridges. A likely impurity is plasminogen. It is purified by glycine precipitation [Mosesson & Sherry *Biochemistry* ***5*** 2829 *1966*, DOI: 10.1021/bi00873a008] to obtain fractions 1-2, then further purified [Blombäck & Blombäck *Arkiv Kemi* **10** 415 *1956*] and contaminating plasminogen is removed by passage through a lysine-Sepharose column. Such preparations are at least 95% clottable as determined by Mosesson and Sherry's method (above ref.) in which the OD_{280} is measured before and after clotting with 5 Units/ml of thrombin (> 3000U/mg). All fibrinogen preparations are treated with calf intestinal alkaline phosphatase to convert any fibrinogen peptide-AP to fibrinogen peptide-A by removing serine-bound phosphate. Solutions are then lyophilised and stored at -20º. [Higgins & Shafer *J Biol Chem* **256** 12013 *1981*, PMID: 7298640.] For the resolution of polypeptide chains of sulfitolysed fibrinogen by polyacrylamide gel electrophoresis (PAGE) see Takagi & Iwanaga [*Biochim Biophys Acta (Protein Structure)* **194** 594 *1969*, DOI: 10.1016/0005-2795(69)90121-4]. It is sparingly soluble in H_2O. Aqueous solutions are viscous with isoelectric point at pH 5.5. It is readily denatured by heating above 56º or by chemical agents, e.g. salicylaldehyde, naphthoquinone sulfonates, ninhydrin or alloxan. [Edsall et al. *J Am Chem Soc* **69** 2731 *1947*, DOI: 10.1021/ja01203a048; Purification: Cama et al. *Naturwissenschaften* **48** 574 *1961*, DOI: 10.1007/ BF00589726; Lorand & Middlebrook *Science* **118** 515 *1953*, DOI: 10.1126/science.118.3070.515; cf. Fuller in *Methods Enzymol* **163** 474 *1988*, DOI: 10.1016/0076-6879(88)63044-8.]
For plasminogen-deficient fibrinogen from blood plasma, the anticoagulated blood is centrifuged and the plasma is frozen and washed with saline solution. It is treated with charcoal, freeze-thawed and dialysed *versus* Tris/NaCl buffer. [Maxwell & Nikel *Biochemical Preparations* **12** 16 *1968*.]

Fibronectin (from human plasma) *[86088-83-7]* **M_r ~220,000.** This glycoprotein contains 5-12% of carbohydrate. It has been purified by glycine fractionation and DEAE-cellulose chromatography. This material is dissolved in 0.25M Tris-phosphate buffer pH 7.0, diluted to 20% and glycine added gradually till 2.1M when the temperature falls to below 15°. The precipitate contains mainly fibrinogen. The supernatant is discarded, and the precipitate is treated with an equal volume of H_2O, cooled (to 0°) and precipitated by adding EtOH to 16% (v/v) at -4°. The precipitate contains some CI (Cold Insoluble) globulin, fibronectin and small quantities of other proteins. To remove these, the precipitate is dissolved in 0.25M Tris-phosphate buffer (pH 7.0) *ca* 0.5% and purified by DEAE-cellulose chromatography after diluting the buffer to 0.05M buffer. [Morrison et al. *J Am Chem Soc* **70** 3103 *1948*, DOI: 10.1021/ja01189a080; Mosesson & Umfleet *J Biol Chem* **245** 5728 *1970*, PMID: 4097343; Mosesson & Amrani *Blood* **56** 145 *1980*, Akiyama & Yamada *Adv Enzymol* **59** 51 *1987*.]

Follicle Stimulating Hormone (FSH, follitropin) *[9002-68-0]* **M_r ~36,000.** FSH is purified by Sephadex G100 gel filtration followed by carboxymethyl-cellulose with NH_4OAc pH 5.5. The latter separates luteinising hormone from FSH. Its solubility in H_2O is 0.5%. It has an isoelectric point of 4.5. A solution of 1mg in saline (100ml) can be kept at 60° for 0.5 hour. Activity is retained in a solution at pH 7-8 for 0.5 hour at 75°. The activity of a 50% aqueous EtOH solution is destroyed at 60° in 15 minutes. [Bloomfield et al. *Biochim Biophys Acta* **533** 371 *1978*, DOI: 10.1016/0005-2795(78)90383-5; Hartree *Biochem J* **100** 754 *1966*, DOI: 10.1042/bj1000754; Pierce & Parsons *Ann Rev Biochem* **50** 465 *1981*, DOI: 10.1146/annurev.bi.50.070181.002341.]

β-Galatosidase (from bovine testes) *[9031-11-2]* **M_r 510,000 [EC 3.2.1.23].** It is purified 600-fold by $(NH_4)_2SO_4$ precipitation, acetone fractionation and affinity chromatography on agarose substituted with terminal thio-ß-galactopyranosyl residues. [Distler & Jourdian *J Biol Chem* **248** 6772 *1973*, PMID: 4270451.]

Glucose oxidase (from *Aspergillus niger*) *[9001-37-0]* **M_r 186,000 [EC 1.1.3.4].** The oxidase is purified by dialysis against deionized water at 6° for 48 hours and by molecular exclusion chromatography with Sephadex G-25 at room temperature. [Holt & Cotton *J Am Chem Soc* **109** 1841 *1987*, DOI: 10.1021/ja00240a039.]

Glucose-6-phosphate dehydrogenase *[9001-40-5]* **M_r 128,000 (from Baker's yeast), 63,300 (from rat mammary gland) [EC 1.1.1.49].** The enzyme is useful for measuring pyridine nucleotides in enzyme recycling. The enzyme from Baker's yeast has been purified by $(NH_4)_2SO_4$ fractionation, Me_2CO precipitation, a second $(NH_4)_2SO_4$ fractionation, concentration by DEAE-SF chromatography, a third $(NH_4)_2SO_4$ fractionation and recrystallisation. Crystallisation is induced by addition of its coenzyme NADP, which in its presence causes rapid separation of crystals at $(NH_4)_2SO_4$ concentration much below that required to precipitate the amorphous enzyme. To recrystallise, the crystals are dissolved in 0.01M NADP (pH 7.3) with $(NH_4)_2SO_4$ at 0.55 saturation, and the crystals appear within 10 to 60 minutes. After standing for 2-3 days (at 4°) the $(NH_4)_2SO_4$ is increased to 0.60 of saturation, and more than 80% of the activity in the original crystals is recovered in the fresh crystals. [Noltmann et al. *J Biol Chem* **236** 1225 *1961*, PMID: 13729473]. Large amounts can be obtained from rat livers. The livers are extracted with 0.025M phosphate buffer (pH 7.5) and precipitated with 3M $(NH_4)_2SO_4$ (70% of activity). The precipitate is dissolved in 3 volumes of 0.025M phosphate (pH 7.5), dialysed against this buffer + 0.2mM EDTA at 4° for 5 hours, then diluted to 1% protein and the nucleic acids are precipitated by addition of 0.4 volumes of 1% protamine sulfate. $(NH_4)_2SO_4$ is added to a concentration of 2M (pH adjusted to 7.0 with NH_3), the precipitate is discarded and the supernatant is adjusted to 2.8M $(NH_4)_2SO_4$, dialysed, and the protein is adjusted to 1% and treated with $Ca_3(PO_4)_2$ gel. The gel is added in three steps (1.5ml of 0.4% gel/ml per step), and the gel is removed by centrifugation after each addition. The third gel adsorbed 50% of the activity. The gel is eluted with 0.2M phosphate buffer (pH 7.4, 40ml/g of gel; 60% recovery). The extract is precipitated in 3 volumes of $(NH_4)_2SO_4$ (adjusted to 4M) to give enzyme with an activity of 30μmoles/mg of protein per hour. [Lowry et al. *J Biol Chem* **236** 2746 *1961*, PMID: 14466981.] The Km values for the yeast enzyme are 20μM for G-6P and 2μM for NADP (Tris pH 8.0, 10^{-2} M $MgCl_2$, 38°) [Noltmann & Kuby *The Enzymes* **VII** 223 *1963*].

Glutathione S-transferase (human liver) *[50812-37-8]* **M_r 25,000 [EC 2.5.1.18].** It is purified by affinity chromatography using a column prepared by coupling glutathione to epoxy-saturated Sepharose. After washing

off contaminating proteins, the pure transferase is eluted with buffer containing reduced glutathione. The solution is then concentrated by ultrafiltration, dialysed against phosphate buffer at pH ~7 and stored in the presence of dithiothreitol (2mM) in aliquots at <-20°. [Simons & Vander Jagt *Anal Biochem* **82** 334 *1977*, DOI: 10.1016/0003-2697(77)90169-5.]

Glyceraldehyde-3-phosphate dehydrogenase *[9001-50-7]* **M_r 144,000 [EC 1.2.1.12].** Purify the dehydrogenase from rabbit muscle by extraction with 0.03N KOH and precipitate it with $(NH_4)_2SO_4$ (0.52 of saturation). The clear supernatant is adjusted to pH 7.5, and NH_3 is added dropwise to pH 8.2-8.4. Crystals appear sometimes even without seeding. The crystals are dissolved in H_2O, filtered to remove suspended material and 2 volumes of saturated $(NH_4)_2SO_4$ at pH 8.2-8.4 is added. After 1 hour the crystals appear. Recrystallise it in the same way. [Cori et al. *J Biol Chem* **173** 605 *1948*, PMID: 18910716; Furfine & Velick *J Biol Chem* **240** 844 *1965,* PMID: 14275144; *The Enzymes* **7** 243 *1963*, Lui & Huskey *Biochemistry* **31** 6898 *1992*, DOI: 10.1021/bi00145a005.] The Km values are: NADH (3.3μM) and 1,3-diphosphoglycerate ($8x10^{-7}$M) in pH 7.4 imidazole buffer at 26°, NAD (13μM), glyceraldehyde-3-P (90μM), P_i ($2.9x10^{-4}$M), and arsenate (69μM) in 8.6 M $NaHCO_3$ buffer at 26°C. [Orsi & Cleland *Biochemistry* **11** 102 *1972*, DOI: 10.1021/bi00751a018.]

Glycerol kinase (from *Candida mycoderma*, *E coli*, rat or pigeoan liver glycerokinase) *[9030-66-4]* **M_r 251,000 [EC 2.7.1.30].** Commercial enzyme has been dialysed against 2mM Hepes, 5mM dithiothreitol and 0.3mM EDTA, followed by several changes of 20mM Hepes and 5mM dithiothreitol prior to storage under N_2 at -20°. [Knight & Cleland *Biochemistry* **28** 5728 *1989*, DOI: 10.1021/bi00440a005.] The enzyme from pigeon liver is purified by acid-precipitation (acetate buffer at pH 5.1), $(NH_4)_2SO_4$ fractionation, heat treatment (60°/1 hour), calcium phosphate gel filtration, a second $(NH_4)_2SO_4$ fractionation, dialysis, elution of inert proteins and crystallisation. This is done by repeatedly extracting the precipitate from the last step with 0.05M sodium pyrophosphate (pH 7.5) containing 1mM EDTA, and 0.2M $(NH_4)_2SO_4$ is added. Careful addition of solid $(NH_4)_2SO_4$ to this solution leads to crystallisation of the enzyme. Recrystallisation is repeated. The enzyme is activated by Mg^{2+} and Mn^{2+} ions and is most stable in solutions in the pH 4.5-5.5 range. The stability is greatly increased in the presence of glycerol. It has Km for glycerol is 60μM, and for ATP is 9μM in glycine buffer pH 9.8 and 25°. [Kennedy *Methods Enzymol* **5** 476 *1962*, DOI: 10.1016/S0076-6879(62)05261-1.]

L-Glycerol-3-phosphate dehydrogenase (GDH, from rabbit muscle) *[9075-65-4]* **M_r 78,000 [EC 1.1.1.8].** The dehydrogenase is recrystallised by adding $(NH_4)_2SO_4$ to 0.45 saturation at pH 5.5 at 4°C, and the small amount of precipitate is removed, then a saturated solution of $(NH_4)_2SO_4$ is added dropwise from time to time over several days in the cold room. The crystals are collected and recrystallised until they have maximum activity. The enzyme is stable in half-saturated $(NH_4)_2SO_4$ for several weeks at 4°. The equilibrium [dihydroxyacetone][NADH][H^+]/[G-3-P][NAD] is 1.0 x 10^{-12}M in Tris buffer at 25°. It uses NAD ten times more efficiently than NADP. The Km for G-3-P is 1.1 x 10^{-4}M, for NAD it is 3.8 x 10^{-4}M and for dihydroxyacetone it is 4.6 x 10^{-4}M in phosphate buffer pH 7.0 and at 23.3°. Dihydroxyacetone phosphate and fructose-1,6-diphosphate are inhibitors. [Baranowski *J Biol Chem* **180** 535 *1949*, PMID: 18135786; *The Enzymes* **7** 85 *1963*, Young & Pace *Arch Biochem Biophys* **75** 125 *1958*, DOI; 10.1016/0003-9861(58)90403-X; Walsh & Sallach *Biochemistry* **4** 1076 *1965*, DOI: 10.1021/bi00882a015.]

Glycogen synthase (from bovine heart) *[9014-56-6]* **M_r 60,000 [EC 2.4.1.11].** Purify the synthase by precipitation in the presence of added glycogen with polyethylene glycol, chromatography on DEAE-Sephacel and high-speed centrifugation through a sucrose-containing buffer. [Dickey-Dunkirk & Killilea *Anal Biochem* **146** 199 *1985*, DOI: 10.1016/0003-2697(85)90416-6.]

Haemoglobin A (from normal human blood) *[9008-02-0]* **M_r ~64,500, amorphous.** Purify it from blood using CM-32 cellulose column chromatography. [Matsukawa et al. *J Am Chem Soc* **107** 1108 *1985*, DOI: 10.1021/ja00291a004.] For the purification of the α and β chains see Hill et al. *Biochemical Preparations* **10** 55 *1963*.

Histones (from S4A mouse lymphoma). The purification of histones uses a macroprocess column, heptafluorobutyric acid as solubilising and ion-pairing agent and an acetonitrile gradient. [McCroskey et al. *Anal Biochem* **163** 427 *1987*, DOI: 10.1016/0003-2697(87)90244-2.]

Hyaluronidase *[9001-54-1, 37326-33-3]* **M_r 43,000 (bovine testes), 89,000 (bacterial) [EC 3.2.1.35].** Hyaluronidase is purified by chromatography on DEAE-cellulose prior to use. [Distler & Jourdain *J Biol Chem* **248** 6772 *1973*, PMID: 4270451.]

D-Hydantoinase [dihydropyrimidinase, also called 5,6-dihydropyrimidine amidohydrolase, from microorganisms e.g. Pseudomonas, Bacillus, Agrobacterium as well as from mammalian and human tissues) *[9030-74-4]* **M 51,720 (monomer from amino acid sequence, usually dimer or tetramer) [EC 3.5.2.2], pI ~6.5.** This cytosolic enzyme hydrolyses dihydropyrimidines and hydantoins to N-carbamoylamino acids, and with the appropriate substrates are useful for preparing D-amino acids. The enzyme from a recently isolated species of *Agrobacterium* was purified to homogeneity and found to possess hydantoinase activity that was free from dihydropyrimidinase activity. It had an estimated subunit molecular weight of ~66,500 and a theoretical molecular weight of 265,000. The preferred substrates were 5-mono-substituted hydantoins with aromatic groups as shown from the Km values. 5,5-Dimethylhydantoin and thio analogues of 5-*p*-hydroxyphenylhydantoins were competitive inhibitors. [Runser & Meyer *Eur J Biochem* **213** 1315 *1993*, DOI: 10.1111/j.1432-1033.1993.tb17883.x]
A commercially available hydantoinase preparation from *Vignia angularis* from aduki bean with a minimum activity of 300U/g is commercially available. These enzymes are generally inhibited by *N*-carbamoylamino acids (reaction products), 8-hydroxyquinoline, EDTA, Sn^{2+} and Zn^{2+}, but are activated by uracil, 2-thiouracil, Co^{2+}, Fe^{2+}, Mg^{2+}, Mn^{2+} and Ni^{2+}, with turnovers of ~27,000min^{-1} for hydantoin. Their pH-range is 6—9.5, and the temperature range is ~4-60°. D-Hydrantoinase genes have been cloned and expressed in *E coli* and the enzymes from several sources have been crystallised.
A **unit** of enzyme activity is defined as the amount that catalyses the formation of 1mmole of *N*-carbamoylglycine from hydantoin per minute at pH 9.0 and 40°. [Morin *Enz Microbiol Technol* **15** 208 *1993*, *Springer Handbook of Enzymes* D. Schonburg & I. Schonburg Eds (A. Chang co-Ed) Springer-Verlag, Berlin, Heidelberg.]

3-Hydroxy butyrate dehydrogenase (from *Rhodopseudomonas spheroides*) *[9028-38-0]* **M_r ~85,000 [EC 1.1.1.30], amorphous.** Purify the dehydrogenase by two sequential chromatography steps on two triazine dye-Sepharose matrices. [Scawen et al. *Biochem J* **203** 699 *1982*, DOI: 10.1042/bj2030699.]

Interferons [αIFN, βIFN and γIFN].

Interferons are a family of glycosylated proteins and are cytokines which are produced a few hours after cells have been infected with a virus. Interferons protect cells from viral infections and have antiviral activities at very low concentrations (~3 x 10^{-4} M; less than 50 molecules are apparently sufficient to protect a single cell). Double-stranded RNAs are very efficient inducers of IFNs. There are three main types of IFNs. The αIFNs are synthesised in lymphocytes, and the βIFNs are formed in infected fibroblasts. The α and β families are fairly similar, consisting of *ca* 166 to 169 amino acids. Although γIFNs are also small glycosylated proteins (*ca* 146 amino acids), they are different because they are not synthesised after viral infections but are produced by lymphocytes when stimulated by **mitogens** (agents that induced cell division).
Several of these IFNs of mouse and human lymphocytes and fibroblasts are available commercially and have been best prepared in quantity by recombinant DNA procedures because they are produced in very small amounts by the cells. The commercial materials do not generally require further purification for their intended purposes. [Pestkas 'Interferons and Interferon standards and general abbreviations' *Methods Enzymol*, Wiley & Sons, **119** *1986,* ISBN 012182019X; Lengyel 'Biochemistry of interferons and their actions' *Ann Rev Biochem* **51** 251-282 *1982*, DOI: 10.1146/annurev.bi.51.070182.001343; De Maeyer & De Maeyer-Guignard, Interferons in *The Cytokine Handbook*, 3rd Edn, Thomson et al. Eds, pp. 491-516 *1998* Academic Press, San Diego, ISBN 0126896623.]

Interleukin (from human source). Purify these using lyophilisation and desalting on a Bio-Rad P-6DC desalting gel, then two steps of HPLC, first with hydroxylapatite, followed by a TSK-125 size exclusion column. [Köck & Luger *J Chromatogr* **296** 293 *1984*, DOI: 10.1016/S0021-9673(01)96423-4.]

Interleukin-2 (recombinant human) *[94218-72-1]* **M_r ~15,000, amorphous.** Purify it by reverse phase HPLC. [Weir & Sparks *Biochem J* **245** 85 *1987*, DOI: 10.1042/bj2450085; Robb et al. *Proc Natl Acad Sci USA* **81** 6486 *1984*, PMID: 6333684.]

Interleukins (IL-1, IL-2 —IL18]. Interleukins are cytokines which cause a variety of effects including stimulation of cell growth and proliferation of specific cells, e.g. stem cells, mast cells, activated T cells, colony stimulating factors etc., as well as stimulating other ILs, prostaglandins release etc. They are small glycosylated proteins (*ca* 15 kD, 130-180 amino acids produced from longer precursors) and are sometimes referred to by other abbreviations, e.g. IL-2 as TCGF (T cell growth factor), IL-3 as multi-CSF (multilineage colony stimulating factor, also as BPA, HCSF, MCSF and PSF). They are produced in very small amounts and are commercially made by recombinant DNA techniques in bacteria or Sf21 insect cells. Interleukins for human (h-IL), mouse (m-IL) and rat (r-IL) are available, and up to IL-18 are available commercially in such purity that they can be used directly without further refinement, particularly those that have been obtained by recombinant DNA procedures which are specific. As well as the interleukins, a variety of antibodies for specific IL reactions are available for research or IL identification. [Symons et al. Lymphokines and Interferons, *A Practical Approach*, Clemens et al. Eds, p.272 *1987*, IRL Press, Oxford, ISBN 1852210354, 1852210362, Thomson et al. Eds, *The Cytokine Handbook,* 3rd Edn, *1998*, Academic Press, San Diego, ISBN 0126896623.]

Lactate dehydrogenase (from dogfish, Beef muscle) *[9001-60-9]* **M_r 140,000 [EC 1.1.1.27].** A forty-fold purification of the dehydrogenase is effected by affinity chromatography using Sepharose 4B coupled to 8-(6-aminohexyl)amino-5'-AMP or -NAD^+. [Lees et al. *Arch Biochem Biophys* **163** 561 *1974*, DOI: 10.1016/0003-9861(74)90515-3; Pesce et al. *J Biol Chem* **239** 1753 *1964*, PMID: 14213346.]

Lactoferrin (from human whey) *[55599-62-7*, Fe Salt*]* ***M_r* ~90,000.** This iron-binding protein is purified by direct adsorption on cellulose phosphate by batch extraction, then eluted by a stepped salt and pH gradient. The Fe bound protein forms red crystals with λ_{max} at 465nm (pH 8.2). [Foley & Bates *Anal Biochem* **162** 296 *1987*, DOI: 10.1016/0003-2697(87)90040-6.]

Lectins (proteins and/or glycoproteins of non-immune origin that agglutinate cells, e.g. from seeds of *Robinia pseudoacacia*), M_r~100,000. Lectins are purified by precipitation with $(NH_4)_2SO_4$ and dialysed, then chromatographed on DE-52, DEAE-cellulose anion-exchanger, hydroxylapatite and Sephacryl S-200. [Wantyghem et al. *Biochem J* **237** 483 *1986*, DOI: 10.1042/bj2370483.]
Lectins are a group of proteins that are classed as sugar-binding proteins or glycoproteins of non-immune origin and which agglutinate cells and/or precipitate glyco-conjugates. They are present in plants (seeds, roots, leaves or bark) and some invertebrates (snails, clams, crabs) and have M_r values of 10,000-400,000. They may contain Mn^{2+} and/or Ca^{2+}. Mono- or oligo- saccharides of appropriate specificity inhibit lectins. Some lectins are specific to human blood groups and induce mitosis in lymphocytes. [Goldstein et al. *Nature* **285** 66 *1980* DOI: 10.1038/285066b0.]

Lipoprotein lipase (from bovine skimmed milk) *[9004-02-8]* **M_r ~34,000 and 63,000 (SDSPAGE), 96,900 (sedimentation and diffusion), 100,000-120,000 (gel filtration) [EC 3.1.1.34].** Purify the lipase by affinity chromatography on heparin-Sepharose. It has Ki 0.026mM for very low density lipoprotein. It is inhibited by 2-mercaptoethanol, Cys, Ca, Hg, Mg and Mn ions. Protamine sulfate, 1mg of bovine serum albumin/ml or in 50% glycerol at -70°, stabilises the lipase for several days. 60% loss of activity occurs at 0°/1hour in the presence of 1% of bovine serum albumin. [Kohji et al. *Biochim Biophys Acta* **665** 504 *1981*, DOI: 10.1016/0005-2760(81)90264-2.]

Lipoproteins (from human plasma). Individual human plasma lipid peaks are removed from plasma by ultra-

centrifugation; then they are separated and purified by agarose-column chromatography. Fractions are characterised immunologically, chemically, electrophoretically and by electron microscopy. [Rudel et al. *Biochem J* **139** 89 *1974*, DOI: 10.1042/bj1390089.]

Lipoteichoic acids (from gram-positive bacteria) *[56411-57-5]***.** These acids, which are present in bacterial cell walls, are extracted by hot phenol/water from disrupted cells. Nucleic acids are also extracted and are removed by treatment with nucleases. Nucleic resistant acids, proteins, polysaccharides and teichoic acids are separated from lipoteichoic acids by anion-exchange chromatography on DEAE-Sephacel or by hydrophobic interaction on octyl-Sepharose [Fischer et al. *Eur J Biochem* **133** 523 *1983*, DOI: 10.1111/j.1432-1033.1983.tb07495.x].

Lysozyme (Muramidase, *N*-acetylmuramyl hydrolase, *N*-acetylmuramide, peptidoglycan *N*-acetylmuramoyl hydrolase, Globulin G_1) *[human 174883-18-2, from human neutrophils 9001-63-2, from human milk 12671-19-1, from chicken egg white 126050-88-3, chloride from chicken egg white 9066-59-5]* **M 14,400 ±100, E_{280nm} 2.65 (c 1mg/ml) Isoelectric Point (IP) 10.5-11.0, [EC 3.2.1.17].** Lysozymes from human and bird sources are 129 amino acid enzymes that contain four disulfide bonds. Hen lysozyme was isolated in quantity from chicken egg white, crystallised, and its X-ray crystalline structure was determined [Phillips *Proc Natl Acad Sci USA* **57** 484 *1967*, Symposium]. Lysozyme occurs in many tissues of invertebrate and vertebrate animals. It is found in milk, blood serum and various secretions (saliva, nasal mucus and tears). It also occurs in some moulds and in the latex of certain plants. Lysozyme from human milk was studied in some detail and is very similar to the hen enzyme [Jollés & Jollés *Helv Chim Acta* **52** 2671 *1969*, DOI: 10.1002/hlca.19690520848 and **54** 2668 *1971*, DOI: 10.1002/hlca.19710540830]. Lysozyme is a glycosidase which dissolves various bacterial cell walls [particularly Gram-positive bacteria (which have surface lipoproteins) to give spheroblasts, and various Gram-negative bacteria in the presence of EDTA in hypotonic solutions, or non-ionic detergents]. Bacterial cell walls contain 1,4-β-*N*-acetylglycosaminyl oligosaccharides which are cleaved by the enzyme at the glycosidic C—O bond between the 4th and 5th sugar residues from the non-reducing end of the chain. The mechanism and kinetics of this hydrolysis have been studied extensively [cf. Fersht *Enzyme Structure and Mechanism, 2nd edn,* W.H. Freeman & Co, Reading *1985,* ISBN 0716716151]. Lysozyme was an extremely useful antibacterial in the pre-antibiotic era. It is a basic protein with 20-22 basic residues and only 3-4 acidic groups (see their isoelectric points); it forms soluble salts and is stable up to 55°.
It is purified from egg white by chromatography through Amberlite IRC50 at pH 7.18 in 0.2M phosphate buffer followed by recrystallisation at pH 9.5 by adding NaCl to a concentration of 5%. *Alternatively*, ~1L of homogenised egg white in the absence of air (from 3 dozen eggs) is added to a 10% suspension of Bentonite *[1302-78-9]* (150ml, a native hydrated aluminium silicate) in 1% aqueous KCl, and stirred vigorously enough to avoid excessive foaming for ~5 minutes to give a smooth suspension. Separate the clay by centrifugation, wash it twice with 0.5M phosphate buffer (300ml each, pH 7.5) and three times with 5% aqueous pyridine (300ml each) while decanting from the clay and discarding inactive supernatants. From the combined washed clay, lysozyme is extracted out twice with 300ml of 5% aqueous pyridine (adjusted to pH5 with H_2SO_4 using a glass electrode). The combined extracts are dialysed against running tap H_2O (at 12-15°) until free from pyridine odour and dialysed further for 24 hours. Essentially pure amorphous lysozyme is obtained by lyophilising the dialysate below 25°. *Crystalline isoelectric lysozyme* is obtained from the amorphous powder by adding 0.5g of NaCl to a 5% aqueous solution of the enzyme (10ml), adjusting the pH to 9.5-10 (glass electrode) with aqueous NaOH and storing at 4°, whereby it crystallises out. *Crystalline lysozyme carbonate* is obtained from the amorphous powder by adding 0.5g of $NaHCO_3$ to a 5% aqueous solution of the enzyme (10ml), giving a final pH of 8.0-8.5 (glass electrode) with aqueous NaOH and allowing to stand at room temperature, whereby the carbonate crystallises out. ***Crystalline lysozyme chloride*** is obtained from a 5% solution of amorphous powder by adjusting the pH to 4.5 with hydrochloric acid (glass electrode) followed by solid NaCl to 5%, and storing at 4°, whereby the ***chloride*** crystallises out in 4 to 5 days. [Alderton & Fevold *J Biol Chem* **164** 1 *1946*, PMID: 20989461; Fevold & Alderton *Biochemical Preparations* **I** 67 *1949*.] Other salts include the **L-*ascorbate*** *[119189-24-1]*, the ***lactate*** *[72497-48-4]*, the ***phosphate*** *[72497-47-3]* and the ***2,3-dihydroxypropyl dihydrogen phosphate*** *[119189-23-0]*.
Dialysis and recrystallisation are simple and yield enzyme of high purity. Several forms of crystals are obtained depending on the pH of the crystallising solution. The activity of lysozyme is measured by the rate of decrease of

turbidity (at 570nm) as hydrolysis of acetone-dried cell walls of the Gram-positive bacterium *Micrococcus lysodeikitus* (as substrate) occurs on addition of the enzyme [Hirs *Methods Enzymol* **I** 113 *1968*, DOI: 10.1016/0076-6879(55)01017-3].
At high concentrations or in the presence of albumin, lysozyme can be lyophilised or desalted without loss of activity. Freezing and thawing does not inactivate it, and Na^+, Mg^{2+}, Ag^+, Ca^{2+}, and Cu^{2+} exert an activating effect. It can be stored for several weeks at -20° without inactivation, and in the presence of 0.1% of bovine serum albumin it can be stored for months at -20° without inactivation. [*Springer Handbook of Enzymes* 2nd edn. Schonburg & Schonburg eds (A. Chang co-ed) Springer-Verlag Berlin, Heidelberg, **Volume 12** *2003* ISBN 3-540-00519-6.]
Agarose-bound lysozyme from hen egg (5,000-10,000 Units/g of solid), a lysozyme Biotin-caproyl solution (20,000 U/mg) and a carboxymethylated-maleylated lysozyme (Lysozyme-RCM, reduced form), and lysozyme of up to 100,000 U/mg protein are commercially available.
The chemical synthesis and high resolution X-ray structure of ***human lysozyme*** has been described by S.B.H. Kent and coworkers [Durek, Torbeev & Kent *Proc Natl Acad Sci* **104**(12) 4846 *2007*, DOI: 10.1073/pnas.0610630104, PMID: 17360367
A ***T_4 bacteriophage lysozyme*** (from phage grown on *E.coli* B^1) *[12585-29-4]* was extracted and freed from DNA, cell debris, intact cells and acidic proteins by precipitation with Rivanol (6,9-diamino-2-ethoxyacridine *dl*-lactate). The filtrate was purified by concentration through an Amberlite IRC50 column which was thoroughly washed with 0.1M phosphate buffer pH 6.5 containing 10^{-3}M $MgSO_4$ and eluted with the phosphate buffer at pH 5.8 containing a 0 to 0.5M NaCl gradient. This was repeated twice, followed by gel filtration through Sephadex G-75 in pH 5.8 phosphate buffer and eluted with 0.5M NaCl. The eluate was dialysed against H_2O and lyophilised to give a 1500-fold purification with 40% recovery. Like the hen lysozyme it is a basic protein but with 164 amino acid residues, and it is unstable >40°. [Tsugita et al. *J Biol Chem* **243** 391 *1968*, PMID: 4865643; Inouye et al. *J Biol Chem* **245** 3439, PMID: 5470815; 3479, PMID: 5470817 *1970*, Matthews *Biochim Biophys Acta* **405** 442 *1975*, DOI: 10.1016/0005-2795(75)90109-9].

Metallothionein (from rabbit liver) *[9038-94-2]***.** Purify the cysteine-rich protein by precipitation to give Zn- and Cd-containing protein fractions and running it on a Sephadex G-75 column, then isoelectric focusing to give two protein peaks. It is made up of several isoforms with Mr 500 to 14000 Da. [Nordberg et al. *Biochem J* **126** 491 *1972*, DOI: 10.1042/bj1260491; Comeau et al. *Prep Biochem* **22** 151 *1992*, DOI: 10.1080/10826069208021365].

Myoglobin (from sperm whale muscle) *[9047-17-0]* **M_r ~17,000.** Myoglobin is purified by CM-cellulose chromatography and Sephadex G-50 followed by chromatography on Amberlite IRC-50 Type III or BioRex 70 (<400mesh). The crystalline product, as a paste in saturated $(NH_4)_2SO_4$ at pH 6.5-7.0, may be stored at 4° for at least 4 years unchanged, but must not be kept in a freezer. [Andres & Atassi *Biochemistry* **12** 942 *1980*, DOI: 10.1021/bi00729a024; Edmundson *Biochemical Preparations* **12** 41 *1968*.]

5'-Nucleotidase (from Electric ray, *Torpedo sp*) *[9027-73-0]* **[EC 3.1.3.5], amorphous.** Purify it by dissolving it in Triton X-100 and deoxycholate, and by affinity chromatography on concanavalin A-Sepharose and AMP-Sepharose [Grondal & Zimmerman *Biochem J* **245** 805 *1987*, DOI: 10.1042/bj2450805].

Orsomucoid (glycoprotein α_1 acid, from human plasma) *[66455-27-4]* **M_r 42000-44000, amorphous.** Purify the glycoprotein α_1 acid by passage through a carboxymethyl cellulose column, then through a Sephadex G-25 column, and lyophilyse the protein fraction. [Aronson et al. *J Biol Chem* **243** 4564 *1968*, PMID: 5684010.]

Papain *[9001-73-4* **M_r ~21,000 [EC 3.4.22.2], amorphous**. A suspension of 50g of papain (freshly ground in a mortar) in 200ml of cold water is stirred at 4° for 4 hours, then filtered through a Whatman No 1 filter paper. The clear yellow filtrate is cooled in an ice-bath while a rapid stream of H_2S is passed through it for 3 hours, and

the suspension is centrifuged at 2000rpm for 20 minutes. Sufficient cold MeOH is added slowly with stirring to the supernatant to give a final MeOH concentration of 70 vol%. The precipitate, collected by centrifugation for 20 minutes at 2000rpm, is then dissolved in 200ml of cold water, the solution is saturated with H_2S, centrifuged, and the enzyme is again precipitated with MeOH. The process is repeated four times. [Bennett & Niemann *J Am Chem Soc* **72** 1798 *1950*, DOI: 10.1021/ja01160a109.] Papain has also been purified by affinity chromatography on a column of GlyGlyTyrArg-agarose [Stewart et al. *J Am Chem Soc* **108** 3480 *1986*, DOI: 10.1021/ ja00272a052].

Pepsin *[9001-75-6]* **M_r 31,500(human), 6000(hog), [EC 3.4.23.1]**. Pepsin is re-chromatographed on a column of Amberlite CG-50 using a pH gradient prior to use. Crystallise it from EtOH. [Richmond et al. *Biochim Biophys Acta* **29** 453 *1958*, DOI: 10.1016/0006-3002(58)90220-8; Huang & Tang, *J Biol Chem* **244** 1085 *1969*, PMID: 4886180; **245** 2189 *1970*, PMID: 4909888.]

Pertussis toxin (from *Bordetella pertussis*) *[70323-44-3]* **M_r 117,000.** Purify the toxin by stepwise elution from 3 columns comprising Blue Sepharose, Phenyl Sepharose and hydroxylapatite, and the purity is checked by SDS-PAGE. [Svoboda et al. *Anal Biochem* **159** 402 *1986*, DOI: 10.1016/0003-2697(86)90360-X; Tamura et al *Biochemistry* **21** 5516 *1982*, DOI: 10.1021/bi00265a021.]

Phosphatase alkaline (alkaline phosphatase) *[9001-78-9]* **M_r ~40,000 (bovine liver), ~140,000 (bovine intestinal mucosa), 80,000 (*E.coli*), [EC 3.1.3.1].** The *E.coli* supernatant in sucrose (20%, 33mM) in Tris-HCl pH 8.0 is purified through a DEAE-cellulose column and recrystallised. To the column eluates in 0.125M NaCl is added $MgCl_2$ (to 0.01M) and brought to 50% saturation in $(NH_4)_2SO_4$ by adding the solid (0.20g/ml). The mixture is centrifuged to remove bubbles and is adjusted to pH 8.0 (with 2N NaOH). Saturated $(NH_4)_2SO_4$ at pH 8.0 is added dropwise until the solution becomes faintly turbid (~61% saturation). It is set aside at ~25º for 1 hour (turbidity will increase). The mixture is placed in an ice bath for several minutes when turbidity disappears and a clear solution is obtained. It is then placed in a large ice bath at 0º (~5L) and allowed to warm slowly to room temperature in a dark room whereby crystals are formed appearing as a silky sheen. The crystals are collected by centrifugation at 25º if necessary. The crystalline solutions are stable at ~25º for many months. They can be stored at 0º, but are unstable when frozen. Cysteine at 10^{-3}M and thioglycolic acid at 10^{-4}M are inhibitory. This is reversed on addition of Zn^{2+} ions. Many organic phosphates are good substrates for this phosphatase. [Malamy & Horecker *Methods Enzymol* **9** 639 *1966*, DOI: 10.1016/0076-6879(66)09129-8; Torriani et al. *Methods Enzymol* **12b** 212 *1968*, DOI: 10.1016/0076-6879(67)12135-6; Engström *Biochim Biophys Acta* **92** 71 *1964*, DOI: 10.1016/0926-6569(64)90270-6.]
Alkaline phosphatase from rat osteosarcoma has been purified by Me_2CO precipitation and chromatography on DEAE-cellulose, Sephacryl S-200, and hydroxylapatite. [Nair et al. *Arch Biochem Biophys* **254** 18 *1987*, DOI: 10.1016/0003-9861(87)90076-2.]

Phosphoproteins (various). These are purified by adsorbing onto an iminodiacetic acid substituted agarose column to which are bound ferric ions. This chelate complex acts as a selective immobilised metal affinity adsorbent for phosphoproteins. [Muszynska et al. *Biochemistry* **25** 6850 *1986*, DOI: 10.1021/bi00370a018.]

5'-Phosphoribosyl pyrophosphate synthetase (from human erythrocytes, or pigeon or chicken liver) *[9015-83-2]* **M_r 60,000 [EC 2.7.6.1].** It is purified 5100-fold by elution from DEAE-cellulose, fractionation with $(NH_4)_2SO_4$, filtration on Sepharose 4B and ultrafiltration. [Fox & Kelley *J Biol Chem* **246** 5739 *1971*, PMID: 4328836; Flaks *Methods Enzymol* **6** 158 *1963*, DOI: 10.1016/0076-6879(63)06158-9; Kornberg et al. *J Biol Chem* **215** 389 *1955*, PMID: 14392173.]

Pituitary Growth Factor (from human pituitary gland) *[336096-71-0]*. It is purified by heparin and copper affinity chromatography, followed by chromatography on carboxymethyl cellulose (Whatman 52). [Rowe et al. *Biochemistry* **25** 6421 *1986*, DOI: 10.1021/bi00369a012.]

Plasmids. These are circular lengths of *double-stranded* DNA which invade bacteria or other cells, e.g. insect cells, yeast cells, and have sequences which are necessary for their replication using enzymes and other ingredients, e.g. nucleotides, present in the cells. They contain engineered, or already have, genes which

produce enzymes that provide the cells with specific antibiotic resistance and are thus useful for selecting bacteria containing specific plasmids. Plasmids have been extremely useful in molecular biology since they can be very easily identified (from their size or the sizes of the DNA fragments derived from their restriction enzyme digests) and can be readily engineered *in vitro* (outside the cells). Genes coding for specific enzymes or other functional proteins can be inserted into these plasmids which have DNA sequences that allow the expression of large quantities of bacterial or non-bacterial (e.g. human) proteins. They have also been engineered in such a way as to produce 'fusion proteins' [in which the desired protein is fused with a specific 'reporter, marker or carrier protein' which will facilitate the isolation of the desired protein e.g. by binding strongly to a nickel support], and then the desired protein can be cleaved from the eluted fusion protein and obtained in very pure form. A large number of plasmids with a variety of sequences for specific purposes are commercially available in very pure form. They can be used to infect cells and can be isolated and purified from cell extracts in large amounts using a number of available procedures. These procedures generally involve lysis of the cells (e.g. with alkaline sodium dodecylsulfate, SDS), separation from nuclear DNA, precipitation of plasmid DNA from the cell debris, adsorbing it on columns which specifically bind DNA, and then eluting the DNA from the column (e.g. with specific Tris buffers as recommended by the suppliers) and precipitating it (e.g. with Tris buffer in 70% EtOH at -70°C). The purity is checked on agarose gels (containing ethidium bromide to visualise the DNA) by electrophoresis. A large number of plasmids are now commercially available (see Clontech GmbH, http://www.clontech.com, Invitrogen http://www.invitrogen.com, among other suppliers) and used as vectors for bacterial, mammalian, yeast and insect cells, and for baculovirus expression.

Protamine kinase (from rainbow trout testes) *[37278-10-7]* **[EC 2.7.1.70].** Partial purification of the kinase is achieved by chromatography through hydroxylapatite followed by biospecific chromatography on nucleotide coupled Sepharose 4B [the nucleotide is 8-(6-aminohexyl)amine coupled cyclic-AMP]. It requires Mg ions specifically, but is inactivated by Ca, Mn, Cu, Zn ions and thiol compounds. [Jergil & Dixon *J Biol Chem* **245** 425 *1970*, PMID: 4312674; Jergil et al. *Biochem J* **139** 441 *1974*, DOI: 10.1042/bj1390441.]

Protamine sulfate (from herring sperm) *[9007-31-2]* **$[\alpha]_D^{22}$ -85.5 (saturated H_2O), pK^{25} 7.4-8.0.** Protamine sulfate is a strongly basic protein (white powder, see pK) used to precipitate nucleic acids from crude protein extracts. It dissolves to the extent of 1.25% in H_2O. It is freely soluble in hot H_2O but separates as an oil on cooling. It has been purified by chromatography on an IRA-400 ion-exchange resin in the SO_4^{2-} form and is washed with dilute H_2SO_4. Eluates are freeze-dried under high vacuum below 20°. This method is used to convert proteamine and protamine hydrochloride to the sulfate. [UV: Rasmussen *Hoppe Seyler's Z Physiol Chem* **224** 97 *1934*, Ando & Sawada *J Biochem (Tokyo)* **49** 252 *1961*, PMID: 13683326; Felix & Hashimoto *Hoppe Seyler's Z Physiol Chem* **330** 205 *1963*.] It reverses the anticoagulant effects of heparin by binding to it, and enhances lipid-mediated gene transfer [Sorgi et al. *Gene therapy* **4**(9) 961 *1997*, DOI: 10.1038/sj.gt.3300484].

Protease nexin (from cultured human fibroblasts) *[148263-58-5]*. This serine protease inhibitor is purified simply in two steps first by affinity binding to dextran sulfate-Sepharose, then purified to homogeneity involving a combination of DEAE-Sepharose in-line with dextran sulfate-Sepharose to simultasously purify and concentrate the protein [Farrell et al. *Biochem J* **237** 907 *1986*, DOI: 10.1042/bj2370907]. [See also Farrell and Cunningham *Biochem J* **245** 543 *1987*, DOI: 10.1042/bj2450543; and for properties and purification see Scott et al. *J Biol Chem* **260** 7029 *1985*, PMID: 3858278]

Proteins. These are usually naturally occurring (or deliberately synthesised in microorganisms, e.g. bacteria, insect cells, or animal tissues), and are composed of a large number of α-*S* (L)amino acid residues (except for L-cysteine which has the *R* absolute configuration), selected from the 20 or so natural amino acids, in specific sequences and in which the α−amino group forms an amide (peptide) bond with the α−carboxyl group of the neighbouring amino acid. The number of residues is usually upwards of 100. Proteins with less than 100 amino acids are better referred to as **polypeptides**. Aqueous soluble proteins generally fold into ball-like structures mainly with hydrophilic residues on the outside of the 'balls' and hydrophobic residues on the inside. Proteins can exist singly or can form dimers, trimers, tetramers etc., consisting of similar or different protein subunits. [See 'Introduction' in this Chapter]. They are produced by cells for a large variety of functions, e.g. enzymology, reaction mediation as in regulation of DNA synthesis or chaperonins for aiding protein folding,

formation of pores in membranes for transport of ions or organic molecules, or for intra or intercellular signalling etc. The purity of proteins can be checked in denaturing (SDS, sodium dodecylsulfate) or non-denaturing polyacrylamide gels using electrophoresis (PAGE), and staining appropriately (e.g. with Coommassie Blue, followed by silver staining for higher sensitivity). If the protein is partly impure, then it should be purified further according to the specific literature procedures for the individual protein (see specific proteins in the *Methods Enzymol*, Wiley series).

Proteoglycans (from cultured human muscle cells). These are separated by ion-exchange HPLC using a Bio-gel TSK-DEAE 5-PW analytical column. [Harper et al. *Anal Biochem* **159** 150 *1986*, DOI: 10.1016/0003-2697(86)90320-9.]

Prothrombin (Factor II, from equine blood plasma) *[9001-26-7]* **M_r 72,000.** Prothrombin is purified by two absorptions on a barium citrate adsorbent, followed by decomposition of the adsorbents with a weak carboxylic cation-exchanger (Amberlite IRF-97), isoelectric precipitation (pH 4.7-4.9) and further purification by chromatography on Sephadex G-200 or IRC-50. Finally it is recrystallised from a 1% solution adjusted to pH 6.0-7.0 and partial lyophilisation to *ca* 1/5 to 1/10th volume and set aside at 2-5º to crystallise. Occasionally seeding is required. [Miller *Biochemical Preparations* **13** 49 *1971*.] For 'Has the time arrived to replace the quick prothrombin time test for monitoring oral anticoagulant therapy?' see Jackson & Esnouf [*Clin Chem* **51**(3) 483–5 *2005*, DOI: 10.1373/clinchem.2004.045393, PMID: 15738512].

Prymnesin (toxic protein from phytoflagellate *Pyrymnesium parvum*) *[11025-94-8]***.** Prymnesin is purified by column chromatography, differential dissolution and precipitation in solvent mixtures and differential partition between diphasic mixtures. The product has at least 6 components as observed by TLC. [Ulitzur & Shilo *Biochim Biophys Acta* **201** 350 *1970*, DOI: 10.1016/0304-4165(70)90310-7.]

Pyruvate kinase isoenzymes (from *Salmonella typhimurium*) *[9001-59-6]* **M_r 64,000 [EC 2.7.1.40], amorphous.** These are purified by $(NH_4)_2SO_4$ fractionation and gel filtration, ion-exchange and affinity chromatography. [Garcia-Olalla & Garrido-Pertierra *Biochem J* **241** 573 *1987*, DOI: 10.1042/bj241057.]

Renal dipeptidase (from porcine kidney cortex) *[9031-96-3]* **M_r 47,000 [EC 3.4.13.11]**. The dipeptidase is purified 700-fold by homogenising the tissue, extracting with Triton X-100, elimination of insoluble material, and ion-exchange, size exclusion and affinity chromatography. [Hitchcock et al. *Anal Biochem* **163** 219 1987, DOI: 10.1016/0003-2697(87)90116-3.]

Restriction enzymes (endonucleases). These are enzymes which cleave double-stranded DNA (linear or circular) at specific nucleotide sequences within the DNA strands which are then used for cloning (by ligating bits of DNA sequences together) or for identifying particular DNA materials, e.g. plasmids, genes etc. A very large number of restriction enzymes are now available commercially and are extensively used in molecular biology. They are highly specific for particular nucleotide arrangements and are sensitive to the reaction conditions, e.g. composition of the medium, pH, salt concentration, temperature etc, which have to be strictly adhered to.
Endonucleases are essentially of two types. One type cleaves the DNA producing *blunt ends*, i.e. the nucleotides are paired at each end. The second type cleaves the DNA leaving *hanging ends*, i.e. the nucleotides at the ends of each strand (usually four nucleotides) of the double strands protrude ahead of the paired nucleotides. The latter enzymes particularly allow ligation of the cleaved sequence to occur in a desired direction.
The enzymes do not require further purification, and the reaction conditions are also provided by the suppliers from which the necessary reaction media can also be purchased (see commercial catalogues).

Reverse transcriptase (from avian or murine RNA tumour viruses) *[9068-38-6]* **M_r ~170,000 [EC 2.7.7.49].** This enzyme produces the complementary DNA from the RNA (as template). These are purified by solubilising the virus with non-ionic detergents. Lysed virions are adsorbed on DEAE-cellulose or DEAE-Sephadex columns, and the enzymes are eluted with a salt gradient, then chromatographed on a phosphocellulose column and fractions with enzyme activity are eluted in a salt gradient. They are also purified

from other viral proteins by affinity chromatography on a pyran-Sepharose column. [Verma *Biochim Biophys Acta* **473** 1 *1977*, DOI: 10.1016/0304-419X(77)90005-1; Smith *Methods Enzymol* **65** 560 *1980*, DOI: 10.1016/S0076-6879(80)65060-5; see commercial catalogues for other transcriptases.]

Ribonuclease (from human plasma) *[9001-99-4]* **M_r ~13,700 [EC 3.1.27.5], amorphous.** Purify it by $(NH_4)_2SO_4$ fractionation, followed by PC cellulose chromatography and affinity chromatography (using Sepharose 4B to which $(G)_n$ is covalently bonded). [Schmukler et al. *J Biol Chem* **250** 2206 *1975*, PMID: 234961.]

Ribozymes. These are ribonucleic acids which act like protein enzyme in catalysing the making and breaking of peptide bonds as well as catalysing reactions and cleavage of DNA and RNA molecules. The short RNAs are being intensively studied (see RNAi below). MicroRNAs (miRNA, see also below) are ubiquitous and are also genetically produced. They are involved in numerous reactions from splicing RNA, e.g. mRNA (messenger RNA) to controlling transcription of DNA to RNA, and translation of RNA to protein. Each miRNA is capable of being involved in a small number to hundreds of interactions with nucleic acids and with proteins.

Ricin (toxin from Castor bean *Ricinus communis*) *[A chain 96638-28-7, B chain 96638-29-8]* **M_r ~30,000, amorphous.** Crude ricin, obtained by aqueous extraction and $(NH_4)_2SO_4$ precipitation, is chromatographed on a galactosyl-Sepharose column with sequential elution of pure ricin. The second peak is due to ricin agglutinin. [Simmons & Russell *Anal Biochem* **146** 206 *1985*, DOI: 10.1016/0003-2697(85)90417-8.] It is an inhibitor of protein synthesis. **EXTREMELY DANGEROUS, USE EXTREME CARE [instructions accompany product].**

RNA (ribonucleic acids). Ribonucleic acids are like DNA except that the 2'-deoxy-D-ribose moiety is replaced by a D-ribose moiety and the fourth nucleotide thymidylic acid (T) is replaced by uridylic acid (U). RNA does not generally form complete duplex molecules like DNA, i.e. it is generally monomeric, except in certain viruses. The two main classes of RNA are **messenger-RNA** (mRNA) and **transfer-RNA** (tRNA). Pre-mRNAs are transcribed from the DNA genes, and non-coding segments (the introns) are spliced out to give the mRNAs which code for specific proteins. There are many different tRNAs, at least one of which is linked to a specific α-amino acid that binds to the mRNA *via* the ribosome (a set of proteins) to the RNA triplets (three nucleotides) which code for the particular α-amino acids. An enzyme then joins the α-amino acids of two adjacent tRNA-α-amino acid ribosome complexes bound to the mRNA to form a peptide bond. Thus peptide bonds and consequently polypeptides and proteins coded by the DNAs, *via* the respective mRNA, are produced. Martin et al. [*Biochem J* **89** 327 *1963*, DOI: 10.1042/bj0890327] purified RNA by dissolving it (5g) in 90ml of 0.1mM EDTA, then homogenised this with 90ml of 90% (w/v) phenol in water using a Teflon pestle. The suspension was stirred vigorously for 1 hour at ~20°, then centrifuged for 1 hour at 0° at 25000rpm. The lower (phenol) layer was extracted four times with 0.1mM EDTA, and the aqueous layers were combined, then made 2% (w/v) with respect to AcOK and 70% (v/v) with respect to EtOH. After standing overnight at -20°, the precipitate was centrifuged down, dissolved in 50ml of 0.1mM EDTA, made 0.3M in NaCl and kept for 3 days at 0°. The purified RNA was then centrifuged down at 10000xg for 30 minutes, dissolved in 100ml of 0.1mM EDTA, dialysed at 4° against water, and freeze-dried. It was stored at -20° in a desiccator. Michelson [*J Chem Soc* 1371 *1959*, DOI: 10.1039/JR9590001371] dissolved 10g of RNA in water, added 2M ammonia to adjust the pH to 7, then dialysed in *Visking* tubing against five volumes of water for 24 hours. The process was repeated three times; then the material after dialysis was treated with 2M HCl and EtOH to precipitate the RNA which was collected, washed with EtOH, ether and dried [see commercial catalogues for further examples]. RNAs are now routinely sequenced.

RNAi (*interfering* RNA). RNAi technology has exploded during the past few years and has become invaluable for exploring gene function, interaction and control. It has considerable potential in therapeutics. This came about from the discovery that a double-stranded RNA (**dsRNA**) complementary to the coding sequence of a muscle protein 'turned off' the gene instead of enhancing the effect. It seemed that the dsRNA activated the cellular machinery to degrade the target mRNA. This led to the development and the use of interfering RNA (RNAi) to 'silence' specific genes. This silencing of genes comes in various different forms. It can be brought about by ***short interfering*** RNA (**siRNA**), ***micro*** RNA (**miRNA**) and ***short-hairpin*** RNA (**shRNA**). RNA can

be notoriously unstable in biological systems, e.g. its half-life in serum is ~6 minutes, but recently methods have been devised (using nanoparticle delivery systems) where they are more stable and can be used to target specific cancer cells.
About 50% of the human genome is apparently transcribed into mRNA and translated into protein or used to produce small RNA fragments. miRNAs are small molecules of about 23 or less ribonucleotides which are cleaved from larger fragments of RNA transcripts encoded from within genes, or large tracts of DNA between the genes. miRNAs are a special group of non-coding RNAs which work by blocking (silencing) gene expression. More than 400 have been discovered in the human genome so far and some appear to regulate many genes, as in embryonic development, e.g, cell growth, apoptosis. A cancer-causing miRNA was identified and called ***onco-mi***RNA. miRNA expression in particular cancers can now be quantified.
Single stranded RNAs consisting of 100s of bases fold back on themselves and undergo complementary base-paring to form double-stranded 'short-hairpin' RNA (shRNA). The loop of the hair-pin is excised by endonucleases, e.g *Dicer*, to produce multiple functional miRNAs.
Many of the above RNAs for specific purposes are available commercially from several suppliers in high purity because they are synthetic. These firms will also synthesise particular RNAi's to suit one's requirements.

Subtilisin (from *Bacillus subtilis*) *[9014-01-1]* **M_r 27,000 (sedimentation equilibrium) [EC 3.4.21.62].** This alkaline protease is purified 211-fold by affinity chromatography using 4-(4-aminophenylazo)phenylarsonic acid complex to activated CH-Sepharose 4B. It is inhibited by 2-phenylethane boronic acid, PMSF, 3,4-dichloroisocoumarin, acetone and benzamide. [Chandrasekaren & Dhar *Anal Biochem* **150** 141 *1985*, DOI: 10.1016/0003-2697(85)90452-X; Schomburg & Schomburg *Springer Handbook of Enzymes* 2nd Edn **vol 7** p 286 *2002*.]

Synexin (from bovine liver) M 47,000 Da. This Ca binding protein is purified by $(NH_4)_2SO_4$ precipitation, then by a specific pH step elution from a chromatofocusing medium in the absence of ampholytes. The pI is 7.5. [Scott et al. *Anal Biochem* **149** 163 *1985*, DOI: 10.1016/0003-2697(85)90489-0.]

Thrombin (from bovine blood plasma) *[9002-04-4]* **M_r 32,600 [EC 3.4.4.13].** Thrombin is purified by chromatography on a DEAE-cellulose column, while eluting with 0.1M NaCl, pH 7.0, followed by chromatography on Sephadex G-200. The final preparation is free from plasminogen and plasmin. [Yin & Wessler *J Biol Chem* **243** 112 *1968*, PMID: 5635939.] Thrombin from bovine blood is also purified by chromatography using *p*-chlorobenzylamino-ε-aminocaproyl agarose, and gel filtration through Sephadex G-25. [Thompson & Davie *Biochim Biophys Acta* **250** 210 *1971*, DOI: 10.1016/0005-2744(71)90136-7.] Thrombin from various species was purified initially by precipitation of impurities with **Rivanol** (see *[6402-23-9]*). [Miller *Nature* **184** 450 *1959* DOI: 10.1038/184450a0.]

Tissue inhibitor of metalloproteins (TIMP, from human blood plasma), M_r ~30,000. These are purified by an [anti-human amniotic fluid-TIMP]-Sepharose immuno-affinity column and eluted with 50mM glycine/HCl pH 3.0 buffer that is 0.5M in NaCl, and followed by gel filtration [Cawston et al. *Biochem J* **238** 677 *1986*, DOI: 10.1042/bj2380677].

Transferrin (from human or bovine serum) *[11096-37-0]* **M_r~80,000.** This transferrin is purified by affinity chromatography on phenyl-boronate agarose followed by DEAE-Sephacel chromatography. The product is free from haemopexin. [Cook et al. *Anal Biochem* **149** 349 *1985*, DOI: 10.1016/0003-2697(85)90581-0; Aisen & Listowsky *Ann Rev Biochem* **49** 357 *1980*, DOI: 10.1146/annurev.bi. 49.070180.002041.]

Trehalase (from kidney cortex, α,α-trehalose glycohydrolase) *[9025-52-9]* **M_r ~80,000 [EC 3.2.1.28].** This trehalase is purified by solubilising in Triton X-100 and sodium deoxycholate, and submitting to gel filtration, ion-exchange chromatography, conA-Sepharose chromatography, phenyl-Sepharose CL-4B hydrophobic interaction chromatography, Tris-Sepharose 6B affinity and hydrolyapatite chromatography. Activity is increased 3000-fold. [Yoneyama *Arch Biochem Biophys* **255** 168 *1987*, DOI: 10.1016/0003-9861(87)90307-9.]

T4-RNA ligase (from bacteriophage-infected *E.coli*) M_r 43,500 [EC 6.5.1.3 for RNA lyase**].** This ligase is purified by differential centrifugation and separation on a Sephadex A-25 column, then through hydroxylapatite and DEAE-glycerol using Aff-Gel Blue to remove DNAase activity. (Greater than 90% of the protein in the enzyme preparation migrated as a single band on gradient polyacrylamide gels containing SDS during electrophoresis.) [McCoy et al. *Biochim Biophys Acta* **562** 149 *1979* DOI: 10.1016/0005-2787(79)90134-5.]

Tyrosine kinases (PTKs) are a large group of ***transferase*** enzymes e.g. **[EC 2.7.10.X]** that transfer a phosphate group from ATP to a protein in living cells, which activate or deactivate cellular functions. As the name implies, the phosphate group is attached to the phenolic oxygen of a tyrosine residue in the protein. Cell signaling (transferring messages within the cell— ***signal transduction***) is an important mechanism for communicating information from one part of the cell to another. It is carried out by phosphorylating proteins with tyrosine kinases. Other kinases, such as serine and threonine kinases, function in an analogous manner. There are two main families of tyrosine kinases: (A) the ***transmembrane kinases*** (**RTKs**) which are anchors for membrane receptors and function by signaling (transducing) for outside of the cell to the interior of the cell thus triggering a cascade of events which may ultimately reach the nucleus and effecting gene expression. (B) ***cytoplasmic-non-receptor*** tryosine kinases which function (traffic) within various parts of the cell.
[Cox & Nelson *Lehninger: Principles of Biochemistry* (5th ed.). W H Freeman & Co *2008*, ISBN 1-4292-2416-9; Dengjel et al. 'Receptor tyrosine kinase signaling: a view from quantitative proteomics' *Mol Biosyst* **5** 1112 *2009*, DOI: 10.1039/b909534a, PMID: 19756300; Hanks et al. 'The protein kinase family: conserved features and deduced phylogeny of the catalytic domains' *Science* **241** (4861) 42 *1988*, DOI: 10.1126/ science.3291115, PMID: 3291115.]

Ubiquinol-cytochrome c reductase (from beef heart mitochondria) *[9027-03-6]* **[EC 1.10.2.2]**. This reductase is purified by solubilising the crude enzyme with Triton X-100, followed by hydroxylapatite and gel chromatography. The minimum unit contains nine polypeptide subunits of M_r 6000 - 49000 kD. [Engel et al. *Biochim Biophys Acta/Bioenergetics* **592** 211 *1980*, DOI: 10.1016/0005-2728(80)90182-6.]

Uridine 5'-diphosphoglucose pyrophosphorylase (from rabbit skeletal muscle) *[9029-22-6]* **M_r 350,000, [EC 2.7.7.9].** The pyrophosphorylase is purified by two hydrophobic chromatographic steps and gel filtration. [Bergamini et al. *Anal Biochem* **143** 35 *1984*, DOI: 10.1016/0003-2697(84)90554-2.] It is also purified from calf liver by $(NH_4)_2SO_4$ (40-58%) precipitation, $Ca_3(PO_4)_2$ gel filtration, DEAE-cellulose chromatography and recrystallisation [by dialysis against concentrations of $(NH_4)_2SO_4$ (from 10%) in 0.02M TEA, at 2.5% increments, until 20% $(NH_4)_2SO_4$ when it crystallises out]. [Hansen et al. *Methods Enzymol* **8** 248 *1966*, DOI: 10.1016/0076-6879(66)08042-X.]

Urokinase (from human urine) *[9039-53-6]* **M_r 53,000 [EC 3.4.21.31].** Crystallisation of this enzyme is induced at pH 5.0 to 5.3 (4°) by careful addition of NaCl with gentle stirring until the solution becomes turbid (silky sheen). The NaCl concentration is increased gradually (over several days) until 98% of saturation is achieved whereby urokinase crystallises out as colourless thin brittle plates. It can be similarly recrystallised to maximum specific activity [104K CTA units/mg of protein (Sherry et al. *J Lab Clin Med* **64** 145 *1964*, PMID: 14192559)]. [Lesuk et al. *Science* **147** 880 *1965*, DOI: 10.1126/science.147.3660.880; NMR: Bogusky et al. *Biochemistry* **28** 6728 *1989*, DOI: 10.1021/bi00442a028.] It is a plasminogen activator [Gold et al. *Biochem J* **262** 529 *1989*, DOI: 10.1042/bj2620529; de Bock & Wang *Med Res Rev* **24**(1) 13 *2004*, DOI: 10.1002/med.10054].

Xylanase (from *Streptomyces lividans*) *[37278-89-0]* **M_r 43,000 [EC 3.2.1.8].** This xylanase is purified by anion-exchange chromatography on an Accell QMA column and finally by HPLC using a ProteinPak DEAE 5PW anion-exchange column. Solutions are stored frozen at -70°. [Morosoli et al. *Biochem J* **239** 587 *1986*, DOI: 10.1042/bj2390587; Wong et al. *Microbiol Rev* **52** 305 *1988*, PMID: 3141761.]

CARBOHYDRATES

This section includes natural and synthetic carbohydrates and glycosides.

Z-*O*-(2-Acetamido-2-deoxy-D-glycopyranosylideneamino)-*N*-phenylcarbamate

(PUGNAC) $C_{15}H_{19}N_3O_7$, *[132063-05-9]* **M 335.3, m 171-174° (dec), 174-180°(dec), $[\alpha]_D^{20}$ +67.5 (c 0.2, MeOH).** Purify PUGNAC by flash chromatography (silica gel and elute with EtOAc/hexane 3:2), evaporate, and the foam is recrystallised from EtOAc/MeOH. The purity is checked by TLC on Merck SiO_2 gel 60 F_{254} and the spots are detected by spraying with 0.025M I_2 in 10% aqueous H_2SO_4 and heating at 200°. It has R_F 0.21. The acetate is hydrolysed with NH_3/MeOH. [Beer & Vasella *Helv Chim Acta* **68** 2254 *1985*, DOI: 10.1002/ hlca.19850680821; Beer et al. *Helv Chim Acta* **73** 1918 *1990*, DOI: 10.1002/hlca.19900730714.] It is an *in vitro* and *in vivo* inhibitor of the acetylglucosaminidase enzyme which removes *O*-linked *N*-acetylglucosamine from *O*-linked glycosylated proteins.

Acetobromo-α-D-galactose *[3068-32-4]* **$C_{14}H_{19}BrO_9$, M 411.2, m 87°, $[\alpha]_{546}^{20}$ +255, $[\alpha]_D^{20}$ +210 (c 3, $CHCl_3$).** Purify acetobromo-α-D-galactose as for the glucose analogue (next entry). If the compound melts lower than 87° or is highly coloured, then dissolve it in $CHCl_3$ (*ca* 3 volumes) and extract with H_2O (2 volumes), 5% aqueous $NaHCO_3$, and again with H_2O and dry it over Na_2SO_4. Filter and evaporate it in a vacuum. The partially crystalline solid or syrup is dissolved in dry Et_2O (must be very dry) and recrystallised by adding petroleum ether (b 40-60°) to give a white product. [McKellan & Horecker *Biochemical Preparations* **11** 111 *1960*, *Beilstein* **17/6** V 369.]

Acetobromo-α-D-glucose (α-acetobromoglucose 2,3,4,6-tetraacetyl-α-D-glucopyranosyl bromide) *[572-09-8]* **$C_{14}H_{19}BrO_9$, M 411.2, m 87-88°, 88-89°, $[\alpha]_{546}^{20}$ +230, $[\alpha]_D^{20}$ +195 (c 3, $CHCl_3$).** If nicely crystalline, recrystallise it from Et_2O/pentane or petroleum ether (b 40-60°). *Alternatively*, dissolve it in diisopropyl ether (dried over $CaCl_2$ for 24 hours, then over P_2O_5 for 24 hours) by shaking and warming (for as short a period as possible), and filter warm. Cool to *ca* 45°, then slowly to room temperature and finally at 5° for more than 2 hours. Collect the solid, wash it with cold dry diisopropyl ether and dry it in a vacuum over $Ca(OH)_2$ and NaOH. Store it dry in a desiccator in the dark. Solutions can be stabilised with 2% $CaCO_3$. [Redemann & Niemann *Org Synth* Coll Vol **3** 11 *1955*, DOI: 10.15227/orgsyn.022.0001; for the preparation of the α−2−cyanoethyl derivative from it see Glese et al. *Org Synth* **65** 236 *1987*, DOI: 10.15227/orgsyn.065.0236; *Beilstein* **17/6** V 368.]

α-Acetyldigitoxin *[5511-98-8, 1111-39-3]* **$C_{43}H_{66}O_{15}$, M 823.0, m 153-180° (monohydrate, dec), 199-201°, 217-221°, 258°(dec), $[\alpha]_D^{20}$ +5.0 (c 0.7, pyridine), +24.5 (c 1, MeOH)**. α-Acetyldigitoxin is obtained from the commercial mixture [α:β (2:1)] *[25395-32-8]*. The α−form is obtained from the β−form by heating in anhydrous or aqueous organic solvent (e.g. aqueous MeOH) at pH 3.5—8. It crystallises from MeOH as plates, $CHCl_3$/Et_2O or Me_2CO/Et_2O. At 20° 1g dissolves in 16ml of MeOH, 66ml of Me_2CO and ~880ml of EtOAc. Store at -20°. [Stoll & Kreis *Helv Chim Acta* **35** 1318, *1952*, DOI: 10.1002/hlca.19520350431; Stoll et al. *Helv Chim Acta* **35** 1324 *1952*, DOI: 10.1002/hlca.19520350432; *Beilstein* **18** III/IV 1479.] It is a cardenolide.

β−Acetyldigitoxin *[5355-48-6, 1264-51-3]* **$C_{43}H_{66}O_{15}$, M 823.0, m 225°, 240°(dec), 271-273°(dec), $[\alpha]_D^{20}$ +16.2 (c 0.7, pyridine), +26.7 (c 0.7, MeOH).** β−Acetyldigitoxin crystallises from MeOH as a methanolate which loses MeOH in a vacuum desiccator. The solubility at room temperature is: H_2O (0.0005%), EtOAc (0.4%), MeOH (0.6%), Me_2CO (1.6%) and $CHCl_3$(12%). Store at -20°. [Stoll & Renz *Helv Chim Acta* **35** 1310 *1952*, DOI: 10.1002/hlca.19520350430; Kreis US 2776963, 1957 to Sandoz; *Beilstein* **18** III/IV 1479]. It is a cardenolide.

***N*-Acetyl-D-lactosamine [LacNAc, 2-acetylamino-*O*-β-D-lactopyranosyl-2-deoxy-D-glucose]** *[32181-59-2]* **$C_{14}H_{25}NO_{11}$, M 383.4, m 169-171°, 170-171°, $[\alpha]_D^{18}$ +51.5→ +28.8 (in 3hrs, c 1, H_2O].** Purify *N*-acetyl-D-lactosamine by recrystallisation from MeOH (with 1 mol of MeOH) or from H_2O. It is available commercially

as a solution of 0.5g/ml of H_2O. Store at -20°. [Zilliken et al. *J Biol Chem* **217** 79 *1955*, http://www.jbc.org/content/ 217/1/79, PMID: 13271370; Zilliken et al. *J Biol Chem* **208** 199 *1954*, http://www.jbc.org/content/208/1/299; PMID: 13174538; *Beilstein* **17** IV 3452.]

1-*O*-Acetyl-2,3,5-tri-*O*-benzoyl-β-D-ribofuranose *[6974-32-9]* **$C_{28}H_{24}O_9$, M 504.5, m 128-130°, 130-131°, 131-132°, $[\alpha]_D^{22}$ +45.1 (c 1.32, $CHCl_3$).** Recrystallise it from EtOH or isoPrOH (10 parts) and dry over P_2O_5. [Synthesis from D-ribose: Recondo & Rinderknecht *Helv Chim Acta* **42** 1171 *1959*, DOI: 10.1002/hlca.19590420409; NMR: Stevens & Fletcher *J Org Chem* **33** 1799 *1968*, DOI: 10.1021/jo01269a021; synthesis and IR of the DL ***racemate*** **m 115-117°**: Iwai et al. IR: *Chem Pharm Bull Jpn* **11** 188 *1963*, DOI: 10.1248/cpb.11.188; *Beilstein* **17/6** V 213.]

***N*-Acetyl muramic acid [NAM]** See 'Physiologically Active….' in this Chapter.

Alginic acid *[9005-32-7]* **$(C_6H_8O_6)_n$, M 48,000-186000**. The acid, found in kelp, a brown algae, is a straight-chain, hydrophilic, colloidal, polyuronic acid (mixed polymer of mann-uronic and gul-uronic acids) composed primarily of anhydro-β-D-mannuronic acid residues with 1→4 linkage. To 5g of acid in 550ml water containing 2.8g $KHCO_3$ are added 0.3ml of acetic acid and 5g potassium acetate. EtOH is added to make the solution to 25% (v/v) in EtOH, and any insoluble material is discarded. Further addition of EtOH, to 37% (v/v), precipitated alginic acid. Collect the acid and dry it *in vacuo* (3.6g). A striking property of alginic acid is that it is capable of absorbing 200-300 times its weight of H_2O and to a lesser extent salts (~60% of its weight). It liberates CO_2 from carbonates (titration point with phenolphthalein). ***Sodium alginate (Algin)*** *[9005-38-3]* has $[\alpha]_D^{20}$ –133 (H_2O). [Prepn from *Macrosystis pyrifera*: Nelson & Cretcher *J Am Chem Soc* **51** 1914 *1929*, DOI: 10.1021/ja01381a045; metachromatic properties: Pal & Schubert *J Am Chem Soc* **84** 4384 *1962*, DOI: 10.1021/ja00882a004.]

Aloin [10-glucopyranosyl-1,8-dihydroxy-3-(hydroxymethyl)-9(10*H*)anthracenone, Barbaloin] *[8015-61-0, 5133-19-7, 1415-73-2]* **$C_{21}H_{22}O_9$, M 418.4, m 148-148.5°, 148-150°.** Aloin forms the ***monohydrate*** as lemon yellow crystals on crystallisation from H_2O (450g/1.5l) which has a lower **m ~70-80°** than the anhydrous substance. Dry *in vacuo* over P_2O_5 at 100°, but picks up lost H_2O on standing in air for 2 days. The ***heptamethyl ether*** (MeI.Ag_2O/Me_2CO/N_2/8hr reflux) crystallises from EtOH and has **m 180-182°**, $[\alpha]_D^{20}$ –12.3 (c 1.46, $CHCl_3$). [For constitution see Cahn & Simonsen *J Chem Soc* 2573 *1932*, DOI: 10.1039/JR9320002573; Hay & Haynes *J Chem Soc* 3141 *1956*, DOI: 10.1039/JR9560003141.]

D(+)-Altrose *[*D- *1990-29-0,* L- *1949-88-8]* **$C_6H_{12}O_6$, M 180.2, m 103-105°, 106-108°, $[\alpha]_{546}$ +35 (c 7.6, H_2O).** Crystallise D-altrose from aqueous EtOH. If it is obtained by hydrolysis of the acetate, then it may contain sodium and acetate ions. Ions are best removed by dissolving in H_2O, passing through suitable columns of ion-exchange resins, e.g. Amberlite IR-120 and Duolite A, and concentrating in a vacuum to a syrup. This is dissolved in MeOH, filtered and evaporated in a vacuum desiccator over granular $CaCl_2$. The thick syrup is inoculated with seed crystals, stirred, and before it sets to a magma of crystals, transfer the crystals with MeOH to a Büchner funnel. Recrystallise them in the same way. β-D-Altrofuranoside has initial $[\alpha]_D^{20}$ ~-69 (c 4, H_2O) which mutarotates to +33. [Richtmeyer *Methods in Carbohydrate Chemistry* **I** 107 Academic Press *1962*, *Beilstein* **1** IV 4301, see Angyal *Adv Carbohydrate Chem Biochem* **42** 15 *1984*, DOI: 10.1016/S0065-2318(08)60122-5, for ratio of anomers in solution.]

D-Amygdalin (D-mandelonitrile-β-gentiobioside) *[29883-15-6]* **$C_{20}H_{27}NO_{11}$, M 457.4, m 214-216° (trihydrate), 220°(anhydrous), $[\alpha]_D^{22}$ −38 (c 1.2, H_2O).** D-Amygdalin recrystallises from water as the ***trihydrate***, or from EtOH. It is present in bitter almonds. After melting at **~220°**, the melt solidifies and re-melts at **125-130°**. [For ORD and sugar structure see Hudson *J Am Chem Soc* **46** 483 *1924*, DOI: 10.1021/ja01667a025; for the biose see Haworth & Wylam *J Chem Soc* **123** 3120 *1923*, DOI: 10.1039/CT9232303120; for catalytic racemisation see Smith *Chem Ber* **64** 1115 *1931*, DOI: 10.1002/cber.19310640527; *Beilstein* **17/8** V 188.]

Amylose *[9005-82-7]* **$(C_6H_{10}O_5)_n$ (*for use in iodine complex formation*).** Amylopectin is removed from impure amylose by dispersing in aqueous 15% pyridine at 80-90° (concentration 0.6-0.7%) and allowing the

solution to stand at 44-45° for 7 days. The precipitate is re-dispersed and recrystallises during 5 days. After a further dispersion in 15% pyridine, it is cooled to 45°, allowed to stand at this temperature for 12 hours, then cooled to 25° and left for a further 10 hours. The combined precipitates are dispersed in warm water, precipitated with EtOH, washed with absolute EtOH, and dried *in vacuo* [Foster & Paschall *J Am Chem Soc* **75** 1181 *1953*, DOI: 10.1021/ja01101a051].

1,6-Anhydro-β-D-glucose (levoglucosan, β-glucosan, β-D-pyranose-form) *[498-07-7]* **$C_6H_{10}O_5$, M 162.1, m 177°, 179-180°, 182-184°, 184°, $[\alpha]_D$ -66.3 (c 2, H_2O).** Levoglucosan is readily formed by pyrolysis (dry distillation) of starch, ash-free amylose, cellulose and *β*-D-glucose in a vacuum. Best results are obtained when the acidity of the distillate is least. The product is dissolved in MeOH, decolourised with charcoal and cooled to give the glucosan in good yields. Other *β*-D-glucosides such as Arbutin, Salicin and Phloridzin also yield levoglucosan, and is evidence for the *β*- linkage configuration because *α*-glucose and *α*-glucosides require more drastic conditions for pyrolysis, i.e. longer heating and higher temperatures since the *α*- orientation at C-1 needs to be inverted to the *β*- orientation [Karrer *Helv Chim Acta* **3** 258 *1920*, DOI: 10.1002/hlca.19200030125; Pictet & Cramer *Helv Chim Acta* **3** 640 *1920*, DOI: 10.1002/hlca.19200030159, Ruchel & Schuerch *J Org Chem* **31** 2233 *1966*, DOI: 10.1021/jo01345a035; Irvine & Oldham *J Chem Soc* 2903 *1925*, DOI: 10.1039/ CT9252702903; Carvalho et al. *J Am Chem Soc* **81** 4054 *1959*, DOI: 10.1021/ja01524a060].
Another ready source of levoglucosan is *β*-phenylglucoside (2.0, see *[1464-44-4]*) which is dissolved 1.3N aqueous KOH (100ml), heated on a boiling water bath for 9 hours, while monitoring the specific optical rotation until it is constant (−64.4). The clear mixture in cooled, neutralised (to methyl orange, the slight colour of the cooled solution does not interfere) with 3N sulfuric acid, evaporated to dryness *in vacuo*, extracted from the K_2SO_4 residue with warm EtOH, evaporated and the residue is recrystallised from EtOH (10ml) to give ***levoglucosan*, m 179-180°**, $[\alpha]_D$ −66.3 (c 2, H_2O), in 88% yield. Other *β*-phenylglyco-*pyrano*-sides give anhydro-glycosans, but the *α*- linked sugars require much longer heating (~20 hours or weeks) to give the anhydro-sugars. This alkaline reaction has been studied in detail, and similarly *β*-phenylgalactoside provided a 91% yield of ***1,6-anhydro-β-D-galactose* (*anhydroglactosan*)** *[644-76-8]* **M 162.1,** with **m 226°** (plates from 50% aqueous EtOH) and **$[\alpha]_D$** -22.0 **(c 2, H_2O)**. [Montgomery et al. *J Am Chem Soc* **65** 3 *1943*, DOI: 10.1021/ja01241a002].
Levoglucosan is one of the more important anhydro-sugars as it, and its 2-, 3- and 4- substituted derivatives, are readily hydrolysed by aqueous acid to give glucose and the respective derivatives [Peat *Adv Carbohydrate Chem* **2** 37 *1946*, DOI: 10.1016/S0096-5332(08)60006-5]. Also at elevated temperature, in the presence of zinc dust, $ZnCl_2$, or platinum black, levoglucosan polymerises to form a variety of oligomers described as ***dextrans***, and these can be commonly 20,000 to 50,000 mers (but 300,000 mers in the extreme); and have found use in chromatographic purification of large molecules, e.g. proteins. The polymerisation process has been studied in detail [Carvalho et al. *J Am Chem Soc* **81** 4054 *1959*, DOI: 10.1021/ja01524a060; Irvine & Oldham *J Chem Soc* 2903 *1925*, DOI: 10.1039/ CT9252702903; Ruchel & Schuerch *J Org Chem* **31** 2233 *1966*, DOI: 10.1021/jo01345a035; see also Pictet & Sarasin *Helv Chim Acta* **1** 87 *1918*, DOI: 10.1002/hlca.19180010109; and later papers]. The 2-, 3- and 4- OH groups are readily derivatised in the usual way, and the ***triacetyl derivative*** has *[13242-55-2]* M 288.2, **m 109.5-110.5°**, **$[\alpha]_D^{25}$ −50.8 ($CHCl_3$)**, the ***trifluoroacetyl derivative*** has M 450.2, **m 63.5-65.0°**, **$[\alpha]_D^{25}$ −39.9 (c 2.1, $CHCl_3$)**, the ***tribenzoyl derivative*** has *[13567-05-7]* M 474.4, **m 202-203°**, **$[\alpha]_D^{20}$ −36.4 ($CHCl_3$)**, the ***tri-O-methyl derivative*** has M 204.2, **m 57.5-58.5°**, **$[\alpha]_D^{25}$ −63.7 (c 2, H_2O)**, the ***tri-O-ethyl derivative*** has M 246.3, **b 90°/0.60mm**, **d^{28} 1.081**, **$[\alpha]_D^{25}$ −51.5 (c 2.8, $CHCl_3$)**, the ***tri-O-benzyl derivative*** has M 432.5, **m 89.5-90.5°**, **$[\alpha]_D^{25}$ −30.8 (c 2.7, $CHCl_3$),** and the ***tri-O-methylsilyl derivative*** has M 378.7, **b 87-87.5°/0.05mm**, **$[\alpha]_D^{30}$ −33.8 (c 3.6, $CHCl_3$)**; all of which have been subjected to the polymerisation process with the '*ether*' derivatives being more successful than the '*ester*' derivatives in producing high polymers. [Ruckel & Scheurch *J Org Chem* **31** 2233 *1966*, DOI: 10.1021/jo01345a035]. The ^{1}H NMR of levoglucosan and its derivatives in DMSO-d_6 and D_2O have been reported in detail [Wollwage & Seib *J Chem Soc (C)* 3143 *1971*, DOI: 10.1039/J39710003143]. [*Beilstein* **19** H 894, **19** I 452, **19** III/V 1181. **19/3** V 498.]

β-L-(+)-Arabinose (natural) *[87-72-9, 5328-37-0]* **$C_5H_{10}O_5$, M 150.1, m 158°, 160-163°, 164-165°, $[\alpha]_D$ +104 (c 4, H_2O after 24hr), pK^{17} 12.4.** ß-L-(+)-Arabinose is recrystallised slowly, twice, from 80% aqueous EtOH, then dried under vacuum over P_2O_5. It can also be purified by heating the arabinose (200g) with glacial acetic acid (300ml) on a boiling water bath for 45 minutes, cooling, filtering, washing with 95% EtOH (500ml)

in four portions and drying at 56-60° over P_2O_5. It has been recrystallised from 5 times its weight of 76% EtOH using charcoal (10g) to yield 127g, **m 155-157°**, $[\alpha]_D^{20}$ +190.6 and mutarotating to +104 (c 4, H_2O). [Anderson & Sands *Org Synth* Coll Vol **1** 67 *1941*, DOI: 10.15227/orgsyn.008.0018; Wolfrom & Christian *J Am Chem Soc* **48** 3172 *1926*, DOI: 10.1021/ja01691a025; *Beilstein* **1** IV 4217.]

D-(-)-Arabinose *[10323-20-3, 28697-53-2 (pyranoside)* **$C_5H_{10}O_5$, M 150.1, m 164°, 164-165°, $[\alpha]_D^{20}$ -104.5 (c 1, H_2O), $[\alpha]_{546}$ -123 (c 10, H_2O after 24 hours), pK^{25} 12.54.** Crystallise D-(-)-arabinose three times from EtOH, dry it *in vacuo* at 60° for 24 hours and store it in a vacuum desiccator. It also crystallises from a mixture of H_2O/MeOH/EtOH with **m 158-160°**, or H_2O with **m 160-161°**. [Whistler & Schweiger *J Am Chem Soc* **81** 5190 *1959*, DOI: 10.1021/ja01528a042; Fletcher et al. *J Am Chem Soc* **72** 4546 *1950*, DOI: 10.1021/ja01166a058; *Beilstein* **1** IV 4215, see Angyal *Adv Carbohydrate Chem Biochem* **42** 15 *1984*, DOI: 10.1016/S0065-2318(08)60122-5; for ratio of anomers in solution.]

D-Arabitol (D-arabinitol) *[488-82-4]* **$C_5H_{12}O_5$, M 152.2, m 103°, 103-104°, $[\alpha]_{546}^{20}$ +13 (c 5, 8% borax solution).** This pentol, which occurs in lichens and fungi, is purified by recrystallisation from 90% EtOH or MeOH. [Ashina & Yanagita *Chem Ber* **67** 799 *1934*, DOI: 10.1002/cber.19340670521; derivatives: Nakagawa et al. *Bull Chem Soc Jpn* **40** 2150 *1967*, DOI: org/10.1246/bcsj.40.2150; Prince & Reichstein *Helv Chim Acta* **20** 101 *1937*, DOI: 10.1002/hlca.19370200113; Hough & Theobald *Methods in Carbohydrate Chemistry* **I** 94 *1962*, Academic Press, *Beilstein* **1** IV *2832*.]

L-Arabitol (L-arabinitol) *[7643-75-6]* **$C_5H_{12}O_5$, M 152.2, m 102°, 103°, $[\alpha]_{546}$ -13 (c 5, 8% borax solution).** This pentol, which occurs in the urine of pentosuric subjects, is purified by recrystallisation from 90% EtOH or MeOH. It has a higher rotation in the presence of molybdate: $[\alpha]_D^{20}$ -130 (c 0.16, acidified molybdate) [Richtmyer & Hudson *J Am Chem Soc* **73** 2249 *1957*, DOI: 10.1021/ja01149a095]. [Gätzi & Reichstein *Helv Chim Acta* **21** 195 *1938*, DOI: 10.1002/hlca.19380210132; *Beilstein* **1** IV 2832.]

DL-Arabitol (DL-arabinitol) *[2152-56-9]* **$C_5H_{12}O_5$, M 152.2, m 105-106°.** This synthetic arabitol is purified by recrystallisation from 90% EtOH, MeOH or EtOH/Me_2CO. [Raphael *J Chem Soc, Supplement* 44 *1949*, DOI: 10.1039/JR9490000S44; Ashina & Yamagita *Chem Ber* **67** 799 *1934*, DOI: 10.1002/cber.19340670521; *Beilstein* **1** IV 2832.]

p-**Arbutin (*p*-hydroquinone-*O*-β-D-glucopyranoside)** *[497-76-7]* **$C_{12}H_{16}O_7$, M 272.3, m 195-198°, 199°, 200°(sintering at 163-164°), $[\alpha]_D^{20}$ -65 (c 2, H_2O), pK_{Est} ~10.0.** The glycoside from *Protea exima* is purified by recrystallisation from H_2O or moist EtOAc (as ***monohydrate***), after chromatography through silica Gel using EtOAc/MeOH. Crystallisation from EtOH/$CHCl_3$ gives crystals **m 199-200°** with intermediate melting at 164° and resolidifying. Its solubility in H_2O is 5g/100ml at ~25°. The ***pentaacetate*** crystallises from EtOH in fine needles with **m** 145-146°, $[\alpha]_D^{20}$ -28.2 (c 2, Me_2CO). [Robinson & Waters *J Chem Soc* 2729 *1930*, DOI: 10.1039/JR9300002729; IR, NMR, MS: Perold et al. *JCS Perkin Trans 1* 239 *1979*, DOI: 10.1039/P19790000239; *Beilstein* **17/7** V 110.]

L(+)-Ascorbic acid [Vitamin C, 5*R*-5-(1*S*-1,2-dihydroxyethyl)-3,4-dihydroxyfuran-2(5*H*)-one] *[50-81-7]* **$C_6H_8O_6$, M 176.1, m 193°(dec), $[\alpha]_{546}$ +23 (c 10, H_2O), pK_1^{25} 4.04, pK_2^{25} 11.34.** Crystallise it from MeOH/Et_2O/petroleum ether. Its solubility in g/100ml at ~25° is 33 (40 at 45°, 80 at 100°) in H_2O, 2.0 in EtOH, 5.0 in propylene glycol, and 1.0 in glycerol. [Herbert et al. *J Chem Soc* 1270 *1933*, DOI: 10.1039/JR9330001270]. It is an important vitamin, is anti-ascorbutic (deficiency causes Pellagra), an antimicrobial, a reducing agent and an antioxidant used also as a food additive. [Davies et al. *Vitamin C: Its Chemistry and Biochemistry*, The Royal Society of Chemistry Publication, p. 48 *1991*, ISBN 0-85186-333-7; *Beilstein* **18/5** V 26.]

6-Bromo-2-naphthyl-α-D-galactopyranoside *[α– 25997-59-5; β– 15548–61–5]* **$C_{16}H_{17}BrO_6$, M 385.2, m 178-180°, 224-226°, 225°, $[\alpha]_D^{28}$ +60 (c 1.2, pyridine).** It is prepared from penta-*O*-acetyl-D-galactoside, 6-bromo-2-naphthol and $ZnCl_2$. The resulting tetra-acetate (2g) is hydrolysed by dissolving in 0.3N KOH (100ml) and heating until the solution is clear, then filtering and cooling to give colourless crystals of the

α-isomer which are collected and recrystallised twice from hot MeOH. The high specific rotation is characteristic of the α-isomer. The ***tetraacetate*** has **m 155-156°**, $[\alpha]_D^{20}$ +60 (c 1, $CHCl_3$) [Dey & Pridham *Biochem J* **115** 47 *1969*, DOI: 10.1042/bj1150047] [reported **m 75-85°**, $[\alpha]_D^{24}$ +94 (c 1.3, dioxane), Monis et al. *J Histochem Cytochem* **11** 653 *1963*, DOI: 10.1177/11.5.653]. [*Beilstein* **17** IV 2972.]

Carminic acid (7-α-D-glucopyranosyl-9,10-dihydro-3,5,6,8-tetrahydroxy-1-methyl-9,10-dioxo-2-anthracene carboxylic acid, Neutral Red 4: CI 75470, hydroxyanthrapurin glucoside) *[1260-17-9]* **$C_{22}H_{20}O_{13}$, M 492.4, m 120°(dec), $[\alpha]_{654}^{15}$ +51.6 (H_2O), $[\alpha]_D^{20}$ +3.1 (c 1, H_2O). (several phenolic pKs).** Carminic acid, the colourant principle of cochineal, forms red prisms from EtOH. It gives a red colour in Ac_2O and yellow to violet in acidic solution. Its UV has λ_{max} (H_2O) at 500nm (ε 6,800); (0.02N HCl) 490-500nm (ε 5,800) and (0.0001N NaOH) 540nm (ε 3,450). Its IR has ν_{max} (Nujol) at 1708s, 1693s, 1677m, 1648m, 1632m, 1606s, 1566s, 1509 cm^{-1}. Periodate oxidation is complete after 4 hours at 0° with the consumption of 6.2 mols. The ***tetra-O-methyl carminate*** has **m 186-188°** (yellow needles from *C_6H_6/petroleum ether). [For IR see Ali & Haynes *J Chem Soc* 1033 *1959*, DOI: 10.1039/JR9590001033; for synthesis see Allevi et al. *JCS Perkin 1* 575 *1998*, DOI: 10.1039/A705145J; and Davis & Smith *Biochemical Preparations* **4** 38 *1955*, *Beilstein* **18** III/1V 6697.] A red dye (e.g. for clothes) found in insects (e.g. cochineal).

λ−Carrageenan *[9064-57-7 (κ), 9000-07-1 (κ + little of λ)]*. This D-galactose-anhydro-D or L-galactoside polysaccharide is precipitated from 4g of Carrageenan in 600ml of water containing 12g of KOAc by addition of EtOH. Collect the fractions that precipitate between 30 and 45% (v/v) of EtOH and dry them *in vacuo*. It is a metachromatic compound, cf. Alginic acid above and Heparin below [Pal & Schubert *J Am Chem Soc* **84** 4384 *1962*, DOI: 10.1021/ja00882a004].

Colchicoside [7*S*-7*N*-[*3*-(β-D-glucopyranosyloxy)-1,2,10-tetramethoxy-9-oxobenzo[*a*]-heptalen-7-yl-(7*S*)]-acetamide, 7-glucosylcolchicine] *[477-29-2]* **$C_{27}H_{33}NO_{11}$, M 547.5, m 194-197°, 216-218° (block), d ^{25} 1.44g/cm^3, $[\alpha]_D^{15}$ -128.5 (c 1, $CHCl_3$), $[\alpha]_D^{15}$ -231 (c 1, MeOH), $[\alpha]_D^{15}$ -355 (c 1, H_2O).** Purify the pale yellow colchicoside by chromatography through alumina and eluting with $CHCl_3$, then recrystallising from Me_2CO, **m 275-280°** (after releasing solvent at 180°). It also crystallises from EtOH; see the aglycon colchicine *[64-86-8]* in 'Physiologically Active…..' in this Chapter. Store in a refrigerator. The ***tetraacetate*** has **m 175-177°**, $[\alpha]_D^{15}$ -57 (c 1, $CHCl_3$). [Bellet et al. *Ann Pharm Fr* **10** 241 *1952*, *Chem Abstr* **47** 3323 *1953*, *Beilstein* **14** IV 946 for colchicine.]

Convallatoxin (α-cardenolide mannoside) *[508-75-8]* **$C_{29}H_{42}O_{10}$, M 550.6, m 238-239°, 238-241° (dec), d ^{25} 1.41g/cm^3, $[\alpha]_D^{20}$ -9.4 (c 0.7, dioxane), $[\alpha]_D^{16}$ -1.0 ±3 (c 0.7, EtOH).** Crystallise convallatoxin from EtOAc, $CHCl_3$/EtOH (9:1) or MeOH/Et_2O. The ***tetraacetate*** has **m 238-242°** (from MeOH/Et_2O), $[\alpha]_D^{25}$ -5 ($CHCl_3$). [Reyle et al. *Helv Chim Acta* **33** 1541 *1950*, DOI: 10.1002/hlca.19500330621; Fieser & Jacobson *J Am Chem Soc* **59** 2335 *1937*, DOI: 10.1021/ja01290a070; for isolation from *lily of the valley* blossoms (*Convallaria majalis* L) see Karrer *Helv Chim Acta* **12** 506 *1929*, DOI: 10.1002/hlca.19290120154; *Beilstein* **18** III/IV 3142.] It is a most potent cardiotoxin.

α-Cyclodextrin (H_2O) *[10016-20-3]* **$C_{36}H_{60}O_{30}$, M 972.9, m >280°(dec), $[\alpha]_{546}$ +175 (c 10, H_2O)**. Recrystallise α-cyclodextrin from 60% aqueous EtOH, then twice from water, and dry it for 12 hours in a vacuum at 80°. It is also purified by precipitation from water with 1,1,2-trichloroethylene. The precipitate is collected, washed and resuspended in water (solubility ~50mg/ml at ~25°). This is boiled to steam distil the trichloroethylene. The solution is then freeze-dried to recover the cyclodextrin. [Armstrong et al. *J Am Chem Soc* **108** 1418 *1986*, DOI: 10.1021/ja00267a010]. [*Beilstein* **19/12** V 789.]

β-Cyclodextrin (H_2O) *[7585-39-9, 68168-23-0]* **$C_{42}H_{70}O_{35}$, M 1135.0, m >300°(dec), $[\alpha]_{546}$ +170 (c 10, H_2O).** Recrystallise ß-cyclodextrin from water and dry it for 12 hours in a vacuum at 110°, or 24 hours in a vacuum at 70°. The purity is assessed by TLC on cellulose containing a fluorescent indicator. [Taguchi, *J Am Chem Soc* **108** 2705 *1986*, DOI: 10.1021/ja00270a032; Tabushi et al. *J Am Chem Soc* **108** 4514 *1986*, DOI: 10.1021/ ja00275a043; for absorption and fluorescence of indole inclusion complex see Orstan & Ross *J Phys Chem* **91** 2739 *1987*, DOI: 10.1021/j100295a019.] [*Beilstein* **19** IV 6287, **19/12** V 801.]

***N*-Decanoyl-*N*-methylglucamine (Mega-10, *N*-D-glucidyl-*N*-methyl deconamide)** *[85261-20-7]* **$C_{17}H_{35}NO_6$, M 349.5, m 91-93°, 92°.** Possible impurities are decanoic acid and *N*-methylglucamine. The former is removed by grinding the solid with Et_2O and then with petroleum ether and drying over P_2O_5. It is twice recrystallised from MeOH/Et_2O (1:9, v/v; 10ml/g) by dissolving in the minimum volume of MeOH, adding Et_2O and drying in a vacuum. To remove the glycamine, the solid (800mg) is dissolved in hot H_2O (10ml) and set aside. Mega-10 crystallises as colourless needles. These are filtered off and dried in a vacuum to constant weight. It is a good non-ionic non-hygroscopic detergent with a critical micelle concentration (CMC) of 7.4mM (0.26%) in 0.1M Tris-HCl pH 7.4 at 25°. [Hildreth *Biochem J* **207** 363 *1982*, DOI: 10.1042/bj2070363; for detergent activity in solubilising microsomes see Taguchi & Armarego *Med Res Rev* **18** 43 *1998*, DOI: 10.1002/(SICI)1098-1128(199801)18:1<43.] The ***N*-Methyl-D-glucamine [(2*R*,3*R*,4*R*,5*S*)-6-(methylamino)hexane-1,2,3,4,5-pentol]** *[6284-40-8]* **$C_7H_{17}NO_5$, M 195.2,** has **m 128-129°, 126-129°, 129-131.5°, $[\alpha]_D^{20}$ -18.5 (c 2, H_2O).** Recrystallise it from MeOH. Its solubility in g/1ml is 1.0 in H_2O (25°) and 0.012 in EtOH (70°). Aqueous solutions are alkaline and its sulfonate salts are detergents. [Karrer & Herkenrath *Helv Chim Acta* **20** 83 *1937*, DOI: 10.1002/hlca.19370200109; *Beilstein* **4** IV 1914.] The antimonite salt *[133-51-7]* is anti-protozoal (leishmanial) in dogs [Chapman et al. *Am J Vet Res* **45** 1028 *1984*, PMID: 6732008].

Dehydro-L(+)-ascorbic acid {DHA, (5*R*)-5-[(1*S*)-1,2-dihydroxyethyl]furan-2,3,4(5*H*)-trione} *[490-83-5]* **$C_6H_6O_6$, M 174.1, m 196°(dec), 228°(dec), $[\alpha]_{546}^{20}$ +42.5 (c 1, H_2O), pK^{25} 3.90.** This is the oxidised form of ***ascorbic*** acid. Crystallise dehydro-L(+)-ascorbic acid from MeOH. The ***anhydrous acid*** is formed by heating it in a vacuum at 100°/1 hour to give a crisp glassy product which when shaken with absolute EtOH and then kept at 0° for 2 days gives microcrystals of the anhydrous acid. This is then washed with absolute EtOH and dried in a vacuum. It has **m 225°(dec)** and is stable in acidic solution but decomposes rapidly in alkaline solution. A 1% solution of the anhydrous acid when dissolved in phthalate/HCl buffer pH 3.5 at 60° and cooled to 20° has $[\alpha]_D^{20}$ +56(0 minutes), +53.5(2 hours), +19(3 days), -2(5 days) and -6(6 days); then it becomes orange in colour. A freshly prepared 1% solution in H_2O has $[\alpha]_D^{20}$ +50(0 minutes), +44(2 hours), +16(3 days) and 0(5 days). [Herbert et al. *J Chem Soc* 1270 *1933*, DOI: 10.1039/JR9330001270; Kenyon et al. *J Chem Soc* 158 *1948*, DOI: 10.1039/JR9480000158; *Beilstein* **18/5** V 411.]

2-Deoxy-D-allose (2-deoxy-D-*ribo*-hexose) *[6605-21-6]* **$C_6H_{12}O_5$, M 164.2, m 140-142°, $[\alpha]_D^{24}$ +57.5 (c 1.2, H_2O).** Purify 2-deoxy-D-allose by two recrystallisations from absolute EtOH. The ***p*-nitrophenylhydrazone** has **m 61-62°**, $[\alpha]_D^{16.5}$ -55 (MeOH). An equilibrium solution at 31° in D_2O contains 15% α-pyranose, 58% β-pyranose, 12% α-furanose and 15% β-furanose forms as estimated by ^{1}HNMR spectroscopy. [see Angyal *Adv Carbohydrate Chem Biochem* **42** 15 *1984*, DOI: 10.1016/S0065-2318(08)60122-5; for ratio of anomers in solution, DOI: 10.1016/S0065-2318(08)60122-5; Zorbach & Ollapally *J Org Chem* **29** 1790 *1964*, DOI: 10.1021/jo01030a030.] [*Beilstein* **1** IV 4283.]

2-Deoxy-β-D-galactose (2-deoxy-D-*lyxo*-hexose) *[1949-89-9]* **$C_6H_{12}O_5$, M 164.2, m 110°, 120-121°, (126-128°), $[\alpha]_D^{20}$ +60 (c 2, H_2O, 2 hours).** Crystallise 2-deoxy-β-D-galactose from MeOH or diethyl ether. The ***aniline derivative*** has **m 142-143°**, $[\alpha]_D^{16.5}$ -149 (c 0.8, pyridine). [Overend et al. *J Chem Soc* 671 *1950*, DOI: 10.1039/JR9500000671; Overend et al. *J Chem Soc* 992 *1951*, DOI: 10.1039/JR9510000992.] A 30% equilibrium solution at 31° in D_2O contains 40% α-pyranose, 44% β-pyranose, 8% α-furanose and 8% β-furanose forms as estimated by ^{1}HNMR spectroscopy [Angyal & Pickles *Aust J Chem* **25** 1711 *1972*, DOI: 10.1071/CH9721711]. [*Beilstein* **1** IV 4283.]

2-Deoxy-α-D-glucose (2-deoxy-D-*arabino*-hexose) *[154-17-6]* **$C_6H_{12}O_5$, M 164.2, m 146-147°, 148-151°, $[\alpha]_D^{20}$ +46 (c 0.5, H_2O after 45 hours).** Crystallise 2-deoxy-α-D-glucose from MeOH/Me_2CO, Me_2CO or butanone to give a mixture of α– and β– ***anomers***, **m 142-144°**, $[\alpha]_D^{18}$ +38 (35 minutes) to +46 (c 0.5, H_2O). Recrystallisation from *iso*PrOH gives mainly the ***α-anomer*** **m 134-136°** , $[\alpha]_D^{18}$ +156 to +103 (c 0.9, pyridine). ^{1}H NMR studies showed that at 44° in D_2O the solution contained 36% of α-pyranose and 64% of β-pyranose sugars, but furanose structures were undetectable. [Snowden & Fischer *J Am Chem Soc* **69** 1048 *1947*, DOI: 10.1021/ja01197a022; derivatives: Bollinger & Schmidt *Helv Chim Acta* **34** 989 *1951*, DOI: 10.1002/hlca.19510340333; see Angyal & Pickles *Aust J Chem* **25** 1711 *1972* for ratio of isomers in solution, DOI: 10.1071/CH9721711; *Beilstein* **1** IV 4282.]

6-Deoxy-D-glucose (D-quinovose) *[7658-08-4]* **$C_6H_{12}O_5$, M 164.2, m 146°, $[\alpha]_D^{20}$ +73 (after 5 minutes) and +30° (final, after 3 hours) (c 8.3, H_2O).** 6-Deoxy-D-glucose is purified by recrystallisation from EtOAc and is soluble in H_2O, EtOH but insoluble in Et_2O and Me_2CO. [Srivastava & Lerner *Carbohydr Res* **64** 263 *1978*, DOI: 10.1016/S0008-6215(00)83707-6; NMR: Angyal & Pickles *Aust J Chem* **25** 1711 *1972*, DOI: 10.1071/CH9721711; *Beilstein* **1** IV 4260.]

2-Deoxy-β-L-ribose *[18546-37-7]* **$C_6H_{10}O_4$, M 134.1, m 77°, 80°, $[\alpha]_D^{25}$ +91.7 (c 7, pyridine, +40 final).** Crystallise 2-deoxy-β-L-ribose from diethyl ether. It can also be purified by dissolving the ribose (7.3g) in EtOAc (3L) by reflux, decanting from any insoluble material and evaporating at 50°/vacuum to 2.2L, setting aside for 1-2 hours, filtering, and concentrating to 840ml. The ribose separates as compact nodules during 3-5 days at 0° and has **m 87-93°**, and after repeated recrystallisations it has **m 92-95°**. Mutarotation is as follows: $[\alpha]_D^{16.5}$ +80(0 minutes), +71(6 minutes), +59(21 minutes) and +59(41 minutes) (c 1.14, H_2O); $[\alpha]_D^{20}$ +105(0 minutes), +71(9.5 minutes), +67(12.5 minutes), +49(81 minutes), +49(136 minutes) (c 0.9, MeOH). [Deriaz et al. *J Chem Soc* 1879 *1949*, DOI: 10.1039/JR9490001879; *Beilstein* **1** IV 4181.]

2-Deoxy-β-D-ribose *[533-67-5]* **$C_6H_{10}O_4$, M 134.1, m 86-87°, 87-90°, $[\alpha]_D^{20}$ -56 (c 1, H_2O after 24 hours).** Dissolve 2-deoxy-β-D-ribose in a little H_2O, evaporate to a syrup (in a vacuum), and seed to crystallise. Triturate the crystals with a little EtOAc containing 5% MeOH, decant and dry in vacuum over P_2O_5. It is best purified *via* the **anilide** which separates from a mixture of the ribose (100-125g) in MeOH (100ml) and redistilled aniline (40ml) in a few minutes. After standing for 20 hours at room temperature, it is cooled to 0°, filtered, washed with 50% aqueous MeOH and Et_2O followed by recrystallisation from ethylene glycol monomethyl ether. The **anilide** has **m 172-173°, $[\alpha]_D^{25}$ +46 (equilibrium in pyridine).** The anilide (5g), benzaldehyde (5ml) and benzoic acid (0.5g) in H_2O (150ml) are shaken mechanically for 20-24 hours. The aqueous phase is extracted with Et_2O (3x), decolourised with a little charcoal and evaporated in a vacuum to a syrup. This is dried over P_2O_5 in high vacuum. The syrupy sugar weighs 3.1g and crystallises in a few days, but more rapidly on seeding. Triturate it with a little EtOAc containing 5% MeOH, decant and dry it over P_2O_5. At this stage it has **m 78-82°, $[\alpha]_D^{25}$ -57 (c 1, H_2O final).** This is a mixture of α- and β- anomers. Pure **β-anomer** is obtained by recrystallisation from EtOAc The β-anomer when recrystallised from EtOAc and isoPrOH has **m 96-98°, $[\alpha]_D^{25}$ -55 (c 0.5, H_2O final)**. [Sowden *Biochemical Preparations* **5** 75 *1957*.] The mutarotation is as follows: $[\alpha]_D^{20.5}$ +96.3(0 minutes), -76(33 minutes), -56(24 hours) (c 5.8 MeOH). It is moderately hygroscopic and should be kept in a well stoppered bottle. It also crystallises from diethyl ether. [Deriaz et al. *J Chem Soc* 1879 *1949*, DOI: 10.1039/JR9490001879; *Beilstein* **1** IV 4181, Hauske & Rapoport *J Org Chem* **44** 2472 *1979*, DOI: 10.1021/jo01328a029.]
The ***1,3,4-tribenzoate (α- and β-mixture)***, obtained by benzoylation, has **m 127°** (after crystallisation from EtOH), **$[\alpha]_D^{23}$ -65 (c 1, $CHCl_3$).** The crude syrupy mixture in $*C_6H_6$ is applied to an acid-washed Alorco Al_2O_3 column. Elution with $*C_6H_6$/hexane (1:1) affords (after crystallisation from MeOH), ***β-1,3,4-tri-O-benzoyl-2-deoxy-D-ribose*, m 159-169°, $[\alpha]_D^{20}$ -196 (c 1, $CHCl_3$).** Further elution with $*C_6H_6$ gives, after recrystallisation from MeOH pure ***α-1,3,4-tri-O-benzoyl-2-deoxy-D-ribose*, m 151-152°, $[\alpha]_D^{20}$ +41.6 (c 083, $CHCl_3$).** [Pedersen et al. *J Am Chem Soc* **82** 3425 *1960*, DOI: 10.1021/ja01498a047; see Angyal *Adv Carbohydrate Chem Biochem* **42** 15 *1984*, for ratio of anomers and ring forms, DOI: 10.1016/S0065-2318(08)60122-5.]

Dextran *[9004-54-0]* **$H(C_6H_{10}O_5)xOH$ M_r 6,000-220,000**. Solutions of dextran keep indefinitely at room temperature if 0.2ml of Roccal (10% alkyldimethylbenzylammonium chloride) or of 2mg phenyl mercuric acetate are added per 100ml solution. This inhibits mould growth. [See Levoglucosan above; Evans & Hibbert *Adv Carbohydr Chem* **2** 203 *1946*, DOI: 10.1016/S0096-5332(08)60011-9; for Dextran: Structure & Synthesis see Neely *Adv Carbohydr Chem* **15** 341 *1961*, DOI: 10.1016/S0096-5332(08)60191-5.]

Diacetone-D-glucose (1,2:5,6-di-*O*-isopropylidene-α-D-glucofuranoside) *[582-52-5]* **$C_{12}H_{20}O_6$, M 260.3, m 107-110°, 110.5°, 111-113°, 112°, $[\alpha]_D^{15}$ -18.4 (c 1, H_2O).** Diacetone-D-glucose crystallises from Et_2O, (needles), petroleum ether or $*C_6H_6$ and sublimes *in vacuo*. It is soluble in 7 volumes of H_2O and 200 volumes of petroleum ether at their boiling points. The solubility in H_2O at 17.5° is 4.3%. It precipitates from aqueous solutions on basification with NaOH. [Schmid & Karrer *Helv Chim Acta* **32** 1371 *1949*, DOI: 10.1002/hlca.19490320504; Fischer & Rund *Chem Ber* **49** 88 *1916*, DOI: 10.1002/cber.19160490111; IR: Kuhn

[Overend et al. *J Chem Soc* 671 *1950*, DOI: 10.1039/JR9500000671; Wood & Fletcher *J Am Chem Soc* **79** 3234 *1957*, DOI: 10.1021/ja01569a064; Distler & Jourdian *J Biol Chem* **248** 6772 *1973*, PMID: 4270451; Seeberger et al. *Aldrichim Acta* **30** 75 *1997*; *Beilstein* **17** III/IV 2332.]

Galactaric acid (mucic acid) *[526-99-6]* **$C_6H_{10}O_8$, M 210.1, m 212-213°(dec), 230°(dec), pK_1^{25} 3.09 (3.29), pK_2^{25} 3.63 (4.41).** Dissolve mucic acid (40g) in the minimum (calculated) volume of N aqueous NaOH (~ 335ml) without heating, decolorise this with charcoal, filter and precipitate it by adding 5N HCl (~ 57ml). Cool for 1 hour at 0°, filter off, wash with cold H_2O and dry it *in vacuo*. All temperatures should be kept below 25°. It is optically inactive. [Barker et al. *J Chem Soc* 4128 *1958*, DOI: 10.1039/JR9580004128; Lewis et al. *Methods in Carbohydrate Chemistry* **II** 39 *1963*, Academic Press, *Beilstein* **3** IV 1292.]

D-Galactonic acid *[576-36-3]* **$C_6H_{12}O_7$, M 196.2, m 141° (hydrate), 148° (anhydrous) pK_{Est} ~3.5.** Crystallise D-galactonic acid from EtOH or aqueous EtOH. It cyclises to ***D-galactono-1,4-lactone***, **m 134-136°**, and mutarotates in 1 hour to $[\alpha]_{546}^{30}$ -92 (c 5, H_2O). It can also be obtained from the Na salt by adding 10 times its weight of acetic acid, warming till just brown, cooling, filtering off the crystals and drying them. It has **m 145-146°, $[\alpha]_D^{25}$ –13.6 (c 1, H_2O, 2 minutes and mutarotates to –57.6)**. [Brackenbury & Upson *J Am Chem Soc* **55** 2512 *1933*, DOI: 10.1021/ja01333a046; *Beilstein* **3** IV 1257, and for the γ-lactone see below.]

D(-)-Galactono-1,4-lactone *[2782-07-2]* **$C_6H_{10}O_6$, M 178.1, m 134-135°, 134-137°, 137°, $[\alpha]_D^{20}$ -78 (c 5, H_2O, 1 hour).** Crystallise the lactone from EtOH, aqueous EtOH, MeOH or EtOAc. It is also purified by passage through a column of Amberlite IR-120 (H^+ form), and the effluent and washings are then freeze-dried [Wolfrom & Thompson *Methods in Carbohydrate Chemistry* **I** 67 *1963*, Academic Press]. The ***5,6-O-isopropylidene-D-galactono-1,4-lactone*** is purified by chromatography (EtOAc) and has **m 165-167°** (from EtOH/hexane), and **167.5-168.5°** (from Me_2CO/*C_6H_6) [for NMR see Copeland & Stick *Aust J Chem* **31** 1371 *1978*, DOI: 10.1071/CH9781371.] [*Beilstein* **18** III/IV 3026, **18/5** V 18.]

D(+)-Galactosamine hydrochloride *[1772-03-8]* **$C_6H_{13}NO_5$. HCl, M 215.6, m 181-185°, $[\alpha]_D^{25}$ +96.4 (after 24 hours, c 3.2 in H_2O), pK_{Est} ~7.7 (free base).** Dissolve the hydrochloride in a small volume of H_2O. Then add three volumes of EtOH, followed by acetone until faintly turbid and keep overnight in a refrigerator. [Roseman & Ludoweig *J Am Chem Soc* **76** 301 *1954*, DOI: 10.1021/ja01630a098; *Beilstein* **4** IV 2024.]

α-D(+)-Galactose *[59-23-4, 3646-73-9 pyranose]* **$C_6H_{12}O_6$, M 180.2, m 167-168°, 168-170°, $[\alpha]_D^{25}$ +80.4 (after 24 hours, c 4 in H_2O), pK^{25} 12.48.** α-D-Galactose is crystallised twice from aqueous 80% EtOH at -10°, then dried in a vacuum oven at 90° over P_2O_5 for 10 hours. [Link *Biochemical Preparations* **3** 75 *1953*, Hansen et al. *Biochemical Preparations* **4** 2 *1955*.] Also purify it by recrystallising the dried solid (150g) in hot H_2O (150ml), then adding hot MeOH (250ml) and hot EtOH (500ml), stirring to mix, filtering through a bed of charcoal, and the clear filtrate is stirred to initiate crystallisation. After standing overnight at 10°, the crystals of the ***α-anomer*** are filtered off by suction, washed with MeOH, then EtOH, and dried (yield 130g); and more can be obtained by evaporation of the filtrate and washing as before. [Wolfrom & Thompson *Methods in Carbohydrate Chemistry* **I** 120 *1962*, Academic Press, *Beilstein* **1** IV 4336.]

β-D-Galactose *[7296-64-2 (pyranose)]* **$C_6H_{12}O_6$, M 180.2, m 167°, $[\alpha]_D^{20}$ +52 (initial, c 4 in H_2O).** α-D-Galactose (40g) is dissolved in hot H_2O to establish the equilibrium of α- and β- anomers; then the solution is cooled to 0° and poured into absolute EtOH (500ml). Stir vigorously and crystallisation occurs within a few minutes, and more rapidly if seeded, filter the crystals immediately (7g, $[\alpha]_D^{20}$ +65 initial, c 4 in H_2O). This mixture of α- and β- anomers is further separated by dissolving in an equal weight of cold H_2O, filtering and adding to ice cold absolute EtOH (250ml) and stirring for 1 minute when crystals separate, then filter them off. After two such crystallisations, the initial $[\alpha]_D^{20}$ is +53. This can be further purified by shaking with 80% EtOH for 2 minutes, filtering, washing with EtOH and Et_2O, and drying in a vacuum desiccator to give ***β-D-galactose*** (15g) with **m 167°,** $[\alpha]_D^{20}$ +52 (initial, c 4 in H_2O) mutarotating to +80.4. Acetylation of D-galactose with hot NaOAc/Ac_2O gives ***β-D-galactopyranoside pentaacetate*** **m 142°, $[\alpha]_D^{25}$ +25 (c 4 in $CHCl_3$)**. [Wolfrom & Thompson *Methods in Carbohydrate Chemistry* **I** 120 *1962*, Academic Press, *Beilstein* **1** IV 4336.]

D(+)-Galacturonic acid *[685-73-4, 91510-62-2 (H_2O)]* **$C_6H_{10}O_7$, M 194.1, m 159-161°, $[\alpha]_D^{20}$ +36 (c 6, H_2O, 2h), pK_{Est} ~ 4.8.** Crystallisation of the acid from 95% EtOH and drying it in a vacuum desiccator (12mm) over P_2O_5 gives the ***monohydrate*** mixture of α- and β- anomers **(mostly α-)** as white micro needles, which sinter at **~100-111°** and melt at **159-160°**, $[\alpha]_D^{20}$ +107 (initial, c 4 in H_2O mutarotating to +51°). [Link & Sell *Biochemical Preparations* **3** 74, 78 *1953*, *Beilstein* **3** IV 2000.] The ***β-anomer*** is obtained by warming the α-anomer in EtOH, AcOH or EtOAc and has **m 160° (165°, sinters at 140°),** $[\alpha]_D^{20}$ +27 (initial, c 2 in H_2O mutarotating to +55.3° in 24 hours). The ***sodium salt*** *[14984-39-5]* **M** 216.1 has $[\alpha]_D^{20}$ +27 (c 10 in H_2O after 5hours). The ***phenylhydrazone*** has **m 141°**(from MeOH). [Ehrlich & Schubert *Chem Ber* ***62*** *1974, 2014* 1929, DOI: 10.1002/cber.19290620818; Anderson & King *J Chem Soc* 5333 *1961*, DOI: 10.1039/JR9610005333; *Beilstein* **3** IV 2001.]

Genistin (4',5,7-trihydroxyisoflavone-7-D-glucoside) *[529-59-9]* **$C_{21}H_{20}O_{10}$, M 432.4, m 256°, $[\alpha]_D^{22}$ -28 (c 0.6, 0.02N NaOH).** Genistin is repeatedly crystallised from hot 80% EtOH/water and treated with charcoal (Nuchar) until free from saponin. The presence of saponin is detected by adding crystals to concentrated H_2SO_4 when the citron yellow colour changes to red, then purple. Pure genistin does not change colour. Its UV in 85% EtOH has λ_{max} at 262.5nm. [Walter *J Am Chem Soc* **63** 3273 *1941*, DOI: 10.1021/ja01857a013; *Beilstein* **18** III/IV 2732.]

α-Gentiobiose (amygdalose, 6-*O*-α-D-glucopyranosyl-D-glucopyranose) *[5995-99-5 (bi-pyranose)]* **$C_{36}H_{86}O_{11}$, M 342.3, m 86° (2MeOH), 189-195°, 195-197° (anhydrous), $[\alpha]_{546}^{20}$ +11 (after 24 hours, c 4, H_2O).** Crystallise α-gentiobiose from MeOH (retains solvent of crystallisation). It is best purified by conversion to the ***α-octaacetate***, **m 191-192°** (recrystallise from absolute EtOH or $CHCl_3$ and excess absolute EtOH), $[\alpha]_D^{20}$ +51.6 (c 4.3, $CHCl_3$) directly [Goldstein & Whelan *Methods in Carbohydrate Chemistry* **I** 313 *1962*, Academic Press, Hudson & Johnson *J Am Chem Soc* **39** 1272 *1917*, DOI: 10.1021/ja02251a016], or from the ***β-octaacetate*** (see entry below) obtained by acetylation with Ac_2O and $ZnCl_2$, and hydrolysed (see entry below). It mutarotates from $[\alpha]_D^{22}$ +16° (3 minutes) to +9.5 (c 2, H_2O). [Reynolds & Evans *J Am Chem Soc* **60** 2559 *1938*, DOI: 10.1021/ja01277a080; NMR analysis: Bradbury & Collins *Carbohydrate Research* **71** 15 *1979*, DOI: 10.1016/S0008-6215(00)86056-5; *Beilstein* **17/7** V 203.]

β-Gentiobiose (6-*O*-β-D-glucopyranosyl-D-glucopyranose) *[5996-00-9 (bi-pyranose), 554-91-6 (one open ring)]* **$C_{36}H_{86}O_{11}$, M 342.3, m 190-195°, $[\alpha]_{546}^{20}$ +8 (after 6 hours, c 3, H_2O).** β-Gentiobiose is best purified *via* the ***octaacetate*** which is recrystallised from MeOH, EtOH or better from methyl cellosolve by heating at 80°. The octaacetate (15g) is hydrolysed by suspending it in dry 0.05N NaOMe in MeOH (180ml) for 1 hour with occasional shaking at room temperature. Dilute this with H_2O to dissolve suspended matter, pass through Amberlite IR-120 and Duolite A-4 columns and the eluate is evaporated under reduced pressure to a syrup. Residual H_2O is removed by repeated distillation with absolute EtOH under reduced pressure. The syrup is dissolved in methyl cellosolve (~40ml), filtered, nucleated and placed in an oven at 80°. The crystals are filtered off, washed with absolute EtOH (yield 6.7g, 89%), dried and have **m 187-189°**. Further recrystallisation from methyl cellosolve gives **m 190°**, and mutarotates from $[\alpha]_D^{28}$ -1.5 (initial) to +10.6 (final, c 4, H_2O). The pure ***β-octaacetate*** has **m 193°** (crystallised from 95% EtOH) and has $[\alpha]_D^{20}$ -5 (c 1.8, $CHCl_3$). [Goldstein & Whelan *Methods in Carbohydrate Chemistry* **I** 313 *1962*, Academic Press, *Beilstein* **17/7** V 203.]

Glucamine (glycamine, 1-amino-1-deoxy-D-glucitol) *[488-43-7]* **$C_6H_{15}NO_5$, M 181.2, m 127°, $[\alpha]_D^{20}$ -8 (c 10, H_2O), pK_{Est} ~9.0.** Crystallise glucamine from MeOH or aqueous MeOH and store it in a CO_2-free atmosphere. For the ***N-methylglucamine*** derivative see below. [Holly et al. *J Am Chem Soc* **72** 5416 *1950*, DOI: 10.1021/ja01168a014; Karrer et al. *Helv Chim Acta* 20 83 *1937*, Kagan et al. *J Am Chem Soc* 79 3541 *1957*, DOI: 10.1021/ja01570a063; Groggins & Stirton *Ind Eng Chem* **29** 1353 *1937*, DOI: 10.1021/ie50336a009.]

D-Gluconamide *[3118-85-2]* **$C_6H_{13}NO_6$, M 195.2, m 142-143°, 144°, $[\alpha]_D^{23}$ +31 (c 2, H_2O).** Crystallise D-gluconamide from EtOH or 1,2-dimethoxyethane. It mutarotates slowly and hydrolytically in aqueous solution from +30.7 to +13.8 in 80 hours to give ***ammonium D-gluconate*** which recrystallises from 95% EtOH with **m 153-154°** and **$[\alpha]_D^{25}$ +11.8 (c 3, H_2O).** [Wolfrom et al. *J Am Chem Soc* **80** 944 *1958*, DOI: 10.1021/ja01537a049; *Beilstein* **3** VI 1259.]

D-Glucono-δ-lactone *[90-80-2]* **$C_6H_{10}NO_6$, M 178.1, m 152-153°, 160°(dec), $[\alpha]_{546}^{20}$ +76 (c 4, H_2O).** Crystallise D-glucono-δ-lactone from ethylene glycol monomethyl ether and dry it for 1 hour at 110°. It can be freed from other sugars *via* a column of Celite and charcoal (750g of each, 90 x 7.5cm) which is washed with 0.01N formic acid until the pH of the wash is equal to that of the entering acid. The lactone is applied in H_2O and eluted with 0.01N formic acid (7L), then eluted with 7.5% EtOH/0.01N formic acid (8L), then 15% EtOH/0.01N formic acid (8L) which removes pentose and isomaltose (the optical rotation of the eluates are used for sugar detection) and finally elution with aqueous formic acid provides glucolactone which is obtained by evaporating or freeze drying. Its solubility in H_2O is 60%, and 1% in EtOH. A solution in H_2O is slightly acidic, and the lactone dissolves in an equivalent of aqueous NaOH to form ***sodium D-gluconate*** *[527-07-1]* **M 218.1,** has **m 200-206°(dec), $[\alpha]_D^{25}$ +12 (c 10, H_2O), pK^{25} 3.6.** [Smith & Whelan *Biochemical Preparations* **10** 127 *1963*, *Beilstein* **3** IV 1255.]

α− and β− Glucosamine (2-amino-2-deoxy-D-glucose) *[3416-24-8]* **$C_6H_{13}NO_5$, M 179.2, m 110°(dec), $[\alpha]_D^{20}$ +28 to +48 (c 5, H_2O), pK^{24} 7.71.** Crystallise the amines from MeOH. The free base has been obtained from the ***hydrochloride*** (21.5g, see entry below) in a mixture of Et_3N (15ml) and EtOH (125ml) by shaking for 2 days at room temperature, and the solid Et_3N.HCl is filtered off and the process repeated with more Et_3N (3-4 times) until the **α−D-glucosamine** (15g) is free from Cl ions. It has **m 88°**, **$[\alpha]_D^{20}$ +100 mutarotating to +47.5 (c 1, H_2O).** When Et_2NH is used as base, the α− to β− conversion is complete giving ***β−D-glucosamine***. The ***pentaacetate*** is purified by dissolving in $CHCl_3$, treating with charcoal, drying ($MgSO_4$), evaporating the solvent, and adding a little dry Et_2O to induce crystallisation. It has **m 124-126**, $[\alpha]_D^{20}$ +113 (c 1, $CHCl_3$) after 16 hours in a desiccator. [Leaback *Biochemical Preparations* **10** 118 *1963*.] The ***N-acetyl derivative***, **m 203-205°** from MeOH/Et_2O (dry in vacuum P_2O_5) has $[\alpha]_D^{20}$ +75 mutarotating to +41 (c 2, H_2O); this derivative can also be purified by dissolving in the minimum volume of H_2O to which is added 7-8 volumes of EtOH followed by Et_2O until turbid and keeping at ~20° to crystallise. Wash the crystals with MeOH then Et_2O and dry *in vacuo* over P_2O_5. [Horton *Biochemical Preparations* **11** 1 *1966*.]

D-Glucosamine hydrochloride *[66-84-2]* **$C_6H_{13}NO_5$. HCl, M 215.6, m 190-194°(dec), >300°, $[\alpha]_D^{25}$ +71.8 (after 20 hours, c 4, H_2O), pK^{24} 7.71.** Crystallise the hydrochloride from 3M HCl, water, and finally water/EtOH/acetone as for ***galactosamine hydrochloride***. [Purchase & Braun *Org Synth* **26** 36 *1946*, DOI: 10.15227/orgsyn.026.0036; Stacey & Webber *Methods in Carbohydrate Chemistry* **I** 228 *1962*, Academic Press.] The salt has also been purified by dissolving in the minimum volume of boiling H_2O (charcoal), filtering and adding a large excess of 95% EtOH (~4 volumes) and stirring vigorously for several hours. Collect the crystals after 4-6 hours to give ***α− anomer*** which mutarotates from **$[\alpha]_D^{25}$ +100 to +72 (equilibrium, c 1, H_2O).** A large amount of the ***β-anomer*** stays in solution. This can be precipitated from the filtrate by adding excess Et_2O. The mixture of α- plus β-anomers has $[\alpha]_D^{25.5}$ +68.8 (c 4.75, H_2O, mutarotating to +70.1) [Leaback *Biochemical Preparations* **10** 118 *1963*]. *Note that* ***if Et_2NH is used instead of Et_3N, conversion to the β-anomer*** *can be complete* (see above). [Stacey et al. *Methods in Carbohydrate Chemistry* **I** 306*1962*, Academic Press, *Beilstein* **4** IV 2018.]

α-D-Glucose *[492-62-6]* **$C_6H_{12}O_6$, M 180.2, m 83° (monohydrate), 146° (anhydrous), mutarotates from $[\alpha]_D^{20}$ +112 to +52.5 (after 24 hours, c 4, H_2O), pK^{25} 12.46.** Recrystallise α-D-glucose slowly from aqueous 80% EtOH, then dry it over P_2O_5 *in vacuo*. *Alternatively*, crystallise it from water at 55°, then dry it for 6 hours in a vacuum oven between 60-70°/2mm. Its solubilities are: H_2O (~50%), EtOH (1.7%). [Hendricks et al. *J Am Chem Soc* **56** 99 *1934*, DOI: 10.1021/ja01316a029; *Beilstein* **1** IV 4302.] [For equilibrium forms see *Adv Carbohydr Chem* **42** 15 *1984*, DOI: 10.1016/S0065-2318(08)60122-5; Angyal & Pickles *Aust J Chem* **25** 1711 *1972*, DOI: 10.1071/CH9721711.]

β-D-Glucose *[50-99-7]* **$C_6H_{12}O_6$, M 180.2, m 148-150°, 150-152°, mutarotates from $[\alpha]_D^{20}$ +18.7 to +52.5 (after 24 hours, c 4, H_2O).** Crystallise β-D-glucose from hot glacial acetic acid or pyridine. Traces of solvent are removed by drying in a vacuum oven at 75° for >3 hours. [Dean & Gottfried *Adv Carbohydr Chem* **5** 127 *1950*, DOI: 10.1016/S0096-5332(08)60337-9; Kjaer & Lindberg *Acta Chem Scand* **13** 1713 *1959,* DOI: 10.3891/acta.chem.scand.13-1713; Whistler & Miller *Methods in Carbohydrate Chemistry* **I** 130*1962*, Academic Press, *Beilstein* **1** IV 4306.] [For equilibrium forms see Angyal *Adv Carbohydr Chem* **42** 15 *1984*, DOI: 10.1016/S0065-2318(08)60122-5; Angyal & Pickles *Aust J Chem* **25** 1711 *1972*, see reference above].

α-D-Glucose pentaacetate *[604-68-2]* **$C_{16}H_{22}O_{11}$, M 390.4, m 110-111°, 112-113°, $[\alpha]_{546}^{20}$ +119, $[\alpha]_{D}^{20}$ +102 (c 5, $CHCl_3$).** Crystallise it from MeOH, EtOH or three recrystallisations from 95% EtOH. [Wolfrom & Thompson *Methods in Carbohydrate Chemistry* **II** 212 *1963*, Academic Press, *Beilstein* **17/7** V 318.]

β-D-Glucose pentaacetate *[604-69-3]* **$C_{16}H_{22}O_{11}$, M 390.4, m 130-132°, 131-132°, $[\alpha]_{546}^{20}$ +5 (c 5, $CHCl_3$).** Crystallise the pentaacetate from MeOH or EtOH. It is best purified by recrystallising 160g from 1L of 95% EtOH (charcoal) and filtering hot. It is important that as soon as the temperature of the filtrate cools to ~20° the pentaacetate is filtered off. ***Note*** that some α-D-isomer will crystallise out in a prolonged crystallisation period. Further crystallisation in this manner and drying in a vacuum over $CaCl_2$ will give ***pure*** β-D-anomer with **m 132°**, $[\alpha]_{D}^{20}$ +4 (c 5, $CHCl_3$). [Wolfrom & Thompson *Methods in Carbohydrate Chemistry* **II** 212 *1963*, Academic Press, Krahl & Cori *Biochemical Preparations* **1** 33 *1955*, *Beilstein* **17/7** V 319.]

D-Glucose phenylhydrazone *[3713-25-5]* **$C_{12}H_{18}N_2O_5$, M 358.4, m three forms.** Crystallise the hydrazone from 70% aqueous EtOH or EtOH/Et_2O. Three forms have been described: 'α' form **m 159°, 160°** which mutarotates from $[\alpha]_{D}^{20}$ -87 to -50 (H_2O) [Fischer *Chem Ber* **20** 821 *1887*, DOI: 10.1002/cber.188702001187; Behrend *Justus Liebigs Ann Chem* **353** 106 *1907*, DOI: 10.1002/jlac.19073530104], 'β' form **m 140-141°, 142°** which mutarotates from $[\alpha]_{D}^{20}$ -2 to -50 (H_2O) [Behrend & Lohr *Justus Liebigs Ann Chem* **362** 78 *1908*, DOI: 10.1002/jlac.19083620107], and Skraup's form **m 115-116°** which mutarotates from $[\alpha]_{D}^{20}$ -70 to -47 (H_2O) [Skraup *Monatsh Chem* **10** 401 *1889*, DOI: 10.1007/BF01516449; Butler & Crechter *J Am Chem Soc* **51** 3161 *1929*, DOI: 10.1021/ja01385a042]. These mutarotate to the **formazan**. [*Beilstein* **1** IV 4322, Mester & Major *J Am Chem Soc* **77** 4297 *1955*, DOI: 10.1021/ja01621a037; Stanek et al. The Monosaccharides, Academic Press *1963*, pp 539-541, 543.]

D-Glucuronic acid *[6556-12-3]* **$C_6H_{10}O_7$, M 194.1, m 159-161°, 165°, $[\alpha]_{D}^{20}$ +36 (c 6, H_2O, 2 hours, mutarotating from +11.5°), pK_2^{20} 3.18.** Crystallise the acid from EtOH or EtOAc, wash it with MeOH and dry it *in vacuo* to give the ***'β' form***. Heating converts it to the lactone (see below). The ***sodium salt monohydrate*** *[207300-70-7]* **M** 234.1 has **m ~136-138°(dec)** $[\alpha]_{D}^{20}$ +21 (c 2, H_2O after 2hours). [Sutter & Reichstein *Helv Chim Acta* **21** 1210 *1938*, DOI: 10.1002/hlca.193802101150; *Beilstein* **3** H 886, **3** IV 1997.]

D-Glucurono-6,3-(δ)−lactone *[32449-92-6]* **$C_6H_8O_6$, M 176.1, m 175-177°, $[\alpha]_{546}^{20}$ +22 (after 24 hours, c 10, H_2O).** Dissolve the lactone or mixture of lactone and acid in H_2O and concentrate the solution on a steam bath until crystallisation begins. Cool rapidly to room temperature wih stirring. After 2 hours the product is filtered off, washed with cold EtOH and dried to **m 174-175°** and $[\alpha]_{D}^{25}$ +19.8 (c 5.2, H_2O). The amount of ***free acid*** can be obtained by titration of an ice-cold aqueous solution with standard alkali. It can be recrystallised from EtOH, EtOH/H_2O or MeOH, and the highest recorded **m** is **180°**. [Stacey *J Chem Soc* 1529 *1939*, DOI: 10.1039/JR9390001529; Mehltretter et al. *J Am Chem Soc* **73** 2424 *1951*, DOI: 10.1021/ja01150a005; *Beilstein* **18** III/IV 3055, **18/5** V 33.]

D(+)-Glycogen *[9005-79-2]* **$(C_6H_{10}O_5)_n$, M 25,000-100,000, m 270-280°(dec), $[\alpha]_{546}^{20}$ +216 (c 5, H_2O).** A 5% aqueous solution (charcoal) of D(+)-glycogen is filtered, and an equal volume of EtOH is added. After standing overnight at 3° the precipitate is collected by centrifugation, washed with absolute EtOH, then EtOH/diethyl ether (1:1) and diethyl ether, and dried. [Sutherland & Wosilait *J Biol Chem* **218** 459 *1956*, http://www.jbc.org/content/218/1/459.]

Glycyrrhizic acid ammonium salt (3H_2O) (Glycyrrhizin) *[53956-04-0]* **$C_{42}H_{62}O_{16}.NH_3$, M 823.0, m 210°(dec), 220°(dec, sintering at 170°), $[\alpha]_{546}^{20}$ +60 (c 1, 50% aqueous EtOH), $[\alpha]_{D}^{20}$ +46.9 (c 1.5, 40% EtOH), pK_{Est} ~4.0.** It is the salt of a glucosylglucoside of a pentacyclic triterpene acid present in *glycyrrhiza* root (licorice). Crystallise the ammonium salt from glacial acetic acid, then dissolve it in ethanolic ammonia and evaporate. The ***pentahydrate*** forms needles from 75% aqueous EtOH, **m 212-217°(dec)**, with UV λ_{max} at 248nm (ε 11,400, in 0.1mM EtOH). It has an intensely sweet taste. The ***free acid***, ***18β-glycyrrhetinic acid*** **(Enoxolone)***[1449-05-4]* M 470.7 crystallises from 75%v/v EtOH/H_2O with **m 284-285°**, with UV similar to the glucoside salt. [Karrer et al. *Helv Chim Acta* **4** 100 *1921*, DOI: 10.1002/hlca.19210040108; Lythgoe & Trippett *J Chem Soc* 1983, 1987 *1950*, DOI: 10.1039/JR9500001983; Marsh & Levvy *Biochem J* **63** 9 *1956*, DOI: 10.1042/bj0630009; *Beilstein* **18** IV 5156.]

Heparin (from pig intestinal mucosa) *[9005-49-6]* **$(C_{12}H_{19}NO_{20}S_3)_n$, M_r ~12,000-15,000, amorphous, $[\alpha]_D^{20}$ ~+55 (H_2O).** Most likely contaminants are mucopolysaccharides including heparin sulfate and dermatan sulfate. Purify heparin by precipitation with cetylpyridinium chloride from saturated solutions of high ionic strength. [Cifonelli & Roden *Biochemical Preparations* **12** 12 *1968*, Wolfrom et al. *J Org Chem* **29** 540 *1964*, DOI: 10.1021/jo01026a005; Foster & Huggard *Adv Carbohydr Chem* **10** 335-368 *1955*, DOI: 10.1016/S0096-5332(08)60397-5] Useful anticoagulant, with protamine sulfate *[9007-31-2]* as antidote.

Heparin (sodium salt) *[9041-08-1]* **M_r ~ 3000 (low Mol Wt, Bovine), amorphous, $[\alpha]_D^{20}$ +47 (c 1.5, H_2O).** Dissolve the salt in 0.1M NaCl (1g/100ml) and precipitate it by adding EtOH (150ml). [Wolfrom et al. *J Org Chem* **29** 540 *1964*, DOI: 10.1021/jo01026a005; Foster & Huggard *Adv Carbohydr Chem* **10** 335-368 *1955*, DOI: 10.1016/S0096-5332(08)60397-5.]

n*-Heptyl-β−D-glucopyranoside** *[78617-12-6]* **$C_{13}H_{26}O_6$, M 278.4, m 74-77°, 76-77°, $[\alpha]_D^{20}$ -34.2 (c 5, H_2O).** Purify this non-ionic detergent by repeated crystallisation from Me_2CO which is a better solvent than EtOAc. Its CMC (critical micellar concentration) in H_2O is 79mM. The ***acetate has **m 66-68.5°** and $[\alpha]_D^{20}$ -20.5 (c 4, $CHCl_3$) [Pigman & Richtmyer *J Am Chem Soc* **64** 369 *1942*, DOI: 10.1021/ja01254a041]. [*Beilstein* **17** IV 2936.]

Heptyl-β−D-1-thioglucopyranoside *[85618-20-8]* **$C_{13}H_{26}O_5S$, M 294.4, m 96.1-98.3°, 98-99°.** The ***tetraacetyl*** derivative is purified by silica gel column chromatography, eluting with a $*C_6H_6/Me_2CO$ gradient (up to 5% of Me_2CO), and recrystallising from *n*-hexane to give colourless needles **m 72-74°** (Erbing & Lindberg *Acta Chem Scand* **B30** 611 *1976*, DOI: 10.3891/acta.chem.scand.30b-0611; gave **m 69-70°**). Hydrolysis with an equivalent of base in methanol gives the ***desired glucoside***. It provides a clear yellow solution in MeOH at 0.1g/ml. This is a non-ionic detergent for reconstituting membrane proteins and has a critical micelle concentration of 30 mM. [Shimamoto et al. *J Biochem (Tokyo)* ***97*** 1807 *1985*, PMID: 2863264; Saito & Tsuchiya *Chem Pharm Bull Jpn* **33** 503 *1985*, DOI: org/10.1248/cpb.33.503; for enzymic syntheses see Shinoyama et al. *Agric Biol Chem* **55** 1679 *1991*, http://dx.doi.org/10.1080/00021369.1991.10870814].

D(-)-Isoascorbic acid (araboascorbic acid, 5*R*-[*R*-1,2-dihydroxyethyl-3,4-dihydroxy-5*H*-furan-2-one]) *[89-65-6]* **$C_6H_8O_6$, M 176.1, m 169°, 174°(0.5 H_2O, dec), $[\alpha]_D^{25}$ -16.8 (c 2, H_2O), $[\alpha]_D^{20}$ +77 (c 2, Me_2CO, acetonylidene derivative), pK^{18} 3.99 (4.23).** Crystallise D(-)-isoascorbic acid from H_2O, EtOH or dioxane. Its UV has λ_{max} is at 245nm with ε 7,500 (EtOH). [Reichstein et al. *Helv Chim Acta* **17** 510, 516 *1934*, DOI: 10.1002/hlca.19340170157; Heslop et al. *J Chem Soc* 225 *1944*, DOI: 10.1039/JR9440000225; *Beilstein* **18** III/IV 3037, **18/5** V 26.]

2-Keto-L-gulonic acid (xylo-2-hexulonic acid) *[526-98-7, 342385-52-8 xH_2O]* **$C_6H_{10}O_7$, M 194.1, m 159-162°, 171°, $[\alpha]_D^{20}$ -34.8 (c 2, MeOH), $[\alpha]_D^{18}$ -48 (c 1, H_2O), pK_{Est} ~ 2.2.** Crystallise 2-keto-L-gulonic acid from half its weight of water, wash it with Me_2CO and dry it *in vacuo*. [*Beilstein* **17/7** V 53.]

***N*-Nonanoyl-*n*-methylglucamine (Mega-9)** *[85261-19-4]* **$C_{16}H_{33}NO_6$, M 335.4, m 87-89°.** It is a non-ionic detergent which is purified as for *n*-decanoyl-*N*-methylglucamine above. [Hildreth *Biochem J* **207** 363 *1982*, DOI: 10.1042/bj2070363.]

Nonyl-β-D-glucopyranoside *[69984-73-2]* **$C_{15}H_{30}O_6$, M 306.4, m 67.5-70°, 70-71°, $[\alpha]_D^{20}$ -34.4 (c 5, H_2O), $[\alpha]_D^{25}$ -28.8 (c 1, MeOH).** Purify nonyl-β-D-glucopyranoside by recrystallisation from Me_2CO or hexane/Et_2O and store it in well-stoppered containers as it is *hygroscopic*. It is a non-ionic detergent with a CMC (critical micellar concentration) of 6.5mM. [Pigman & Richtmyer *J Am Chem Soc* **64** 369 *1942*, DOI: 10.1021/ja01254a041.] It is a UV transparent non-ionic detergent for solubilising membrane proteins [Schwendener et al. *Biochem Biophys Res Commun* **100** 1055 *1981*, DOI: 10.1016/0006-291X(81)91930-6]. [*Beilstein* **17** III/IV 2937, **17/7** V 39.]

1-*O*-Octyl-β-D-glucopyranoside *[29836-26-8]* **$C_{14}H_{28}O_6$, M 292.4, m 62-65°, 63.8-65°, $[\alpha]_D^{20}$ -34° (c 4, H_2O).** Purify octyl-β-D-glucopyranoside by recrystallisation from Me_2CO. It is ***hygroscopic*** and should be stored in a well-stoppered container. [Noller & Rockwell *J Am Chem Soc* **60** 2076 *1938*, DOI: 10.1021/ja01276a017; Pigman & Richtmyer *J Am Chem Soc* **64** 369 *1942*, DOI: 10.1021/ja01254a041.] It is a UV transparent non-ionic dialysable detergent for solubilising membrane proteins. Its CMC (critical micellar concentration) is 20-25mM in H_2O (20-25°), with average micellar wt of 25,000 and aggregation number of 84. The ***2,3,4,6-tetraacetate*** *[38954-67-5]* **$C_{22}H_{36}O_{10}$, M 460.5,** has **m 50-52°**, and $[\alpha]_D^{20}$ -16 (c 1.8, $CHCl_3$)**.** The ***α−D-isomer*** with $[\alpha]_D^{20}$ +118 (c 1, MeOH) has similar solubilising properties. [Lazo & Quinn *Anal Biochem* **102** 68 *1980*, DOI: 10.1016/0003-2697(80)90318-8; Stubbs et al. *Biochim Biophys Acta* **426** 46 *1976*, DOI: 10.1016/0005-2736(76)90428-4; *Beilstein* **17/7** V 38.]

Pectic acid *[9046-40-6]* **$(C_6H_8O_6)_n$, M_r ~500,000, amorphous, $[\alpha]_D$ +250 (c 1, 0.1M NaOH).** Citrus pectic acid (500g) is refluxed for 18 hours with 1.5L of 70% EtOH, and the suspension is filtered hot. The residue is washed with hot 70% EtOH and finally with ether. It is dried in a current of air, ground and dried for 18 hours at 80° under vacuum. [Morell & Link *J Biol Chem* **100** 385 *1933*, http://www.jbc.org/content/ 100/2/385.] It can be further purified by dispersing it in water and adding just enough dilute NaOH to dissolve the pectic acid, then passing the solution through columns of cation- and anion-exchange resins [Williams & Johnson *Ind Eng Chem (Anal Ed)* **16** 23 *1944*, DOI: 10.1021/i560125a007], and precipitating with two volumes of 95% EtOH containing 0.01% HCl. The precipitate is worked with 95% EtOH, then Et_2O, dried and ground. [Rees & Walsh *Angew Chem Int Ed* **16** 214 *1977*, DOI: 10.1002/anie.197702141; Rees *Adv Carbohydr Chem* **24** 267 *1969*, DOI: 10.1016/S0065-2318(08)60352-2.]

Pectin (1-4 linked heteropolysaccharide) *[9000-69-5]* **M_r 30,000-100,000, amorphous.** Dissolve the pectin in hot water to give a 1% solution, then cool, and make it to about 0.05M in HCl by addition of concentrated HCl, and precipitate it by pouring it slowly, with vigorous stirring into two volumes of 95% EtOH. After standing for several hours, the pectin is filtered through a nylon cloth, then re-dispersed in 95% EtOH and set aside overnight. The precipitate is filtered off, washed with EtOH/Et_2O, then Et_2O and dried in air. [Rees & Walsh *Angew Chem Int Ed* **16** 214 *1977*, DOI: 10.1002/anie.197702141; Rees *Adv Carbohydr Chem* **24** 267

1969, DOI: 10.1016/S0065-2318(08)60352-2.]

Pentaerythritol (2,2-bis[hydroxymethyl]-1,3-propanediol) *[115-77-5]* **$C(CH_2OH)_4$, M 136.2, m 253-258°, 260.5°, 268-269°, b 276°/30mm.** Reflux pentaerythritol with an equal volume of MeOH, then cool, and the precipitate is collected and dried at 90°. It can also be recrystallised from dilute aqueous HCl. After sublimation under high vacuum at 200° it has **m 265.5°**. Its solubility in H_2O is 10%. [*Beilstein* **18** III 2361, **1** IV 2812.]

Pentaerythritol tetraacetate *[597-71-7]* **$C_{13}H_{20}O_8$, M 304.3, m 83-84°, 84-86°.** Crystallise pentaerythritol tetraacetate from hot water, then leach it with cold water until the odour of acetic acid is no longer detectable. It also crystallises from 95% EtOH after dissolving in $CHCl_3$, washing with saturated $NaHCO_3$, then H_2O, drying over anhydrous $CaCl_2$ and evaporating. It has been prepared by acetolysis of the ***tetranitrate*** (see next entry) in 95% yield [Wolfrom et al. *J Am Chem Soc* **73** 874 *1951*, DOI: 10.1021/ja01146a534]. [Breusch & Oğuzer *Chem Ber* **88** 1511 *1955*, DOI: 10.1002/cber.19550881007; LeFèvre et al. *J Chem Soc* 16 *1958*, DOI: 10.1039/JR9580000016; *Beilstein* **1** IV 1812, **2** IV 264.]

Pentaerythritol tetranitrate *[78-11-5]* **$C_5H_8N_4O_{12}$, M 316.2, m 140.1°, 141.3°, decomp >150°.** Crystallise pentaerythritol tetranitrate from acetone or acetone/EtOH. When crystallised from H_2O at 0°, it may have **m 26-28°** (hydrate?). It detonates more easily than TNT on percussion. The ***O-acetate***, when crystallised from EtOH, has **m 87-88°**. Although it has been distilled at 60°/2mm, distillation should **NOT** be attempted as it is **VERY EXPLOSIVE.** The ***autoignition*** temperature is **150°**. It is a vasodilator and used in the management of angina. [Marans et al. *J Am Chem Soc* **76** 1304 *1954*, DOI: 10.1021/ja01634a032; Camp et al. *J Am Chem Soc* **77** 751 *1955*, DOI: 10.1021/ja01608a059; *Beilstein* **1** IV 2816, **2** IV 264.]

Pentaerythrityl laurate (pentaerythrityl tetra-*n*-dodecanoate) *[13057-50-6]* **$C_{53}H_{109}O_8$, M 865.3, m 50°, 50.8-51.8°.** Crystallise the laurate from Me_2CO, Et_2O or petroleum ether. [Breusch & Oğuzer *Chem Ber* **88** 1511 *1955*, DOI: 10.1002/cber.19550881007, and includes a large number of other esters.]

2-Phenylethyl-β-D-thiogalactoside *[63407-54-5]* **$C_{14}H_{20}O_5S$, M 300.4, m 108°, $[\alpha]_D^{23}$ -32.2 (c 5, MeOH).** Recrystallise the thiogalactoside from H_2O and dry in air to give the $1.5.H_2O$ which has **m 80°**. The ***anhydrous*** surfactant is obtained by drying it at 78° over P_2O_5. [Helferich & Türk *Chem Ber* **89** 2215 *1956*, DOI: 10.1002/cber.19560891002.]

Phenyl-β-D-galactopyranoside *[2818-58-8]* **$C_{12}H_{16}O_6$, M 256.3, m 153-154°, 146-148°, 155-156°(dried at 105°), $[\alpha]_D^{20}$ -42 (c 1, H_2O).** Recrystallisation of phenyl-β-D-galactopyranoside from H_2O gives the $0.5H_2O$. [Conchie & Hay *Biochem J* **73** 327 *1959*, DOI: 10.1042/bj0730327; IR: Whistler & House *Anal Chem* **25** 1463 *1953*, DOI: 10.1021/ac60082a013.] It is an ***acceptor substrate*** for fucosyltransferase [Chester et al. *Eur J Biochem* **69** 583 *1976* DOI: 10.1111/j.1432-1033.1976.tb10944.x]. [*Beilstein* **17/7** V 47.]

Phenyl-β-D-glucopyranoside *[1464-44-4]* **$C_{12}H_{16}O_6$, M 256.3, m 174-175° 174-176°, 176°, 176-178°, $[\alpha]_D^{20}$ -72.2 (c 1 for dihydrate, H_2O).** Phenyl-β-D-glucopyranoside crystallises from H_2O with $2H_2O$ and can be dried *in vacuo* at 100°/P_2O_5. The dry preparation has $[\alpha]_D^{25}$ -70.7 (c 2, H_2O). [Robertson & Waters *J Chem Soc* 2729 *1930*, IR: Bunton et al. *J Chem Soc* 4419 *1955*, DOI: 10.1039/JR9550004419; Takahashi *Yakugaku Zasshi (J Pharm Soc Jpn)* **74** 706 *1954*, Whistler & House *Anal Chem* **25** 1463 *1953*, DOI: 10.1021/ac60082a013; UV: Lewis *J Am Chem Soc* **57** 898 *1935*, DOI: 10.1021/ja01308a032.] It is a ***substrate*** for β−D-glucosidase [deBryne *Eur J Biochem* **102** 257 *1979*, DOI: 10.1111/j.1432-1033.1979.tb06288.x]. [*Beilstein* **17** III/V 2946, **17/7** V 46.]

Phlorizin ($2H_2O$) (Phloridzin, phloretin 2'-*O*-β-D-glucoside) *[60-81-1]* **$C_{21}H_{24}O_{10}$, M 436.4, m 106-109°, 110°, $[\alpha]_{546}^{20}$ -62 (c 3.2, EtOH).** This flavonoid glucoside crystallises as the ***dihydrate*** from water and causes glycosuria. [Brazy & Dennis *Am J Physiol* **234** 1279 *1978*, for effect of phloretin and theophylline on 3-O-methylglucose transport by intestinal epitheial cells see Randles & Kimmich *Am J Physiol (cell physiol)* **234** C64 *1978*, PMID: 629334; Zemplén & Bognár *Chem Ber* **75** 1040 *1942*, DOI: 10.1002/cber.19420750903; *Beilstein* **17/7** V 177.] It is a glucoside in *Malus* (apple) species of trees, and is sweet with a bitter after taste.

D(+)-Raffinose ($5H_2O$) **(Melitose, 6-O-α-D-galactopyranosyl-D-glucopyranosyl-β-D-fructo-furanose** *[17629-30-0 ($5H_2O$), 512-69-6 (anhydrous)]* **$C_{18}H_{32}O_{16}$. $5H_2O$, M 594.5, m 80°, 80-82°, $[\alpha]_{546}^{20}$ +124 (c 10, H_2O), $[\alpha]_D^{20}$ +105 (c 1 for pentahydrate, H_2O), pK_1^{25} 12.40, pK_2^{25} 13.44, pK_3^{25} 13.52.** D(+)-Raffinose crystallises from H_2O, 90% aqueous EtOH or MeOH as the ***pentahydrate***. The ***anhydrous*** sugar has **m 132-135°**. It has R_F 0.8 on TLC (Silica Gel, and 1:3:3 $CHCl_3$/butanone:/MeOH). The ***undecaacetate*** has been purified through an alumina column by elution with $CHCl_3$, and recrystallised from EtOH/MeOH/H_2O (3:2:5), with **m 99-100°**, and $[\alpha]_D^{20}$ +92.8 (c 5.14, EtOH). [For pK see Coccioli & Vicedomini *Ann Chim (Rome)* **66** 269, 275 *1976*, and for ^{1}H NMR see Suami et al. *Carbohydr Research* **26** 234 *1973*, DOI: 10.1016/S0008-6215(00)85044-2; *Beilstein* **17** III/IV 3801, **17/8** V 403.]

L(+)-α-Rhamnose (H_2O) (6-deoxy-L-mannose) *[10030-85-0 (H_2O), 3615-41-6 (anhydrous)]* **$C_6H_{12}O_5$. H_2O, M 182.2, m 90-92°, 101°, 105°, $[\alpha]_D^{18}$ -6.8 mutarotating to +9.1 (c 1, H_2O).** Crystallise the rhamnose from H_2O or EtOH. It crystallises easily as the ***monohydrate*** by evaporating a solution in MeOH (90%) and H_2O (10%). It is also purified by dissolving in a small volume of EtOH, adding a few drops of H_2O and cooling. The ^{1}H NMR in D_2O at 44° shows 60% α-pyranose and 40% β-pyranose forms [Angyal *Adv Carbohydr Chem* **42** 15 *1984*, DOI: 10.1016/S0065-2318(08)60122-5.] [Smith *J Chem Soc* 1035 *1940*, DOI: 10.1039/JR9400001035; McGeachin & Beevers *Acta Cryst* **10** 227,230 *1957*, DOI: 10.1107/S0365110X57000687; *Beilstein* **1** IV 4261.]

D-(+)-Ribonic acid-γ-lactone *[5336-08-3]* **$C_5H_8O_5$, M 148.12, m 80°, 84-86°, 85-87°, $[\alpha]_D^{20}$ +18.3 (c 5, H_2O).** Purify D-(+)-ribonic acid-γ-lactone by recrystallisation from EtOAc. The ***tribenzoate*** has **m 54-56°** (from AcOH), $[\alpha]_D^{25}$ +27 (c 2.37, Me_2NCHO), and the ***3,5-O-benzylidene derivative*** has **m 230-231.5°** (needles from Me_2CO-petroleum ether) and $[\alpha]_D^{25}$ -177 ($CHCl_3$). [Chen & Joullié *J Org Chem* **49** 2168 *1984*, DOI: 10.1021/jo00186a018; Zinner & Voigt *J Carbohydr Research* **7** 38 *1968*, DOI: 10.1016/S0008-6215(00)81432-9.]

α-D(-)-Ribose *[50-69-1]* **$C_5H_{10}O_5$, M 150.1, m 88-92°, 90°, $[\alpha]_{546}^{20}$ -24 (after 24 hours, c 10, H_2O), pK^{25} 12.22.** Crystallise α-D(-)-ribose from aqueous 80% EtOH, dry it under vacuum at 60° over P_2O_5 and store it in a vacuum desiccator. It exhibits complex mutarotation with : $[\alpha]_D^{10}$ -23.1 (1.5 minutes), -21.3° (5 minutes), -19.5 (10 minutes), -19.1 (30 minutes), -21.2 (60 minutes), -23.1 (120 minutes), -23.7 (300 minutes), (c 4.5, H_2O) [Phelps et al. *J Am Chem Soc* **56** 747 *1934*, DOI: 10.1021/ja01318a506]. The ^{1}H NMR in D_2O at 44° shows 17% α-pyranose, 59% β-pyranose, 9% α-furanose and 15% β-furanose forms with **furanose** α-H at 5.34ppm (J = 3.0Hz) and β-H at 5.31 (J = 1.7Hz) [Angyal *Adv Carbohydr Chem* **42** 15 *1984*, DOI: 10.1016/S0065-2318(08)60122-5; Angyal & Pickles *Aust J Chem* **25** 1711 *1972*, DOI: 10.1071/CH9721711]. The ***phenylhydrazone*** crystallises from aqueous pyridine in yellow needles, **m 163-164°**, and the ***benzylphenylhydrazone*** has **m 127-128°** [Sowden *J Am Chem Soc* **72** 808 *1950*, DOI: 10.1021/ja01158a041.] [*Beilstein* **1** IV 4211.]

(+)-Rutin (quercetin-3-rubinoside) See Vitamin P in 'Physiologically Active….', this chapter.

Saccharides. They are separated by anion-exchange chromatography. [Walborg & Kondo *Anal Biochem* **37** 320 *1970*, DOI: 10.1016/0003-2697(70)90054-0.]

D(-)-Salicin [2-(hydroxymethyl)phenyl-β−D-glucopyranoside) *[138-52-3]* **$C_{13}H_{18}O_7$, M 286.3, m 204-208°, $[\alpha]_D^{25}$ -63.5 (c** *ca* **3, H_2O).** Crystallise D(-)-salicin from EtOAc, EtOH or water and sublime it at 190-195°/12mm. [Armour et al. *J Chem Soc* 412 *1961*, DOI: 10.1039/JR9610000412; for IR see Pearl & Darling *J Org Chem* **24** 731 *1959*, DOI: 10.1021/jo01088a001; *Beilstein* **17** III/IV 2986, **17/7** V 113.]

Sennoside A (bianthraquinonyl-bis-glucoside *R,R*-enantiomer) *[81-27-6]* **$C_{42}H_{38}O_{20}$, M 862.7, m 220-240°(dec), $[\alpha]_D^{20}$ -164 (c 0.1, Me_2CO/H_2O 6:4), $[\alpha]_D^{20}$ -24 (c 0.2, 70% aqueous dioxane).** Sennoside A forms yellow crystals from aqueous acetone, 2-ethoxyethanol or large volumes of H_2O. [Stoll et al. *Helv Chim Acta* **32** 1892 *1949*, DOI: 10.1002/hlca.19490320613; *Beilstein* **17** III/IV 3403.] It is an analytical chromatography standard, and the laxative principle of *senna*.

Sennoside B (bianthraquinonyl-bis-glucoside *R,S*-enantiomer) *[128-57-4]* **$C_{42}H_{38}O_{20}$, M 862.7, m 209-212°(dec), $[\alpha]_D^{20}$ -100 (c 2, Me_2CO/H_2O 7:1), $[\alpha]_D^{20}$ -67 (c 0.2, 70% aqueous dioxane).** Sennoside B forms yellow crystals from aqueous acetone or large volumes of H_2O. [Stoll et al. *Helv Chim Acta* **32** 1892 *1949*, DOI: 10.1002/hlca.19490320613; *Beilstein* **17** III/IV 3402.] It is an analytical chromatography standard.

Sinigrin monohydrate (Myronate K, 1-thio-β−D-glucopyranose 1-[N-(sulfooxy)-3-butenimidate] monopotassium salt) *[64550-88-5]* **$C_{10}H_{18}NO_{10}S_2.K$, M 415.5, m 125-127°, 128°, 127-129°, 179°(anhydrous), $[\alpha]_D^{20}$ -17 (c 0.2, H_2O), pK_{Est} <0.** Purify sinigrin by recrystallising it three times from EtOH and once from MeOH. The ***tetraacetate*** has **m 193-195°**, $[\alpha]_D^{20}$ -16 (c 0.14, H_2O). [Benn & Ettlinger *JCS Chem Commun* 445 *1965*, DOI: 10.1039/C19650000445; Kjaer et al. *Acta Chem Scand* **10** 432 *1956*, DOI: 10.3891/acta.chem.scand.10-0432; Marsh & Waser *Acta Cryst* (*Sect B*) **26** 1030 *1970*, DOI: 10.1107/S0567740870003539.] It is a β-D-thioglucopyranoside ***substrate*** for thiogluconidase, and is present in horseradish. [MacLeod & Rossiter *Phytochem* **25** 1047 *1986*, DOI: 10.1016/S0031-9422(00)81551-4]. [*Beilstein* **31** H 476, **17** III/IV 3738.]

α-Solanine (solan-5-en-3β-yl-[O^3-β-D-glucopyranosyl-O^2-α-L-rhamnopyranosyl-β-D-galactopyranoside], a solanidine triglycoside) *[20562-02-1]* **$C_{45}H_{73}NO_{15}$, M 868.1, m 285°(dec), 286°(dec) (sintering >190°), $[\alpha]_D^{20}$ -58 (c 0.8, pyridine), pK^{15} 6.66.** Recrystallise α-solanine from EtOH, 85% aqueous EtOH, MeOH or aqueous MeOH as ***dihydrate*** **m 276-278°**. Its solubility in H_2O is 25mg/l, and 5% in pyridine, but it is very soluble in Et_2O and $CHCl_3$. The ***hydrochloride*** is gummy or amorphous but has been crystallised (**m ~212° dec**). It is present in potato sprouts and has insecticidal properties. [Kuhn et al. *Chem Ber* **88** 1492 *1955*, DOI: 10.1002/cber.19550881005; *Beilstein* **21** III/IV 1402.] For *solanidine* (aglycone) *[80-78-4]* see p 988.

Solasonine (solasodine-3-*O*-triglycoside) *[19121-58-5]* **$C_{45}H_{73}NO_{16}$, M 884.1, m 301-303° (sinters at ~296°), $[\alpha]_D^{20}$ -75 (c 0.5, MeOH), pK_{Est} ~ 7.7.** Solasonine crystallises from aqueous 80% dioxane or MeOH in needles. [Bell & Briggs *J Chem Soc* 1 *1942*, DOI: 10.1039/JR9420000001; Briggs et al. *J Chem Soc* 4645 *1961*, DOI: 10.1039/JR9610004645; Briggs et al. *J Chem Soc* 2848 *1963*, DOI: 10.1039/JR9630002848.] The ***picrate*** crystallises from 30% aqueous EtOH with **m 197-198°(dec)** [Briggs & Cambie *J Chem Soc* 1422 *1958*, DOI: 10.1039/JR9580001422]. [*Beilstein* **27** III/IV 2006.] For *solasodine* (aglycone) *[126-17-0]* see p 988.

D(-)-Sorbitol (D-glucitol) *[50-70-4]* **$C_6H_{14}O_6$, M 182.2, m 89-93° (hemihydrate), 98-100°, 110-111° (anhydrous), $[\alpha]_{546}^{20}$ -1.8 (c 10, H_2O), pK^{60} 13.00.** Crystallise D(-)-sorbitol (as ***hemihydrate***) several times from EtOH/water (1:1), then dry it by fusing and storing over anhydrous $MgSO_4$. [Koch et al. *J Am Chem Soc* **75** 953 *1953*, DOI: 10.1021/ja01100a054; *Beilstein* **1** IV 2839.]

Starch *[9005-84-9]* **$(C_6H_{10}O_5)_n$, M $(162.1)_n$.** Starch is de-fatted by Soxhlet extraction with Et_2O or 95% EtOH. For fractionation of starch into 'amylose' and 'amylopectin' fractions, see Lansky et al. [*J Am Chem Soc* **71** 4066 *1949*, DOI: 10.1021/ja01180a056].

Streptozotocin (*N*-[methylnitrosocarbamoyl]-α-D-glucosamine, streptozocin) *[18883-66-4]* **$C_8H_{15}N_3O_7$, M 265.2, m 111-114°(dec), 114-115°(dec), 115°(dec with evolution of gas), 121°(dec), $[\alpha]_D^{20}$ ~+39 (H_2O, may vary due to mutarotation).** Recrystallise streptozotocin from 95% EtOH. It is soluble in H_2O, MeOH and Me_2CO. It has UV with λ_{max} at 228nm (ε 6360) in EtOH. The ***tetraacetate*** has **m 111-114°(dec)**, and $[\alpha]_D^{25}$ +41 (c 0.78, 95% EtOH) after recrystallisation from EtOAc. [Herr et al. *J Am Chem Soc* **89** 4808 *1967*, DOI: 10.1021/ja00994a053; NMR: Wiley et al. *J Org Chem* **44** 9 *1979*, DOI: 10.1021/jo01315a003.] It is a potent methylating agent for DNA [Bennett & Pegg *Cancer Res* **41** 2786 *1981*, PMID: 6454479].

D(+)-Sucrose (β-D-fructofuranosyl-α-D-glucopyranoside) *[57-50-1]* **$C_{12}H_{22}O_{11}$, M 342.3, m 160-186°, 185-187°, 186-188°, $[\alpha]_{546}^{20}$ +78 (c 10, H_2O), $[\alpha]_D^{20}$ + 66 (c 26, H_2O), pK^{25} 12.62.** Crystallise D(+)-sucrose from water (solubility: 1g in 0.5ml H_2O at 20°, 1g in 0.2ml in boiling H_2O). It is soluble in EtOH (0.6%) and MeOH (1%). ***Sucrose diacetate hexaisobutyrate*** *[27216-37-1]* $C_{40}H_{62}O_{19}$, M 846.9, is purified by melting and, while molten, treated with $NaHCO_3$ and charcoal, then filtered, and has **m -7°**, **b 288°/atm**, d ^{25} 1.146g/ml, $[\alpha]_D^{20}$ +49 (c 1, $CHCl_3$). [Hynes & Le Page 'Sucrose, a convenient test crystal for absolute structures' *J Appl Cryst* **24** (4) 352 *1991*, DOI: 10.1107/S0021889891002492; *Beilstein* **17/8** V 399.]

D(+)-Sucrose octaacetate *[126-14-7]* **$C_{28}H_{38}O_{19}$, M 678.6, m 82-85°, 83-85°, b 260°/1mm, $[\alpha]_{546}^{20}$ +71 (c 2.5, EtOH).** After three recrystallisations from EtOH or 95% EtOH (charcoal), the **m** of the ***octaacetate*** rises to **88-90°**, or Et_2O with **m 89°** and $[\alpha]_D^{25}$ +58.5° (c 2.6, EtOH). It has a bitter taste. [Linstead et al. *J Am Chem Soc* **62** 3260 *1940*, DOI: 10.1021/ja01868a509; Lemieux & Huber *J Am Chem Soc* **78** 4117 *1956*, DOI: 10.1021/ja01597a070; *Beilstein* **17/8** V 410.]

D(-)-Tagatose *[87-81-0]* **$C_6H_{12}O_6$, M 180.2, m 131-132°, 134-135°, $[\alpha]_{546}$ -6.5 (c 1, H_2O).** Crystallise D(-)-tagatose from EtOH/H_2O (6:1). It mutarotates from $[\alpha]_D^{22}$ +2 (2 minutes) to –5.0 (30 minutes) (c 4, H_2O). The ***phenylosazone*** crystallises from aqueous EtOH with **m 185-187°(dec)**, and $[\alpha]_D^{23}$ +47 (c 0.82, 2-methoxyethanol). [Totton & Lardy *J Am Chem Soc* **71** 3076 *1949*, DOI: 10.1021/ja01177a037; Gorin et al. *Canad J Chem* **33** 1116 *1955*, DOI: 10.1139/v55-130; Reichstein & Bosshard *Helv Chem Acta* **17** 753 *1934*, DOI: 10.1002/hlca.19340170194; Wolfrom & Bennett *J Org Chem* **30** 1284 *1965*, DOI: 10.1021/jo01015a532; *Beilstein* **1** IV 4414.] In D_2O at 27° the ^1H NMR showed the following ratios: α-pyranose (79), β-pyranose (16), α-furanose (1) and β-furanose (4) [Angyal *Adv Carbohydr Chem* **42** 15 *1984*, DOI: 10.1016/S0065-2318(08)60122-5; Angyal & Pickles *Aust J Chem* **25** 1711 *1972*, DOI: 10.1071/CH9721711]. ***Sugar substitute***, not commonly found in nature, but is produced using L-arabinose isomerase as biocatalyst and D-galactose as substrate [Review: Deok-Kun Oh *Appl Microbiol Biotechnol* **76** 1 *2007*, DOI: 10.1007/s00253-007-0981-1].

Thevetin A (cardenolide glycoside) *[37933-66-7]* **$C_{42}H_{64}O_{19}$, M 872.9, m softens at 194°, m 208-210°, $[\alpha]_D^{20}$ -72 (c 1.48, MeOH).** This cardiac glycoside of *Thevetia nerifolia Juss* seeds crystallises from H_2O. The ***acetyl derivative*** crystallises from MeOH/Et_2O at -15° with **m 145-149°**, and $[\alpha]_D^{26}$ -54.2 (c 1.86, $CHCl_3$). Store at -20°. [Block et al. *Helv Chim Acta* **43** 652 *1960*, DOI: 10.1002/hlca.19600430306; for ^{13}C NMR see Tori et al. *Tetrahedron Lett* **18** 717 *1977*, DOI: 10.1016/S0040-4039(01)92735-2; *Beilstein* **18** III/IV 2552, **18/4** V 439.] Unlike Thevetin B (below, which occurs with it), it has an aldehyde group at C10 in the steroid moiety.

Thevetin B (cardenolide glycoside) *[11018-93-2, 27127-79-3]* **$C_{42}H_{66}O_{18}$, M 858.9, m 197-201°, $[\alpha]_D^{24}$ -61.4 (c 1.5, MeOH).** This cardiac glycoside of *Thevetia nerifolia Juss* seeds crystallises (as ***trihydrate***) from isopropanol. Dry it at 100°/0.01mm to give the ***hemihydrate*** (***very hygroscopic***). [Block et al. *Helv Chim Acta* **43** 652 *1960*, DOI: 10.1002/hlca.19600430306; ^{13}C NMR: Tori et al. *Tetrahedron Lett* **18** 717 *1977*, DOI: 10.1016/S0040-4039(01)92735-2; for thevetin B evaluation in serum by fluorescence polarisation immunoassay using anti-digitoxin antibodies see Uber-Bucek et al. *J Pharm Biomed Anal* **10**(6) 413 *1992*, PMID: 1420463; *Beilstein* **18** III/IV 1493.]

α,α'-D(+)-Trehalose dihydrate (α-D-glucopyranosyl-α-D-glucopyranoside) *[6138-23-4]* **$C_{12}H_{22}O_{11}.2H_2O$, M 378.3, m 96.5-97.5°, 94-100° (dihydrate), 214-216° (anhydrous), $[\alpha]_D^{20}$ +180 (dihydrate, c 4, H_2O), $[\alpha]_D^{20}$ +199 (anhydrous, c 4, H_2O).** α,α'-D(+)-Trehalose crystallises (as the ***dihydrate***) from aqueous EtOH. Dry it at 13°. For the ***anhydrous*** compound dissolve 10g in pyridine (200ml) and distil off this solvent at atmospheric pressure, and when the temperature rises to 115.3° all the H_2O is removed and 73ml of distillate is collected. Most of the anhydrous material crystallises out at this stage. The crystals are collected (6.8g), washed with Et_2O to give 6.1g of ***anhydrous*** product. Higher yields are obtained by slightly more prolonged distillation. [Birch *J Chem Soc* 3489 *1965*, DOI: 10.1039/JR9650003473; X-ray cryst: Brown et al. *Acta Cryst* **28B** 3145 *1972*, DOI: 10.1107/S0567740872007654; *Beilstein* **17/8** V 3.]

D(+)-Turanose [3-*O*-α−D-glucopyranosyl-D-fructose] *[547-25-1]* **$C_{12}H_{22}O_{11}$, M 342.3, m 168-170°, $[\alpha]_D^{20}$ +88 (c 4, H_2O).** Crystallise D(+)-turanose from H_2O by addition of EtOH (its solubility is 5.3% in 95% EtOH). Form **m** 157° is obtained by crystallisation from hot MeOH, and mutarotates from $[\alpha]_D^{20}$ +27.3 to +88 (c 4, H_2O). The ***phenylosazone*** crystallises from 15 parts of 95% EtOH with **m 200-205°**, $[\alpha]_D^{20}$ 24.5 mutarotating to +33 [in 24 hours, c 0.82, pyridine/EtOH (4:6)]. [Pascu *Methods in Carbohydrate Chemistry* **I** 353 *1962*, Academic Press, *Beilstein* **17/7** V 213.] In D_2O at 36° the ^1H NMR showed the following ratios: α-pyranose (<4), β-pyranose (39), α-furanose (20) and β-furanose (41) [Angyal *Adv Carbohydr Chem* **42** 15 *1984*, DOI: 10.1016/S0065-2318(08)60122-5]. Although it is a carbon source for micro-organisms and many bacteria and fungi. It is not metabolised in higher plants but can be taken into plant cells by sucrose transporters where it is involved in sugar signalling.

Ustilagic acid (Ustizeain B, di-D-glucosyldihydroxyhexadecanoic acid) *[8002-36-6]* **$C_{37}H_{62\text{-}66}O_{17}$, M ~780, m 146-147°, $[\alpha]_D^{23}$ +7 (c 1, pyridine), pK^{25} ~ 4.9.** Ustilagic acid is a mixture of partly acetylated di-D-glucosyldihydroxyhexadecanoic acid which crystallises from Et_2O. It has also been purified from corn smut fungal culture by dissolving it in hot MeOH, filtering and concentrating by blowing a current of air until the solution becomes turbid, then heating to 50° and adding 4 volumes of H_2O (also at 50°), and cooling very slowly. Filter off the white solid and dry it in air. It crystallises from Et_2O, and is soluble in MeOH, butan-1,2-diol, poorly soluble in EtOH, *n*-BuOH, Me_2CO and insoluble in H_2O, EtOAc and $*C_6H_6$. [Lemieux et al. *Can J Chem* **29** 409 *1951*, DOI: 10.1139/v51-049; for structure and hydrolysis to ***ustilic acid*** **A, m 114-115°**, $[\alpha]_D^{20}$ -6.3 (MeOH) which gave a ***methyl ester*** **m 80-81.5°**, $[\alpha]_D^{20}$ -0.2 ($CHCl_3$) see Lemieux *Can J Chem* **29** 415 *1951*, DOI: 10.1139/v51-050; for structure and configurations of ***ustilic acids*** see Lemieux *Can J Chem* **31** 396 *1953*, DOI: 10.1139/v53-056; for biosynthesis see Boothroyd et al. *Can J Biochem Physiol* **33** 289 *1955*; DOI: 10.1139/o55-039.]

Vicine (2,4-diamino-5-β-D-glucopyranosidoxy-6-hydroxypyrimidine) *[152-93-2]* **$C_{10}H_{16}N_4O_7$, M 304.3, m 243-244°(dec), $[\alpha]_D^{20}$ -12.1 (c 4, 0.2N NaOH).** Crystallise Vicine from water (1%) or aqueous 85% EtOH, and dry it at 135°, then or over P_2O_5 at ~25°. [For isolation from mixed vetch seeds (*Vicia sative*) and complete structure determination including UV spectra see Bendich & Clements *Biochim Biophys Acta* **12** 462 *1953*, DOI: 10.1016/0006-3002(53)90166-8; *Beilstein* **31** H 163, **25** III/IV 4285.]

Xanthorhamnin {xanthene rhamnoside, 3-[(2*S*,3*R*,4*S*,5*R*,6*R*)-6-[[(2*R*,3*R*,4*R*,5*S*,6S)-3,5-dihydroxy-6-methyl-4-[(2*S*,3*R*,4*R*,5*R*,6*S*)-3,4,5-trihydroxy-6-methyloxan-2-yl]oxyoxan-2-yl]oxymethyl]-3,4,5-trihydroxy-oxan-2-yl]oxy-2-(3,4-dihydroxyphenyl)-5-hydroxy-7-methoxychromen-4-one} *[1324-63-6]* **$C_{34}H_{42}O_{20}$, M 770.7, m 195°, $[\alpha]_D^{20}$ +3.75 (EtOH), pK_1^{24} 8.69, pK_2^{24} 11.28, pK_3^{24} 12.22.** Crystallise xanthorhamnin from a mixture of ethyl and isopropyl alcohols, dry it in air, then dry it further for several hours at 110°. The UV (EtOH) has λ_{max} at 258 and 362nm. [Nystrom et al. *J Org Chem* **22** 1272 *1957*, DOI: 10.1021/jo01361a619; *Beilstein* **18** III/IV 3498.] It has been isolated from buckthorn berries (*Rhamnus catharticus*), and forms a ***pentahydrate***, M 860.8, which holds its H_2O tenaciously.

α-D(+)-Xylose (wood sugar) *[58-86-6]* **$C_5H_{10}O_5$, M 150.1, m 146-147°, 153-154°, 154-158°, $[\alpha]_D^{20}$ +92 mutarotating to +18.8 (16 hours, c 10, H_2O), pK^{18} 12.14.** α-D(+)-Xylose forms needles or prisms (which have a very sweet taste) by slow crystallisation from aqueous 80% EtOH or absolute EtOH, which are then dried at 60° *in vacuo* over P_2O_5. Store it in a vacuum desiccator over $CaSO_4$. One gram dissolves in 0.8ml H_2O. [Bragg & Hough *J Chem Soc* 4347 *1957*, Hudson & Yanovsky *J Am Chem Soc* **39** 1013 *1917*, DOI: 10.1021/ja02250a019; Monroe *J Am Chem Soc* **41** 1002 *1919*, DOI: 10.1021/ja02227a010; *Beilstein* **1** IV 4223.] In D_2O at 31°, the ^1H NMR showed the following ratios: α-pyranose (36.5), β-pyranose (63), α-furanose + β-furanose (~1) [Angyal *Adv Carbohydr Chem* **42** 15 *1984*, DOI: 10.1016/S0065-2318(08)60122-5; Angyal & Pickles *Aust J Chem* **25** 1711 *1972*, DOI: 10.1071/CH9721711; *Beilstein* **1** IV 4223]. The enantiomeric **α-L(-)-xylose** *[609-06-3]* has identical properties except for the optical rotation which is negative.

CAROTENOIDS

Introduction

Carotenoids are polyene pigments that are mostly naturally occurring in bacteria, plants and animals. They have been isolated from the natural sources and obtained first by extraction with solvents and then purified by column chromatography through Al_2O_3 of various grades, $Ca(OH)_2$ alone or with $CaCO_3$, MgO or Silica Gel and eluted with solvents of various polarities. The progress of separation can be followed visually because the bands of most carotenoids are of various colours. The bands can be collected by elution, or the column can be extruded and the bands cut out and extracted with a polar solvent, e.g. MeOH. This chromatography can be repeated with the separate bands, and finally the carotenoids are recrystallised to analytical purity. The purity can be checked by TLC on Silica Gel or Al_2O_3 plates or paper chromatography and eluted in two dimensions. Gas-liquid or HPLC has been used for preparative work as well as for checking the purity and identifying them using internal standards such as tocopherol acetate (vitamin E acetate) and retinyl acetate.
Carotenoids are generally light sensitive, easily oxidised by air and are affected by traces of acid, e.g. in solvents. These cause the polyenes to bleach or polymerise. The necessary precautions are therefore required to minimize these effects during isolation, purification and storage. They are identified by their UV-VIS spectra, and their molar extinction coefficients at specific wavelengths (λ_{max}) have been used for characterisation and for quantitation. More recently ORD, CD, NMR, IR and mass spectroscopy have been used extensively.

Antheraxanthin [5,6-epoxy-zeaxanthin, (3*R*,3'*S*,5'*R*,6'*S*)-5',6'-dihydro-5',6'-epoxy-β,β-carotene-3,3'-diol] *[9Z- 68831-78-7, all-trans- 640-03-9]* **$C_{40}H_{56}O_3$, M 584.8, m 205°, λ_{max} 460.5, 490.5nm, in $CHCl_3$.** This xanthophyll cycle pigment is a bright yellow ***accessory*** pigment found in many organisms that perform photosynthesis (e.g. algae, euglenoids) and plants. Likely impurities are violaxanthin (see later) and mutatoxanthin (which contains a dihydrofuran ring derived from the epoxy group of antheraxanthin). Purify it by chromatography on columns of $Ca(OH)_2$ and of $ZnCO_3$. It crystallises from $*C_6H_6$/MeOH as needles or thin plates. Store it in the dark, under N_2 or argon at -20°. In $CHCl_3$/$SbCl_2$ it gives a blue colour with λ_{max} at 587nm and gives a stable blue colour with conc HCl. [Karrer & Oswald *Helv Chim Acta* **18** 1303 *1935*, DOI: 10.1002/hlca.193501801182; Karrer & Jucker *Helv Chim Acta* **28** 300 *1945*, DOI: 10.1002/hlca.660280137.]

ß-Apo-4'-carotenal *[12676-20-9]* **$C_{30}H_{40}O$, M 416.7, m 139°, $A^{1\%}_{1cm}$ 2640 at 461nm.** Recrystallise the carotenal from $CHCl_3$/EtOH mixture or *n*-hexane. The λ_{max} of the absorption spectra of the radical anions and cations of such polyenals formed by pulse radiolysis are linearly dependent on the number of conjugated double bonds [Land et al. *JCS Faraday Trans 1* **74** 538 *1978*, DOI: 10.1039/F19787400538; Bobrowski & Das *J Phys Chem* **91** 1210 *1987*, DOI: 10.1021/j100289a035; *Beilstein* **7** IV 1782.]

trans*-β-Apo-8'-carotenal** *[1107-26-2]* **$C_{30}H_{40}O$, M 416.7, m 136-139°.** Recrystallise ß-apo-8'-carotenal from $CHCl_3$/EtOH mixture or *n*-hexane. The absorption spectra of the radical anion of this C_{30} aldehyde in CTAB and Triton X100 micelles suggested an alcohol-like nature of the environment probed by the long-chain polyenal. For effect of conjugation on spectra see preceding entry [Bobrowski & Das *J Phys Chem* **91** 1210 *1987*, DOI: 10.1021/j100289a035; Land et al. *JCS Faraday Trans 1* **74** 538 *1978*, DOI: 10.1039/F19787400538; *Beilstein* **7** III 2622, **7** IV 1782.] It has been stated to form red to deep violet crystals, or a crystalline powder with a metallic lustre, and is sensitive to oxygen and light and should be stored in the dark under inert gas. Also described as ***Apocarotenal, which has an orange to orange-red (C.I. Food Orange 6) colour used in foods, pharmaceutical and cosmetic products.

β-Apo-8'-carotenoic acid ethyl ester *[1109-11-1]* **$C_{32}H_{44}O_2$, M 460.7, m 134-138°, $A^{1\%}_{1cm}$ 2550 at 449nm, CI Food Orange 7; CI (1075) No 40825, INS No 160f.** Recrystallise the ester from petroleum ether or petroleum ether/EtOAc. The A_{475}/A_{449} is between 0.82 to 0.86. The colour of a sample in Me_2CO disappears after successive aditions of a 5% solution of $NaNO_2$ and 1N H_2SO_4. Carr-Price reaction: a solution of a sample in $CHCl_3$ turns blue on addition of excess of Carr-Price reagent TS. See also colour reaction with CF_3CO_2H [Dugan et al. *Anal Chem* **36** 114 *1964*, DOI: 10.1021/ac60207a035]. Store it in the dark under N_2 or argon at

-20°. [*Beilstein* **9** IV 2701 for Me ester*]* ***β-Apo-8'-carotenoic acid*** and its esters (ethyl and glyceryl) were obtained from sunflower oil oxidation [Yanishlieva et al. *J Am Oil Chem Soc* **78** 641 *2001*, DOI: 10.1007/s11746-001-0319-7].

β-Apo-8'-carotenoic acid methyl ester *[16266-99-2]* **$C_{31}H_{42}O_2$, M 512.7, m 136-137°, $A^{1\%}_{1cm}$ 2575 at 446nm and 2160 at 471nm, in petroleum ether.** Recrystallise the methyl ester from petroleum ether or petroleum ether/EtOAc. Store it in the dark in an inert atmosphere at -20°. [See ethyl ester above, *Beilstein* **9** IV 2701.]

Astacene (β, β-carotene-3,3',4,4'-tetraone, Astacin ***not to be confused with the metallopeptidases*****)** *[514-76-1]* **$C_{40}H_{48}O_4$, M 592.8, m 228°, 232-233°, 240-243°(evacuated tube), $\varepsilon^{1\%}_{1cm}$ 550,000 at 498nm (pyridine).** Astacene is a red pigment found in marine organisms (protozoa, algae, crustacians, sponges, fish, reptiles) together with astaxanthin (see below) from which it is possibly formed by autoxidation [Kuhn & Lederer *Chem Ber* **66** 488 *1933*, DOI: 10.1002/cber.19330660410]. A probable impurity is astaxanthin (3,3'-dihydroxy-β,β-carotene-4,4'-dione) which may be its precursor. It has been prepared by adding a solution of ***canthaxanthene*** (1.0g, see *[514-78-3]* below) in $*C_6H_6$ (15ml) to *t*-BuOK in *t*-BuOH (1.40N, 130ml) and shaken with O_2 at 20° for 30 hours. Water (200ml) is added, then 0.5N HCl (800ml) and extracted with $CHCl_3$ (300ml). The extract is washed with aqueous $NaHCO_3$ (3 x 300ml), H_2O (2 x 200ml), diluted with $*C_6H_6$ (50ml) and the organic layer is evaporated *in vacuo*. The residue is recrystallised from $CHCl_3$-EtOH (1:5) to give ***astacene*** (450mg, ~90%) as deep purple leaflets **m 232-233°** with λ_{max} (pyridine) 498mm (ε 100 x 10^3), (CS_2) 513mm, (hexane) 477mm, (EtOH) 483mm, and (KOH-EtOH) 478mm; the IR ($CHCl_3$) has ν_{max} at 3410br (ε ~90), 1610 (ε 1200), 1550, 1327, 969 (ε 895) cm^{-1}; the ^1H NMR (60MHz, $CDCl_3$, TMS) has δ at 1.30 (12H, C-1 Me_2 and C-1' Me_2), 2.10 (6H, C-5 Me and C-5' Me), 2.02 (6H, C-9 Me and C-9' Me), 2.02 (6H, C-13 Me and C-13' Me), and 6.06 (C-2 H and C-2' H) (14 olefinic H-7,7', 8,8', 10,10', 11,11', 12,12', 14,14', and 15,15' are not included); and *m/z* 592 $M^{\cdot+}$. [Cooper et al. *JCS Perkin Trans I* 2195 1975, DOI: 10.1039/P19750002195.] *Alternatively*, purify ***astacin*** by chromatography on alumina/fibrous clay (1:4) or mixed chromatograms on sucrose using $*C_6H_6$/light petroleum 1:4 as eluant; or by partition between petroleum ether and MeOH (alkaline). It crystallises from pyridine/water in purple leaflets or needles with a metallic lustre. Store it in the dark under N_2 at -20°. It is very soluble in pyridine, dioxane, CS_2, $CHCl_3$ and dilute aqueous NaOH, slightly soluble in AcOH, EtOAc and $*C_6H_6$, but almost insoluble in H_2O, Et_2O, petroleum ether and MeOH. Its ***diacetate (enol-acetate)***, obtained by Ac_2O/pyridine treatment at 25° for 34 hours has **m 232-233° (dec)** (from $CHCl_3$/EtOH, 1:5) or **235° (dec)** (from pyridine + H_2O), and forms violet/black needles with λ_{max} (pyridine) at 497mm (ε 109 x 10^3) and (EtOH) 474mm; the IR ($CHCl_3$) has ν_{max} at 1756 (ε 530), 1639 (ε 1150), 1555 and 972 cm^{-1}; the ^1H NMR (60MHz, $CDCl_3$, TMS) has δ at 1.35 (12H, C-1 Me_2 and C-1' Me_2), 2.04 (6H, C-5 Me and C-5' Me), 2.04 (6H, C-9 Me and C-9' Me), 2.02 (6H, C-13 Me and C-13' Me), and 2.29 (2 OAc) (14 olefinic H-7,7', 8,8', 10,10', 11,11', 12,12', 14,14', and 15,15' are not included); and *m/z* 576 $M^{\cdot+}$. The ***dipalmitate (enol-ester, Astacein)*** has **m 121°**, and forms red square leaflets from petroleum ether. [Davis & Weedon *Proc Chem Soc* 182 *1960*, DOI: 10.1039/PS9600000161 for first page of *Notes* is 161; Widmer et al. *Helv Chim Acta* **65** 671 *1982*, DOI: 10.1002/hlca.19820650306; Karrer et al. *Helv Chim Acta* **17** 412 *1934*, DOI: 10.1002/hlca.19340170147; 745 *1934*, DOI: 10.1002/hlca.19340170192; **18** 96 *1935*, DOI: 10.1002/hlca.19350180114; **19** 479 *1936*, DOI: 10.1002/hlca.19360190174; for synthesis see Choi & Koo *J Org Chem* **70** 3328 *2005*, DOI: 10.1021/jo050101l; for isolation from brown trout see Steven *Nature* **160** 507 *1947*, PubMed: 20267555; *Beilstein* H **30** 102, **7** III 4797.]

Astaxanthin (3,3'-dihydroxy-β,β-carotene-4,4'-dione) *[472-61-7]* **$C_{40}H_{52}O_4$, M 596.8, m 182-183° (for ±, see below).** It is a potent antioxidant from marine algae, red yeast and other plant and marine animal sources. It was isolated from lobster eggs, is present in salmon, the red feathers of some birds (*Laniarius* spp, and flamingo), and occurs in flower petals of some ***Ranunculaceae***. Racemic astaxanthin has been synthesised from astacene (see above) by reduction with KBH_4 to β, β-carotene-3,4,3',4'-tetra-ol followed by oxidation with 2,3-dichloro-5,6-dicyano-*p*-benzoquinone and purification by preparative TLC on Kieselgel (20%Me_2CO/light petroleum) to give ***(±)-astaxanthin*** **m 182-183°** as red needles, after crystallisation from Me_2CO/light petroleum. It has λ_{max} (MeOH) 472mm, (hexane) 466-467mm, ($CHCl_3$) 485 and (CS_2) 503mm; the IR ($CHCl_3$) has ν_{max} at 3620, 3510, 1660, 1610 and 975 cm^{-1}; the ^1H NMR (60MHz, $CDCl_3$, TMS) has δ at 1.31 (6H, C-1 Me and C-1' Me), 1.20 (6H, C-1 Me and C-1' Me), 1.94 (6H, C-5 Me and C-5' Me), 1.98 (12H, C-9 Me, C-9' Me, C-13 Me and C-13' Me), (14 olefinic H-7,7', 8,8', 10,10', 11,11', 12,12', 14,14', and 15,15' are not included); and *m/z* 592.386 $M^{\cdot+}$.

TLC in the above system or Micro-Cel did not separate it from natural (3*S*,3'*S*)-astaxanthin from the common lobster or sea water crayfish. Synthetic ***(±)-astaxanthin*** combined with the appropriate apoprotein to form ***α-crustacyanin*** with λ_{max} (MeOH) at 630mm. Its ***diacetate*** has **m 203-205°** (blue-black needles from pyridine/H_2O, **m 189-191°** also reported), the UV has λ_{max} ($CHCl_3$) with 482mm, and is also indistinguishable by mixed TLC on Kieselgel, Micro-Cel or alumina from natural **(3*S*,3'*S*)-astaxanthindiacetate, m 187-189°**. All manipulations have to be carried out under argon to avoid their ready oxidation to ***astacin*** (see above). [Cooper et al *JCS Perkin Trans I* 2195 1975, DOI: 10.1039/P19750002195; Kienzel & Mayer *Helv Chim Acta* **61** 2609 *1978*, DOI: 10.1002/hlca.19780610732.]

An efficient synthesis of natural **(3*S*,3'*S*)-astaxanthin** from (4*R*,4'*R*)-4-hydroxy-2,2,6-trimethylcyclohexanone in 67% yield and high optical purity has been described and was purified by recrystallisation from CH_2Cl_2/MeOH to give dark violet crystals, **m 216-218°**, with R_F 0.30 on TLC with kieselgel (CH_2Cl_2/Me_2CO/HCOOH, 95:5:3); its **UV** has λ_{max} nm (ε), ($CHCl_3$) at 492 (1920), 488 (125,000), and (CH_2Cl_2) 324(14,500), 298 (15,500), ~285sh (~14,000), 251 (14,500), ~225 (~15,000); and **IR** (KBr) has ν_{max} at 3486m (OH), 1664s (C=O, conjugated), 1607m, 1557s (C=O, conjugated), 1399w, 1390m, 1366w (gem Me_2), 1076s, 1039m (OH) and 969s (CH=CH, *trans*) cm^{-1}. [Widmer et al. *Helv Chim Acta* **64** 2405 *1981*, DOI: 10.1002/hlca.19810640749]. Other high yielding syntheses have been achieved [Becher et al. *Helv Chim Acta* **64** 2419 *1981*, DOI: 10.1002/hlca.19810640750; Kienzle & Mayer *Helv Chim Acta* **61** 2609 *1978*, DOI: 10.1002/hlca.19780610732], and the absolute configuration of natural ***(3S,3'S)-astaxanthin***, **m 219-220°** has been determined by X-ray analysis of a crystalline synthetic intermediate [Widmer et al. *Helv Chim Acta* **64** 2405 *1981*, DOI: 10.1002/hlca.19810640749] and comparison of CD spectra [Englert et al. *Helv Chim Acta* **60** 1209 *1977*, DOI: 10.1002/hlca.19770600409]. Its **^{1}H NMR** (270MHz, $CDCl_3$, TMS) has δ for olefinic protons at 6.21 (H-7 and H-7'), 6.43 (H-8 and H-8'), 6.30 (H-10 and H-10'), 6.66 (H-11 and H-11'), 6.45 (H-12 and H-12'), ~6.30 (H-14 and H-14') and ~6.68 (H-15 and H-15') with $J_{7,8}$ or $J_{7',8'}$ = 16.3Hz, $J_{10,11}$ or $J_{10',11'}$ = 11.5Hz and $J_{11,12}$ or $J_{11',12'}$ = 14.7Hz; δ for Me groups at 1.21 and 1.32 (6H, C-1 Me and C-1' Me), 1.95 (6H, C-5 Me and C-5' Me), 2.00 (6H, C-9 Me and C-9' Me), 1.99 (6H, C-13 Me and C-13' Me); and δ for cyclohexenone protons at 1.82 (2H, axial H-2 and H-2'), 2.16 (2H, equatorial H-2 and H-2'), 4.32 (2H, H-3 and H-3'), and 3.70 (2H, 3-OH and 3'-OH, J = 1.8Hz,) with $J_{2,2\ (gem)}$ or $J_{2',2'\ (gem)}$ = 12.7Hz, $J_{2e,3a\ (vic)}$ = 5.7Hz and $J_{2a',3a'\ (vic)}$ = 14.0Hz, $J_{2e',3a'\ (vic)}$ = 5.7Hz and $J_{2a',3a'\ (vic)}$ = 14.0Hz; the **^{13}C NMR** (23MHz, $CDCl_3$, TMS) has δ for methyl group carbons at 12.8 (13,13'), 12.6 (9,9'), 13.9 (5,5'), 26.2 (1 or 1'), 30.8 (1' or 1); for end group carbons 36.8 (1,1'), 45.6 (2,2'), 69.2 (3,3'), 200.3 (4,4'), 126.9 (5,5'), 162.4 (6,6'); and for olefinic carbons at 123.2 (7,7'), 142.2 (8,8'), 134.7 (9,9'), 135.1 (10,10'), 124.6 (11,11'), 139.7 (12,12'), 136.7 (13,13'), 133.8 (14,14') and 130.7 (15,15'); and the **CD** spectrum in CH_2Cl_2 has λ_{max} (Δε) at 224 (+12.8), 249 (−14.4), 280 (+ 12.5), 323 (−23.1), 384 (+6.7) and 521 (−3.2, very broad) [Englert et al. *Helv Chim Acta* **60** 1209 *1977*, DOI: 10.1002/hlca.19770600409].

It is the prosthetic group in many carotenoproteins, mainly in invertebrates, which vary from colourless to bright blue. It reduces blood glucose and improves some parameters in diabetic metabolism. It ameliorates blood flow and vascular tone in hypertension models and regulates ***connexin* 43** in *in vitro* studies, and may be a cancer chemopreventive drug. It is obtained on a large scale from the heterobasidiomycetous yeast *Phaffia rhodozyma* and plays an important role in carotene biosynthesis [Schroeder & Johnson *J Biol Chem* **270** 18374 *1995*, DOI: 10.1074/jbc.270.31.18374]. For an efficient synhesis see Choi & Koo *J Org Chem* **70** 3328 *2005*, DOI: 10.1021/jo050101l.

Bixin (6,6'-diapo-ψ,ψ-carotenedioic acid monomethyl ester) *[6983-79-5 for* cis- *or* α*-bixin]* **$C_{25}H_{30}O_4$, M 394.5, m 198°, 217°(dec), λ_{max} ($CHCl_3$) 209, 475 and 443nm, pK_{Est} ~4.3.** The natural half ester, ***α-bixin Annatto*** (a pigment from *Bixa orellana* shrub native of S. America, India, E. Africa, Caribbean and Phillippines) has a *cis*-double bond conjugated with the ester group and is unstable when isolated. It readily isomerises to the stable *all-trans* halfester ***α-bixin*** (*trans*-bixin, also present in nature) *[39937-23-0]* in $CHCl_3$ solution containing I_2. Crystallise bixin from Me_2CO (violet prisms). Synthetic **cis-*methylbixin*** crystallised from EtOAc with **m 163°**, whereas the synthetic **all-trans-*methylbixin***, which also crystallises from EtOAc has **m 204-205°**, distinguished by ^{1}H NMR spectroscopy. [For synthesis of methylbixins see Pattenden et al. *J Chem Soc (C)* 235 *1970*, DOI: 10.1039/J39700000235]. [For the synthesis, UV and IR of Me and Et diesters see Isler et al. *Helv Chim Acta* **40** 1242 *1957*, DOI: 10.1002/hlca.19570400515; Buchta & Andree *Chem Ber* **92** 3111 *1959*, DOI: 10.1002/cber.19590921214]. [*Beilstein* **2** III 2020, **2** IV 2455, H **30** 110.] The ***free*** acid, ***Norbixin***, a dicarboxylic acid, and the esters have been used to colour magarine and impart a red colour to cheddar cheese.

Canthaxanthin (*trans*) (β, β-carotene-4,4'-dione) *[514-78-3]* **$C_{40}H_{52}O_2$, M 564.9, m 211-212°, 213°, ε_{mol} 124,100 (at 466nm, petroleum ether), 118,000 (at 484nm *C_6H_6).** Purify canthaxanthin by chromatography on a column of deactivated alumina or magnesium oxide, or on a thin layer plate of silica gel G (Merck), using dichloromethane/diethyl ether (9:1) to develop the chromatogram. Crystallise it from CH_2Cl_2 or CH_2Cl_2/MeOH (violet crystals). Store it in the dark and in an inert atmosphere at -20°. [For an efficient synthesis see Choi & Koo *J Org Chem* **70** 3328 *2005*, DOI: 10.1021/jo0501011; for 'Isolation and light-stimulated expression of canthaxanthin and spirilloxanthin biosynthesis genes from the photosynthetic bacterium *Bradyrhizobium* sp. strain ORS278', see Giraud & Verméglio *Methods in molecular biology (Clifton NJ)* **892** 173 *2012*, PMID: 22623302.] [*Beilstein* **7** III 4364, **7** IV 2680.] It has been found in birds and fish.

Capsanthin [(3*R*,3'*S*,5'*R*)-3,3'-dihydroxy-β,κ-carotene-6-one) *[465-42-9]* **$C_{40}H_{56}O_3$, M 584.9, m 170°, 177-178°, λ_{max} 484 (ε_{mol} 121,000), inflexion at 515 nm, in hexane.** It has been isolated from paprika extract (main carotenoid), and possible impurities are zeaxanthin and capsorubin (below). Purify capsanthin by chromatography on a column of alumina (grade IV) and develop with 0.2% EtOH in *C_6H_6. It crystallises from petroleum ether in red needles, IR has ν_{max} at 3600, 1664cm^{-1}, and $\varepsilon_{1033}/\varepsilon_{1664}$ ~ 4.1. [Barber et al. *J Chem Soc* 4019 *1961,* DOI: 10.1039/JR9610004019; for ORD & absolute configuration see Bartlett et al. *J Chem Soc (C)* 2527 *1969*, DOI: 10.1039/J39690002527.] The ***di-O-acetate*** is purified on an alumina (grade II) column in *C_6H_6 and it is recrystallised from MeOH with **m 160-162°**. [Faigle & Karrer *Helv Chim Acta* **44** 1257 *1961*, DOI: 10.1002/hlca.19610440510; *Beilstein* **8** II 415, **8** III 3047, **8** IV 2657.] It has anti-neoplastic properties.

Capsorubin (3,3'-dihydroxy-κ,κ-carotene-6,6'dione) *[470-38-2]* **$C_{40}H_{56}O_4$, M 600.9, m 218°, λ_{max} 443, 468, 503 nm, in hexane.** Possible impurities are zeaxanthin and capsanthin. Purify capsorubin by chromatography on a column of $CaCO_3$ or MgO. Crystallise it from *benzene/petroleum ether or CS_2. [*Beilstein* **1** III 3327, **8** III 3873, **8** IV 3304.] It is a red pigment in paprika which contains capsanthin-capsorubin synthase whose gene has been cloned [Bouvier et al. *Plant Mol. Biol.* **36**: 785 *1998*, DOI: 10.1023/A:1005966313415].

α-Carotene (6'*R*-α-carotene) *[7488-99-5]* **$C_{40}H_{56}$, M 536.9, m 184-188°, 187.5° (evacuated tube), $[\alpha]_{643}^{20}$ +385° (c 0.08, *C_6H_6), $[\alpha]_D^{25}$ +538°, λ_{max} 422, 446, 474 nm, in hexane, $A_{1cm}^{1\%}$ 2725 (at 446nm), 2490 (at 474nm), ε_{mol} 145,300 (at 455nm, hexane), and 456 (at 485nm, *C_6H_6).** Purify α-carotene by chromatography on columns of calcium hydroxide, alumina or magnesia. Crystallise it from CS_2/MeOH, toluene/MeOH, diethyl ether/petroleum ether, or acetone/petroleum ether. Store it in the dark, under N_2 or Ar at -20°. It gives a blue colour with λ_{max} at 542nm when mixed with $SbCl_3$ in $CHCl_3$. [Karrer & Walker *Helv Chim Acta* **16** 641 *1933*, DOI: 10.1002/hlca.19330160193; Eugster et al. *Helv Chim Acta* **52** 1729 *1969*, DOI: 10.1002/hlca.19690520627; Eugster & Karrer *Helv Chim Acta* **38** 610 *1955*, DOI: 10.1002/hlca.19550380307; Strain *J Biol Chem* **105** 523 *1934*, http://www.jbc.org/content/105/3/523; *Beilstein* **5** III 2457, **5** IV 2620.]

all-*trans*-β-Carotene *[7235-40-7]* **$C_{40}H_{56}$, M 536.9, m 178-179°, 179-180°, 180°, 181°, 183° (evacuated capillary), ε_{mol} 138,900 (at 450 nm, petroleum ether), 124,300 (at 462nm, *C_6H_6), CI Food Orange 5, INS No. 160a(i); CI (1975) No. 40800.** It forms purple prisms when crystallised from *C_6H_6/MeOH and red rhombs from petroleum ether. Its solubility in hexane is 0.1% at 0°. It is **oxygen sensitive** and should be stored under N_2 at -20° in the dark. It gives a deep blue colour with λ_{max} at 590nm when mixed with $SbCl_3$ in $CHCl_3$. Its UV (*C_6H_6) has λ_{max} at 429infl, 454 and 484nm. The principal peak at λ_{max} 454nm has $A_{1cm}^{1\%}$ 2000. [Synthesis: Surmatis & Ofner *J Org Chem* **26** 1171 *1961*, DOI: 10.1021/jo01063a048; Milas et al. *J Am Chem Soc* **72** 4844 *1950*, DOI: 10.1021/ja01166a541.] β-Carotene is also purified by column chromatography (Al_2O_3 activity I-II). It is dissolved in petroleum ether/*C_6H_6 (10:1), applied to the column and eluted with petroleum ether/EtOH; the desired fraction is evaporated and the residue is recrystallised from *C_6H_6/MeOH (violet-red plates). [For UV see Inhoffen et al. *Justus Liebigs Ann Chem* **570** 54, 68 *1950*, DOI: 10.1002/jlac.19505700105; Review: Fleming *Selected Organic Synthesis* (J Wiley, Lond) pp. 70-74 *1973*.] *Alternatively*, it can be purified by chromatography on a magnesia column, thin layer of Kieselguhr or magnesia. Crystallise it from CS_2/MeOH, Et_2O/petroleum ether, acetone/petroleum ether or toluene/MeOH. Store it in the dark, under an inert atmosphere, at -20°. Recrystallise it also from 1:1 EtOH/$CHCl_3$. [Bobrowski & Das *J Phys Chem* **89** 5079 *1985*, DOI: 10.1021/j100269a038; Johnston & Scaiano *J Am Chem Soc* **108** 2349 *1986*, DOI: 10.1021/ja00269a035; Strain *J Biol Chem* **105** 523 *1934*, http://www.jbc.org/content/105/3/523; **4** 1

δ-Carotene (6*R*-ε,ψ−carotene) *[472-92-4]* **$C_{40}H_{56}$, M 536.9, m 140.4°, 142° (evacuated capillary) $[\alpha]_D^{25}$ +352 (c 16 hexane), $[\alpha]_{Cd}$ +317 (CS_2), λ_{max} 430, 456, 486nm (hexane).** δ-Carotene crystallises from CS_2/hexane/EtOH as red needles. The ***racemic*** carotene is purified through an alumina (Grade II) column by elution with 15% *C_6H_6/petroleum ether (b 60-80°), and the main band eluent is evaporated and the residue is crystallised from MeOH/petroleum ether (b 60-80°) to give ***δ-carotene*** with **m 150-151°**. Store at -20°. [Porter & Anderson *Arch Biochem Biophys* **32** 21 *1951*, DOI: 10.1016/0003-9861(51)90233-0; Synthesis: Manchand et al. *J Chem Soc* 2019 *1965*, DOI: 10.1039/JR9650002019; for Absolute Configuration see Buchecker & Eugster *Helv Chim Acta* **54** 327 *1971*, DOI: 10.1002/hlca.19710540131; *Beilstein* **5** III 2453, **5** IV 2617.]

γ-Carotene (β,ψ−carotene) *[472-93-5, 10593-83-6]* **$C_{40}H_{56}$, M 536.9, m 152-153.5° (synthetic), 177.5° (polymorph), $A^{1\%}_{1m}(\lambda_{max})$ 2055 (at 437nm), 3100 (at 462nm), 2720 (at 494nm) in hexane.** Purify γ-carotene by chromatography on alumina [Grade II in petroleum ether (b 60-80°) and elute with *C_6H_6], or magnesia columns. When crystallised from *C_6H_6/MeOH (2:1), it had **m 177.5°**. Store it in the dark, under an inert atmosphere at 0°, or in an evacuated tube at -20°. The purity is verified by TLC on $Ca(OH)_2$/Kieselgel (8:2) using petroleum ether (b 60-80°) as eluant. [Manchand et al. *J Chem Soc* 2019 *1965*, DOI: 10.1039/JR9650002019; Ruegg et al. *Helv Chim Acta* **44** 985 *1961*, DOI: 10.1002/hlca.19610440414; *Beilstein* **5** III 2453, **5** IV 2617.]

ξ-Carotene *[38894-81-4]* **$C_{40}H_{56}$, M 536.9, m 38-42°, λ_{max} 378, 400, 425nm, $A^{1\%}_{1m}(\lambda_{max})$ 2270 (400nm), in petroleum ether.** Purify ξ-carotene by chromatography on 50% magnesia-HyfloSupercel, developing with hexane and eluting with 10% EtOH in hexane. It crystallises from toluene/MeOH. [Gorman et al. *J Am Chem Soc* **107** 4404 *1985*, DOI: 10.1021/ja00301a006.] Store it in the dark under N_2 or argon at -20°. Also purify it like γ-Carotene. [*Beilstein* **5** IV 2623.]

Citranaxanthin [5,9,14,18-tetramethyl-20-(2,6,6-trimethyl-1-cyclohex-1-enyl)- 3,5,7,9, 11,13,15,17,19-eicosanonen-2-one] *[3604-90-8]* **$C_{33}H_{44}O$, M 456.7, m 155-156°, $A^{1\%}_{1m}(\lambda_{max})$ 410 (349nm), 275 (466nm) in hexane (food additive E161i).** Purify it by chromatography on a column of 1:1 MgO and HyfloSupercel (diatomaceous filter aid). Crystallise it from petroleum ether (deep violet crystals). Store it in the dark under N_2 or argon at 0°.

Crocetin diethyl ester (8,8'-diapo-ψ,ψ-carotenedioic acid diethyl ester) *[5056-14-4]* **$C_{24}H_{32}O_4$, M 384.5, m 216-218°, 218-219°, 222.5°, $A^{1\%}_{1m}(\lambda_{max})$ 2340 (at 400nm), 3820 (at 422nm), 3850 (at 450nm) in petroleum ether.** Purify the diethyl ester by chromatography on a column of silica gel G. Recrystallise it from *benzene. Store it in the dark, under N_2 or argon, at 0°. The ***dimethyl ester***, purified in the same way, has **m 225-227°** and similar spectra. [For synthesis, UV and IR see Isler et al. *Helv Chim Acta* **40** 1242 *1957*, DOI: 10.1002/hlca.19570400515; *Beilstein* **2** III 2018, H **30** 106.] The ***free acid***, ***Crocetin*** (***all-trans tetramethylhexadeca-2,4,6,8,10,14-heptaenedioic acid***) *[27876-94-4, di-Na salt 64603-92-5]* $C_{20}H_{24}O_4$, M 328.4, forms brick red crystals from acetic anhydride with **m** 286° and **pK_1^{25} 4.39.** [See details in Gainer & Grabiak Patent, US 7759506 B2, publication date July 20, 2010; Buchta & Andree *Chem Ber* **93** 1349 *1960*, DOI: 10.1002/cber.19600930617.]

α-Cryptoxanthin (all-*trans*-3*R*,6*R'*-β, ε-carotene-3-ol, zeinoxanthin, physoxanthin) *[24480-38-4]* **$C_{40}H_{56}O$, M 552.9, m 175-176° (racemate 157.5-158.5°), $[\alpha]_D^{25}$ -508 (c 0.4 Me_2CO), CD$_{max}$ Δε -3.6 (218nm), +4.4 (245nm) and –9.0 (283nm), λ_{max} (hexane) 421, 446, 474nm, ε_{mol} 145,500 (at 446nm, hexane), 130,000 (at 459nm, *C_6H_6).** It crystallises from *C_6H_6/MeOH in red needles. The ***racemate*** is purified through an Al_2O_3 column, eluting with *C_6H_6 and recrystallising from MeOH/Et_2O. It has λmax (ε 10^{-3}) (hexane) at 421, 444, 471nm (90, 133, 122). [Loeber et al. *J Chem Soc (C)* 404 *1971*, DOI: 10.1039/J39710000404; Goodfellow et al. *J Chem Soc (D)* 1578 *1970*, DOI: 10.1039/C29700001578; *Beilstein* **6** IV 5113.]

β-Cryptoxanthin (all-*trans*-3*R*-β,β-carotene-3-ol, caricaxanthin) *[472-70-8]* **$C_{40}H_{56}O$, M 552.9, m 169° (natural), (racemate m 172-173°), ε_{mol} 131,900 (at 449nm, petroleum ether).** Purify it by chromatography on MgO, $CaCO_3$ or deactivated alumina, using EtOH or diethyl ether to develop the column. Crystallise it from

*C_6H_6/EtOH (metallic prisms), or needles from *C_6H_6. Store it in the dark under N_2 or argon at -20°. The ***acetate*** has **m 117.5°**. The ***racemate*** is purified through a column of alumina (grade IV), eluted with *C_6H_6 then EtOAc/*C_6H_6 (1:9) and recrystallised from petroleum ether (b 60-80°) with **m 172-173°**. [Loeber et al. *J Chem Soc (C)* 404 *1971*, DOI: 10.1039/J39710000404; Goodfellow et al. *JCS Chem Commun* 1578 *1970,* DOI: 10.1039/C29700001578; Isler et al. *Helv Chim Acta* **40** 456 *1957*, DOI: 10.1002/hlca.19570400225; *Beilstein* **6** III 3772, **6** IV 5111.]

3,30-Diketospirilloxanthin (all-*trans*-2,31-dimethoxy-2,6,10,14,19,23,27,31-octamethyl-4,6,8,10,12,-14,16,18,20,22,24,26,28-dotriacontatridecene-3,30-dione, 2,2'-diketospirilloxanthin) *[24009-17-4]* **$C_{42}H_{56}O_4$, M 624.9, m 225-227°, $\varepsilon^{1\%}_{lm}(\lambda_{max})$ 550 (at 349nm), 820 (at 422nm), 2125 (at 488nm), 2725(516nm), 2130(at 551nm) in hexane.** Purify it by chromatography on a column of partially deactivated alumina. Recrystallise it from acetone/petroleum ether. Store it in the dark, in an inert atmosphere at 0°. [cf. *Beilstein* **1** III 2297, **1** IV 2750.]

Dolichols *[11029-02-0; 2067-66-5 for* $C_{100}H_{164}O$, M 1382.4*]* **C_{80}-C_{105} polypren-mono-ols**. Crystallise each dolichol 6 times from petroleum ether/EtOH at -20°. The pure individual ***prenol*** should run as an entity on a chromatogram on paraffin impregnated paper, with acetone as the mobile phase. [For isolation, UV, IR, ^{1}H NMR and characterisation of a C100 dolichol from pig liver see Burgos et al. *Biochem J* **88** 470 *1963*, DOI: 10.1042/bj0880470] Dolichols are a group of long-chain polyunsaturated alcohols made up of isoprene units (head to tail) where the terminal isoprene unit is saturated and the terminal carbon atom possesses a hydroxyl group. Their biosynthesis proceeds *via* the HMG-CoA reductase (mevalonate) pathway, which is ***inhibited*** by ***Statins***, where at first a *cis* (Z) prenyltransferase catalyses the condensation of farnesyl pyrophosphate (FPP) with varying numbers of isopentenyl pyrophosphates (depending on the transferase). This produces polyprenyl pyrophosphates, known as ***dehydrodolichyl diphosphates***, which lose the diphosphate group to form ***dehydrodolichols***, and finally the terminal isoprene residue is reduced to produce the α-saturated polyprenyl alcohols, the ***dolichols***. The lengths of these straight-chain isoprene residues can run up to more than C_{100}. They are widely distributed in the plant and animal kingdoms, and play an important role in the mammalian nervous systems including brain tissue. [For occurrence in mammalian nervous system see Fedorow et al. *J Neurochemistry* **92** 990 *2005*, DOI: 10.1111/j.1471-4159.2004.02975.x; and Ward & Guan et al. 'Identification and quantification of dolichols and dolichoic acids in neuromelanin from ***substantia nigra*** of the human brain' *J Lipid Res* **48**(7) 1457–1462 *2007*, DOI: 10.1194/jlr.C700008-JLR200; for biological role see Chojnacki & Dallner *Biochem J* **251** 1 *1988*, DOI: 10.1042/bj2510001, PMID: 3291859; for metabolic disorders of dolichol biosynthesis defects see Cantagrel & Lefeber *J Inherit Metab Dis* **34** 859 *2011*, DOI: 10.1007/s10545-011-9301-0]. Dolichols tend to be formed and found with varying poly-isoprene lengths together and named according to the number of isoprene residues, e.g. Dol-14 to Dol-18 [for recent results of structural studies see Skorupinska-Tudek et al. *Chem Rec* **8**(1) 33-54 *2008*, DOI: 10.1002/tcr.20137].

Echinenone (β,β-caroten-4-one) *[432-68-8]* **$C_{40}H_{54}O$, M 550.8, m 178-179°, $A^{1\%}_{lm}(\lambda_{max})$ 2160 (at 458nm) in petroleum ether.** Purify this xanthophyll (found in some cyanobaceteria; and isolated from sea urchins) by chromatography on partially deactivated alumina or magnesia, or by using a thin layer plate of silica gel G with 4:1 cyclohexane/diethyl ether as the developing solvent. Recrystallise it from *C_6H_6/MeOH. Store it in the dark at -20°. The ***oxime*** crystallises from *C_6H_6 with **m 208°**. [For isolation from sea urchins see Lederer & Moore 'Echinenone as a Provitamin A', *Nature* **137**(3476): 996–996 *1936*, DOI: 10.1038/137996b0; for isolation from *Micrococcus roseus* see Schwartzel & Cooney *J bacteriol* **104** 272–274 *1970*, PMID: 5473895; *Beilstein* **7** III 2858, **7** IV 1881.]

Ethyl bixin (6,6'-diapo-Ψ,Ψ−carotenedioic acid monomethyl ester monoethyl ester) *[6895-43-8]* **M 436.6, m 138°.** Crystallise the ester from EtOH. ***Diethyl-norbixin***, **$C_{28}H_{36}O_4$**, M 436.6, prepared by synthesis, purified through Al_2O_3/CH_2Cl_2 and eluted with EtOH, then recrystallised from *C_6H_6 has **m 199°**, and UV(petroleum ether) with λ_{max} at 431, 455 and 488nm ($E^{1\%}_{1cm}$ 2340, 3580 and 3590) [synthesis, UV and IR: Isler et al. *Helv Chim Acta* **40** 1242 *1957*, DOI: 10.1002/hlca.19570400515]. [cf. Bixin above, *Beilstein* **2** III 2020, **2** IV 2356.]

Lutein See xanthophyll.

Lycopene (all-*trans*-Ψ,Ψ−carotene) *[502-65-8]* **$C_{40}H_{56}$, M 536.9, m 172-173°, 174°, ε_{mol} 184,900 (470nm petroleum ether), 180,600 (at 487nm *C_6H_6).** This bright red cartenoid pigment which is found in tomato species crystallises from CS_2/MeOH, diethyl ether/petroleum ether, or acetone/petroleum ether. It can also be purified by column chromatography on deactivated alumina, $CaCO_3$, calcium hydroxide or magnesia. Its solubility in hexane is 1g/L at ~15°. The deep red solid is oxygen sensitive and should be stored in the dark, in an inert atmosphere. Also purified like γ-Carotene. [*Beilstein* **1** III 1076, **1** IV 1165.]

Lycoxanthin (all*trans*−Ψ,Ψ−carotene-16,16'-ol) *[19891-74-8]* **$C_{40}H_{56}O$, M 552.9, m 168°, 173-174°, $\varepsilon^{1\%}_{1cm}$ 3360 (472.5nm), also λ_{max} 444 and 503nm in petroleum ether.** Crystallise lycoxanthin from diethyl ether/light petroleum, *C_6H_6/petroleum ether (red-brown round crystal aggregates) or CS_2 (purple needles). Purify it also by chromatography on columns of $CaCO_3$, $Ca(OH)_2$ or deactivated alumina, and washing with *benzene and eluting with 3:1 *C_6H_6/MeOH. Its UV(Me_2CO) has λ_{max} at 448, 474 ($E^{1\%}_{1cm}$ 3080) and 505nm; also λ_{max} (*C_6H_6) at 458, 487 and 521nm ($10^{-3}\varepsilon$ 141.8, 162.7 and 108.8). Store it in the dark, in an inert atmosphere, at -20°. The ***monoacetate*** forms deep purple needles from *C_6H_6/MeOH **m 137°**. The ***dipalmitate ester*** crystallises from *C_6H_6/MeOH and has **m 76°**. [For revised structure of lycoxanthin and lycophyll see Cholnoky, Szabolcs & Waight *Tetrahedron Lett* **9** 1931 *1968*, DOI: 10.1016/S0040-4039(01)99058-6; for stereochemistry see Kelly et al. *Acta Chem Scand* **25** 1607 *1971*, DOI: 10.3891/acta.chem.scand.25-1607; for total synthesis see Kjosen & Liaaen-Jensen *Acta Chem Scand* **25** 1500 *1971*, DOI: 10.3891/acta.chem.scand.25-1500; *Beilstein* **1** III 2051, **1** IV 2368.]

Methylbixin (6,6'-diapo-Ψ,Ψ−carotenedioic acid dimethyl ester) *[26585-94-4]* **$C_{26}H_{32}O_4$, M 408.5, m stable *trans* form 203°, 205-206° (corr), unstable *cis* form 164°, λ_{max} 405, 425, 450, 484nm in hexane.** Crystallise the dimethyl ester from EtOH/$CHCl_3$, or *benzene (blue-purple needles with **m 203°**). Also purify it by chromatography on alumina (Grade III) and eluting with 9:1 *C_6H_6/petroleum ether (b 60-80°), and recrystallising from EtOAc. [Pattenden et al. *J Chem Soc (C)* 235 *1970*, DOI: 10.1039/J39700000235; *Beilstein* **2** III 2020, **2** IV 2356.] Its UV(petroleum ether) has λ_{max} 432, 456 and 490nm ($E^{1\%}_{1cm}$ 2650, 4050 and 4050) [for synthesis, UV and IR see Isler et al. *Helv Chim Acta* **40** 1242 *1957*, DOI: 10.1002/hlca.19570400515; Buchta & Andree *Chem Ber* **92** 3111 *1959*, DOI: 10.1002/cber.19590921214]. See Bixin above.

Physalien (all-*trans* β-carotene-3,3'(*R,R*)-diol dipalmitate) *[144-67-2]* **$C_{72}H_{116}O_4$, M 1045.7, m 98.5-99.5°, $A^{1\%}_{1m}(\lambda_{max})$ 1410 (at 449nm), 1255 (at 478nm) in hexane.** Purify it by chromatography on water-deactivated alumina, using hexane/diethyl ether (19:1) to develop the column. It crystallises from *benzene/EtOH in red needles. Store in the dark, in an inert atmosphere, at 0°. [See Zeaxanthin dipalmitate.] [*Beilstein* **6** III 5970.]

Phytoene (7,7',8,8',11,11',12,12'-octahydro−ψ,ψ−carotene) *[540-04-5; 15-cis- 13920-14-4]* **$C_{40}H_{64}$, M 544.9, $A^{1\%}_{1m}(\lambda_{max})$ 850 (at 287nm) in hexane, λ_{max} 275, 287 and 297nm.** Purify phytoene by chromatography on columns of magnesium oxide-Supercel (a diatomaceous filter aid) or alumina [For total synthesis see Davis et al. *J Chem Soc* (C) 2154 *1966*, DOI: 10.1039/J39660002154; for isolation and properties see Rabourn et al. *Arch Biochem Biophys* **48** 267 *1954*, DOI: 10.1016/0003-9861(54)90341-0]. Store it as a solution in petroleum ether under nitrogen at -20°. [*Beilstein* **1** IV 1155.]

Phytofluene (all-*trans*- 5,6,7,8,9,10,10',9',8',7',6',5'-dodecahydrolycopene) *[540-05-6; 15-cis- 27664-65-9]* **$C_{40}H_{62}$, M 542.9, b 140-185°(bath temperature)/0.0001mm, $A^{1\%}_{1m}(\lambda_{max})$ 1350 (at 348nm) in petroleum ether, λ_{max} 331, 348, 267.** Purify the viscous orange oil by chromatography on partially deactivated alumina [Goodwin *Biochem J* **53** 538 *1953*, Kushwaha et al. *J Biol Chem* **245** 4708 *1970*, PMID: 4393960; Davis et al. *J Chem Soc* (C) 2154 *1966*, DOI: 10.1039/J39660002154]. Store it as a solution in petroleum ether under N_2 at -20°. [*Beilstein* **1** III 1072, **1** IV 1159.]

Prolycopene (all-*cis* [*Z*]-ψ,ψ−carotene or lycopene) *[2361-24-2]* **$C_{40}H_{56}$, M 536.5, m 111°, λ_{max} 443.5, 470**

nm in petroleum ether. Purify prolycopene by chromatography on deactivated alumina [Kushwaha et al. *J Biol Chem* **245** 4708 *1970*, PMID: 4393960]. Crystallise it from petroleum ether. Store it in the dark, under N_2 or argon at -20°. [*Beilstein* **1** III 1079, **1** IV 1167.] It is a naturally occurring stereoisomer of lycopene [Zechmeister et al. *Proc Natl Acad Sci U S A*. 1941 Oct 15; **27**(10) 468–474*1941*, PMCID: PMC1078363]. For the stepwise isomerisation of prolycopene, a poly*cis*-carotenoid, to *all-trans*-lycopene, and characterisation see Magoon & Zechmeister [*Arch Biochem Biophys* **69** 535-47 *1957*, DOI: 10.1016/0003-9861(57)90518-0]

Proneurosporene (3,4,7',8'-tetrahydrolycopene, 7,9,9-tri*cis*-neurosporene) *[10467-46-6]* **$C_{40}H_{58}$, M 538.5, λ_{max} 408, 432, 461 nm, $\varepsilon\,^{1\%}_{1cm}$ 2040 (at 432nm) in hexane.** Purify proneurosporene by chromatography on deactivated alumina [Kushwaha et al. *J Biol Chem* **245** 4708 *1970*, PMID: 4393960;]. Store it in the dark, in an inert atmosphere at 0°. [*Beilstein* **1** IV 1156.]

Retinol (vitamin A alcohol), retinoic acid (vitamin A acid), retinyl acetate (vitamin A acetate), retinal (vitamin A aldehyde), retinyl palmitate (vitamin A palmitate) See in 'Physiologically Active.. ', this chapter.

Spirilloxanthin [rhodoviolascein, 2,31-dimethoxy-2,6,10,14,19,23,27,31-octamethyl-dotriaconta-4,6,8,10,12,14,16,18,20,22,24,26,28-tridecaene, (3*E*,3'*E*)-1,1'-Dimethoxy-3,3',4,4'-tetradehydro-1,1',2,2'-tetrahydro-ψ,ψ-carotene] *[928-13-2, 22076-36-4, 26645-74-9, 34255-08-8]* **$C_{42}H_{60}O_2$, M 596.9, m 216-218°, 218°, λ_{max} 463, 493, 528 nm, $\varepsilon\,^{1\%}_{1cm}$ 2680 (at 493nm) in petroleum ether (b 40-70°).** Spirilloxanthin crystallises from $CHCl_3$/petroleum ether, acetone/petroleum ether, *C_6H_6/petroleum ether or *C_6H_6 as deep red spindle-like crystals. Purify it also by chromatography on a column of $CaCO_3$/$Ca(OH)_2$ mixture, $Ca(OH)_2$ or deactivated alumina and elute it with a *C_6H_6/MeOH mixture. It gives a blue colour with $SbCl_3$ in $CHCl_3$ with λ_{max} at 642nm. [Polgar et al. *Arch Biochem Biophys* **5** 243 *1944*; for synthesis see Surmatis & Ofner *J Org Chem* **28** 2735 *1963*, DOI: 10.1021/jo01045a057; Karrer & Koenig *Helv Chim Acta* **23** 460 *1940*, DOI: 10.1002/hlca.19400230160; for 'Isolation and light-stimulated expression of canthaxanthin and spirilloxanthin biosynthesis genes from the photosynthetic bacterium *Bradyrhizobium* sp. strain ORS278', see Giraud & Verméglio *Methods in molecular biology (Clifton NJ)* **892** 173 *2012*, PMID: 22623302.] Store it in the dark in an inert atmosphere at -20°. [*Beilstein* **1** III 2297, **1** IV 2750.]

Squalane (Cosbiol, 2,6,10,15,19,23-hexamethyltetracosane, perhydrosqualene) *[111-01-3]* **$C_{30}H_{62}$, M 422.8, m -38°, b 176°/0.05mm, 210-215°/1mm, 274°/10mm, ~350°/760mm, d_4^{20} 0.80785, n_D^{20} 1.416.** Purify squalane by fractional distillation *in vacuo* or evaporative distillation. It is soluble in petroleum ether, *C_6H_6, Et_2O and $CHCl_3$, slightly soluble in alcohols, Me_2CO and AcOH but insoluble in H_2O. Small quantities can be purified by TLC as for squalene below. It is used as a marker in GLC and HPLC. [Staudinger & Leupold *Helv Chim Acta* **15** 221 *1932*, DOI: 10.1002/hlca.19320150120; Sax & Stross *Anal Chem* **29** 1700 *1957*, DOI: 10.1021/ac60131a044; Mandai et al. *Tetrahedron Lett* **22** 763 *1981*, DOI: 10.1016/0040-4039(81)80145-1; *Beilstein* **1** IV 593.]

Squalene (all-*trans*-2,6,10,15,19,23-hexamethyl-2,6,10,14,18,22-tetracosahexaene) *[111-02-4]* **$C_{30}H_{50}$, M 410.7, m -5°, ~75°, b 203°/0.1mm, 213°/1mm, 285°/25mm, d^{25} 0.8670, n_D^{20} 1.4905.** Crystallise squalene repeatedly from Me_2CO (1.4ml/g) using a Dry-ice bath, wash the crystals with cold acetone, then freeze the squalene under vacuum. Squalene is further purified by passage through a column (or TLC plate) of silica gel or chromatographed on activated alumina, using petroleum ether as eluent and stored in a vacuum in the dark. Dauben et al. [*J Am Chem Soc* **74** 4321 *1952*, DOI: 10.1021/ja01137a022] purified squalene *via* its ***hexachloride*** which is anti-bactericidal. Squalene is a key intermediate in sterol biosynthesis. [Capstack et al. *J Biol Chem* **240** 3258 *1965*, PMID: 14321361; Krishna et al. *Arch Biochem Biophys* **114** 200 *1966*, DOI: 10.1016/0003-9861(66)90322-5; Heilbron & Thompson *J Chem Soc* 883 *1929*, DOI: 10.1039/JR9290000883; Karrer et al. *Helv Chim Acta* **13** 1084 *1930*, DOI: 10.1002/hlca.19300130532; UV: Farmer et al. *J Chem Soc* 541*1943*, DOI: 10.1039/JR9430000541; *Beilstein* **1** III 1071.] Squalene is abundant in nature and particularly in shark liver oil. In animals it is the main natural precursor of sterols (*via* lanosterol), and in plants also it is the main precursor of sterols (*via* cycloartenol).

Violaxanthin (5*S*,6*S*,5'*S*,6'*S*-diepoxyzeaxanthin) *[126-29-4]* **$C_{40}H_{56}O_4$, M 600.9, m 200°, 207-208°, $[\alpha]_{Cd}^{18}$ +35 (c 0.1, $CHCl_3$).** Crystallise violaxanthin from MeOH (orange prisms) by adding a little Et_2O in MeOH, or CS_2 (red brown crystals). Also purify it by column chromatography, and the purity is checked by TLC (see δ-carotene). It has λ_{max} at 415, 440 and 469nm. [Kuhn & Winterstein *Ber* **64** 326 *1931*, Karrer & Morf *Helv Chim Acta* **14** 1044 *1931*, DOI: 10.1002/hlca.19310140513; for absolute configuration see Bartlett et al. *J Chem Soc (C)* 2527 *1969*, DOI: 10.1039/J39690002527; *Beilstein* **19** III/IV 1139.] It is a food additive and is biosynthesised from zeaxanthin (below) by epoxidation.

Xanthophyll (Lutein, 3*R*,3'*R*-α-carotene-3,3'-diol) *[127-40-2]* **$C_{40}H_{56}O_2$, M 568.9, m 183°, 193°, 196°, $[\alpha]_{Cd}^{18}$ +165 (c 0.7, *C_6H_6)[NB: Cd I and II have λ 533 & 537 nm], $\varepsilon_{1cm}^{1\%}(\lambda_{max})$ 1750 (423nm), 2560 (446nm), 2340 (477.5nm) and ε_{mol} 144,800 (at 445nm) in EtOH; λ_{max} in CS_2 446, 479 and 511nm, and ε_{mol} 127,000 (at 458nm, *C_6H_6).** Crystallise lutein from MeOH (1g/700ml; copper-coloured prisms with a metallic lustre) or from diethyl ether by adding MeOH. Also purify it by chromatography on columns of magnesia or calcium hydroxide, and recrystallise it from CS_2/EtOH. The UV has λ_{max} (ε) (dioxane) at 268nm (35,000), 333nm (15,500), 429nm (100,000), 453nm (152,000) and 481nm (142,000). It may be purified *via* the ***dipalmitate ester*** which crystallises from EtOH (red needles) with **m 92°.** Store it in the dark, in an inert atmosphere, e.g. argon [Zechmeister *Chem Rev* **34** 267 *1944*, DOI: 10.1021/cr60108a004; Buchecker et al. *Helv Chim Acta* **57** 631 *1974,* DOI: 10.1002/hlca.19740570317; Karrer *Helv Chim Acta* **34** 2160 *1951*, DOI: 10.1002/hlca.19510340708; for absolute configuration see Goodfellow et al. *JCS Chem Commun* 1578 *1970*, DOI: 10.1039/C29700001578; *Beilstein* **6** II 1026, **6** III 5871, **6** IV 7017.] The yellow colour of chicken egg yolks, fat and skin comes from ingested xanthophyll and zeaxanthin.

Zeaxanthin [all*trans*-β-carotene-3,3'(*R*,*R*')-diol] *[144-68-3]* **$C_{40}H_{56}O_2$, M 568.9, m 205-206° (natural), 207°, 215.5°, $[\alpha]_{Cd}^{18}$ -44° (c 0.7, $CHCl_3$), [NB: Cd I and II have λ 533 & 537 nm], λ_{max} 275nm (log ε 4.34), 450nm (log ε 5.14), 480nm (log ε 5.07) in EtOH, ε_{mol} 132,900 (at 452nm, Me_2CO).** Zeaxanthin, one of the most common carotenoid alcohols in nature, forms yellow plates (with a blue lustre) from MeOH, EtOH and with 0.5 MeOH from *C_6H_6/MeOH. The ***diacetate*** (from natural) has **m 154-155°** (from CH_2Cl_2/MeOH), the UV has λ_{max} ($\varepsilon_{1cm}^{1\%}$) at 452, 480nm (2210, 1945). The ***dipalmitate (Physalein)*** (from natural source) has **m 95-96°** (from CH_2Cl_2/MeOH), the UV has λ_{max} ($\varepsilon_{1cm}^{1\%}$) at 452, 480nm (1335, 1190). [Isler et al. *Helv Chim Acta* **39** 2041 *1956*, DOI: 10.1002/hlca.19560390717; Hlubucek et al. *JCS Perkin Trans 1* 848 *1974*, DOI: 10.1039/P19740000848.] The ***racemate*** is purified by chromatography on an alumina (Grade IV) column by elution with a gradient of petroleum ether (b 60-80°), *C_6H_6 and EtOAc. The red band gives a solid which recrystallises from MeOH with **m 211°**, and the UV has λ_{max} at 439infl, 462, 589nm (ε 10^{-3}: 90, 126, 110 respectively). [Loeber et al. *J Chem Soc (C)* 404 *1971*, DOI: 10.1039/J39710000404, *Beilstein* **6** II 1026, **6** III 5865, **6** IV 7017.]

STEROIDS

This section also includes steroidal hormones, steroidal alkaloids and cardenolides.

(-)-3-β-Acetoxy-5-etienic acid [3-β-acetoxy-5-etiocholenic acid, androst-5-ene-17-β-carboxylic acid] *[7150-18-7, 51424-66-9]* **$C_{22}H_{32}O_4$, M 306.5, m 238-240°, 241-242°, 243-245°, 246-247°, $[\alpha]_D^{20}$ -19.9 (c 1, Me_2CO), -36 (c 1, dioxane), -33.5° ($CHCl_3$), pK_{Est} ~ 4.7.** The acid is purified by recrystallisation from Me_2CO, Et_2O/pentane, or AcOH, dried in a vacuum oven (105°/20mm) and sublimed at high vacuum. [Staunton & Eisenbraun *Org Synth* **42** 4 *1962*, DOI: 10.15227/orgsyn.042.0004; Steiger & Reichstein *Helv Chim Acta* **20** 1040 *1937*, DOI: 10.1002/hlca.193702001150.] A useful acid for the ***optical resolutions*** of alcohols [J. Jacques et al. *Enantiomers, Racemates, and Resolutions* Wiley-Interscience, New York, p 333 *1981*].

21-Acetoxypregnenolone (3β-hydroxy-21-acetoxypregn-5-en-20-one) *[566-78-9]* **$C_{23}H_{34}O_4$, M 374.3, m 184-185°.** Crystallise 21-acetoxypregnenolone from Me_2CO by allowing the solvent to evaporate in a vacuum to a small volume, collect the colourless needles and wash them with Et_2O, then dry it *in vacuo*. The crystals become opaque on standing. [Steiger & Reichstein *Helv Chim Acta* **20** 1164 *1937*, DOI: 10.1002/hlca.193702001158.]

Adrenosterone (Reichstein's G, androst-4-ene-3,11,17-trione) *[382-45-6]* **$C_{19}H_{24}O_3$, M 300.4, m 214-217°, 219-222°, 220-224°, 224-226°, $[\alpha]_{546}^{20}$ +364 (c 0.18, EtOH), $[\alpha]_D^{20}$ +300 (c 1, $CHCl_3$).** Dissolve adrenosterone in Me_2CO, decolorise it with charcoal, filter, add H_2O, Me_2CO evaporate and the solid is recrystallised from aqueous EtOH. Also recrystallise it from Et_2O or Et_2O/pentane and dry it at 110°/0.1mm for 2 hours. It can be sublimed under high vacuum. [Reichstein *Helv Chim Acta* **20** 953, *1937* DOI: 10.1002/hlca.193702001138; 979 *1937*, DOI: 10.1002/hlca.193702001141, Mason et al. *J Biol Chem* **116** 267 *1936*, http://www.jbc.org/content/116/1/267; *Beilstein* **7** III 4601.]

Aldosterone (18-aldocorticosterone, Reichstein's X) *[52-39-1]* **$C_{21}H_{28}O_5$, M 360.5, m 108-112°(hydrate), 164°(anhydrous), $[\alpha]_D^{25}$ +161 (c 1, $CHCl_3$).** Crystallise aldosterone from aqueous acetone. It exists in solution as an equilibrium mixture of free aldehyde and its cyclic hemiacetal, favouring the hemiacetal. The ***d- isomer*** is considered as the biologically active one. The ***21-acetate*** crystallises from Me_2CO/Et_2O or CH_2Cl_2/EtOAc and has **m 198-199°**, and $[\alpha]_D^{25}$ +121.7 (c 0.7, $CHCl_3$). [Barton et al. *JCS Perkin Trans 1* 2243 *1975*, DOI: 10.1039/P19750002243; *Beilstein* **8** IV 3491.]

5α-Androstane (etioallocholane) *[5α- 438-22-2, 24887-75-0]* **$C_{19}H_{32}$, M 260.5, m 50-50.5°, $[\alpha]_D$ +2 (c 0.12, $CHCl_3$).** Purify 5α-androstane by chromatography through Al_2O_3 (grade III) and elute with petroleum ether then recrystallise it from MeOH (2x) and Me_2CO/MeOH. It sublimes at 60°/high vacuum. Also dissolve it in petroleum ether, filter it through silica gel, evaporate and recrystallise it. [Steiger & Reichstein *Helv Chim Acta* **20** 817 *1937*, DOI: 10.1002/hlca.193702001117; Prelog et al. *Helv Chim Acta* **27** 66 *1944*, DOI: 10.1002/hlca.19440270109; IR, NMR: Halkes & Havinga *Recl Trav Chim Pays-Bas* **84** 889 *1965,* DOI: 10.1002/recl.19650840710; Allinger et al. *Tetrahedron* **27** 5093 *1971*, DOI: 10.1016/S0040-4020(01)90764-1; *Beilstein* **5** III 1110, **5** IV 1211.]

5β-Androstane (etiocholane, testane) *[438-23-3]* **$C_{19}H_{32}$, M 260.5, m 78-79°, 78-80°, $[\alpha]_D^{20}$ +2.03, $[\alpha]_{546}^{18}$ +5 (c 1, $CHCl_3$).** Crystallise etiocholane from acetone. The method of purification for 5α-androstane (above) could be used here. [Shoppee *Helv Chim Acta* **27** 246, 260 *1944*, DOI: 10.1002/hlca.19440270128; Butenandt & Dannerbaum *Hoppe Seyler's Z Physiol Chem* **229** 192 *1934*, *Beilstein* **5** III 1110, **5** IV 1211.]

4-Androstene-3,17-dione (androstenedione) *[63-05-8]* **$C_{19}H_{26}O_2$, M 286.4, m 170-171°, 173-174°, $[\alpha]_D^{20}$ +196 (c 0.13, EtOH).** Crystallise the dione from hexane. It is soluble in $*C_6H_6$, $CHCl_3$ and EtOH. It has λ_{max} at 239nm. It is a precursor of estrone or testosterone and has androgenic activity. [Ruzicka & Wettstein *Helv Chim Acta* **18** 986 *1935*, DOI: 10.1002/hlca.193501801132; *Beilstein* **7** III 3636, **7** IV 2381.]

Androsterone (*Cis*) (3α,5α-3-hydroxyandrostan-17-one) *[53-41-8]* **$C_{19}H_{30}O_2$, M 290.4, m 181-184°, 185-185.5°, $[\alpha]_{546}$ +118 (c 1, EtOH), $[\alpha]_D^{20}$ +96 (c 0.7, EtOH).** Crystallise androsterone from Me_2CO/Et_2O or Me_2CO and sublime it at high vacuum. The ***acetate*** [1164-95-0] crystallises from Et_2O, Me_2CO/Et_2O or aqueous EtOH, and sublimes at high vacuum with **m 165-166°**, and $[\alpha]_D^{25}$ +87 (c 2, EtOH). [Ruzicka et al. *Helv Chim Acta* **17** 1389 *1934*, DOI: 10.1002/hlca.193401701169; Marker *J Am Chem Soc* **57** 1755 *1935*, DOI: 10.1021/ja01312a505; Göndös & Orr *JCS Chem Commun* 1239 *1982*, DOI: 10.1039/C39820001239; *Beilstein* **8** IV 642.]

epi*-Androsterone (*Trans*, 3β-hydroxy-5α-androstan-17-one)** *[481-29-8]* **$C_{19}H_{30}O_2$, M 290.4, m 172-173°, (161-162° *dl*-), $[\alpha]_{546}$ +115 (c 1, MeOH), $[\alpha]_D^{20}$ +44.4 (c 0.27, $CHCl_3$).** Purify *epi*-androsterone *via* the acetate, hydrolyse this and recrystallise it from $CHCl_3$/hexane or aqueous EtOH. The ***acetate *[1239-31-2]* is purified by chromatography and when crystallised from petroleum ether has **m 103-104°**, and $[\alpha]_D$ +68.5 (c 1, $CHCl_3$). The ***oxime*** has **m 194-196°** (from MeOH), and $[\alpha]_D$ +17.5 (c 6.2, $CHCl_3$). The ***racemic ketone*** is sublimed at 130°/high vacuum and after two crystallisations from methylcyclohexane it gives prisms with **m 161-162°** (which changed crystal form at 140-145°). [Ruzicka & Wettstein *Helv Chim Acta* **18** 1264 *1935*, DOI: 10.1002/hlca.193501801176; Johnson et al. *J Am Chem Soc* **75** 2275 *1953,* DOI: 10.1021/ja01105a530; **78** 6331 *1956*, DOI: 10.1021/ja01605a020; Cardwell et al. *J Chem. Soc* 361 *1953*, DOI: 10.1039/JR9530000361; *Beilstein* **8** IV 462.] It is a steroid hormone with weak androgenic activity.

Betamethasone (9α-fluoro-11β,17α,21-trihydroxy-16β-methylpregna-1,4-diene-3,20-dione) *[378-44-9]* **$C_{22}H_{29}FO_5$, M 392.5, m 231-136°(dec), 235-237°(dec), $[\alpha]_D^{20}$ +108 (c 1, Me_2CO).** Betamethasone crystallises from ethyl acetate, and has λ_{max} at 238nm (log ε 4.18) in MeOH. The ***21-acetate*** *[287-24-6]* crystallises from Me_2CO/Et_2O (charcoal) with **m 196-201°** (**205-208°**) and has $[\alpha]_D^{20}$ +140 ($CHCl_3$). [Taub et al. *J Am Chem Soc* **82** 4012 *1960*, DOI: 10.1021/ja01500a053; Oliveto et al. *J Am Chem Soc* **80** 6687 *1958*, DOI: 10.1021/ja01557a058; *Beilstein* **8** IV 3501.]

Bisnorcholanic acid (pregnane-20-carboxylic acid) *[28393-20-6]* **$C_{22}H_{36}O_2$, M 332.5, m 214° (α-form), 242° (β-form), 210-211° (γ-form), 184° (δ-form), 181° (ε-form), pK_{Est} ~5.0.** Bisnorcholanic acid crystallises from EtOH (***α-form***), or acetic acid (***all forms***). The α-form has $[\alpha]_D^{20}$ -7.5 (c 0.8, EtOH), and its ***ethyl ester*** has **m 106-107°**; the ***β-form*** has $[\alpha]_D^{20}$ +23.3 (c 0.86, EtOH), and its ***ethyl ester*** is an oil; the ***γ-form*** has $[\alpha]_D^{20}$ 0, and its ***ethyl ester*** has **m 82-83°**; the ***δ-form*** has $[\alpha]_D^{20}$ +31.7 (c 0.76, EtOH), and its ***methyl ester*** has **m 99°**; the *ε-form* has $[\alpha]_D^{20}$ +14.3 (c 0.8, EtOH), and its ***methyl ester*** has **m 117°**. Crystallise 5β-cholanic acid from EtOH, Me_2CO or AcOH. The ***ethyl ester*** has **m 93-94°** (from 80% EtOH), **b** 273°/12mm, $[\alpha]_D^{20}$ +21 ($CHCl_3$), and the ***methyl ester*** has **m 86-87°** (from MeOH) after purification through Al_2O_3 and eluting with *C_6H_6; and has $[\alpha]_D^{20}$ +21.2 ($CHCl_3$). The ^1H NMR ($CDCl_3$) for the C18 & C19 protons has δ at 0.65 and 0.92 [see 5α-cholanic acid above**,** Mandava et al. *Steroids* **23** 357 *1974*, DOI: 10.1016/0039-128X(74)90087-7]. [Stoll et al. *Helv Chim Act* **18** 644 *1935*, DOI: 10.1002/hlca.19350180184; Huang-Minlon *J Am Chem Soc* **71** 3301 *1949*, DOI: 10.1021/ja01178a008; *Beilstein* **9** III 2656, **9** IV 1992.]

Cholesta-3,5-diene *[747-90-0]* **$C_{27}H_{44}$, M 368.6, m 77-78°, 78°, 78-79°, 79-80°, 79.5-80.5°, 80-81°, $[\alpha]_D^{16}$ −116 (c 1.1, $CHCl_3$).** This diene has been prepared in many ways, but several of these are from solvolysis of epicholesteryl toluene-*p*-sulfonate using KOAc/Ac_2O (38 hours at 75°), then methanolic KOAc (reflux at 3.5 hours), followed by reduction with $LiAH_4$/Et_2O (20 hours at 20°) in *ca* 60% yield [Schmid & Kägi *Helv Chim Acta* **35** 2194 *1952*, DOI: 10.1002/hlca.19520350704], or AgOAc/AcOH, KOAc/MeOH or KOAc/AcOH (reflux ~3 hours 92-99% yield), and with neutralised Al_2O_3 at 20° [Evans & Shoppee *J Chem Soc* 540 *1953*, DOI: 10.1039/JR9530000540; Shoppee et al. *J Chem Soc* 2876 *1955*, DOI: 10.1039/JR9550002876], KOAc/aqueous Me_2CO [Becker & Wallis *J Org Chem* **20** 353 *1955*, DOI: 10.1021/jo01121a013], and diphenylguanidinium salts accelerate solvolysis [Shoppee & Williams *J Chem Soc* 686 *1955*, DOI: 10.1039/JR9550000686]. After the usual workup involving washing with $NaHCO_3$ and H_2O, the diene is separated from other steroids and impurities by chromatography through Al_2O_3 (various grades, including activity II-III, neutralised, basic or activated at 250-310°) and usually eluted with pentane, pentane/*C_6H_6 or Et_2O/MeOH. It is then recrystallised from Me_2CO, Et_2O/MeOH or Et_2O/EtOH, dried *in vacuo* and stored at −20°. The UV has λ_{max} (log ε) at 228.5 (4.308), 235 (4.344) and 243 (4.163) nm.

Cholesta-5,7-dien-3β-ol (7-dehydrocholesterol, 3β-hydroxy-5,7-cholestadiene, Provitamin D_3) *[434-16-2]* **$C_{27}H_{44}O$, M 384.6, m 150-151° (anhydrous), 148-152°, $[\alpha]_D^{20}$ −113.6 (c 1, $CHCl_3$), $[\alpha]_D^{20}$ −127 (*C_6H_6).** It

occurs in humans and higher animals, and has been isolated from pig skin or the horned snail (*Buccinum undatum*). It is purified by recrystallisation from MeOH, Et_2O/MeOH or aqueous Et_2O (plates) and holds to H_2O tenaciously. It is insoluble in H_2O but is soluble in most organic solvents. Store it at -20° in the dark and absence of air which oxidises it slowly. Irradiation with UV light produces vitamin D_3 and like all provitamin D have λ_{max} at 260, 270, 281 and 293.5 nm. The ***acetate*** *[1059-86-5]* has **m 129-130°,** and **$[\alpha]_D^{20}$ −85.3 (c 1.2, *C_6H_6),** crystallises from MeOH; and the ***benzoate*** has **m 139-140°,** and **$[\alpha]_D^{20}$ −53.2 (c 1.2, $CHCl_3$)**, and crystallises from $CHCl_3$/Me_2CO in plates. [Bernstein et al. *J Org Chem* **14** 433 *1949*, DOI: 10.1021/jo01155a015; *Beilstein* **6** IV 4153]. Not to be confused with *dihydrocholesterol*.

Cholesta-5,7-dien-3α-ol *[57651-84-0]* **$C_{27}H_{44}O$, M 384.6, m 125-126°, $[\alpha]_D^{20}$ −70.5 ($CHCl_3$)**, crystallises from MeOH in needles, and its ***acetate***, has **m 114.5°,** and **$[\alpha]_D^{20}$ −35 ($CHCl_3$)**. It also crystallises from MeOH in needles. [Aberhart et al. *J Org Chem* **41** 1067 *1976*, DOI: 10.1021/jo00868a031]. [for NMR of steroids see Kirk et al. *JCS Perkin Trans 2* 1567 *1990*, DOI: 10.1039/P29900001567; and Anastasia et al. *Steroids* **49** 543 *1987*, DOI: 10.1016/0039-128X(87)90094-8; and for ORD see Weiss et al. *Tetrahedron* **21** 3105 *1965*, DOI: 10.1016/S0040-4020(01)90764-1].

Cholesta-5,24-dien-3β-ol (Desmosterol, 24-dehydrocholesterol, 3β-hydroxy-5,24-cholestadiene, natural 3β,20*R*-form) *[313-04-2]* **$C_{27}H_{44}O$, M 384.6, m 117-118°, 119-119.5°, 120.5-121°, 121.5°, 121.5-122.5°, $[\alpha]_D^{20}$ −38.2 (c 1.14, $CHCl_3$).** It occurs in chick embryos, rat skins, red algae, barnacles and *Funtmia latifolia* seeds. This is a useful intermediate for the synthesis of vitamin D metabolites [Koreeda et al. *J Org Chem* **45** 1172 *1980*, DOI: 10.1021/jo01294a056]. The sterol in hexane can be purifed by chromatography on a $AgNO_3$/silicic acid/Super-Cel column in *C_6H_6, then re-chromatographed on Alumina F20, eluting with *C_6H_6 followed by *C_6H_6/EtOAc (1:1 v/v) and recrystallised from distilled MeOH or from Me_2CO/MeOH. It has IR (KBr) with ν_{max} at 1373, 1056, 1022, 959, 950, 835 and 800 cm^{-1}; and HRMS has *m/z* 384.3421 ($M^{\cdot+}$), $C_{27}H_{44}O$ requires 384.3389 [Apfel *J Org Chem* **43** 2284 *1978*, DOI: 10.1021/jo00405a044]. The ***acetate*** *[2665-04-5]* **m 99°, $[\alpha]_D^{28}$ −44.8 (c 1, $CHCl_3$)**, can be obtained by refluxing 3-chlorocholesta-5,24-diene with AcOH/AcOK for 2.5 hours, cooling, adding H_2O, extracting with Et_2O, drying ($MgSO_4$), evaporating the extract, followed by chromatography through silica gel, eluting with *C_6H_6, evaporating and the white crystalline residue is recrystallised from Me_2CO/MeOH. The ***acetate*** has ^1H NMR (60MHz, CCl_4, TMS) with δ at 0.68 (s, 3H, H_3C18), 0.98 (s, 3H, H_3C19), 1.00 (s, 3H, H_3C21), 1.58 (s, 3H, H_3C26 or H_3C27), 1.65 (s, 3H, H_3C27 or H_3C26), 1.94 (s, 3H, 3-$OCOCH_3$), 4.50 (m, 1H*ax*, H-C3), 5.00 (m, H, H-C24) and 5.35 (m, 1H, H-C5). Hydrolysis of the acetate with MeOH/KOH gave ***desmosterol*** with **m 119-120°,** and **$[\alpha]_D^{28}$ −41 ($CHCl_3$)**. [Ochi et al. *Steroids* **30** 795 *1977*, DOI: 10.1016/0039-128X(87)90094-8]. ***Desmosterol*** has also been obtained from the readily available ***3-hydroxy-bisnorcholenic acid*** in several synthetic steps and finally *via* the 3-tetrahydropyranyl ether which was hydrolysed in THF containing a few drops of concentrated HCl at 40°/5 minutes to give the ***sterol*** **m 120-122°** in 70% yield after recrystallisation from MeOH. It has ^1H NMR (60MHz, $CDCl_3$, TMS) with δ at 0.41 (s, H_3C18), 0.51 (d, *J* = 6Hz, H_3C21), 0.61 (s, H_3C19), 1.97 and 1.02 (2s, H_3C26, H_3C27), 2.10 (1H*ax*, H-C3), 3.03 (24-H) and 3.20 (6- H). [Dasgupta et al. *J Org Chem* **39** 1658 *1974*, DOI: 10.1021/jo00925a013.] Store it at −20°.

Cholesta-5,24-dien-3α-ol *[67392-80-7]* **M 384.6,** has **m 137-139°** (from MeOH), **$[\alpha]_D^{28}$ −43.5 ($CHCl_3$)**, and its ***acetate*** *[67383-62-4]* **M 426.6,** has **m 112-115°** (from MeOH), **$[\alpha]_D^{28}$ −47.5 ($CHCl_3$)**.

The **3β,20*S*-form** *[59532-46-6]* **M 384.6,** has **m 125-127°** (from MeOH), and is obtained by dehydration of 20*S*-3β,25-dihydroxycholest-5-ene with dioxane/H_2SO_4 (50% yield). It has IR (KBr) with ν_{max} at 3000 (OH) cm^{-1}, and ^1H NMR (60MHz, $CDCl_3$, TMS) with δ at 0.70 (s, H_3C18), 0.84 (d, H_3C21), 1.02 (s, H_3C19), 1.62 and 1.70 (2s, H_3C26, H_3C27). It is an ***inhibitor*** of the *cholesterol side-chain cleavage enzyme system* in bovine adrenocortical preparations [Burstein et al. *Steroids* **27** 361 *1976*, DOI: 10.1016/0039-128X(76)90057-X]; and is the ***immediate precursor*** of cholesterol in the *Bloch biosynthetic pathway*.

5α-Cholestane *[481-21-0]* **$C_{27}H_{48}$, M 372.7, m 80°, 80-80.5°, $[\alpha]_{546}^{20}$ +29.5, $[\alpha]_D^{20}$ +24, $[\alpha]_D^{18}$ +30.2, (c 2, $CHCl_3$).** 5α-Cholestane is prepared by catalytic reduction of cholestene with EtOAc/PtO_2/H_2, and recrystallised from EtOAc or Et_2O/EtOH. Store it at room temperature. The ^1H NMR (100MHz, $CDCl_3$, TMS) signals of the methyl groups have δ at 0.645 (s, 13-Me), 0.778 (s, 10-Me), 0.898 (, *J* = 6.0Hz, 20-Me) and 0.861 (d, *J* = 6.3Hz, 25-Me_2) [Wittstruck et al. *JCS Perkin Trans I* 1403 *1977*, DOI: 10.1039/P19770001403], and its CD spectrum in hexane has a Δε value of +0.5 at the longest wavelength of 183nm [Kirk et al. *Tetrahedron Lett* 1355 *1973*,

DOI: 10.1016/S0040-4039(01)95941-6]. ***Note*** that catalytic hydrogenation of cholest-4-ene in acidic medium provides ***5-α-cholestane*** whereas hydrogenation in neutral media results in *5-β-cholestane* [Windaus *Chem Ber* **52** 170 *1919*, DOI: 10.1002/cber.19190520122]. [Ruzicka et al. *Helv Chim Acta* **16** 327, 334 *1933,* DOI: 10.1002/hlca.19330160146; *Beilstein* **5** III 1132, **5** IV 1227.]

5β-Cholestane (coprostane, ψ-cholestane, pseudocholestane) *[481-20-9, 25269-18-5 + 21 other numbers + 105308-41-6]* **$C_{27}H_{48}$, M 372.7, m 70°, 71-72°, $[\alpha]_D^{20}$ +25 (c 2, $CHCl_3$).** Catalytic hydrogenation (Pt_2O/Et_2O) of 3-chlorocholest-4-ene (see above) followed by crystallisation from Me_2CO [Young et al. *J Am Chem Soc* **81** 1452 *1959*, DOI: 10.1021/ja01515a042], or catalytic reduction (Pt_2O/Et_2O) followed by chromatography through an Al_2O_3 column and eluting with petroleum ether followed by recrystallisation of the residual oil from Et_2O/EtOH give high yields of coprostane [Nickon & Bagli *J Am Chem Soc* **83** 1498 *1961*, DOI: 10.1021/ja01467a049] (see previous entry). It also crystallises in needles from EtOH. Store it at room temperature. Its CD spectrum in hexane has a Δε value of +1.1 at the longest wavelength of 184nm (see previous entry) [Kirk et al. *Tetrahedron Lett* 1355 *1973*, DOI: 10.1016/S0040-4039(01)95941-6].

5α-Cholestan-3ß-ol (β-cholestanol, dihydrocholesterol) *[80-97-7]* **$C_{27}H_{48}O$, M 388.7, m 142-143°(monohydrate), $[\alpha]_{546}^{20}$ +28 (c 1, $CHCl_3$), $[\alpha]_D$ +27.4 (in $CHCl_3$).** Purify 5-α-cholestan-3β-ol *via* acetylation, crystallisation and de-acetylation, then recrystallisation from EtOH or slightly aqueous EtOH, or MeOH. Its solubility is: 0.5% (MeOH) and 1% (EtOH) at 25°. [Mizutani & Whitten *J Am Chem Soc* **107** 3621 *1985*, DOI: 10.1021/ja00298a036.] The ***acetate*** has **m 114-115°** from EtOAc/MeOH and $[\alpha]_D^{20}$ +13 (c 2, $CHCl_3$). [Bruce & Ralls *Org Synth* Coll Vol **2** 191 *1943,* DOI: 10.15227/orgsyn.017.0045; *Beilstein* **6** IV 3577.]

5β-Cholestan-3α-ol (Epicoprostanol, epi-5β-cholestanol) *[516-88-7, 516-92-7]* **$C_{27}H_{48}O$, M 388.7, m 113-114°, 115-116°, 116-117°, 118°, $[\alpha]_D^{20}$ +32 (c 1.8, $CHCl_3$).** It is the main product from the acetolysis of 3β-chlorocoprostane (KOAc/AcOH, reflux for 6 hours) involving a ***Walden inversion***, and purified as in the following entry [Bridgewater & Shoppee *J Chem Soc* 1709 *1953*, DOI: 10.1039/JR9530001709]. It has also been obtained by reduction of 5β-coprostan-3-one with $LiAH_4$ to give a 94% yield of epicoprostanol **m 115-116°**, which did not form a precipitate with digitonin, and the small amount of digitonide formed gave a small quantity of coprostanol **m 100°** (~4% yield and crystallised from MeOH, see below) [Shoppee & Summers *J Chem Soc* 687 *1950*, DOI: 10.1039/ JR9500000687]. *Alternatively*, the residue is purified as described in the succeeding entry or recrystallised from Me_2CO or $Et_2O/{}^*C_6H_6$ to give the desired **3α-ol**, after drying *in vacuo* at 80°. ***Note*** that crystals from EtOH have **m 115-116°**, and from Me_2CO have **m 117-118°**. Store it at room temperature. The ***3α-yl-acetate*** (obtained by catalytic reduction of coprostan-3-one, Et_2O/MeOH/PtO_2/H_2, followed by chromatographic separation as below and acetylation) has **m 87-89°**, **89-91°**, and **$[\alpha]_D^{18}$ +42 (c 1.42, $CHCl_3$)**. [Shoppee & Summers *J Chem Soc* 687 *1950*, DOI: 10.1039/JR9500000687; Ruzicka et al. *Helv Chim Acta* **17** 1407 *1934*, DOI: 10.1002/hlca.193401701171.]

5β-Cholestan-3β-ol (coprostan-3β-ol) *[360-68-9]* **$C_{27}H_{48}O$, M 388.7, m 100-101°, 101°, 102°, $[\alpha]_D^{20}$ +28 (c 1.8, $CHCl_3$).** It is the main product from the acetolysis of 3α-chlorocoprostane (KOAc/AcOH, reflux for 6 hours) involving a ***Walden inversion***. Unlike epicoprostanol (above), coprostanol is precipitated by a 1.33% solution of digitonin in 95% EtOH, the digitonide can be collected, decomposed by dissolving in pyridine, precipitating the digitonin with excess of Et_2O, filtering off digitonin and the coprostanol is obtained by evaporation of the organic solvent. A possible impurity is the ***3α-ol*** from which it can be separated by chromatography on Al_2O_3 and eluting with $Et_2O/{}^*C_6H_6$ (1:24) whereby the ***3α-ol*** runs first (**m 116-117°**, see preceding entry) and further elution gives the pure ***3β-coprosterol*** (**m 99-101°**). Crystallise it from MeOH (needles) or aqueous EtOH. Store it at room temperature. The ***3β-yl-acetate*** from acetylation with Ac_2O (also obtained by catalytic reduction of coprostan-3-one, AcOH/PtO_2/H_2, followed by chromatographic separation as above and acetylation) has **m 91°**, **90- 91°**, and **$[\alpha]_D^{18}$ +14.5 (c 1.8, $CHCl_3$)**. Its solubility is 0.79% in H_2O at 25°. [Bridgewater & Shoppee *J Chem Soc* 1709 *1953,* DOI: 10.1039/JR9530001709; Shoppee & Summers *J Chem Soc* 687 *1950*, DOI: 10.1039/JR9500000687; see Ruzicka et al. *Helv Chim Acta* **17** 1407 *1934*, DOI: 10.1002/hlca.193401701171.]

Cholest-2-ene *[15910-23-3]* **$C_{27}H_{46}$, M 370.6, m 75-76°, $[\alpha]_D^{20}$ +66 (c 1.65, $CHCl_3$).** Purify cholest-2-ene by chromatography on Al_2O_3 (Spence H) and elute with petroleum ether (b 40-60°), then recrystallise the residue

from EtOAc/MeOH. Also recrystallise it from MeOH or diethyl ether/acetone. [Alt & Barton *J Chem Soc* 4284 *1954,* DOI: 10.1039/JR9540004284; Bergbreiter & Chandran *J Am Chem Soc* **109** 174 *1987*, DOI: 10.1021/ja00235a027; *Beilstein* **5** III 1320, **5** IV 1507.]

Cholesterol (cholest-5-en-3β-ol) *[57-88-5]* **$C_{27}H_{46}O$, M 386.7, m 147-149°, 148.9-149.4°, b 360°/atm, $[\alpha]_D^{25}$ -35 (hexane), $[\alpha]_D^{20}$ -39 (c 2, $CHCl_3$).** Crystallise cholesterol from ethyl acetate, EtOH or isopropyl ether/MeOH. [Hiromitsu & Kevan *J Am Chem Soc* **109** 4501 *1987*, DOI: 10.1021/ja00249a012.] For extensive details of purification through the dibromide, see Fieser [*J Am Chem Soc* **75** 5421 *1953*, DOI: 10.1021/ja01117a508] and Schwenk and Werthessen [*Arch Biochem Biophys* **40** 334 *1952*, DOI: 10.1016/0003-9861(52)90119-7], and by repeated crystallisation from acetic acid; see Fieser [*J Am Chem Soc* **75** 4395 *1953,* DOI: 10.1021/ja01114a003]. Like many sterols, cholesterol gives colour reactions with concentrated H_2SO_4. When cholesterol is dissolved in a small volume of $CHCl_3$ and mixed with concentrated H_2SO_4, the colour of the organic layer becomes crimson, then changes to purple, and on further standing in air it turns to blue, then green and finally yellow. The H_2SO_4 layer develops a green fluorescence. [*Beilstein* **6** III 2607, **6** IV 4000; Fieser **1** 141.]

Cholesteryl acetate *[604-35-3]* **$C_{29}H_{48}O_2$, M 428.7, m 112-114°, 113-115°, 115-116°, $[\alpha]_{546}^{20}$ -51 (c 5, $CHCl_3$), $[\alpha]_D^{20}$ -39 (c 2, $CHCl_3$).** Crystallise the acetate from *n*-pentanol or Me_2CO. Also purify it by chromatography through silica gel and eluting with MeOH. [*Beilstein* **6** III 2607, **6** IV 4004.]

Cholesteryl myristate *[1989-52-2]* **$C_{41}H_{72}O_2$, M 597.0, m 69-71°, 84°, $[\alpha]_D^{20}$ -25.4 (c 1, $CHCl_3$).** Crystallise the myristate ester from Me_2CO, EtOH/EtOAc or EtOH/Et_2O or *n*-pentanol. Purify it also by column chromatography on silica gel and eluting with MeOH then evaporating to dryness. Recrystallise it and finally, dry it *in vacuo* over P_2O_5 and store it at -20°. [Labarrere et al. *Analyt Chem* **30** 1466 *1958*, DOI: 10.1021/ac60141a008; Malanik & Malát *Anal Chim Acta* **76** 464 *1975*, DOI: 10.1016/S0003-2670(01)85421-0; *Beilstein* **6** III 2638].

Cholesteryl oleate *[303-43-5]* **$C_{45}H_{78}O_2$, M 651.1, m 44-47°, 48.8-49.4°, $[\alpha]_D^{20}$ -24 (c 1, $CHCl_3$).** Purify the oleate ester by chromatography on silica gel and eluting with MeOH. [*Beilstein* **6** III 2642.]

3α-5β-7α-12α-Cholic acid (3α-7α-12α-trihydroxy-5ß-cholan-24-oic acid, Cholalin) *[81-25-4]* **$C_{24}H_{40}O_5$, M 408.6 (anhydrous), 426.6 (hydate) m 196-198°, 198-200°, 200-201°, $[\alpha]_D^{20}$ +37, $[\alpha]_{546}$ +41 (c 0.6, EtOH), pK^{20} 4.98.** This bile acid crystallises from H_2O, aqueous AcOH (as ***hydrate***), wet Et_2O (as ***hydrate***) or EtOH (as ***alcoholate***). Dry it under vacuum at 94° to give the ***anhydrous acid*** **m 198°**. Its solublity (w/v) at 15° is 0.028% in H_2O, 3.06% in EtOH, 0.12% in Et_2O, 0.51% in $CHCl_3$, 0.036% in $*C_6H_6$, 2.82% in Me_2CO and 15.2% in AcOH. When an alcoholic solution of cholic acid + I_2 is added to aqueous KI, it forms a molecular compound ***$(C_{24}H_{40}O_5I)_4$ KI. H_2O***. The ***methyl ester*** is ***dimorphic*** with **m 155-156°** and **162°** (from 95% aqueous EtOH), and $[\alpha]_D^{20}$ +25 (EtOH); and the ***ethyl ester*** has **m 155° (162-163°** after recrystallisation from EtOAc/petroleum ether (b 30-60°) 2:8. [Cortese *J Am Chem Soc* **59** 2532 *1937*, DOI: 10.1021/ja01291a014). It has also been used in ***liposome preparations*** [Yang & Lundahl *Anal Biochem* **218** 210 *1994*, DOI: 10.1006/abio.1994.1162.] [*Beilstein* **10** III 2162, **10** IV 2072.]

4,5-Coprosten-3-ol (cholest-4-ene-3ß-ol, allocholesterol) *[517-10-2]* **$C_{27}H_{46}O$, M 386.7, m 132°, $[\alpha]_D^{24}$ +43.7, (c 1, $*C_6H_6$).** Purify 4,5-coprosten-3-ol by dissolving it in Et_2O, adding an equal volume of MeOH and removing the Et_2O with a stream of CO_2 until crystallisation begins. The sterol crystallises in needles when cooled in an ice-salt bath. Dry it *in vacuo*. It is precipitated by digitonin, and gives a red colour with 90% trichloroacetic acid (***Rosenheim reaction***). The ***acetate*** crystallises from aqueous MeOH **m 85°** (long white needles). [Schoenheimer & Evans *J Biol Chem* **114** 567 *1936*, http://www.jbc.org/content/114/3/567; for the separation from cholesterol see Stoll *Hoppe Seyler's Z Physiol Chem* **246** 10 *1937, Beilstein* **6** IV 3577.]

Corticosterone (11β, 21-dihydroxypregn-4-en-3,20-dione, Reichstein's substance H) *[50-22-6]* **$C_{21}H_{30}O_4$, M 346.5, m 179-183°, 180-181°, 180-182°, 181-184°, $[\alpha]_D^{15}$ +223 (c 1.1, EtOH), $[\alpha]_D^{23-25}$ +194 (c 0.1, dioxane).** Purify corticosterone by recrystallisation from Me_2CO (trigonal plates), EtOH or isoPrOH. It has UV with λ_{max} at 240nm, and gives an orange-yellow solution with strong fluorescence on treatment with concentrated H_2SO_4. It is insoluble in H_2O but soluble in organic solvents. [Reichstein & Euw *Helv Chim Acta* **21** 1197 *1938*, DOI: 10.1002/hlca.193802101149; **27** 1287 *1944*, DOI: 10.1002/hlca.194402701164; Mason et al. *J Biol Chem* **114** 613 *1936*, http://www.jbc.org/content/114/3/613; ORD: Foltz et al. *J Am Chem Soc* **77** 4359 *1955*, DOI: 10.1021/ja01621a052; NMR: Shoolery & Rogers *J Am Chem Soc* **80** 5121 *1958*, DOI: 10.1021/ja01552a031.] The ***21-O-acetyl derivative*** *[1173-26-8]* crystallises from Me_2CO/Et_2O with **m 152.5-153°**, and $[\alpha]_D^{20}$ +195 (c 0.6, Me_2CO); and the ***21-O-benzoyl derivative*** crystallises from $AcOH/Et_2O$ with **m 201-202°** [Reichstein *Helv Chim Acta* **20** 953 *1937*, DOI: 10.1002/hlca.193702001138]. [*Beilstein* **8** IV 2907.] This drug activates both ***mineralocorticoid*** [Krozowski & Funder et al. *Proc Natl Acad Sci USA (PNAS)* **80** 6056 *1983*, PubMedID 6310613] and ***glucocorticoid*** [Rousseau et al. *J Mol Biol* **67** 99 *1972*, DOI:10.1016/0022-2836(72)90389-0] ***receptors***.

Cortisol See hydrocortisone *[50-23-7]* below.

Cortisone (17α,21-dehydrocorticosterone, 17α,21-dihydroxy-4-pregnene-3,11,20-trione, Reichstein's substance Fa) *[53-06-5]* **$C_{21}H_{28}O_5$, M 360.5, m 223-228°, 230-231°, $[\alpha]_{546}^{20}$ +225 (c 1, EtOH).** Crystallise cortisone from 95% EtOH or acetone. The UV has ε 14,000 $M^{-1}cm^{-1}$ at 237nm (EtOH). [Hems *J Pharm Pharmacol* **5** 408 *1953,* PMID: 13070171; *Beilstein* **8** IV 3480.] It is a corticosterone analogue with *ca* twice the anti-inflammatory potency, but with much lower Na ion retention potency.

Cortisone-21-acetate *[50-04-4]* **$C_{23}H_{30}O_6$, M 402.5, m 237-240°, 242-243°, $[\alpha]_{546}^{20}$ +227 (c 1, $CHCl_3$).** Crystallise cortisone-21-acetate from acetone or $CHCl_3$. The UV has ε 15,800 $M^{-1}cm^{-1}$ at 238nm in dioxane. [Sarett *J Biol Chem* **162** 601 *1946*, PMID: 21018769; *Beilstein* **8** III 4058, **5** IV 3481.]

Deoxycholic acid *[83-44-3]* **$C_{23}H_{30}O_6$, M 392.6, m 171-174°, 176°, 176-178°, $[\alpha]_{546}^{20}$ +64 (c 1, EtOH), $[\alpha]_D^{20}$ +55 (c 2.5, EtOH), pK^{25} 6.58.** Reflux the bile acid with CCl_4 (50ml/g), filter, evaporate under vacuum at 25°, recrystallise the residue from acetone and dry it under vacuum at 155° [Trenner et al. *J Am Chem Soc* **76** 1196 *1954*, DOI**:** 10.1021/ja01633a094]. A solution of (cholic acid-free) material (100ml) in 500ml of hot EtOH is filtered, evaporate it to less than 500ml on a hot plate, and pour it into 1500ml of cold diethyl ether. The precipitate, filtered off by suction, is crystallised twice from 1-2 parts of absolute EtOH, to give an ***alcoholate***, **m 118-120°**, which is dissolved in EtOH (100ml for 60g) and poured into boiling water. After boiling until free of the EtOH, the precipitate is filtered off, dried, ground and dried to constant weight *in vacuo* [Sobotka & Goldberg *Biochem J* **26** 555 *1932*, DOI: 10.1042/bj0260555]. Deoxycholic acid is also freed from fatty acids and cholic acid by silica gel chromatography and elution with 0.5% acetic acid in ethyl acetate [Tang et al. *J Am Chem Soc* **107** 4058 *1985*, DOI: 10.1021/ja00299a048]. It can also be recrystallised from butanone. Its solubility in H_2O at 15° is 0.24g/L, but in EtOH it is 22.07g/L. [*Beilstein* **10** IV 1608.]

11-Deoxycorticosterone (21-hydroxyprogesterone) *[64-85-7]* **$C_{21}H_{30}O_3$, M 330.5, m 141-142°, $[\alpha]_{546}^{20}$ +178 and $[\alpha]_{546}$ +223 (c 1, EtOH).** Crystallise 11-deoxycorticosterone from diethyl ether. [Schindler et al. *Helv Chim Acta* **24** 360 *1941*, DOI: 10.1002/hlca.19410240152; Steiger & Reichstein *Helv Chim Acta* **20** 1164 *1937*, DOI: 10.1002/hlca.193702001158.]

11-Deoxycorticosterone acetate (21-acetoxy-4-pregnen-3,20-dione) *[56-47-3]* **$C_{23}H_{32}O_4$, M 372.5, m 154-159°, 154-160°, 155-157°, 155-161°, $[\alpha]_D^{20}$ +174 (c 1, dioxane), $[\alpha]_D^{22-24}$ +196 (c 1, $CHCl_3$).** 11-Deoxycorticosterone acetate recrystallises from EtOH as needles or Me_2CO/hexane, and sublimes at high vacuum. It is partly soluble in MeOH, Me_2CO, Et_2O and dioxane but insoluble in H_2O. [Reichstein & Euw *Helv Chim Acta* **23** 136 *1940*, DOI: 10.1002/hlca.19400230116; Romo et al. *J Am Chem Soc* **79** 5034 *1957*, DOI: 10.1021/ja01575a055; NMR: Shoolery & Rogers *J Am Chem Soc* **80** 5121 *1959*, DOI: 10.1021/ja01552a031; *Beilstein* **8** IV 2195.]

Dexamethasone (9-α−fluoro-16-α-methylprednisolone, prednisolone F) *[50-02-2]* **$C_{22}H_{29}FO_5$, M 392.5, m 262-264°, 268-271°, $[\alpha]_D^{25}$ +77.5 (c 1, dioxane).** Dexamethasone has been recrystallised from Et_2O or small volumes of EtOAc. Its solubility in H_2O is 10 mg/100ml at 25°; and is freely soluble in Me_2CO, EtOH and $CHCl_3$. Store it below 8°. A stock solution of 20μg/ml is generally made by adding 1ml of absolute EtOH to 100μg of steroid, stir gently to dissolve then add 49ml of sterile medium while mixing. [Arth et al. *J Am Chem Soc* **80** 3161 *1958*, DOI: 10.1021/ja01545a061; for the ***β-methyl*** isomer see Taub et al. *J Am Chem Soc* **82** 4012 *1960*, DOI: 10.1021/ja01500a053; see *Beilstein* **8** IV 3501.] This is a glucocorticoid steroidal anti-inflammatory drug.

Dexamethasone 21-acetate (9-α−fluoro-16-α-methylprednisolone-21-acetate, prednisolone F acetate) *[1177-87-3]* **$C_{24}H_{31}FO_6$, M 434.5, m 215-225°, 229-231°, $[\alpha]_D^{25}$ +77.6 (c 1, dioxane), +73 (c 1, $CHCl_3$).** Dexamethasone 21-acetate is purified on neutral Al_2O_3 using $CHCl_3$ as eluent, the fractions are evaporated, and the residue is recrystallised from $CHCl_3$. Store it below 8°. It has λ_{max} at 239nm (ε 14,900) in EtOH. It is a glucocorticoid steroidal anti-inflammatory agent. [Oliveto et al. *J Am Chem Soc* **80** 4431 *1958*, DOI: 10.1021/ja01549a090]. [*Beilstein* **8** IV 3501.]

Dexamethasone 21-phosphate disodium salt (Baldex, Colvasone, Dexabene, Desone among many trade names) *[2392-39-4]* **$C_{22}H_{28}FNa_2O_8P$, M 516.4, m 233-255°, $[\alpha]_D^{25}$ +74 (for anhydrous salt, c 1, H_2O).** Recrystallise it from EtOH and dry it *in vacuo*. It has λ_{max} at 238-239nm (ε 14,000) in EtOH. Store it below 8°, but ethanolic solutions should be stored at ~0°. Like the preceding two drugs it is also an ***anti-inflammatory*** agent, but is more soluble in H_2O. It is a ***pro-drug*** and is converted to dexamethasone *in vivo*; it also ***stimulates glutamine uptake*** in the ***cerebral cortex***.

Digitoxigenin (3β,14β-dihydroxy-20(22)-norcholenic acid lactone) *[143-62-4]* **$C_{23}H_{34}O_4$, M 374.5, m 253°, 249-255°, $[\alpha]_{546}^{20}$ +17 (c 1, MeOH).** Dissolve digitoxigenin in EtOAc, wash it with H_2O, dry it (Na_2SO_4), evaporate and recrystallise it from 40% aqueous EtOH or aqueous MeOH then EtOAc/Et_2O. The UV has λ_{max} at 218nm (ε 14,500 $M^{-1}cm^{-1}$). The ***3-acetate*** crystallises from Me_2CO/Et_2O with **m 222-227°**, and $[\alpha]_D^{20}$ +21 (c 1, $CHCl_3$). [Wyss et al. *Helv Chim Acta* **43** 664 *1960*, DOI: 10.1002/hlca.19600430308; Cruz et al. *J Org Chem* **42** 3580 *1977*, DOI: 10.1021/jo00442a029; *Beilstein* **18** IV 1468.]

Dihydrotachysterol *[67-96-9]* **$C_{28}H_{46}O$, M 398.7, m 125-127°, $[\alpha]_D^{20}$ +97 ($CHCl_3$).** It was prepared by reduction of ***tachysterol*** (see below) with Na/isoPrOH. Crystallise the sterol from 90% MeOH, and UV with λ_{max} at 242, 251 and 261nm ($E_{1cm}^{1\%}$ 760, 1010 and 650) in EtOH. The ***acetate*** has **m 108-110°** and $[\alpha]_D^{20}$ +32.8° ($CHCl_3$); and UV with λ_{max} at 242, 251 and 261nm ($E_{1cm}^{1\%}$ 780, 910 and 600) in EtOH. The ***propionate*** has **m 97-98°** and $[\alpha]_D^{20}$ +37 ($CHCl_3$); and UV with λ_{max} 242, 251 and 261nm ($E_{1cm}^{1\%}$ 750, 860 and 570) in EtOH. The ***2,4-dinitrobenzoate*** has **m 164-165°** (yellow needles from Me_2CO/MeOH) and **$[\alpha]_D^{18}$ +138 (c 0.58, Me_2CO)**[Werder *Hoppe Seyler's Z Physiol Chem* **260** 119 *1939*, Werder USPat 2228491 (to Winthrop *1941*); Windaus et al. *Justus Liebigs Ann Chem* **499** 188 *1932*, DOI: 10.1002/jlac.19324990116; *Beilstein* **6** III 2833, **6** IV 3994, 4161.] This is a synthetic ***vitamin D analogue*** which is activated in the liver and has a rapid onset of action, albeit a shorter half-life.

Diosgenin (25*R*-spirostaen-3β-ol) *[512-04-9]* **$C_{27}H_{42}O_3$, M 414.6, m 204-207°, $[\alpha]_D^{25}$ -129 (in Me_2CO).** Crystallise the saponin (present in wild yams) from acetone, and chromatograph it on Al_2O_3 and elute with *C_6H_6/Et_2O (9:1), then recrystallise it from MeOH. Its solubility is ~4% in H_2O and 5% in $CHCl_3$. The ***acetate*** crystallises from AcOH with **m 198°**; and has $[\alpha]_D^{20}$ -119 (pyridine). [Marker et al. *J Am Chem Soc* **65** 1199 *1943*, DOI: 10.1021/ja01246a051; Mazur et al. *J Am Chem Soc* **82** 5889 *1960*, DOI: 10.1021/ja01507a028; *Beilstein* **19** IV 862.]

α-Ecdyson (2β,3β,14α,22(*R*),25-pentahydroxy-7-cholesten-6-one) *[3604-87-3]* **$C_{27}H_{44}O_6$, M 464.7, m 239-242°, 242°, $[\alpha]_D^{20}$ +72 (c 1, EtOH).** Recrystallise α-ecdyson from tetrahydrofuran/petroleum ether and from H_2O as a ***hydrate***. It has been purified by chromatogaphy on Al_2O_3 and elution with EtOAc/MeOH. It has λ_{max} at 242nm (ε 12,400). Its ***acetate*** has **m 214-216°** from EtOAc/petroleum ether, and the ***2,4-dinitrophenyl-***

hydrazone has **m 170-175°**(dec) from EtOAc. [Karlson et al. *Justus Liebigs Ann Chem* **662** 1 *1963*, DOI: 10.1002/jlac.19636620102; Karlson *Pure Appl Chem* **14** 75 *1967*, DOI: org/10.1351/pac196714010075; *Beilstein* **8** IV 3613.]

β-Ecdyson (β-echdysterone, crustecdyson, 20-hydroxyechdyson) *[5289-74-7]* **$C_{27}H_{44}O_7$, M 480.7, m 240-242°, 245-247°, $[\alpha]_D^{20}$ +66 (c 1, MeOH).** Crystallise β-ecdyson from water, tetrahydrofuran/petroleum ether, MeOH and EtOAc after chromatographic purification. It has λ_{max} (EtOH) at 240nm (ε 12,670 $M^{-1}cm^{-1}$). [Also IR & NMR: Hueppi & Siddall *J Am Chem Soc* **89** 6790 *1967*, DOI: 10.1021/ja01001a087; Kametani et al. *Tetrahedron Lett* **21** 4855 *1980*, DOI: 10.1016/0040-4039(80)80158-4; *Beilstein* **8** IV 343.]

(+)-Equilenin (3-hydroxyestra-1,3,5,7,9-pentaen-17-one) *[517-09-9]* **$C_{18}H_{18}O_2$, M 266.3, m 250-252°, 258-259° (vac), $[\alpha]_D^{16}$ +87 (c 0.1, dioxane).** Crystallise (+)-equilenin from EtOH (solubility is 0.63% at 18°, 2.5% at 78°), aqueous EtOH or *C_6H_6 (Norite) and dry it in a vacuum. It sublimes on melting and at 170-180°/0.01mm. The ***acetate*** crystallises from MeOH with **m 165-167°** and $[\alpha]_D^{20}$ +71 (c 1, $CHCl_3$). [Bachmann et al. *J Am Chem Soc* **62** 824 *1940*, DOI: 10.1021/ja01861a036; *Beilstein* **8** III 1522, 1523, 1525, 8 IV 1420.]

Ergosterol (Provitamin D_2) *[57-87-4]* **$C_{28}H_{44}O$, M 396.7, m 160°, 165-166°, $[\alpha]_{546}^{20}$ -171 (c 1, $CHCl_3$), $[\alpha]_D^{20}$ -135 (c 1, $CHCl_3$).** Crystallise ergosterol from EtOAc, then from ethylene dichloride or EtOH/*C_6H_6 (3:1). It has been purified by conversion to the ***isobutyl ester*** which crystallises in massive snow-white crystals from Et_2O/Me_2CO (1:3) which have **m**: turbid at **148°**, melts to a turbid liquid at **159°** and becomes clear at **162°**, which had $[\alpha]_D^{20}$ -84 (c 1, $CHCl_3$), followed by hydrolysis. [When crystallised from EtOH, it forms the ***1,5-hydrate*** **m 168°**. The water is difficult to remove giving an ***amorphous*** solid **m 166-183°**, **b 250°/high vacuum**. It is light sensitive. The ***benzoate*** has **m 169-171°**, after crystallisation from Me_2CO/*C_6H_6 (4:1) [whose crystals becomes highly charged after prolonged standing at 0°] and has $[\alpha]_D^{20}$ -177 (c 1, $CHCl_3$). [For highly purified material and its esters see Bills & Honeywell *J Biol Chem* **80** 15 *1928*, http://www.jbc.org/content/80/1/15; for UV of sterols see Hogness et al. *J Biol Chem* **120** 239 *1937*, http://www.jbc.org/content/120/1/239. *Beilstein* **6** IV 4407.]

17α-Estradiol [1,3,5(10)-estratriene-3,17α-diol] *[57-91-0]* **$C_{18}H_{24}O_2$, M 272.4, m 223, $[\alpha]_D^{20}$ +57 (c 1, EtOH).** 17α-Estradiol recrystallises from aqueous EtOH (80%) as the ***hemihydrate*** and differs from the ***β-anomer*** (below) by not precipitating with digitonin in 80% aqueous EtOH. The ***diacetate*** *[1474-52-8]* crystallises from aqueous EtOH in needles with **m 139-140°**. The ***3-benzoate*** crystallises in three forms **m 158°**, **153°** and **63°**. [See references for 17β-Estradiol below.]

17β-Estradiol (1,3,5-estratrien-3,17β-diol, 17-β-estradiol was incorrectly called α-estradiol) *[50-28-2]* **$C_{18}H_{24}O_2$, M 272.4, m 173-179°, 176-178°, $[\alpha]_D^{20}$ +76 to +83 (c 1, dioxane).** 17β-Estradiol (***previously known as α-estradiol***) is purified by chromatography on SiO_2 (toluene/EtOAc 4:1) and recrystallised from $CHCl_3$/hexane or 80% EtOH. It is stable in air, is insoluble in H_2O, and is precipitated by digitonin. The UV has λ_{max} at 225 and 280 nm. The ***diacetate*** *[3434-88-6]* has **m 97-98°** and forms leaflets from aqueous EtOH. The ***3-benzoate*** *[50-50-0]* crystallises from aqueous MeOH with **m 193°** and $[\alpha]_D^{25}$ +58 to 63 (c 1, dioxane). [Miescher & Scholz *Helv Chim Acta* **20** 263 *1937*, DOI: 10.1002/hlca.19370200137;1237 *1937*, DOI: 10.1002/hlca.193702001168; *Biochem J* **32** 1273 *1938*, DOI: 10.1042/bj0321273b; Oppolzer & Roberts *Helv Chim Acta* **63** 1703 *1980*, DOI: 10.1002/hlca.19800630638; Inhoffen & Zühlsdorff *Chem Ber* **74** 1911 *1941*, DOI: 10.1002/cber.19410741215; *Beilstein* **6** IV 6611.] It is a primary female sex hormone.

β-Estradiol-6-one (1,3,5-estratriene-3,17β-diol-6-one) *[571-92-6]* **$C_{18}H_{22}O_3$, M 286.4, m 278-280°, 281-283°, $[\alpha]_D^{20}$ +4.2 (c 0.7, EtOH).** β-Estradiol-6-one forms plates from EtOH. The ***3,17-diacetate*** has **m 173-175°** after recrystallisation from aqueous EtOH. [Longwell & Wintersteiner *J Biol Chem* **133** 219 *1940*, http://www.jbc.org/content/133/1/219.] The UV has λ_{max} at 255 and 326nm in EtOH [Slaunwhite et al. *J Biol Chem* **191** 627 *1951*, PMID: 14861208]. [*Beilstein* **8** IV 2398.]

Estriol (1,3,5-estratrien-3ß,16a,17ß-triol) *[50-27-1]* **$C_{18}H_{24}O_3$, M 288.4, m 278.5-284°, 283°, $[\alpha]_{546}^{20}$ +66 (c 1, dioxane).** Crystallise estriol from EtOH/ethyl acetate. Also purify it by countercurrent distribution with

cyclohexane/EtOAc (1:1) and EtOH/H_2O (1:1). The UV (EtOH) has λ_{max} at 280nm (ε 2,090 $M^{-1}cm^{-1}$). [Huffmann & Lott *J Am Chem Soc* **71** 719 *1949*, DOI: 10.1021/ja01170a096; Leeds et al. *J Am Chem Soc* **76** 2943 *1954*, DOI: 10.1021/ja01640a026; *Beilstein* **6** IV 7550.] Estrogenic.

Estrone (1,3,5-Estratrien-3-ol-17-one, Folliculin) *[53-16-7]* **$C_{18}H_{22}O_2$, M 270.4, m 260-261°, polymorphs have m 254° and 256°, $[\alpha]_{546}^{20}$ +198 (c 1, dioxane), pK^{25} 0.91.** Purify estrone by chromatography on silica gel, eluting with 2:1 hexane/EtOAc and recrystallising from EtOH or Et_2O/EtOH. [Danishefsky & Cain *J Am Chem Soc* **98** 4975 *1976*, DOI: 10.1021/ja00432a044.] The ***acetate*** *[901-93-9]* crystallises from EtOH with **m 125-127°.** [*Beilstein* **8** III 1171.] Estrogenic.

Estrone 3-*O*-sulfamate [1,3,5(10)-estratrien-17-one 3-sulfamate] *[148672-09-7]* **$C_{18}H_{23}NO_4S$, M 349.5.** Estrone 3-*O*-sulfamate is purified by silica gel flash chromatography to give a product with one spot on TLC. It is an ***active site-directed inhibitor of estrone sulfatase***, i.e. a time-dependent enzyme inactivator. [Woo et al. *J Med Chem* **39** 1349 *1996,* DOI: 10.1021/jm950931z; Purohit et al. *Biochemistry* **34** 11508 *1995*, DOI: 10.1021/bi00036a025.]

17-α-Ethynylestradiol *[57-63-6]* **$C_{20}H_{24}O_2$, M 296.4, m 141-146°, 145-146°, $[\alpha]_D^{20}$ +4 (c 1, $CHCl_3$).** 17-α-Ethynylestradiol forms a ***hemihydrate*** on recrystallising from MeOH/H_2O. It dehydrates on melting and re-melts on further heating at **m 182-184°**. The UV has λ_{max} at 281nm (ε 2040) in EtOH. Its solubility is 17% in EtOH, 25% in Et_2O, 20% in Me_2CO, 25% in dioxane and 5% in $CHCl_3$. [Petit & Muller *Bull Soc Chim Fr* 121 *1951*.] The ***diacetyl*** derivative has **m 143-144°** (from MeOH) and $[\alpha]_D^{20}$ +1 (c 1, $CHCl_3$) [Mills et al. *J Am Chem Soc* **80** 6118 *1958*, DOI: 10.1021/ja01555a055]. [*Beilstein* **6** IV 6877.] Estrogenic.

Etiocholanic acid (5β,17β-androstane-17-carboxylic acid) *[438-08-4]* **$C_{20}H_{32}O_2$, M 304.5, m 228-229°, pK_{Est} ~4.7.** Crystallise etiocholanic acid from glacial acetic acid (needles) and sublime it at 160°/0.002mm. The ***ethyl ester*** has **m 77.5-78.5°** (from EtOH) $[\alpha]_{546}^{20}$ +52.5 (c 0.61, pyridine). [Jacobs & Elderfield *J Biol Chem* **108** 497 *1935,* http://www.jbc.org/content/108/2/497; Weiland et al. *Hoppe Seyler's Z Physiol Chem* **161** 80 *1926*, *Beilstein* **9** III 2644.]

Finastride [(5α,17β)-*N*-(1,1-dimethylethyl)-3-oxo-4-azaandrost-1-ene-17-carboxamide] *[98319-26-7]* **$C_{23}H_{36}N_2O_2$, M 372.5, m 252-254°, ~257°, $[\alpha]_{405}^{25}$ -59 (c 1, MeOH).** Several 17-carbamoyl-4-azaandrostan-1-en-3-ones have been synthesised from androstenones essentially by cleaving the Steroid A ring, replacing C-4 by a nitrogen atom and altering the C-17 substituent while keeping most of the rest of the steroid intact. The study was devised to find an active ***testosterone 5α-reductase inhibitor*** as is the case with ***Finastride***. The purification of the crude products was performed by chromatography on silica gel (e.g. one or two PrePaks, 325g each) in CH_2Cl_2 and eluting the azasteroidcarboxamide with a solvent mixture, e.g. CH_2Cl_2-Me_2CO (or cyclohexane-EtOAc 3:1) and finally EtOAc, checking the fractions by analytical HPLC using a μ-Porasil column or TLC run on silica gel coated plates (e.g. 250μm analytical, 1000 or 2000μm thicknesses) and visualised in the usual way (e.g spraying with H_2SO_4 and heating in a hot oven until spots show colour). The desired fractions are collected, evaporated and the solid recrystallised from hexane, Et_2O, EtOAc or mixtures of these or aqueous EtOH. ***Finastride*** is soluble in most organic solvents but is a very weak base (both nitrogen atoms are linked in amide bonds) and it is poorly soluble in aqueous 0.1N NaOH and 0.1N HCl. [Rasmusson et al. 'Azasteroids: structure-activity relationships for ***inhibition of 5α-reductase and of androgen receptor*** binding' *J Med Chem* **29** 2298 *1986*, DOI: 10.1021/jm00161a028; Rasmusson & Reyolds US Patent 4760071 A to Merck & Co, Juky 26 *1988*; Bhattacharya et al. *J Am Chem Soc*, **110** 3318 *1988*, DOI: 10.1021/ja00218a062.]

Finastride is a ***competitive inhibitor*** of steroid 5α-reductase, i.e. it suppresses the conversion of testosterone to dihydrotestosterone, and reduces prostatic dihydrotestosterone levels and prostate size *in vivo*. It is 100-fold more potent as a competitive inhibitor of the rat NADPH:Δ 4-3-oxosteroid-5α-oxidoreductase (steroid 5α-reductase) type 1 enzyme (Ki = 3-5 nM), and of the human type 1 enzyme (Ki greater than or equal to 300 nM). It is orally active and has been used to restore baldness. [Thigpen & Russell 'Four-amino acid segment in steroid 5α-reductase 1 confers sensitivity to ***Finasteride***, a competitive inhibitor' *J Biol Chem* **267** 8577 *1992*, PMID: 1314830.]

Gitoxigenin (3β,14,16β,21-tetrahydroxy-20(22)-norcholenic acid lactone) *[545-26-6]* **$C_{23}H_{34}O_5$, M 390.5, m 223-226°, 234°, 239-240° (anhydrous by drying at 60°), $[\alpha]_D^{20}$ +30 (c 1, MeOH).** Recrystallisation of gitoxigenin from aqueous EtOH produces plates of the ***sesquihydrate*** which dehydrate on drying at 100° *in vacuo*. It also crystallises from Me_2CO/MeOH and from EtOAc (the crystals contain 1 mol of EtOAc) with $[\alpha]_D^{21}$ +24.8 (c 1, dioxane). It has UV with λ_{max} at 310, 485 and 520nm in 96% H_2SO_4. On heating with ethanolic HCl it yields ***digitaligenin*** with loss of H_2O. [Smith *J Chem Soc* 23 *1931*, DOI: 10.1039/JR9310000023; *Beilstein* **8** IV 2456.]

Glycocholic acid (*N*-cholylglycine) *[475-31-0]* **$C_{26}H_{43}NO_6$, M 465.6, m 130° (hydrate) 154-155°, 165-168°(anhydrous), $[\alpha]_{546}^{20}$ +37 (c 1, EtOH), pK^{25} 4.4.** Glycocholic acid crystallises from hot water as the ***sesquihydrate***. Dry it at 110° *in vacuo*. An analytical sample is prepared by suspending the acid (4g) in H_2O (400ml) at ~20°, heating to boiling with slow stirring, filtering hot and allowing to cool to ~20°. The acid is filtered off, washed with H_2O, dried in air, recrystallised from 5% aqueous EtOH, washed well and dried over P_2O_5 in a moderate vacuum to constant weight. Recrystallisation from EtOH/EtOAc, and drying, gave the ***anhydrous*** acid. [Cortese & Bauman *J Am Chem Soc* **57** 1393 *1935*, DOI: 10.1021/ja01311a002; Bergstrom & Norman *Acta Chem Scand* **7** 1126 *1953*, DOI: 10.3891/acta.chem.scand.07-1126; *Beilstein* **10** IV 2077.] It emulsifies oils and fats.

Glycodeoxycholic acid monohydrate [*N*-(3α-12α-dihydroxy-5β-cholan-24-oyl)glycine] *[360-65-6]* **$C_{26}H_{43}NO_5$, M 467.6, m 186-177°(dec), 187-188°, $[\alpha]_D^{23}$ +45.9 (c 1, EtOH), pK_{Est} ~ 4.4.** Glycodeoxycholic acid recrystallises from H_2O or aqueous EtOH with 1 mol of H_2O and is dried at 100° *in vacuo*. Its solubility in EtOH is ~5%. [UV: Lindstedt & Sjövall *Acta Chem Scand* **11** 421 *1957*, DOI: 10.3891/acta.chem.scand.11-0421.] The ***Na salt*** recrystallises from EtOH/Et_2O with **m 245-250°** and $[\alpha]_D^{23}$ +41.2 (c 1, H_2O) [Wieland *Hoppe Seyler's Z Physiol Chem* **106** 181 *1919*, Cortese *J Am Chem Soc* **59** 2532 *1937*, DOI: 10.1021/ja01291a014]. [*Beilstein* **10** IV 1611.] It is an emulsifying bile acid.

Hecogenin (25*R*-5α-spirostan-3β-ol-12-one) *[467-55-0]* **$C_{27}H_{42}O_4$, M 430.6, m 245-250°, 253°, 264-266°, 268°, $[\alpha]_D^{23}$ +8 (c 1, $CHCl_3$).** The steroidal saponin (~35 mg) in EtOAc is chromatographed on Al_2O_3 and eluted with *C_6H_6/Et_2O, and the residue on evaporation is recrystallised from Me_2CO. [Mazur et al. *J Am Chem Soc* **82** 5889 *1960*, DOI: 10.1021/ja01507a028; Marker et al. *J Am Chem Soc* **69** 2167 *1947*, DOI: 10.1021/ja01201a032; *Beilstein* **19** III/IV 2581.]

Hecogenin acetate *[915-35-5]* **$C_{29}H_{44}O_5$, M 472.7, m 265-268°(dec), $[\alpha]_D^{20}$ -6.0 (c 1, $CHCl_3$).** Crystallise the ***acetate*** from MeOH. [*Beilstein* **19** IV 2583.]

Hydrocortisone (Cortisol, 11β,17α,21-trihydroxypregn-4-ene-3,20-dione) *[50-23-7]* **$C_{21}H_{30}O_5$, M 362.5, m 212-213°, 214-217°, 218-221°, 220-222°, $[\alpha]_D^{22}$ +167 (c 1, EtOH).** Recrystallise hydrocortisone from EtOH or isoPrOH. It is bitter tasting and has UV with λ_{max} at 242 nm (log ε 4.20). Its solubility at 25° is: H_2O (0.28%), EtOH (1.5%), MeOH (0.62%), Me_2CO (0.93%), $CHCl_3$ (0.16%), propylene glycol (1.3%) and Et_2O (0.35%). It gives an intense green colour with concentrated H_2SO_4. [Wendler et al. *J Am Chem Soc* **72** 5793 *1950*, DOI: 10.1021/ja01168a551; *Beilstein* **8** IV 3422.] It is a glucocorticoid hormone released in response to stress and low blood glucose. Topically used to reduce swelling and rashes from sting bites and allergies.

Hydrocortisone acetate (21-acetoxy-11β,17α-trihydroxypregn-4-ene-3,20-dione) *[50-03-3]* **$C_{23}H_{32}O_6$, M 404.5, m 218-221.5°, 221-223°, 222-225°, $[\alpha]_D^{25}$ +166 (c 0.4, dioxane), +150.7 (c 0.5, Me_2CO).** The acetate recrystallises from Me_2CO/Et_2O or aqueous Me_2CO as ***hygroscopic*** monoclinic crystals. Its UV has λ_{max} at 242 nm ($A_{1cm}^{1\%}$ 390) in MeOH. Its solubility at 25° is: H_2O (0.001%), EtOH (0.45%), MeOH (0.04%), Me_2CO (1.1%), $CHCl_3$ (0.5%), Et_2O (0.15%), and it is very soluble in Me_2NCHO. [Wendler et al. *J Am Chem Soc* **74** 3630 *1952*, DOI: 10.1021/ja01134a049; Antonucci et al. *J Org Chem* **18** 70 *1953*, DOI: 10.1021/jo01129a013; *Beilstein* **8** IV 3424.]

19-Hydroxy-4-androsten-3,17-dione *[510-64-5]* **$C_{19}H_{26}O_3$, M 302.4, m 167-169°, 168-170°, 169-170°, 172-173°, $[\alpha]_D^{20}$ +190 (c 1, $CHCl_3$).** Recrystallise 19-hydroxy-4-androsten-3,17-dione from Me_2CO/hexane or Et_2O/

hexane. It has UV with λ_{max} at 242nm in EtOH or MeOH. The *19-acetoxy* derivative has $[\alpha]_D^{26}$ +185 ($CHCl_3$) and λ_{max} with 237.5nm in EtOH. [Ehrenstein & Dünnenberger *J Org Chem* **21** 774 *1956*, DOI: 10.1021/jo01113a015; *Beilstein* **8** IV2162.]

25-Hydroxycholesterol (cholest-5-en-3β,25-diol) *[2140-46-7]* **$C_{27}H_{46}O_2$, M 402.7, m 177-179°, 178-180°, 181.5-182.5°, $[\alpha]_D^{25}$ -39 (c 1.05, $CHCl_3$).** 25-Hydroxycholesterol forms colourless needles from MeOH [Riediker & Schwartz *Tetrahedron Lett* **22** 4655 *1981*, DOI: 10.1016/S0040-4039(01)83005-7]. The ***3β−acetoxy derivative*** has **m 142-142.8°** (from Me_2CO) and $[\alpha]_D^{25}$ -40.4 (c 2, $CHCl_3$). The ***3β,25-diacetoxy derivative*** has **m 119-120.5°** (from MeOH) and $[\alpha]_D^{25}$ -35.5 ($CHCl_3$). [Dauben & Bradlow *J Am Chem Soc* **72** 4248 *1950*, DOI: 10.1021/ja01165a117; Ryer et al. *J Am Chem Soc* **72** 4247 *1950*, DOI: 10.1021/ja01165a116; *Beilstein* **6** IV 6437.] It suppresses interleukin-1-driven inflammation downstream of type 1 interferon [Reboldi et al. *Science* **345** 679 *2014*, DOI: 10.1126/science.1254790].

18-Hydroxy-11-deoxycorticosterone (18,21-dihydroxypregn-4-en-3,20-dione tautomeric with 18,20-epoxy-20,21-dihydroxypregn-4-en-3-one) *[379-68-0]* **$C_{21}H_{30}O_4$, M 346.5, m 168-170°, 171-173°, 191-195°, 200-205°, $[\alpha]_D^{20}$ +151 (c 1, $CHCl_3$).** Recrystallise 18-hydroxy-11-deoxycorticosterone from Et_2O/Me_2CO to give crystals **m** 200-205°. When it is recrystallised from M_2CO, it has **m 191-195°**. It has UV with λ_{max} at 240nm. The ***21-O-acetoxy-18-hydroxy derivative*** has **m 158-159°** (from $Et_2O/*C_6H_6$), and the ***21-O-acetoxy-18,20-epoxy derivative*** has **m 149-154°** (from Et_2O). [Kahnt et al. *Helv Chim Acta* **38** 1237 *1955*, DOI: 10.1002/hlca.19550380519; Pappo *J Am Chem Soc* **81** 1010 *1959*, DOI: 10.1021/ja01513a068.]

17β-Hydroxy-17α-methyl-3-androsterone (Mestanolone, Ermalone) *[521-11-9]* **$C_{20}H_{32}O_2$, M 304.5, m 192-193°.** Dissolve mestanolone in Et_2O, wash it with N NaOH, H_2O, dry it (Na_2SO_4), evaporate and recrystallise it from EtOAc. The ***semicarbazone*** has **m 235-236°** (from EtOH). [Ruzicka et al. *Helv Chim Acta* **18** 1487 *1935*, DOI: 10.1002/hlca.193501801203.] It is an oral androgenic (anabolic) steroid.

17α-Hydroxy-6α-methylprogesterone (Medroxyprogesterone) *[520-85-4]* **$C_{22}H_{32}O_3$, M 344.5, m 220°, $[\alpha]_D^{25}$ +75 ($CHCl_3$).** If it contains the ***epi-isomer*** (TLC), then dissolve it in $CHCl_3$, bubble dry HCl gas to epimerise it, evaporate and recrystallise it from chloroform. The UV has λ_{max} at 241nm (ε 16,150) in EtOH. The ***17-acetate*** *[71-58-9]* crystallises from MeOH with **m 207-208°** and $[\alpha]_D^{25}$ +61 ($CHCl_3$). Its UV has λ_{max} at 240nm (ε 15,950) in EtOH. [Babcock et al. *J Am Chem Soc* **80** 2904 *1958*, DOI: 10.1021/ja01544a079; *Beilstein* **8** IV 2212.] It is a steroidal progestin drug.

α-Hyodeoxycholic acid *[83-49-8]* **$C_{24}H_{40}O_4$, M 392.6, m 196-197°, 200-201°, $[\alpha]_{546}^{20}$ +8 (c 2, EtOH), pK_{Est} ~4.9.** Crystallise α-hyodeoxycholic acid from EtOAc or Me_2CO. The K salt separates in needles from an alcoholic solution of the acid when an equivalent of KOMe is added (see lithocholic acid *[434-13-9]*). [Weiland & Gumlish *Hoppe Seyler's Z Physiol Chem* **215** 18 *1933*, Windaus & Bohne *Justus Liebigs Ann Chem* **433** 278 *1923*, DOI: 10.1002/jlac.19234330126; *Beilstein* **10** III 1631.]

Lanosterol *[79-63-0]* **$C_{30}H_{50}O$, M 426.7, m 138-140°, $[\alpha]_D^{20}$ +62.0 (c 1, $CHCl_3$).** If very impure, then it should be acetylated, converted to the ***dibromide acetate*** [crystallised from EtOAc with slow cooling, **m 168-170°**, $[\alpha]_D^{20}$ +214° ($CHCl_3$)], de-brominated with Zn dust to give the acetate (below) which is recrystallised from 3-4 parts of Me_2CO/MeOH (4:1) and hydrolysed as for stigmasterol (below). Recrystallise it from anhydrous MeOH. Dry it *in vacuo* over P_2O_5 for 3 hours at 90°. The purity is checked by proton magnetic resonance. The ***acetate*** crystallises from MeOH with **m 131-133°**, $[\alpha]_D^{25}$ +62 (c 1,$CHCl_3$). [Block & Urech *Biochemical Preparations* **6** 32 *1958*, Van Tamelen et al. *J Am Chem Soc* **104** 6479, 6480 *1982*, DOI: 10.1021/ja00387a069; *Beilstein* **6** III 2880, **6** IV 4188.] It is the recursor of animal and fungus steroids.

Lithocholic acid (3α-hydroxy-5β-cholan-24-oic acid) *[434-13-9]* **$C_{24}H_{40}O_3$, M 376.6, m 183-188°, 184-186°, $[\alpha]_D^{23}$ +35 (c 1, EtOH), pK_{Est} ~4.8.** Lithocholic acid can be purified by conversion to the rather insoluble Na or K salt by addition of the equivalent amount of aqueous NaOH or KOH, filtering off the alkali salt, washing it with ice cold H_2O, dissolving it in the least volume of boiling H_2O, acidifying with dilute HCl (slight excess), filtering off the acid, washing with cold H_2O and drying it thoroughly in a vacuum. Recrystallise it

from Me_2CO, EtOH or acetic acid. The ***methyl ester*** crystallises from MeOH, with 0.5 mol of MeOH, and has **m 92-93°**, $[\alpha]_D^{25}$ +34 (MeOH). It has also been purified by recrystallisation from petroleum ether (b 40-60°) and, after chromatography on Al_2O_3 in petroleum ether, gave a ***labile form*** **m 92-93°** which is transformed to the ***stable form*** **m 125-126°** after standing for 2 days in a vacuum desiccator. [Hoehn & Mason *J Am Chem Soc* **62** 569 *1940*, DOI: 10.1021/ja00387a069; Sarel & Yanuka *J Org Chem* **24** 2018 *1959*, DOI: 10.1021/jo01094a602; *Beilstein* **10** IV 785.] It has been used in a study to investigate the regulation of hepatic phospholipid and bile acid homeostasis through SMAD3 activation by TGFβ [Matsubara et al. *J Lipid Res* **53** 2698 *2012*, PMID: 23034213].

6-α-Methylprednisolone (Medrol, 11β,17-21-trihydroxy-6α-methylpregna-1,4-dien-3,20-dione) *[83-43-2]* **$C_{22}H_{30}O_5$, M 347.5, m 226-237°, 228-237°, 240-242°, $[\alpha]_D^{24}$ +91 (c 0.5, dioxane).** Recrystallise medrol from EtOAc. The UV has λ_{max} at in 95% EtOH 243nm (ε 14,875). The ***21-acetoxy derivative*** has **m 205-208°** (from EtOAc), and $[\alpha]_D^{24}$ +95 (c 1, $CHCl_3$). [Spero et al. *J Am Chem Soc* **78** 6213 *1956*, DOI: 10.1021/ja01604a078; Fried et al. *J Am Chem Soc* **81** 1235 *1959*, DOI: 10.1021/ja01514a055; for ^{1}H NMR see Slomp & McGarvey *J Am Chem Soc* **81** 2200 *1959*, DOI: 10.1021/ja01518a047; *Beilstein* **8** IV 3498.] Useful for the treatment of patients with cardiac arrest [Mentzelopoulos et al. *Arch Intern Med* **169** 15 *2009*, DOI: 10.1001/archinternmed.2008.509].

17α-Methyltestosterone (Android, Mesterone) *[58-18-4]* **$C_{20}H_{30}O_2$, M 302.5, m 163.5°, 164-165°, 167°, 162-168°, $[\alpha]_{546}^{20}$ +87 (c 1, dioxane), $[\alpha]_D^{20}$+82.3 (c 1, EtOH) $A_{1cm}^{1\%}$ 241nm is 495-530 (EtOH).** This ***anabolic steroid*** is crystallised from hexane or hexane/*benzene. It has $E_{1cm}^{1\%}$ 495-530 at 241nm (EtOH). The colour reaction with 2,4-dinitrophenyl hydrazine is used for assaying it. [Gornall & Macdonald *J Biol Chem* **201** 279 *1953*, PMID: 13044797.] In another ***colour reaction*** the sterone (1mg) in acetic acid (0.2ml) + 88% H_3PO_4 (2ml) is allowed to stand for 1 hour when it becames fluorescent. After 1 hour it is diluted with acetic acid (~3ml) and provides a strong yellow fluorescence with the intensity of 50-100 times that of estrone. [Stuart & Stuckey *J Pharm Pharmacol* **1** 130 *1949*, DOI: 10.1111/j.2042-7158.1949.tb12388.x; Oppenauer *Recl Trav Chim Pays-Bas* **56** 137 *1937*, DOI: 10.1002/recl.19370560206; *Beilstein* **8** IV 1010.]

Norcholanic acid (5β-24-norcholan-23-oic acid) *[511-18-2]* **$C_{23}H_{38}O_2$, M 346.5, m 175.5-176.5°, 177°, 186°, $[\alpha]_D^{20}$ +32 (EtOH), pK_{Est} ~4.8.** Recrystallise the acid from AcOH. The ***methyl ester*** has **m 74°** (needles from MeOH), and the ***ethyl ester*** has **m 65-66°**. [For ***synthesis*** from 12-ketonorcholanic acid, *via* the semicarbazone then reduction with NaOEt see Cook & Haselwood *J Chem Soc* 428 *1934*, DOI: 10.1039/JR9340000428; Yanuka et al. *Tetrahedron Lett* 1725 *1968,* DOI: 10.1016/S0040-4039(01)99037-9; *Beilstein* **9** III 2652, **10** IV 2083.]

α-Oestradiol See estradiol above *[57-91-0]*, and **β-Oestradiol-3-benzoate** see estradiol 3-benzoate above *[50-50-0]*.

Ouabain [3-{(6-deoxy-α-L-mannopyranosyl)oxy}-1,5,11a,14,19-pentahydroxycard-20(22)-enolide. G-Strophanthin, Acocantherine] *[630-60-4, 312619-45-7 (hydrate), 11018-89-6 (octahydrate)]* **$C_{29}H_{44}O_{12}$, M 728.8 (8 H_2O), m 190°(dec), 200-202°(dec), $[\alpha]_{546}^{20}$ -30 (c 1, H_2O).** It crystallises from water as the ***octahydrate***. Dry it at 130°. It decomposes at 190° when dry. Store it in the dark as it is light sensitive, but it is stable in air. Its solubility (g/100ml) in H_2O is 1.3 (~25°), 20 (~100°), and in EtOH it is 1.0 (~25°) and 12.5 (~78°). It is highly **TOXIC** cardiac glycoside as it is a ***strong inhibitor of cation transport*** and of *Na^+ and K^+ ATPase*. At lower doses it is used to treat hypotension and some arrhythmia. [Fürstenwerth 'Ouabain - The Insulin of the Heart'. *Int J Clin Pract* **64** 1591 *2010*, DOI: 10.1111/j.1742-1241.2010.02395.x, PMID: 20946265.] [*Beilstein* **18/5** V 625.]

Pancuronium bromide (2β,16β−dipiperidino-5α-androstan-3α,17β−diol diacetate dimetho-bromide)

[15500-66-0] **$C_{35}H_{60}N_2O_4.Br_2$, M 732.7, m 212-215°, 215°.** The bromide forms odourless crystals with a bitter taste which are purified through acid-washed Al_2O_3 and eluted with isoPrOH/EtOAc (3:1) to remove impurities (e.g. the monomethobromide) and eluted with isoPrOH to give the pure dibromide which is recrystallised from CH_2Cl_2/Me_2CO or isoPrOH/Me_2CO. It is soluble in H_2O (10%) and $CHCl_3$ (3.3%) at 20°. It is a non-depolarising muscle relaxant, and used in ***euthenasia***. [Buckett et al. *J Med Chem* **16** 1116 *1973*, DOI: 10.1021/jm00268a011.]

Prednisolone acetate (21-acetoxypregna-1,4-diene-11β-17α-diol-3,20-dione) *[52-21-1]* **$C_{23}H_{30}O_6$, M 402.5, m 237-239°, 240-242°, 240-243°, 244°, $[\alpha]_D^{20}$ +116 (c 1, dioxane).** Recrystallise prednisolone acetate from EtOH, Me_2CO, Me_2CO/hexane, and it has UV with λ_{max} at 243nm in EtOH. [Joly et al. *Bull Soc Chim Fr* 366 *1958*; Herzog et al. *J Am Chem Soc* **77** 4781 *1955*, DOI: 10.1021/ja01623a027; *Beilstein* **8** IV 3468.]

Prednisone (17,21-dihydroxypregna-1,4-diene-3,11,20-trione, deltacortisone, dehydrocortisone) *[53-03-2]* **$C_{21}H_{26}O_5$, M 358.5, m 238° (dec), $[\alpha]_D^{20}$ +172 (c 0.5, dioxane), λ_{max} 238nm (log ε 4.18) in MeOH.** Crystallise prednisone from acetone/hexane, then recrystallise it from Me_2CO. The ***monoacetate*** crystallises from Me_2CO/hexane with **m 227-233°(dec)**, and $[\alpha]_D^{25}$ +186 (c 1, dioxane); and the ***diacetate*** crystallises from Me_2CO/hexane with **m 219-221°(dec)**, and $[\alpha]_D^{25}$ +125 (c 1, $CHCl_3$). Solanidine (solanid-5-en-3β-ol) *[80-78-4]* **$C_{27}H_{43}NO$, M 397.6, m 218-219°(sublimes), $[\alpha]_D^{20}$ -29 (c 0.5, $CHCl_3$), pK^{15} 6.66.** Solanidine crystallises from $CHCl_3$/MeOH, aqueous EtOH or aqueous MeOH as needles. TLC on Al_2O_3 plates using CH_2Cl_2/MeOH (98:2) gives a spot at R_F 0.47. The ***hydrochloride*** crystallises from aqueous EtOH with **m 345°(dec)**. The ***acetate*** crystallises from EtOH with **m 208°**. [Schreiber & Rönsch *Tetrahedron* **21** 645 *1965*, DOI: 10.1016/S0040-4020(01)82235-3; Kessar et al. *Tetrahedron* **27** 2153 *1971*, DOI: 10.1016/S0040-4020(01)91614-X; Reichestein & Reich *Ann Rev Biochem* **15** 155 *1946*, DOI: 10.1146/annurev.bi.15.070146.001103; *Beilstein* **21** III/IV 1398, **27** III/IV 2000.] This is a poisonous steroidal alkaloid from *Solanaceaea* family.

α-Solanine (solan-5-en-3β-yl-[*O*^{3}-β-D-glucopyranosyl-*O*^{2}-α-L-rhamnopyranosyl-β-D-galactopyrano-side]) See 'Carbohydrates' in this Chapter.

Solasodine (22α,25*R*-spirosol-5-en-3β-ol) *[126-17-0]* **$C_{27}H_{43}NO_2$, M 413.6, m 202°, $[\alpha]_D^{25}$ -100 (c 2, MeOH), pK^{25} 7.7.** Solasodine crystallises (as ***monohydrate***) from MeOH as lustrous plates (on heating, the plates change to needles as they melt and resolidify in needles), or aqueous 80% EtOH, and sublimes at high vacuum. After recrystallisation from H_2O, **m 198-199°**, then from Me_2CO/H_2O, **m 199-201°**, it has $[\alpha]_D^{22}$ -109.3 (c 0.581, $CHCl_3$). On TLC with silica gel G (*C_6H_6/absolute EtOH, 8:2) it has R_F 0.45. The IR (KBr) has ν_{max} at 10.3, 10.4, 11.2, 11.5μ (azaoxaspirane bands). [Schreiber et al. *Tetrahedron* **20** 1939 *1964*, DO1: 10.1016/S0040-4020(01)98462-5; Uhle *J Org Chem* **27** 656 *1962*, DOI: 10.1021/jo01049a525; Kessar et al.

Tetrahedron **27** 2153 *1971*, DOI: 10.1016/S0040-4020(01)91614-X; *Beilstein* **27** III/IV 2000.] This is a poisonous steroidal alkaloid from *Solanaceaea* plants and is teratogenic.

Stigmasterol (3β-hydroxy-24-ethylcholesta-5,22-diene) *[83-48-7]* **$C_{29}H_{48}O$, M 412.7, m 160-164°, 170°, $[\alpha]_D^{22}$ -51 ($CHCl_3$), $[\alpha]_{546}^{20}$ -59 (c 2, $CHCl_3$).** Stigmasterol is best purified *via* the ***tetrabromide-acetate***. The impure sterol (3g) is acetylated with Ac_2O (60ml) by refluxing for 1.5 hour. The mixture is cooled at 20° for 1 hour, and the crude acetate is collected. The acetate (3g) in Et_2O (30ml) is then treated with Br_2/AcOH (38ml, from 5g Br_2 in 100ml AcOH), and after cooling at 6° overnight, the tetrabromoacetate is filtered off and washed with Et_2O. After six recrystallisations from $CHCl_3$/MeOH the ***tetrabromoacetate*** has **m 194-196°**. This product (1g) in AcOH (12ml) and Zn dust (1g) is refluxed for 1.5 hours, filtered hot, diluted with H_2O (30m L) and extracted with Et_2O. The extract is washed with dilute aqueous sodium sulfite, then H_2O, the extract is dried (Na_2SO_4) and the stigmasterol acetate (~550mg) is recrystallised (4x) from EtOH and twice from MeOH/$CHCl_3$ (2:1) to give the ***acetate*** with **m 139-148°**. This acetate (400mg) is hydrolysed in boiling 10% alcoholic KOH (1ml) for 1 hour. Then H_2O (30ml) is added and the mixture is extracted with Et_2O. The extract is washed with aqueous Na_2CO_3, then H_2O, the solvent is distilled off and the residue is recrystallised (3x) from 95% EtOH to give ~110mg of pure stigmasterol. It is dried in a vacuum over P_2O_5 for 3 hours at 90°. The purity is checked by NMR. The ***acetate*** crystallises from MeOH with **m 145°**, $[\alpha]_D^{25}$ -56 (c 2, $CHCl_3$). [Byerrum & Ball *Biochemical Preparations* **7** 86 *1959*, Thornton et al. *J Am Chem Soc* **62** 2006 *1940*, DOI: 10.1021/ja01865a028; Colin et al. *Anal Chem* **51** 1661 *1979*, DOI: 10.1021/ac50047a018; *Beilstein* **6** IV 4170.] This is a common phytosterols in plant fats and like phytosterols is generally broken down in the bile.

Tachysterol [3-β, 6E,22,E)-9,19-secoergosta-5(10),6,8,22-teraene-3-ol] *[115-61-7]* **$C_{28}H_{44}O$, M 396.7, oil, $[\alpha]_D^{18}$ -70 (c 0.12, Et_2O), $[\alpha]_D^{18}$ -86.3 (petroleum ether).** Windaus first obtained tachysterol by irradiation of 7-dehydrocholesterol where he readily obtained adducts with citraconic anhydride, or maleic acid [Windaus et al. *Justus Liebigs Ann Chem* **499** 188 *1932*, DOI: 10.1002/jlac.19324990116; Windaus et al. *Justus Liebigs Ann Chem* **492** 226 *1932*, DOI: 10.1002/jlac.19324920111]. This sterol is among the products which lead to the antirachitic agent *ergocalciferol (calciferol* Vitamin D_2*)*. Its name is derived from the great ease with which it forms these adducts (Gr. *Tachys*, swift). Steroids which possess the 5,6 and 7,8 conjugated double bonds in ring B undergo this photolytic reaction with UVB light which first causes epimerisation of the angular 10-methyl group followed by scission of the C9—C10 bond. These include *ergosterol*, *lumisterol* and *precalciferol*. The citraconic anhydride adduct of the latter is obtained in ~30% yield by irradiation of ***precaliferol*** in Et_2O with UVB light at ~0°/~7.5hrs under N_2, followed by treatment with the anhydride. Recrystallisation from AcOH gave ***tachysterol-citraconic anhydride acetate*** **m 161-162°, $[\alpha]_D$ +75 (c 1, $CHCl_3$)**. This adduct gave ***calciferol 3,5-dinitrobenzoate*** with **m 158-159°, $[\alpha]_D$ +57 (c 1, $*C_6H_6$)** on treatment with 3,5-dinitrobenzoyl chloride/pyridine in $*C_6H_6$ [Velluz et al. US 2847426A (to Roussell UCLAF *1956*]. The sterol is an oil with UV λ_{max} ($10^{-3}\varepsilon$) at 264nm (18), 280nm (23), and 294nm (in C_4H_6), which is characterised by its adducts, the ***4-methyl-3,5-dinitrobenzoate*** **m 155°** (yellow crystals from AcOH) and by reduction to ***dihydrotachysterol*** *[67-96-9]* above. It is a precursor of the active vitamin D_2 and the interconversions of provitamin D, lumisterol, previtamin D and tachysterol in the photolytic process have been revisited by Havinga et al. [*Tetrahedron* **11** 276 *1960*, DOI:10.1016/S0040-4020(01)93178-3]. Tachysterol is insoluble in H_2O and MeOH but soluble in most organic solvents and is ***not*** precipitated by ***digionin***. It should be stored at low temperature in the dark under N_2 because it is very sensitive to oxidation by air, to heat and light transforms it. [For structure see Grundmann *Z Physiol* **252** 151 *1938*; and for stereochemistry see Inhoffen et al. *Chem Ber* **88** 1424 *1955*, DOI: 10.1002/cber.19550880913; Verloop et al. *Recl Trav Chim Pays-Bas* **76** 689 *1957*, DOI: 10.1002/recl.19570760903; Braude & Wheeler *J Chem Soc* 329 *1955*, DOI: 10.1039/JR9550000329; Dimroth *Chem Ber* **70** 1631*1937*, DOI: 10.1002/cber.19370700731.]

Taurocholic acid (3α, 7α,12α-trihydroxy-5β-cholestan-24-oic acid *N*-(2-sulfoethyl) amide, *N*-coloyotaurine) *[81-24-3]* **$C_{26}H_{45}NO_7S$, M 515.6 (free acid), m ~125°(dec), $[\alpha]_D$ +38.8 (c 2, EtOH), pK^{25} 1.4.** The acid is present in bile and is isolated as an amorphous pale yellow powder. Crystallise it from EtOH/EtOAc/Et_2O (amorphous **m 125°**) or EtOH/Et_2O [Josephson *Biochem J* **29** 1484 *1935*, DOI: 10.1042/bj0291484]. The anhydrous acid is ***hygroscopic***, freely soluble in H_2O and EtOH but insoluble in Et_2O and EtOAc. It is hydrolysed by acids or alkalis to cholic acid and taurine. The ***sodium salt (hydrate)*** [*312693-83-7,*

345909-26-4 (xH_2O)] crystallises from aqueous EtOH/Et_2O with **m 231-232°**, and $[\alpha]_D^{23}$ +23,6 (c 2.5, H_2O); and it has UV λ_{max} (H_2SO_4) at 303, 389 and 480nm. [cf Cortese *J Am Chem Soc* **59** 2532 *1937*, DOI: 10.1021/ja01291a014; *Beilstein* **10** III 2177, **10** IV 2078.] Its sodium salt is present in the bile of mammals.

Taurodeoxycholic acid sodium salt monohydrate (3a, 12a-dihydroxy-5b-cholestan-24-oic acid *N*-(2-sulfoethyl) amide Na salt monohydrate, *N*-[desoxycholyl)taurine Na salt H_2O) *[1180-95-6, 207737-97-1 (x H_2O)]* **$C_{26}H_{44}NO_6SNa$, M 539.7(anhydrous), m 168°(dec), 171-175°, $[\alpha]_D^{23}$ +37 (c 1, H_2O), pK^{25} 1.4 (free acid).** The Na salt is dissolved in the smallest volume of H_2O, a saturated solution of aqueous NaCl/Et_2O is added and the mixture is stored at 0° for 24 hours. Then shake the mixture well, keep it in the cold for another day and filter the crystals with gentle shaking, wash them with ice-cold saturated aqueous NaCl saturated with Et_2O, dry them over $CaCl_2$ and extract them with absolute EtOH. Add ~10ml of H_2O to the solid followed by enough Et_2O to incipient cloudiness. Store it overnight at 0°. Add ice-cold Et_2O to make 250ml, collect the crystals, wash them with Et_2O then petroleum ether and dry them in air. The purification can be repeated with NaCl and Et_2O with ~85% recovery. ***Note*** that precipitation will not occur unless enough H_2O is present. Its solubility in H_2O is 10%. [Cortese *J Am Chem Soc* **59** 2532 *1937*, DOI: 10.1021/ja01291a014.] It forms mixed micelles with micellar average Mol Wt of 3100, aggregation number 6, and CMC (critical micellar concentration) of 1-4mM at 20-25°. It is a useful ***anionic detergent*** for solubilising membrane proteins [Hajjar et al. *J Biol Chem* **258** 192 *1983*, PMID: 6848493]. [*Beilstein* **10** IV 1611.] The ***free bile acid*** [(3α,5β,12α,20R,24Z)-3,12-dihydroxy-*N*-(2-sulfoethyl)cholan-24-imidic acid] *[516-50-7]* $C_{26}H_{45}NO_6S$, M 499.7 has **m 204-208°** (**141-144°** also reported), pKa -0.94, and a solubility in H_2O of 41mg/ml at 25° [for preparation of the ***acid dihydrate*** see Parenti, *Eur Pat Appl* (1990), 3 pages. CODEN: EPXXDW EP 400695 A219901205 CAN 114:82269 AN 1991:82269; and Bloch &Watkins for the 'Determination of conjugated bile acids in human bile and duodenal fluid by reverse-phase HPLC' *J Lipid Res* **19**(4) 510 *1978*, PMID: 659989]. The deoxycholyltaurine rescues human colon cancer cells from apoptosis by signaling activated by EGFR-dependent PI3K/Akt. Bile acids are ***steroidal physiological amphipathic detergents*** that facilitate digestion, excretion, absorption, and transport of fats and sterols in the intestine and liver.

Testosterone (17-β-hydroxyandrost-4-ene-3-one) *[58-22-0]* **$C_{19}H_{28}O_2$, M 288.4, m 155°, $[\alpha]_{546}^{20}$ +130 (c 1, dioxane).** Crystallise testosterone from aqueous acetone, hexane or isoPrOH. The long needles that separated from EtOH/AcOH were used for X-ray crystallography [Roberts et al. *JCS Perkin Trans 2* 1978 *1973*, DOI: 10.1039/P29730001978.] The ***acetate*** *[1045-69-8]* crystallises from MeOH or aqueous Me_2CO, with **m 140-141°** and $[\alpha]_D^{20}$ +87.8 (c 1, EtOH). [Ruzicka et al. *Helv Chim Acta* **18** 1478 *1935*, DOI: 10.1002/hlca.193501801201; and **19** 99 *1936* DOI: 10.1002/hlca.19360190115; 842 *1936*, DOI: 10.1002/hlca.193601901115; *Beilstein* **8** IV 974.] It is secreted in male testes and to a lesser extent in female ovaries of mammals.

Testosterone propionate *[57-85-2]* **$C_{22}H_{32}O_3$, M 344.5, m 120°, 118-122°, $[\alpha]_{546}^{20}$ +102 (c 2, dioxane).** Crystallise the propionate from aqueous EtOH, or Et_2O/petroleum ether (**m 121°**), and its UV has λ_{max} at 240nm (EtOH), and $[\alpha]_{546}^{20}$ +114 (c 1, $CHCl_3$). Also purify it by HPLC. Its solubility in H_2O very low at 1.48mg/L at 25°. [Ercoli & de Ruggieri *J Am Chem Soc* **75** 650, 652 *1953*, DOI: 10.1021/ja01099a040; polymorphism: Brandstätter-Kuhnert & Kofler *Microkim Acta* 847, 850 *1959*, DOI: 10.1007/BF01216751; *Beilstein* **8** IV 977.]

Ursodiol (ursodeoxycholic acid, 3α,7β-dihydroxy-5β-cholan-24-oic acid, 7β-hydroxylithocholic acid, ursodeoxycholic acid) *[128-13-2]* **$C_{24}H_{40}O_4$, M 392.5, m 203°, $[\alpha]_D^{20}$ +60 (c 0.2, EtOH), pK_{Est} ~4.8.** Recrystallise ursodiol from wet Et_2O, EtOH or EtOH/MeOH. It is almost insoluble in H_2O, sparingly soluble in Et_2O, very slightly soluble in $CHCl_3$ but freely soluble in AcOH. The ***diformate*** has **m 170°**, and the ***diacetate*** has **m 100-102°**. It is an ***anticholelithogenic*** drug. [Iwasaki *Hoppe Seyler's Z Physiol Chem* **244** 181, 183 *1936*, Ward et al. *Drugs* **27** 95 *1984*, *Beilstein* **10** III 1635, **10** IV 1604.] It is present in bear bile.

PHYSIOLOGICALLY ACTIVE COMPOUNDS (including miscellaneous low-molecular-weight bioactive substances, drugs, antibiotics, coenzymes, vitamins, lipids, phospholipids, nucleosides, nucleotides polynucleotides and useful reagents)

NOTE: Several physiologically active compounds are also present in previous chapters, and their bio-activities are briefly mentioned in their respective entries. They should be located from the CAS Registry Numbers Index.

Acetoacetyl coenzyme A trisodium salt trihydrate *[102029-52-7, anhydrous free acid 1420-36-6]* **$C_{25}H_{37}N_7Na_3O_{18}P_3S.\ 3H_2O$, M 971.6, 851.6(anhydrous free acid), pK_1 4.0 (NH_2), pK_2 6.4 (PO_4^-).** Purification can be carried out by passage through a DEAE-cellulose formate column, then through a Dowex 50 (H^+) column to remove Na^+ ions, concentrated by lyophilisation and redissolved in H_2O. It is commercially available as a solution of 0.05g/ml of H_2O. The concentration of acetoacetylcoenzyme A is determined by the method of Stern et al. [*J Biol Chem* **221** 15 *1956*, PMID: 13345795]. It is stable at pH 7-7.5 for several hours at 0° (half-life *ca* 1-2 hours). At room temperature it is hydrolysed in *ca* 1-2 hours at pH 7-7.5. At pH 1.0/20° it is more stable than at neutrality. A solution of the trisodium salt (0.05g/ml H_2O) adjusted to pH 5 with 2N NaOH can be stored frozen for several weeks. It is stable at pH 2-3/-17° for at least 6 months. Store at -20°. [Hersch & Jencks *J Biol Chem* **242** 3468 *1967*, http://www.jbc.org/content/242/15/3468; Clikenbeard et al. *J Biol Chem* **250** 3108 *1975*, PMID: 164460; Simon & Shemin *J Am Chem Soc* **75** 2520 *1953,* DOI: 10.1021/ja01106a522; Moffatt & Khorana *J Am Chem Soc* **81** 1265 *1959*, DOI: 10.1021/ja01514a073; Salam et al. *Biochem J* **258** 563 *1989* DOI: 10.1042/bj2580563; *Beilstein* **26** III/IV 3668.]

Acetylcholine bromide *[66-23-9, anion-free 51-84-3]* **$C_7H_{16}NO_2$. Br, M 226.1, m 140-143°, 143°, 146°.** The bromide is a ***hygroscopic*** solid, but less so than the hydrochloride salt. It crystallises from EtOH as prisms or needles. Some hydrolysis occurs in boiling EtOH, particularly if it contains some H_2O. It can also be recrystallised from EtOH or MeOH by adding dry Et_2O. [Siegal & Sapru *Essential Neuroscience* Revised 1st ed, Philadelphia: Lippincott, Williams & Wilkins **Ch 15** pp 255–267. *2006*: *Beilstein* **4** IV 1446.] It is a neuro-modulator and transmitter.
Acetylcholine chloride *[60-31-1]* **$C_7H_{16}NO_2$. Cl, M 181.7,** has **m 148-150°, 151°.** It is very soluble in H_2O (>10%), and is very ***hygroscopic***. If pasty, dry it in a vacuum desiccator over H_2SO_4 until a solid residue is obtained. Dissolve this in absolute EtOH, filter it and add dry Et_2O, when the hydrochloride separates. Collect by filtration and store it under very dry conditions. [Jones & Major *J Am Chem Soc* **52** 307 *1930*, DOI: 10.1021/ja01364a043.] The ***chloroplatinate*** crystallises from hot H_2O in yellow needles and can be recrystallised from 50% EtOH, **m 242-244°** [Dudley *Biochem J* **23** 1064 *1929*, DOI: 10.1042/bj0231064]; other **m** given is **256-257°**. The ***perchlorate*** crystallises from EtOH as prisms **m 116-117°**. [Bell & Carr *J Am Pharm Assoc* **36** 272 *1947*, DOI: 10.1002/jps.3030360907; for heat of hydrolysis see Annis & Eley *Biochem J* **53** 34 *1953*, DOI: 10.1042/bj0530034; *Beilstein* **4** IV 1446.] It is a neuro- modulator and transmitter [Yu & Dayan 'Uncertainty, neuromodulation, and attention' *Neuron* **46**(4) 681 *2005*, DOI: 10.1016/j.neuron.2005.04.026, PMID: 15944135].

N^4*-Acetylcytosine** *[14631-20-0]* **$C_6H_7N_3O_2$, M 153.1, m >300°, 326-328°, $pK_{Est(1)}$ ~1.7, $pK_{Est(2)}$ ~10.0.** If TLC or paper chromatography shows that it contains unacetylated cytosine, then reflux it in Ac_2O for 4 hours, cool at 3-4° for a few days, collect the crystals, wash them with cold H_2O, then EtOH and dry at 100°. It is insoluble in EtOH and dissolves in H_2O with difficulty, but crystallises in prisms from hot H_2O. It is hydrolysed by 80% aqueous AcOH at 100°/1 hour. [UV: Brown et al. *J Chem Soc* 2384 *1956*, DOI: 10.1039/JR9560002384; Codington et al. *J Am Chem Soc* **80** 5164 *1958*, DOI: 10.1021/ja01552a038.] It forms an ***Hg salt [Fox et al. *J Am Chem Soc* **79** 5060 *1957*, DOI: 10.1021/ja01575a063; for the synthesis of cytidine see Schwartz & Lerner *J Org Chem* **40** 24 *1975*, DOI: 10.1021/jo00889a005]. [*Beilstein* **25** III/IV 3657.]

N*-Acetylhistamine [*N*-(2-1{3}*H*-imidazol-4-yl)ethylacetamide]** *[673-49-4]* **$C_7H_{11}N_3O$, M 153.2, m 147-148°, 148-149°, pK^{25} 6.99.** It is purified by recrystallisation from Et_2O/EtOH or EtOAc/EtOH (needles), and dried *in vacuo*. It sublimes at 148°/0.05mm. It is slightly soluble in H_2O and EtOH, soluble in Me_2CO and verysoluble in Et_2O. The ***nitrate has **m 170°**, the ***picrate*** is ***dimorphic*** with **m 169-171°** (from EtOH/Et_2O) and **m 181-183°** (from EtOH). [Tabor & Mosettig *J Biol Chem* **80** 703 *1949*, PMID: 18135805; Nagarajan et al.

Indian J Chem, Sect B **16** 629, 633 *1977*, *Beilstein* **25** II 304, **25** III/IV 2053, **25/9** V 523.]

O*-Acetyl-β-methylcholine chloride [Methacholine chloride, Amechol, Provocholine, 2-acetoxypropyl-ammonium chloride]** *[62-51-1]* **$C_8H_{18}NO_2$. Cl, M 195.7, m 171-173º, 172º, 172-173º.** It forms white ***hygroscopic needles from Et_2O and is soluble in H_2O, EtOH and $CHCl_3$. It decomposes readily in alkaline solutions and slowly in H_2O. It should be handled and stored in a dry atmosphere at 2-8º. The ***bromide*** is less hygroscopic, and the ***picrate*** has **m 129.5-131º** (from EtOH). [For racemate, heat of hydrolysis see Annis & Eley *Biochem J* **53** 34 *1953*, DOI: 10.1042/bj0530034; for ***acetyl β–mehylthiocholine bromide*** *see* Hansen *Acta Chem Scand* **13** 159 *1959*, DOI: 10.3891/acta.chem.scand.13-0159; *Beilstein* **4** IV 1670.] A cholinergic agent, used mainly to diagnose bronchial hyper-reactivity [see Birnbaum & Barreiro 'Methacholine challenge testing: identifying its diagnostic role, testing, coding, and reimbursement' *Chest* **131**(6) 1932 *2007*, DOI: 10.1378/chest.06-1385, PMID: 17565027]. It is an anti-hypertensive and anti-anginal agent.

N*-Acetyl neuraminic acid (NANA, *O*-Sialic acid, 5-acetamido-3,5-dideoxy-D-*glycero*-D-*galacto*-2-nonulosonic acid, lactaminic acid)** *[131-48-6]* **$C_{11}H_{19}NO_9$, M 309.3, m 159º(dec), 181-183º(dec), 186º(dec), 185-187º(dec), $[\alpha]_D^{25}$ -33 (c 2, H_2O), pK^{25} 2.6.** A Dowex-1x8 (200-400 mesh) in the formate form is used, and is prepared by washing with 0.1M NaOH, then 2N sodium formate; excess formate is removed by washing with H_2O. *N*-Acetyl neuraminic acid in H_2O is applied to this column, washed with H_2O, then eluted with 2N formic acid at a flow rate of 1ml/minute. Fractions (20ml) are collected and tested (Bial's orcinol reagent, cf. *Biochemical Preparations* **7** 1 *1960*). NANA elutes at a formic acid molarity of 0.38, and the Bial positive fractions are collected and lyophilised. The residue is recrystallised from aqueous AcOH: suspend 1.35g of residue in AcOH, heat rapidly to boiling, add H_2O dropwise until the suspension dissolves (do not add excess H_2O), filter hot and then keep at +5º for several hours until crystallisation is complete. Collect NANA and dry it in a vacuum over P_2O_5. *Alternatively*, dissolve 1.35g of NANA in 14ml of H_2O, filter, add 160ml of MeOH followed by 360ml of Et_2O. Then add petroleum ether (b 40-60º) until heavy turbidity. Cool at 20º overnight. The yield of NANA is *ca* 1.3g. Dry it over P_2O_5 at 100º/1mm to constant weight. It ***mutarotates in Me_2SO: $[\alpha]_D^{20}$ -115º (after 7 minutes) to -32º (after 24 hours). It is commercially available as an aqueous solution (0.01g/ml). [For IR and synthesis see Cornforth et al. *Biochem J* **68** 57 *1958*, DOI: 10.1042/bj0680057; Zillikin & O'Brien *Biochemical Preparations* **7** 1 *1960*; for ^{13}C NMR and 1-^{13}C synthesis see Benzing-Nguyen & Perry *J Org Chem* **43** 551 *1978*, DOI: 10.1021/jo00398a005; Danishefsky & DeNinno *J Org Chem* **51** 2615 *1986*, DOI: 10.1021/jo00363a047; Gottschalk, *The Chemistry and Biology of Sialic Acids and Related Substances,* Cambridge University Press, London, ISBN 10: 0521051231 ISBN 13: 9780521051231; *1960*, *Beilstein* **4** IV 3288.]

N*-Acetyl penicillamine (*N*-acetyl-3-mercapto-D-valine)** *[*D- *15537-71-0*, DL *-59-53-0]* **$C_7H_{13}NO_3S$, M 191.3, m 183º, 186-187º (DL-form), 189-190º (D-form), D-form $[\alpha]_D^{25}$+18 (c 1, 50% EtOH), $pK_{Est(1)}$~3.0 (CO_2H), $pK_{Est(2)}$~ 8.0 (SH).** Both forms are recrystallised from hot H_2O. A pure sample of the ***D-form is obtained after five recrystallisations. [Crooks in *The Chemistry of Penicillin* Clarke, Johnson and Robinson eds, Princeton University Press, 470 *1949*, ISBN: 9780691653471, ISBN: 9781400874910; Review: Chain et al. (*Antibiotics* Oxford University Press) **2** *1949*, *Beilstein* **4** III 1662.] ***S-Nitroso-N-acetylpenicillamine*** *[67776-06-1]* $C_7H_{12}N_2O_4S$, M 220.3, is an *S*-nitrosothiol used as a model in nitric oxide studies of biological systems, particularly related to vasodilation [Zhang & Hogg '*S*-Nitrosothiols: Cellular Formation and Transport' *Free Radical Biology and Medicine* **38** 831 *2005*, DOI: 10.1016/ j.freeradbiomed.2004.12.016. PMID: 15749378].

p*-Acetylphenyl sulfate potassium salt** *[38533-41-4]* **$C_8H_7O_5S$. K, M 254.3, m dec on heating, pK_{Est} ~2.1.** Purify the salt by dissolving it in the minimum volume of hot water (60º) and adding EtOH, with stirring, then leave at 0º for 1hour. The crystals are filtered off and recrystallised from H_2O until free of Cl^- and SO_4^{2-} ions. Dry it in a vacuum over P_2O_5 at room temperature. It is a ***specific substrate for arylsulfatases which hydrolyse it to *p*-acetylphenol [UV has λ_{max} at 327nm (ε 21700 $M^{-1}cm^{-1}$)] [Milsom et al. *Biochem J* **128** 331 *1972*, DOI: 10.1042/bj1280331].

S-Acetylthiocholine bromide *[25025-59-6]* **$C_7H_{16}NOS$. Br, M 242.2, m 217-223º(dec).** It is a ***hygroscopic*** solid which can be recrystallised from ligroin/EtOH (1:1), dried and kept in a vacuum desiccator. Crystallisation from *C_6H_6/EtOH gives **m** 227º or from propan-1-ol the **m** is 213º. [Hansen *Acta Chem Scand* **11** 537 *1957*,

DOI: 10.3891/acta.chem.scand.11-0537; for hydrolysis studies see Heilbronn *Acta Chem Scand* **12** 1481 *1958*, DOI: 10.3891/acta.chem.scand.12-1481; Heilbronn *Acta Chem Scand* **12** 1492 *1958*, DOI: 10.3891/acta.chem.scand.12-1492; *Beilstein* **4** IV 1585.] It is a skin and eye irritant.

S-Acetylthiocholine chloride *[6050-81-3]* **$C_7H_{16}NOS.Cl$, M 197.7,** has **m 172-173°.** The chloride can be purified in the same way as the bromide, and it can be prepared from the iodide. A few milligrams dissolved in H_2O can be purified by applying onto a Dowex-1 Cl^- resin column (prepared by washing with N HCl followed by CO_3^{2-} -free H_2O until the pH is 5.8). After equilibration for 10 minutes, elution is started with CO_3^{2-}-free distilled H_2O, and 3ml fractions are collected and their OD values at λ 229nm are measured. The fractions with appreciable absorption are pooled and lyophilised at 0-5°. ***Note*** that at higher temperatures decomposition of the ester is appreciable; hydrolysis is appreciable at pH >10.5/20°. The residue is dried *in vacuo* over P_2O_5, checked for traces of iodine (add concentrated H_2SO_4 and heat, violet vapours are released), and recrystallised from propan-1-ol. [For hydrolysis studies see Heilbronn in previous entry; and for electrical conductivity studies see El-Hammamy et al. *Adv Appl Sci Res* **2**(1) 90-94 *2011*, pelagiaresearchlibrary.com/advances.../AASR-2011-2-1-90-94.pdf; Gal & Roth *Clin Chim Acta* **2** 316 *1957*, DOI: 10.1016/0009-8981(57)90009-8; Beilstein **4** IV 1585.]

S-Acetylthiocholine iodide *[1866-15-5]* **$C_7H_{16}NOS.I$, M 289.2,** has **m 203-204°, 204°, 204-205°.** Recrystallise the iodide from propan-1-ol (or *iso*-PrOH, or EtOH/Et_2O) until almost colourless and dry it in a vacuum desiccator over P_2O_5. Its solubility in H_2O is 10% w/v at ~25°. A 0.075M (21.7mg/ml) solution in 0.1M phosphate buffer pH 8.0 is stable for 10-15 days if kept refrigerated. Store it away from light. It is commercially available as a 1% solution in H_2O. [Ellman et al. *Biochemical Pharmacology* **7**, 88 *1961*, DOI: 10.1016/0006-2952(61)90145-9; Hansen *Acta Chem Scand* **13** 151 *1959*, **11** 537 *1957*, DOI: 10.3891/acta.chem.scand.11-0537; Gal & Roth *Clin Chim Acta* **2** 316 *1957*, DOI: 10.1016/0009-8981(57)90009-8; for hydrolysis studies see Heilbronn in previous entry; *Beilstein* **4** III 726, **4** IV 1585.]

Actinomycin C (Cactinomycin) *[8052-16-2]* **$C_{63}H_{88}N_{12}O_{16}$, M 1268.6.** (A commercial mixture of Actinomycin C_1 ~5%, C_2 ~30% and C_3 ~65% is available). ***Actinomycin C_1 (native)*** crystallises from EtOAc as red crystals, is soluble in $CHCl_3$, $*C_6H_6$ and Me_2CO, and has **m** 246-247°(dec), with $[\alpha]_D^{20}$ -328 (0.22, MeOH) and λ_{max} 443nm (ε 25,000) and 240nm (ε 34,000). ***Actinomycin C_2 (native)*** crystallises as red needles from EtOAc and has **m** 244-246°(dec), with $[\alpha]_D^{20}$ -325 (c 0.2, MeOH), λ_{max} 443nm (ε 25,300) and 240nm (ε 33,400). ***Actinomycin C_3 (native)*** recrystallises from cyclohexane, or $*C_6H_6$/MeOH/cyclohexane as red needles with **m** 238-241° (dec), $[\alpha]_D^{20}$ -321 (c 0.2, MeOH), and λ_{max} 443nm (ε 25,000) and 240nm (ε 33,300). [Brockman & Lackner, *Chem Ber* **101** 1312 *1968*, DOI: 10.1002/cber.19681010425.] It is ***light sensitive***. [*Beilstein* **27** III/IV 9642.] **TOXIC.**

Actinomycin D **(Dactinomycin)** *[50-76-0]* **$C_{62}H_{86}N_{12}O_{16}$, M 1255.4,** has **m 241-243°(dec), 251-253°(dec), $[\alpha]_D^{22}$-296 (c 0.22, MeOH).** It crystallises as bright red (red-orange) rhombic crystals from absolute EtOH or from MeOH/EtOH (1:3). It will also crystallise from EtOAc/cyclohexane (**m 246-247° dec**), $CHCl_3$/petroleum ether (**m 245-246° dec**), and EtOAc/MeOH/$*C_6H_6$ (**m 241-243° dec**). Its solubility in MeCN is 1mg/ml. $[\alpha]_D^{20}$ varies from -296° to -327° (c 0.2, MeOH). λ_{max} (MeOH) 445, 240nm (log ε 4.43, 4.49), λ_{max} (MeOH, 10N HCl, 1:1) 477nm (log ε 4.21) and λ_{max} (MeOH, 0.1N NaOH) 458, 344, 285 (log ε 3.05, 4.28, 4.13). It is **HIGHLY TOXIC,** light sensitive and anti-neoplastic. [Bullock & Johnson, *J Chem Soc* 3280 *1957*, DOI: 10.1039/JR9570003280; *Beilstein* **27** III/IV 9642.]

Adenosine-5'-diphosphate [adenosine-5'-pyrophosphate, ADP] *[58-64-0]* **$C_{10}H_{15}N_5O_{10}P_2$, M 427.2, $[\alpha]_D^{25}$ -25.7 (c 2, H_2O), pK_1^{25} <2 (PO_4H), pK_2^{25} <2 (PO_4H), pK_3^{25} 3.95 (NH_2), pK_4^{25} 6.26 (PO_4H).** It is characterised by conversion to the ***acridine salt*** by addition of alcoholic acridine (1.1g in 50ml), filtering off the yellow salt and recrystallising from H_2O. Store at -20°. The ***salt*** has **m 215°(dec)**, and UV with λ_{max} at 259nm (ε 15,400) in H_2O. [Baddiley & Todd *J Chem Soc* 648 *1947*, DOI: 10.1039/JR9470000648; 582 *1949*, DOI: 10.1039/JR9490000582; cf. LePage *Biochemical Preparations* **1** 1 *1949*, Martell & Schwarzenbach *Helv Chim Acta* **39** 653 *1956*, DOI: 10.1002/hlca.19560390302]. [*Beilstein* **26** III/IV 2369.]

Adenosine-3'-monophosphoric acid hydrate [3'-adenylic acid, 3'-AMP] *[84-21-9]* **$C_{10}H_{16}N_5O_8P.xH_2O$, M 347.3(anhydrous), m 197°(dec, as $2H_2O$), 210°(dec), m 210°(dec), $[\alpha]_{546}$ -50 (c 0.5, 0.5M Na_2HPO_4), pK_1^{25} 3.65, pK_2^{25} 6.05.** It crystallises from large volumes of H_2O in needles as the ***monohydrate***, but is not very soluble in boiling H_2O. Under acidic conditions it forms an equilibrium mixture of 2' and 3' adenylic acids *via*

the 2',3'-cyclic phosphate. When heated with 20% HCl, it gives a quantitative yield of furfural after 3 hours, unlike 5'-adenylic acid which only gives traces of furfural. The yellow ***monoacridine salt*** has **m 175°(dec)**, and the ***diacridine salt*** has **m 177°** (**225°**)(**dec**). [Brown & Todd *J Chem Soc* 44 *1952*, DOI: 10.1039/JR9520000044; Ueda & Takaku *Chem Pharm Bull Jpn* **32** 1650 *1984*, DOI: org/10.1248/cpb.32.1650; for phosphorylation of an OH group with *N*-phosphoryl-*N'*-methylimidazole see Takaku et al. *Chem Pharm Bull Jpn* **21** 2068 *1973*, DOI: org/10.1248/cpb.21.444; NMR: Ts'o et al. *Biochemistry* **8** 997 *1969*, DOI: 10.1021/bi00831a033; *Beilstein* **26** III/IV 3607.]

Adenosine-5'-monophosphoric acid monohydrate (5'-adenylic acid, 5'-AMP) *[18422-05-4]* **$C_{10}H_{16}N_5O_8P.H_2O$, M 365.2, m 178°, 183-188°(dec), 196-200°, 200° (sintering at 181°), $[\alpha]_D^{20}$ -47.5, $[\alpha]_{546}$ -56 (c 2, in 2% NaOH), -26.0 (c 2, 10% HCl), -38 (c 1, 0.5M Na_2HPO_4), pK_1^{25} 3.89, pK_2^{25} 6.14, pK_3^{25} 13.1.** The acid has been recrystallised from H_2O (fine needles) and is freely soluble in boiling H_2O. It crystallises also from H_2O on addition of acetone. *Alternatively*, purify it by chromatography on Dowex 1 (in formate form), and eluting with 0.25M formic acid. It is then adsorbed onto charcoal (which had been boiled for 15 minutes with M HCl, washed free of chloride ions and dried at 100°) and recovered by stirring three times with isoamyl alcohol/H_2O (1:9 v/v). The aqueous layer from the combined extracts is evaporated to dryness under reduced pressure, and the product is crystallised twice from hot H_2O. [Morrison & Doherty *Biochem J* **79** 433 *1961*, DOI: 10.1042/bj0790433d]. It has UV with λ_{max} at 259nm (ε 15,400) in H_2O at pH 7.0. [Alberty et al. *J Biol Chem* **193** 425 *1951*, PMID: 14907730; Martell & Schwarzenbach *Helv Chim Acta* **39** 653 *1956*, DOI: 10.1002/hlca.19560390302]. The ***acridinium salt*** has **m** 208° [Baddiley & Todd *J Chem Soc* 648 *1947*, DOI: 10.1039/JR9470000648; Pettit *Synthetic Nucleotides,* van Nostrand-Reinhold, NY, **Vol 1** 252 *1972*, NMR: Sarma et al. *J Am Chem Soc* **96** 7337 *1974*, DOI: 10.1021/ja00830a028; Norton & Allerhand *J Am Chem Soc* **98** 1007 *1976*, DOI: 10.1021/ja00420a025; for IR of ***diNa salt*** see Miles *Biochem Biophys Acta* **27** 46 *1958*, DOI: 10.1016/0006-3002(58)90291-9]. Adenosine 5'-[β-thio]diphosphate tri-lithium salt *[73536-95-5]* **$C_{10}H_{12}N_5O_9P_2S.3Li$, M 461.1.** Purify it by ion-exchange chromatography on DEAE-Sephadex A-25 using gradient elution with 0.1-0.5M triethylammonium bicarbonate. It has UV with λ_{max} at (H_2O) 259nm (ε 15,000). Store at -20°. [Goody & Echstein *J Am Chem Soc* **93** 6252 *1971*, DOI: 10.1021/ja00752a042; Goody et al. *Biochem Biophys Acta* **276** 155 *1972*, DOI: 10.1016/0005-2744(72)90016-2.]

Adenosine 5'-[α-thio]monophosphate di-lithium salt *[19341-57-2, 93839-85-1]* **$C_{10}H_{12}N_5O_6PS.2Li$, M 375.2.** Purify it as for the diNa salt [Murray & Atkinson *Biochemistry* **7** 4023 *1968*, DOI: 10.1021/bi00851a032, PMID: 4301880]. Dissolve 0.3g in dry MeOH (7ml) and 1M LiI (6ml) in dry Me_2CO containing 1% of mercaptoethanol, and the Li salt is precipitated by adding Me_2CO (75ml). The residue is washed with Me_2CO (4 x 30ml) and dried at 55°/25mm. Store at -20°. It has UV with λ_{max} in HCl, pH 1.2 at 257nm (ε 14,800); (0.015M NaOAc, pH 4.8) 259nm (ε 14,800); and in 0.015M NH_4OH, pH 10.1 at 259nm (ε 15,300). It is an AMP-dependent enzyme inhibitor.

Adenosine-5'-triphosphate (ATP) *[56-65-5]* **$C_{10}H_{16}N_5O_{13}P_3$, M 507.2, m 187°, $[\alpha]_{546}$ -35.5 (c 1, 0.5 M Na_2HPO_4), pK_1^{25} 4.00, pK_2^{25} 6.48.** ATP is purified by precipitating it as the ***barium salt*** on adding excess barium acetate solution to a 5% solution of ATP in water. The precipitate is filtered off, washed with distilled water, dissolved in 0.2M HNO_3 and again precipitated with barium acetate. The precipitate, after several washings with distilled water, is redissolved in 0.2M HNO_3, and slightly more than an equivalent of 0.2M H_2SO_4 is added to precipitate all the barium as $BaSO_4$ which is filtered off. The ATP is then precipitated by addition of a large excess of 95% ethanol. It is filtered off, washed several times with 100% EtOH and finally with dry diethyl ether. It is dried *in vacuo*. [Kashiwagi & Rabinovitch *J Phys Chem* **59** 498 *1955*, DOI: 10.1021/j150528a006; *Beilstein* **26** III/IV 3654.]

S-(5'-Adenosyl)-L-homocysteine (SAH) *[979-92-0]* **$C_{14}H_{20}N_6O_5S$, M 384.4, m 202°(dec), 204°(dec), 205-207°(dec), $[\alpha]_D^{25}$ +93 (c 1, 0.2N HCl), $[\alpha]_D^{23}$ +44 (c 0.1, 0.05N HCl), (pK see SAM hydrochloride below).** It has been recrystallised several times from aqueous EtOH or H_2O to give small prisms, and the UV has λ_{max} at 260nm in H_2O. The solubility in 1M HCl is 19.6-20.4 mg/ml at ~25° (faintly yellow solution). Store at -20°. The ***picrate*** has **m** 170°(dec) from H_2O. [Baddiley & Jamieson *J Chem Soc* 1085 *1955*, DOI: 10.1039/

JR9550001085; de la Haba & Cantoni *J Biol Chem* **234** 603 *1959*, PMID: 13641268; Borchardt et al. *J Org Chem* **41** 565 *1976*, DOI: 10.1021/jo00865a038; NMR: Follmann & Gremels *Eur J Biochem* **47** 187 *1974*, DOI: 10.1111/j.1432-1033.1974.tb03682.x; *Beilstein* **26** III/IV 3676.]

(+)-S-Adenosyl-L-methionine chloride (SAM hydrochloride) *[24346-00-7*; zwitterion-(-) *29908-03-0]* **$C_{15}H_{22}N_6O_5S$. HCl, M 434.9, $[\alpha]_D^{25}$ +32 (c 3.3, H_2O) $pK_{Est(1)}$~ 2.13, $pK_{Est(2)}$~ 4.12, $pK_{Est(3)}$~ 9.28.** Purify it by ion exchange on Amberlite IRC-150 and eluting with 0.1-4M HCl. [Stolowitz & Minch *J Am Chem Soc* **103** 6015 1981, DOI: 10.1021/ja00410a004.] It has been isolated as the ***tri-reineckate salt*** by adding 2 volumes of 1% solution of ammonium reineckate in 2% perchloric acid. The reineckate salt separates at once but is kept at 2º overnight. The salt is collected on a sintered glass funnel, washed with 0.5% of ammonium reineckate, dried (all operations at 2º) and stored at 2º. To obtain adenosylmethionine, the reineckate is dissolved in a small volume of methyl ethyl ketone (MEK) and centrifuged at room temperature to remove a small amount of solid. The clear dark red supernatant is extracted (in a separating funnel) with a slight excess of 0.1N H_2SO_4. The aqueous phase is re-extracted with fresh MEK until it is colourless. [***Note*** that reineckates have UV absorption at 305nm (ε 15,000), and the optical density at 305nm is used to detect and estimate reineckate ions.] MEK is removed from the aqueous layer containing adenosylmethionine sulfate; the pH is adjusted to 5.6-6.0 and extracted with two volumes of Et_2O. The ***sulfate*** is obtained by evaporating the aqueous layer in *vacuo*. The ***hydrochloride*** can be obtained in the same way but using HCl instead of H_2SO_4. SAM-HCl has a solubility of 10 w/v% in H_2O. The salts are stable in the cold at pH 4-6 but decompose in alkaline media. Store at -70º. [Cantoni *Biochemical Preparations* **5** 58 *1957*.] The purity of SAM can be determined by paper chromatography [Cantoni *J Biol Chem* **204** 403 *1953*, www.jbc.org/content/204/1/403, PMID: 13084611; *Methods Enzymol* **3** 600 *1957*, DOI: 10.1016/S0076-6879(57)03427-8; for electrophoretic methods or enzymic analysis see Cantoni & Vignos *J Biol Chem* **209** 647 *1954*, PMID: 13192118]. [*Beilstein* **26** III/IV 3676.]

L-Adrenaline [*R*-(-)-epinephrine, L(-)-(3,4-dihydroxyphenyl)-2-methylaminoethanol] *[51-43-4]* **$C_9H_{13}NO_3$, M 183.2, m 210º(dec), 211º(dec), 211-212º(dec), 215º(dec), $[\alpha]_{546}^{20}$ -61 (c 5, 0.5M HCl), $[\alpha]_D^{20}$ -52 (c 2, 5% HCl), pK_1^{25} 8.88 (8.75), pK_2^{25} 9.90 (9.89), pK_3^{25} 12.0 (~13).** L-Adrenaline has been recrystallised from EtOH/AcOH/NH_3 [Jensen *J Am Chem Soc* **57** 1765 *1935*, DOI: 10.1021/ja01313a002]. It is sparingly soluble in H_2O, readily soluble in acidic or basic solutions but insoluble in aqueous NH_3, alkali carbonate solutions, EtOH, $CHCl_3$, Et_2O or Me_2CO. It has also been purified by dissolving in dilute aqueous acid, then precipitating it by adding dilute aqueous ammonia or alkali carbonates. It is readily oxidised in air and turns brown on exposure to light and air. (*Epinephrine* readily oxidises in neutral alkaline solution. This can be diminished if a little sulfite is added). Store it in the dark under N_2. [Lewis *Br J Pharmacol Chemother* **9** 488 *1954*, DOI: 10.1111/j.1476-5381.1954.tb00866.x]. The ***hydrogen oxalate salt*** has **m 191-192º(dec**, evacuated capillary) after recrystallisation from H_2O or EtOH [Petrow et al. *J Chem Soc* 927 *1945*, DOI: 10.1039/JR9450000927]. [*Beilstein* **13** III/IV 2927.] It is a cardiac stimulant and adrenoreceptor agonist.

Adrenalone hydrochloride (3',4'-dihydroxy-2-methylaminoacetophenone hydrochloride) *[62-13-5]* **$C_9H_{11}NO_3$. HCl, M 217.7, m 243º(dec), 244-249º(dec), 248º(dec), 256º(dec), pK^{25} 5.5.** The salt is synthesised from α-(*p*-toluenesulfonylmethylamino)-3,4-dimethoxyacetophenone by heating with HCl under pressure [DE Patent 277540 to Bayer, *1914*]. *Alternatively*, catechol (*o*-hydroxyphenol) is melted with chloroacetyl chloride and $POCl_3$ whereby catechol monchloroacetate is formed as intermediate which rearranges to 4-chloroacetylcatechol. Treatment of the latter (100g) in EtOH (50ml) with 40% $MeNH_2$ (200ml) with cooling and shaking for 1 hour then allowing to stand overnight at ~25º, gives a salt that is filtered off, washed with a little EtOH, dissolved in dilute HCl. The ***free base*** is precipitated with ammonia, filtered off washed with a little H_2O, EtOH and Et_2O to give 60g of base which is best converted to the ***hydrochloride*** for storage. The ***hydrochloride*** is purified by recrystallisation from EtOH or aqueous EtOH (prisms, decomposing >240º). The solubility at ~25º in H_2O is ~12.5w/v% and in 94%EtOH it is 2.2w/v%. For X-ray crystallography, well developed, water clear crystals were obtained by slow evaporation of an aqueous solution of pure ***hydrochloride*** [for the crystal structure of the ***hydrochloride monohydrate*** see Bergin *Acta Crystallogr Section B* **27** 2139 *1971*, DOI: 10.1107/S0567740871005478]. The ***free base*** *[99-45-6]* is obtained by basifying an aqueous solution of the hydrochloride from which it precipitates out, and is recrystallised from H_2O, washed with H_2O, EtOH and Et_2O in which it is poorly soluble, to give microscopic needles **m 235-236º(dec) (**darkening at ~200º and decomposing >230º) [Stolz *Chem Ber* **37** 4149 *1904*, DOI: not available; DE 152814 to Hoechst.] The ***tris-***

benzenesulfonyl derivative has **m 106-107°(dec)** from aqueous EtOH. Similarly, Stolz prepared ***2-amino-1-(3,4-dihydroxyphenyl)ethan-1-one*** **(3',4'-dihydroxy-2-aminoaceto-phenone, noradrenalone)** *[499-61-6]* **$C_8H_9NO_3$, M 167.2, m** darkens at **200°** and decomposes at **300°)** as pale yellow microscopic crystals, by using NH_3 instead of $MeNH_2$, and its ***hydrochloride*** had **m 260°(dec)** (colourless plates from aqueous EtOH). Stolz also prepared ***2-ethylamino-1-(3,4-dihydroxyphenyl)ethan-1-one*** [pale yellow microscopic crystals from H_2O, **m 185°(dec)]** by using $EtNH_2$ instead of NH_3, and its ***hydrochloride*** crystallises as needles **m 260°(dec)** from hot H_2O, but is poorly soluble in EtOH.
It is an andrenergic agonist, is a topical vasoconstrictor, is hemostatic and its activity is similar to that of adrenaline. It is used as a topical anaesthetic. [Gero *J Org Chem* **16** 1222 *1951*, DOI: 10.1021/jo50002a006; Kindler & Peschke *Arch Pharm* **269** 581, 603 *1931*, DOI: 10.1002/ardp.19312693504; *Beilstein* **14** IV 832.]

Allopurinol [Allosig, Progout, 1,5-dihydro-4*H*-pyrazolo(3,4-*d*)pyrimidin-4-one] *[315-30-0]* **$C_5H_4N_4O$, M 136.1, m >350°, pK^{25} 10.2.** It is obtained from 3-amino-4-pyrazolecarboxamide sulfate (75g) in formamide (200ml) at 180-190°/45min, cooled, diluted with cold H_2O (1L) and the ***purinol*** (48g) is filtered off. It is purified by recrystallisation from H_2O. It has also been purified by dissolving in aqueous 2N NaOH, shake with Norit (charcoal), filter, acidify with 2N HCl to pH 3-4, collect the purinol and recrystallise it from hot H_2O. It does not melt when heated to 350°. Its solubility (w/v%) in H_2O is 0.78 (25°) and 190 (100°), in DMSO it is 4.6 (25°), in $CHCl_2$ it is 0.6 (25°), in EtOH it is 0.3 (25°), and in *n*-octanol it is <0.01 (25°). It has UV with λ_{max} at 250nm (ε 7600) in 0.1N HCl; 257nm (ε 7200), in 0.1N NaOH, and 252nm (ε 7600) IN MeOH. [Robins *J Am Chem Soc* **78** 784 *1956*, DOI: 10.1021/ja01585a023; Schmidt & Druey *Helv Chim Acta* **39** 986 *1956*, DOI: 10.1002/hlca.19560390345].
Allopurinol is a ***xanthine oxidase*** inhibitor and interferes with uric acid biosynthesis. It is a commonly used drug for the treatment of gout, and renal calculi. [For '*Allopurinol prevents formation of renal calculi in many cases*' see *InPharma* **106** 9 *1977*, DOI: 10.1007/BF03284284; and for '*Allopurinol treatment and its effect on renal function in gout: a controlled study*' see Gibson *Ann Rheum Dis* **41** 59 *1982*, PMCID: PMC1000865.]

Amethopterin (Methotrexate, 4-amino-4-deoxy-*N^{10}*-methylpteroyl-L-glutamic acid) *[59-05-2]* **$C_{20}H_{22}N_8O_5$, M 454.4, m 185-204°(dec), $[\alpha]_D^{20}$ +19 (c 2, 0.1N aqueous NaOH), pK_1 <0.5 (pyrimidine^{2+}), pK_2 2.5 (N5-Me$^+$), pK_3 3.49 (α-CO_2H), pK_4 4.99 (γ-CO_2H), pK_5 5.50 (pyrimidine$^+$).** Most common impurities are 10-methylpteroyl-glutamic acid, aminopterin and pteroylglutamic acid. Purify the yellow solid by chromatography on Dowex-1 acetate, followed by filtration through a mixture of cellulose and charcoal. It has been recrystallised from aqueous HCl or by dissolution in the minimum volume of N NaOH and acidified until precipitation is complete, filter or ***better*** collect by centrifugation, wash with H_2O (also by centrifugation) and dry at 100°/3mm. It has UV with λ_{max} at 244 and 307nm (ε 17300 and 19700) in H_2O at pH 1; 257, 302 and 370nm (ε 23000, 22000 and 7100) in H_2O at pH 13. [Momle *Biochemical Preparations* **8** 20 *1961*, Seeger et al. *J Am Chem Soc* **71** 1753 *1949*, DOI: 10.1021/ja01173a061.] It is a ***potent inhibitor*** of dihydrofolate reductase and is used in cancer chemotherapy. [Blakley *The Biochemistry of Folic Acid and Related Pteridines*, North-Holland Publ Co., Amsterdam, NY, pp157-163 *1969*, ISSN 0071-965X; *Beilstein* **26** IV 3833.] It is **CARCINOGENIC; HANDLE WITH EXTREME CARE.** Antifolate used extensively in cancer chemotherapy.

Aminopterin (4-amino-4-deoxypteroyl-L-glutamic acid) *[54-62-6]* **$C_{19}H_{22}N_8O_5$, M 440.4, m 231-235°(dec), $[\alpha]_D^{20}$ +18 (c 2, 0.1N aqueous NaOH), pK_1 <0.5 (pyrimidine^{2+}), pK_2 2.5 (N5-Me$^+$), pK_3 3.49 (α-CO_2H), pK_4 4.65 (γ-CO_2H), pK_5 5.50 (pyrimidine$^+$).** Purify aminopterin by recrystallisation from H_2O. It has properties similar to those of methotrexate (above). It has UV at λ_{max} 244, 290 and 355nm (ε 18600, 21300 and 12000) in H_2O at pH 1; 260, 284 and 370nm (ε 28500, 26400 and 8600) in H_2O at pH 13. [Seeger et al. *J Am Chem Soc* **71** 1753 *1949*, DOI: 10.1021/ja01173a061; Angier & Curran *J Am Chem Soc* **81** 2814 *1959*, DOI: 10.1021/ja01520a049; Blakley *The Biochemistry of Folic Acid and Related Pteridines*, North-Holland Publ Co., Amsterdam, NY, pp 157-163 *1969*, ISSN 0071-965X.] For small quantities, chromatograph it on DEAE cellulose with a linear gradient of ammonium bicarbonate pH 8 and increase the molarity from 0.1 to 0.4. Monitoring is by following the UV absorption of the fractions. For larger quantities, a near boiling solution of aminopterin (5g) in H_2O (400ml) is slowly treated with small portions of MgO powder (~0.7g, calcined magnesia) with vigorous stirring until a small amount of MgO remained undissolved and the pH rises from 3-4 to 7-8. Charcoal (1g) is added to the hot solution and filtered immediately through a large sintered glass funnel

of medium porosity and lined with a hot wet pad of Celite (~2-3 mm thick). The filtrate is cooled in ice, and the crystals of the ***Mg salt*** are collected by filtration and recrystallised from boiling H_2O (200ml). The crystals are washed with EtOH and dried *in vacuo*. The Mg salt is redissolved in boiling H_2O (200ml) and carefully acidified with vigorous agitation with AcOH (2ml). Pure aminopterin (3g) separates in fine yellow needles (***dihydrate***) which are easily filtered. The solid is washed with cold H_2O, then Me_2CO and dried *in vacuo*. If a trace of impurity is still present as shown by DEAE cellulose chromatography or TLC, repetition of the process will remove it; see UV above. [Loo *J Med Chem* **8** 139 *1965*, DOI: 10.1021/jm00325a036; *Beilstein* **26** IV 3831.] **CARCINOGENIC.** It strongly inhibits ***dihydrofolate reductase*** from producing tetrahydrofolate then 5,10-methylenetetrahydrofolate consequently arresting the formation of thymidine, a DNA building block.

3-Aminopyridine adenine dinucleotide *[21106-96-7]* **M 635.4 (see NAD for pK)** Purify it by ion-exchange chromatography as described [for interaction with dehydrogenases see Fisher et al. *J Biol Chem* **248** 4293 *1973*, PMID: 4351221; Anderson & Fisher *Methods Enzymol* **66** 81 *1980*, DOI: 10.1016/0076-6879(80)66441-6].

Amiodarone {2-butyl-3-[3,5-diiodo-4-(β-diethylaminoethoxy)benzoyl]benzofuran, (2-butyl-1-benzofuran-3-yl)-[4-[2-(diethyl**ami**no)ethoxy]-3,5-di**iodo**ph**en**yl]methan**one; phen = ar**, hence Amiodarone**}** *[1951-25-3]* **$C_{25}H_{29}I_2NO_3$, M 645.3, pK^{25} 6.56 ±0.06.** The simplest synthesis starts from 2-phenoxy-*n*-hexaldehyde (e.g. 2mmol) which is cyclised to 2-*n*-butylbenzofuran in toluene (15ml) by boiling under reflux in the presence of Amberlyst-15 resin (0.75g) for 20min, filtered to remove the resin, washed with aqueous $NaHCO_3$, H_2O and dried ($MgSO_4$), filtered and evaporated to dryness. The residue is distilled (b 80-82°/3mm, 114-116°/8mm) to give the ***furan*** in 94% yield. A Friedel-Crafts reaction of the furan with *p*-methoxybenzoyl chloride/$AlCl_3$ gave 2-*n*-butyl-3-(*p*-hydroxybenzoyl)benzofuran in 84% yield, and is followed by treatment with KI and I_2 (to di-iodinate the phenolic group) then NaOMe (to form the Na-phenolate) and *N*-(β-chloroethyl)diethylamine to provide ***Amiodarone*** in 43% yield. The ***free base*** is a strong enough base to form a stable ***hydrochloride***. [Prepn: **FR 1339389**; Tondeur & Binon, **US 3248401** (1963, 1966 to Soc. Belge l'Azote Prod. Chim. Marly); for the synthesis of 2-*n*-butylbenzofuran see Witczak & Kwiecień *Synth Commun* **35** 2223 *2005*, DOI: 10.1080/00397910500182747; Wang for the 'Synthetic Process for 2-Butyl-3-(hydroxy-3,5-diiodobenzoyl)-benzofuran' Chin. Patent 1,858,042, Nov 8, *2006*; Ha et al. *Eur J Clin Pharmacol* **55** 807 *2000*, DOI: 10.1007/s002280050701.]

Amiodarone hydrochloride **(Amiodor)** *[19774-82-4]* **$C_{25}H_{29}I_2NO_3$. HCl, M 681.8,** has **m 156°, m 159.2°.** It is purified by recrystallisation from acetone. Its solubilities at 25° in g/100ml are: $CHCl_3$(44.5), CH_2Cl_2(19.2), MeOH(9.98), EtOH(1.28), *C_6H_6(0.65), THF(0.60), MeCN(0.32), 1-octanol(0.30), Et_2O(0.17), *n*-PrOH(0.13), H_2O at pH 1.5-7.5(~0.07), hexane(0.03), petroleum ether(0.001) and *iso*-PrOH(<0.001). Its UV (MeOH) has λ_{max} nm (ε) at 208 (4,700), 241 (4,400), 270sh (1,800) and 280sh (1,600), and the IR (KBr) has ν_{max} at 3000-3070(Ar C-H), 2860-2960(aliph C-H), 2200-2900(*tert*-NH^+), 1636(diAr C=O), 1560-1015(benzofuran C=C), 1580(aliph CH_3), 1285(ketonic C-C), 1250 and 1075(ether C-O-C) and 1225-1025(*tert*-amine C-N) cm^{-1}. [For physicochemical properties see Bonati et al. *J Pharm Sci* **73** 829 *1984*, DOI: 10.1002/jps.2600730632]

Amiodarone hydrochloride is an ***anti-arrhythmic (Class III)*** and ***anti-angina*** drug used in cardiac surgery, cardiac resuscitation, after out-of-hospital cardiac arrest and atrial fibrilation [Kudenchuk et al. *N Engl J Med* **341** 871 *1999*, PMID: 10486418; Doy et al. *N Engl J Med* **342** 913 *2000*, DOI: 10.1056/NEJM200003303421302, PMID: 10738049].

Anion exchange resins. These should be conditioned before use by successive washing with water, EtOH and water, and taken through two OH^-—H^+—OH^- cycles by successive treatment with N NaOH, water, N HCl, water and N NaOH, then washing with water until neutral to give the ***OH^- form***. (See commercial catalogues on ion-exchange resins.)

R*(-)-Apocodeine {(6a*R*)-5,6,6a,7-tetrahydro-10-methoxy-6-methyl-4*H*-dibenzo[de,g]quinolin-11-ol}** *[641-36-1]* **$C_{18}H_{19}NO_2$, M 281.3, m 124°, $[\alpha]_D^{25}$ -27 (0.45, MeOH), $pK_{Est(1)}$~ 7.0, $pK_{Est(2)}$~ 8.2.** Recrystallise apocodeine from absolute EtOH by boiling and allowing to stand at 0° to give the ***alcoholate, **m 104.5-106.5°**; EtOH is lost slowly at 25°/2mm but readily at 78°/2mm, and the ***anhydrous base*** has **m 122.5-124.5°**. It is soluble in Et_2O. [Folkers *J Am Chem Soc* **58** 1814 *1936*, DOI: 10.1021/ja01300a502.] It has also been crystallised from MeOH (small prisms) or MeOH with a little CH_2Cl_2 as a waxy solid and dried at 80°/2mm. It softens above 100° before melting and is sensitive to air and light. The ***hydrochloride*** *[641-36-1]* **$C_{18}H_{19}NO_2$.**

HCl, M 317.7, which is formed from the base in EtOH containing an equivalent amount of HCl followed by addition of Et_2O, is recrystallised from 95% EtOH and adding Et_2O until crystals separate. It melts at 260-263º (dec, with softening at 140º) and has $[\alpha]_D^{20}$ -41.3 to - 43.3 (c 0.81, H_2O). It is an emetic. [for configuration see Corrodi & Hardegger *Helv Chim Acta* **38** 2038 *1955*, DOI: 10.1002/hlca.19550380746; for synthesis and pharmacology see Neumeyer et al. *J Med Chem* **16** 1223 *1973*, DOI: 10.1021/jm00269a601.]

R*-Apomorphine** *[58-00-4, 41372-20-7 (0.5H_2O)]* **$C_{17}H_{17}NO_2$, M 267.3, m 195º(dec), pK_1^{15} 7.20 (NH_2), pK_2^{15} 8.91 (phenolic OH).** Crystallise *R*-apomorphine from $CHCl_3$ and a little petroleum ether, also from Et_2O with 1 mol of Et_2O which it loses at 100º. It sublimes in a high vacuum. It is white but turns green in moist air or in alkaline solution. Its UV has λ_{max} at 336, 399 (98% EtOH). The ***di-O-methylether is an oil **b** 175º/high vacuum, whose ***picrate*** crystallises from MeOH and has **m 140º (dec)**. The ***di-O-acetate*** crystallises from EtOAc/petroleum ether with **m 127-128º**, $[\alpha]_D^{25}$ -88 (c 1, 0.1 N HCl). The ***di-O-benzoyl derivative*** has **m 156-158º** (from EtOH) and $[\alpha]_D^{18}$ +43.44 (c 3.3, $CHCl_3$). [Pschorr et al. *Chem* Ber **35** 4377 *1902*, DOI: 10.1002/cber.19020350496; *Beilstein* **21** H 246. **NARCOTIC.** It is a dopamine (D1 and D2) receptor agonist, an emetic and an anti-parkinsonian. ***R-Apomorphine hydrochloride*** *[41372-20-7]* **$C_{17}H_{17}NO_2$. HCl, M 312.8,** has **m 285-287º(dec), $[\alpha]_D^{20}$ -48 (c 1, H_2O).** Crystallise the salt from H_2O (***hemihydrate***) and from EtOH. Crystals turn green on exposure to light. (see previous entry). **NARCOTIC.**

Atenolol {4-[(2-hydroxy-3-*iso*-propylamino)propoxy]phenylacetamide, Tensig} *[RS- 29122-68-7, S- 93379-54-5]* **$C_{14}H_{22}N_2O_3$, M 266.3, m 146-147º, 150-151º (sealed capillary), pK^{25} 9.6.** The physiologically active *S*-enantiomer was synthesised in seven steps starting with *p*-hydroxyacetophenone and involving a ***hydrolytic kinetic resolution*** (HKR after Jacobsen et al.) of a terminal epoxide using (*R,R*) salen CoIII acetate (see Jacobsen salen catalysts in Catalysts-Part 1, Chapter 5) and *iso*-propylamine. The final step involved converting the methyl 4-[(*2S-2*-hydroxy-3-*iso*-propylamino)propoxy]phenylacetate formed into the amide (***S-Atenolol***) by reaction in MeOH with NH_4OH for 2 hours, evaporating and purifying the drug (72% yield of last step) by recrystallisation from EtOAc. It has **m 148-150º**, $[\alpha]_D^{21}$ -17.0 (c 1, 1 N HCl), IR (KBr) has ν_{max} at 3325, 3170, 2950, 2839, 1687, 1596, 1506, 1329, 1263, 1139, 1054, 968 and 835 cm^{-1}; the ^1H NMR [Gemini 200 spectrometer, DMSO d_6, TMS internal standard] has δ at 1.05 (d, 6H, *J* = 7.0 Hz), 2.70-2.90 (m, 1H), 3.25 (d, 2H, *J* = 6.0 Hz), 3.42 (s, 2H), 3.90-4.10 (m, 2H), 6.18 (br s, 2H), 6.85 (d, 2H, *J* = 7.2 Hz), 7.15 (d, 2H, *J* = 7.2 Hz), 7.55 (br s, 1H); EIMS *m/z* (%): 266(M^+, 45), 248(21), 208(11), 190(10), 150(22), **132**(**100**), 104(31), 78(16), 52(31). The HKR was carried out at room temperature with excellent ***enantio*** selectivity. The method can be applied to large-scale preparations of *S*-atenolol without any problems. [Bose & Narsaiah *Bioorg Med Chem* **13** 627 *2005*, PMID: 15653330.]
It is a ***β-blocker*** that decreases the activity of the heart by stopping nerve messages to it. It is a prescription drug for the treatment of hypertension, supraventricular tachycardia, atrial and ventricular fibrillation, atrial flutter, myocardial infarction and ***angina pectoris***. Stoschitzky et al. [*Chiralty* **5** 15 *1993*, DOI: 10.1002/chir.530050104; Lindner US Patent No 4,652,672 *1987*] conclude that in man it is the ***S-enantiomer*** that has the ***β-blocking effect***. [Kähönen et al. *Br J Pharmacol* **112** 925 *1994*, PMCID: PMC1910195; Amery et al. *New Engl J Med* **290** 284 *1974*, DOI: 10.1056/NEJM197401312900515, PMID: 4148766.]

Atorvastatin {Lipitor, Atorva, 7-[(4-fluorophenyl)- 3-phenyl-4-(phenylaminocarbonyl)-5-propan-2-ylpyrrol-1-yl]- β*R*,δ*R*)-3(*R*),5(*R*)-dihydroxyheptan-1-oic acid} *[134523-00-5]* **$C_{33}H_{35}FN_2O_5$, M 558.6, m 159.9º.** Its solubility in H_2O is <1mg/ml, and 100mg/ml in DMSO. In the final stage of the synthesis of the ***Na salt*** of the ***cis-drug*** described by Cho et al. (Patent US 8124790B2 *2012* to Medichem Korea Co Ltd) the *tert*-butyl ester in MeOH is cooled to 0º and the pH carefully adjusted to 12 using aqueous 3N NaOH with stirring at ~25 for 2 hours while maintaining the pH consant. After the starting material is consumed, checked by TLC and HPLC, stirring is continued for 2 hours at 0º; the white ***Na salt*** is filtered off, dried at 35-40º *in vacuo* to give the sodium salt of atorvastatin (6.4g, 74.4%) as a white powder. It has ^1H NMR (DMSO d_6) signals at 9.84(s, 1H), 7.4-7.9(m, 2H), 6.9-7.9(m, 12H), 3.93(br, 1H), 3.74(br, 2H), 3.0-3.2(m, 1H), 2.0-1.93 (m, 4H), 1.2-1.36(m, 9H).
The lactone, ***R-(+)-trans-2-(4-fluorophenyl)-5-(1-methylethyl)-N,3-diphenyl-1-[(tetrahydro-4-hydroxy-2-oxo-2H-pyran-6-yl)ethyl]-1H-pyrrole-4-carboxamide***, was prepared by Roth et al. [*J Med Chem* **34** 357 *1991*, DOI: 10.1021/jm00105a056] from the respective *t*-butyl β-ketoheptanoate with $Et_3B/NaBH_4$ followed by refluxing in toluene (Dean-Stark trap, to cyclise to the lactone intramolecularly), then the crude colourless foam in $CHCl_3$ was chromatographed through a silica gel column and eluted with EtOAc/heptane (1:1 v/v) followed by further

chromatography (silica gel; $CHCl_3$/propanol 98.5:1.5 v/v) and finally gave pure ***R-(+)-enantiomer lactone*** as a colourless foamy solid mixture (9:1 trans/cis **m 90-97°**). Recrystallisation from toluene/EtOAc gave pure ***R-form*** **m 148-149°**, with **$[\alpha]_D^{23}$ +24.53 (c .053 $CHCl_3$)**. Hydrolysis of this isomer (10g, 18.5mmol) with NaOH (0.74g, 18.5mmol) in a mixture of tetrahydrofuran/H_2O (1:2, 90ml) at 0° by warming slowly to 25°, then concentrated and the solid was collected and dried *in vacuo*. Its IR (KBr) has ν_{max} at 3400, 1651, 1598, 1565, 1511, 1438, 1412, 1316, 1224, 1139, 1159, 844, 754 and 702 cm^{-1}; the ^1H NMR (90MHz, in DMSO d_6) has the following signals downfield from TMS in ppm: 1.34 (d, *J* = 7Hz, 6H); 1.5 (m, 4H); 1.80 (d of d, *J* = 15, 8 Hz, 1H); 1.99 (d of d, *J* = 15, 4 Hz, 1H); 3-4 (m, 8H); 6.9-7.3 (m, 12H); 7.50 (d, *J* = 8 Hz, 2H) and 9.85 (s, 1H) {compare with above]. The ***S-(-)-enantiomer lactone*** was similarly prepared and found to have a relative potency as a ***HMG-CoA reductase inhibitor*** of ~13.9 compared to ~500 for the ***R-(+)-enantiomer***. An elegant synthesis has been accomplished starting from the freely available and cheap ***isoascorbic acid*** *[*see *89-65-6]* and provides the correct (+)-3*R*, 5*R*- configuration in the heptanoic (or lactone) chain for the most active enantiomer of the drug, without requiring optical resolution steps in which half of the molecule is not needed [Sletzinger et al. '*A diastereospecific, non-racemic synthesis of a novel β-hydroxy-δ-lactone HMG-CoA reductase inhibitor*' *Tetrahedron Lett* **26** 2951 *1985*, DOI: 10.1016/S0040-4039(00)98589-7; Bock et al. *Acta Chem Scand* **37B** 341 *1983*, DOI: 10.3891/acta.chem.scand.37b-0341; Isbell & Frush *Carbohydr Res* **72** 301 *1979*, DOI: 10.1016/S0008-6215(00)83954-3; review: Roth *Progr Med Chem* **40** 1 *2002*, DOI: 10.1016/S0079-6468(08)70080-8, PMID: 12516521.] In the form of the free acid, the Na or Ca salts or the lactone these ***statins*** are lipid lowering agents and ***strong inhibitors of 3-hydroxy-3-methylglutamylCoA reductase*** which is the first enzyme of the *de novo* biosynthesis of cholesterol (e.g. in mammalian liver) and have the effect of increasing LDL (low density lipoproteins) uptake by hepatocytes, decreasing HDL-C (high density lipoprotein cholesterol) and lowering triglyceride levels. [Roth US patent 4681893, to Warner-Lambert Co, issued *1987-07-21*.]

Aureomycin (7-chlorotetracycline) *[57-62-5]* **$C_{22}H_{23}ClN_2O_8$, M 478.8, m 172-174°(dec), $[\alpha]_D^{23}$ -275 (MeOH), pK_1 3.3, pK_2 7.44, pK_3 9.27.** Aureomycin is dehydrated by azeotropic distillation of its solution with toluene. On cooling, the anhydrous material crystallises out and is recrystallised from $*C_6H_6$, then dried under vacuum at 100° over paraffin wax. (If it is crystallised from MeOH, it contains ***MeOH*** in the crystals which is not removed on drying.) [Stephens et al. *J Am Chem Soc* **76** 3568 *1954*, DOI: 10.1021/ja01642a064; Laskin & Chan *Biochem Biophys Res Commun* **14** 137 *1964*, DOI: 10.1016/0006-291X(64)90243-8]. [*Beilstein* **14** IV 2631.] ***Aureomycin hydrochloride*** **(7-chlorotetracycline hydrochloride)** *[64-72-2]* **$C_{22}H_{23}ClN_2O_8$. HCl, M 514.0,** has **m 210-215°(dec), 234-236°(dec), $[\alpha]_D^{25}$ -23.5 (H_2O).** Purify the salt by dissolving 1g in 20ml of hot water, cooling rapidly to 40°, treating with 0.1ml of 2M HCl, and chilling in an ice-bath. The process is repeated twice. It is also recrystallised from Me_2NCHO/Me_2CO. Store at 2-8°. [Stephens et al. *J Am Chem Soc* **76** 3568 *1954*, DOI: 10.1021/ja01642a064; UV: McCormick et al. *J Am Chem Soc* **79** 2849 *1975*, DOI: 10.1021/ja01568a050; *Beilstein* **14** IV 2631.]

Bacitracin **(Altracin, Topitracin, a cyclic polypeptide with a peptide chain tail)** *[1405-87-4]* **$C_{66}H_{103}N_{17}O_{16}S$, M 1422.7, $[\alpha]_D^{23}$ +5 (H_2O).** Bacitracin has been purified by carrier displacement using *n*-heptanol, *n*-octanol and *n*-nonanol as ***carriers*** and 50% EtOH in 0.1 N HCl. The pure material gives one spot with R_F ~0.5 on paper chromatography using AcOH:*n*-BuOH:H_2O (4:1:5). [Porath *Acta Chem Scand* **6** 1237 1952, DOI: 10.3891/acta.chem.scand.06-1237.] It has also been purified by ion-exchange chromatography. It is a white powder soluble in H_2O and EtOH but insoluble in Et_2O, $CHCl_3$ and Me_2CO. It is stable in acidic solution but unstable in base. It is a strong topical antibacterial. [Newton & Abraham *Biochem J* **47** 257 *1950*, DOI: 10.1042/bj0470257; Synthesis: Munekata et al. *Bull Chem Soc Jpn* **46** 3187 *1973*, DOI: 10.1246/bcsj.46.3187; 3835 *1973*, DOI: 10.1246/bcsj.46.3835; *Beilstein* **27** III/IV 5746.]

***N^6*-Benzyladenosine** *[4294-16-0]* **$C_{17}H_{19}N_5O_4$, M 357.4, m 177-179°, 185-187°, $[\alpha]_D^{25}$ -68.6 (c 0.6, EtOH)(see pK of adenosine).** Purify it by recrystallisation from EtOH. It has UV with λ_{max} at 266nm (aqueous EtOH/HCl) and 269 nm (aqueous EtOH/NaOH). [Kissman & Weiss *J Org Chem* **21** 1053 *1956*, DOI: 10.1021/jo01115a621; *Beilstein* **26** III/IV 3682.] It has plant growth activity [Strnad *J Plant Growth Reg* **15**(4) 179 *1996,* DOI: 10.1007/BF00190582].

***N*-Benzylpenicillin sodium salt (penicillin G Na salt)** *[69-57-8]* **$C_{16}H_{17}N_2O_4S$. Na, M 356.4, m 215° (char-**

ring and dec), 225° (dec), $[\alpha]_D^{20}$ +269 (c 0.7, MeOH), $[\alpha]_D^{25}$ +305 (c 1, H_2O), pK^{25} 2.76 (4.84 in 80% aqueous EtOH)(for free acid). Purify the salt by dissolving it in a small volume of MeOH (in which it is more soluble than EtOH) and treating gradually with ~5 volumes of EtOAc. This gives an almost colourless crystalline solid (rosettes of clear-cut needles) and recrystallising twice more if slightly yellow in colour. The salt has also been conveniently recrystallised from the minimum volume of 90% Me_2CO and adding an excess of absolute Me_2CO. A similar procedure can be used with wet *n*-BuOH. If yellow in colour, then dissolve (~3.8g) in the minimum volume of H_2O (3ml), add *n*-BuOH and filter through a bed of charcoal. The salt forms long white needles on standing in a refrigerator overnight. More crystals can be obtained on concentrating the mother liquors *in vacuo* at 40°. A further recrystallisation (without charcoal) yields practically pure salt. A good preparation has ~600 Units/mg. The presence of H_2O in the solvents increases the solubility considerably. The solubility in mg/100ml at 0° is 6.0 (Me_2CO), 15.0 (Me_2CO/0.5% H_2O), 31.0 (Me_2CO/1.0% H_2O), 2.4 (methyl ethyl ketone), 81.0 (*n*-butanol) and 15.0 (dioxane at 14°). *Alternatively*, it is dissolved in H_2O (solubility is ~10%), filtered if necessary and precipitated by addition of EtOH and dried in a vacuum over P_2O_5. A sample can be kept for 24 hours at 100° without loss of physiological activity. It also crystallises from MeOH/EtOAc. [IR: Barnes et al. *Anal Chem* **19** 620 *1947*, DOI: 10.1021/ac60009a002; *The Chemistry of Penicillin* (Clarke, Johnson and Robinson eds.) Princeton University Press, Princeton NJ, Chapter V 85 *1949*, Open library OL16386917M; *Beilstein* **27** III/IV 5861.]
Other salts, e.g. the ***potassium salt*** (M 372.5 *[113-58-4]*) can be prepared from the Na salt by dissolving it (147mg) ice-cold in H_2O acidified to pH 2, extracting with Et_2O (~50ml), washing once with H_2O, and extracting with 2ml portions of 0.3% $KHCO_3$ until the pH of the extract rises to ~6.5 (~7 extractions). The combined aqueous extracts are lyophilised, and the white residue is dissolved in *n*-BuOH (1ml, absolute) with the addition of enough H_2O to effect solution. Remove insoluble material by centrifugation and add absolute *n*-BuOH to the supernatant. Crystals should separate on scratching, and after 2.5 hours in a refrigerator they are collected, washed with absolute *n*-BuOH and EtOAc and dried (yield 51.4mg). It also crystallises from aqueous Me_2CO. The ***potassium salt*** has **m** 214-217° (dec) (block preincubated at 200°; heating rate of 3°/min) and $[\alpha]_D^{22}$ +285 (c 0.748, H_2O). [*Beilstein* **27** III/IV 5861.]
The ***free acid (penicillin G)*** (**M** 334.5, *[61-33-6]*) has **m 186-187°** (MeOH/Me_2CO), and **m 190-191°** (H_2O) $[\alpha]_D^{25}$ +282 (EtOH). [Review: Sheehan & Henery-Logan *J Am Chem Soc* **84** 2983 *1962*, DOI: 10.1021/ja00874a029; Chain et al. *Antibiotics* (Oxford University Press) **2** *1949*, and Cook *Quarterly Reviews (Chemical Society)* **2** 203 *1948*, DOI: 10.1039/QR9480200203.]

Bergapten (5-methoxypsoralen, 4-methoxy-7*H*-furo[3,2-*g*]chromen-7-one) *[484-20-8]* **$C_{12}H_8O_4$, M 216.2, m 190-193°, 191-193°**. Crystallise it from EtOH or aqueous MeOH, and it sublimes *in vacuo*. Its properties are similar to those of its 9-methoxy isomer (xanthotoxin, see below). It is slightly soluble in $*C_6H_6$, $CHCl_3$ and AcOH but insoluble in H_2O. Its fluorescence has λ_{ex} at 352nm with λ_{em} at 480nm. It is a DNA intercalator and **possible carcinogen**. [Howell & Robertson *J Chem Soc* 293 *1937*, DOI: 10.1039/JR9370000293; Boyer et al. *Biochemistry* **27** 3011 *1988*, DOI: 10.1021/bi00408a052; *Beilstein* **19/6** V 4.] It is present in Bergamot oil [Sakamaki et al. *J Food Hygienic Soc Jpn* **49**(4) 326 *2008*, DOI: 10.3358/shokueishi.49.326, PMID: 18787320].

(+)-Bicuculine [*R*-6(5,6,7,8-tetrahydro-6-methyl-1,3-dioxolo[4,5-*g*]isoquinolin-5-yl)-furo-[3,4-*c*]-1,3-benzo-dioxolo-8(6*H*)-one] *[485-49-4]* **$C_{20}H_{17}NO_6$, M 367.4, m 177°, 193-195°, 193-197°, 215°, $[\alpha]_D^{20}$ +126 (c 1, $CHCl_3$), $[\alpha]_{546}^{20}$ +159 (c 1, $CHCl_3$), pK^{25} 4.84.** It crystallises from $CHCl_3$/MeOH as plates. The crystals melt at 177°, then solidify and re-melt at 193-195° [Manske *Canad J Research* **21B** 13 *1943*, DOI: 10.1139/cjr43b-002]. It is soluble in $CHCl_3$, $*C_6H_6$, EtOAc but sparingly soluble in EtOH, MeOH and Et_2O. [For Stereochemistry see Bláha et al. *Coll Czech Chem Commun* **29** 2328 *1964*, DOI: org/10.1135/cccc19642328; Snatzke et al. *Tetrahedron* **25** 5059 *1969*, DOI: 10.1016/S0040-4020(01)83253-1; Pharmcol: Curtis et al. *Nature* **226** 1222 *1970*, DOI: 10.1038/2261222a0; *Beilstein* **27** III/IV 1900]. It is a light sensitive strong GABAA receptor antagonist. [Khawaled et al. *Pflügers Archiv: Eur J Physiol* **438**(3) 314 *1999*, DOI: 10.1007/s004240050915, ISSN 0031-6768. PMID: 10398861.]

L-*erythro*-Biopterin (2-amino-4-hydroxy-6-[{1*R*,2*S*}-1,2-dihydroxypropyl]pteridine) *[22150-76-1]* **$C_9H_{11}N_5O_3$, M 237.2, m >300°(dec), $[\alpha]_{546}^{20}$ -80, $[\alpha]_D^{20}$ -65 (c 2.0, M HCl), pK_1^{25} 2.23(2.45), pK_2^{25} 7.89(8.05).** Purify L-*erythro*-biopterin by chromatography on Florisil, which was washed thoroughly with 2M HCl, and eluted with 2M HCl. The fractions with UV-fluorescence are pooled, evaporated *in vacuo* and the

residue is recrystallised. Biopterin is best recrystallised (90% recovery) by dissolving in 1% aqueous NH_3 (*ca* 100 parts), and adding this solution dropwise to an equal volume of M aqueous formic acid at 100° and allowing to cool at 4° overnight. It is dried at 20° to 50°/0.1mm in the presence of P_2O_5. [Schircks et al. *Helv Chim Acta* **60** 211 *1977*, DOI: 10.1002/hlca.19770600125; Armarego et al. *Aust J Chem* **35** 785 *1982*, DOI: 10.1071/CH9820785.] It also crystallises from *ca* 50 parts of water or 100 parts of hot 3M aqueous HCl by adding hot 3M aqueous NH_3 and cooling. It has UV with λ_{max} at 212, 248 and 321nm (log ε 4.21, 4.09 and 3.94) in H_2O at pH 0.0; 223infl, 235.5, 274.5 and 345nm (log ε 4.07infl, 4.10, 4.18 and 3.82) in H_2O at pH 5.0; 221.5, 254.5 and 364nm (log ε 3.92, 4.38 and 3.84) in H_2O at pH 10.0. [Sugimoto & Matsuura *Bull Chem Soc Jpn* **48** 3767 *1975*, DOI: 10.1246/bcsj.48.1679 *Beilstein* **26** III/IV 4032.] Several urinary pteridine levels are used as ***potential biomarkers*** for non-invasive diagnosis of cancer [Gamagedara et al. *Clinica Chimica Acta* 1 14 *2011*; PMID: 20869359].

D-(+)-Biotin (vitamin H, hexahydro-2-oxo-1*H*-thieno[3,4-d]imidazole-4-pentanoic acid) *[58-85-5]* **$C_{10}H_{16}N_2O_3S$, M 244.3, m 229-231°, 230.2°(dec), 230-231°, 231-233°, 232-234°(dec), $[\alpha]_{546}^{20}$ +108, $[\alpha]_D^{20}$ +91.3 (c 1, 0.1N NaOH), pK_{Est} ~ 4.8.** D-(+)-Biotin crystallises from hot water in fine long needles with a solubility of 22 mg/100ml at 25°. Its solubility in 95% EtOH is 80 mg/100 ml at 25°. Its isoelectric point is at pH 3.5. Store the solid and solutions under sterile conditions because it is susceptible to mould growth. [Confalone *J Am Chem Soc* **97** 5936 *1975*, DOI: 10.1021/ja00853a061; Wolf et al. *J Am Chem Soc* **67** 2100 *1945*, DOI: 10.1021/ja01228a013; Ohrui & Emoto *Tetrahedron Lett* 2765 *1975*, DOI: 10.1016/S0040-4039(00)75234-8; Harris et al. *J Am Chem Soc* **66** 1756 *1944*, DOI: 10.1021/ja01238a041.] The ***(+)-methyl ester*** has **m 166-167°** (from MeOH/Et_2O), $[\alpha]_D^{22}$ +57 (c 1, $CHCl_3$) [du Vigneaud et al. *J Biol Chem* **140** 643 *1941*, http://www.jbc.org/content/140/2/643; 763 *1941*]; **the *(+)-S-oxide*** has **m 200-203°**, and $[\alpha]_D^{20}$ +130 (c 1.2, 0.1N NaOH) [Melville *J Biol Chem* **208** 495 *1954*, PMID: 13174559]; the ***SS-dioxide*** has **m 274-275°(dec, 268-270°)**, and the ***SS-dioxide methyl ester*** has **m 239-241°** (from MeOH/Et_2O) [Hofmann et al. *J Biol Chem* **141** 207 *1941*,http://www.jbc.org/content/141/1/207]. [*Beilstein* **27** III/IV 7979.] It is a ***coenzyme*** for lipid and protein metabolism, converting food into glucose. Also vital for maintaining skin, hair and mucous membranes.
D-(+)-Biotin hydrazide *[66640-86-6]* **$C_{10}H_{18}N_4O_2S$, M 258.3,** has **m 238-240°, 245-247°, $[\alpha]_D^{20}$ +66 (c 1, Me_2NCHO).** Wash the hydrazide with H_2O, dry it, wash it with MeOH then Et_2O, and dry. Recrystallise it from hot H_2O (clusters of prisms) [Hofmann et al. *J Biol Chem* **144** 513 *1942*, http://www.jbc.org/content/144/2/513]. [*Beilstein* **27** III/IV 7980.]
D-(+)-Biotin N-hydroxysuccinimide ester **(+-biotin *N*-succinimidyl ester)** *[35013-72-0]* **$C_{14}H_{19}N_3O_5S$, M 341.4,** has **m 210°, 212-214°, $[\alpha]_D^{20}$ +53 (c 1, Me_2NCHO).** Recrystallise the ester from refluxing isoPrOH and dry it in a vacuum over P_2O_5 + KOH. Its solubility in dry DMF is ~50mg/ml, and it is stable for at least 30 days at ~20°. Store it at -20°. [Jasiewicz et al. *Exp Cell Biol* **100** 213 *1976*, DOI: 10.1016/0014-4827(76)90344-X.]

D-(+)-Biotin 4-nitrophenyl ester *[33755-53-2]* **$C_{16}H_{19}N_3O_5S$, M 365.4,** has **m 160-163°, 163-165°, $[\alpha]_D^{25}$ +47 (c 2, Me_2NCHO containing 1% AcOH), $[\alpha]_D^{25}$ +51 also reported.** The ester has been recrystallised by dissolving 2g in 95% EtOH (30ml), heated to dissolve, then cooled in an ice-water bath. The crystals are collected, washed with ice-cold 95% EtOH (5ml) and dried over P_2O_5. Its solubility in MeOH is 25mg/ml at ~25° (colourless to green-yellow solution). The R_F on silica plates ($CHCl_3$/MeOH 19:1) is 0.19 [Bodanszky & Fagan *J Am Chem Soc* **99** 235 *1977*, DOI: 10.1021/ja00443a040].
N-(+)-Biotinyl-4-aminobenzoic acid *[6929-40-4]* **$C_{17}H_{21}N_3O_4S$, M 363.4,** has **m 295-297°, 295-300°, $[\alpha]_D^{23}$ +56.55 (c 0.5, 0.1N NaOH), pK_{Est} ~4.0.** Dissolve the acid in $NaHCO_3$ solution, cool and precipitate it by adding N HCl. Collect the solid, dry it at 100° and recrystallise it from MeOH. ***Note*** that it is hydrolysed by aqueous 3M, 1M and 0.2M HCl at 120°, but can be stored in 5% aqueous $NaHCO_3$ at -20° without appreciable hydrolysis [Knappe et al *Biochem Zeitschrift*. **338** 599 *1963*, PMID: 14087327; Wolf et al. *J Am Chem Soc* **73** 4142 *1951*, DOI: 10.1021/ja01153a027; Bayer & Wilchek *Methods Enzymol* **26** 1 *1980*]. [*Beilstein* **27** III/IV 7984.] It is a substrate used in biotinidase assays [Craft et al. *Biochemistry* **24** 2471 *1985*, DOI: 10.1021/bi00331a012; Hayakawa & Oizumi *J Chromatogr* **383**(1) 148 *1986*, PMID: 3493251].
N-Biotinyl-6-aminocaproic N-succinimidyl ester *[72040-63-2]* **$C_{20}H_{30}N_4O_6S$, M 454.5,** has **m 149-152°**, **169-171°**. Dissolve ~400mg of the ester in dry propan-2-ol (~25ml) with gentle heating. Reduce the volume to ~10ml by gentle boiling and allow the solution to cool. Decant the supernatant carefully from the white crystals, dry the crystals in a vacuum over P_2O_5 at 60° overnight. This material gives one spot on TLC. [Costello et al.

Clin Chem **25** 1572 *1979*, PMID: 572747; Kincaid et al. *Methods Enzymol* **159** 605 *1988*, DOI: 10.1016/0076-6879(88)59058-4; PMID: 2842624.]

***N-(+)-Biotinyl-6-aminocaproyl hydrazide* (biotin-6-aminohexanoic hydrazide)** *[109276-34-8]* **$C_{16}H_{29}N_5O_3S$, M 371.5,** has **m 189-191°, 195-196°, 210°, $[\alpha]_D^{20}$ +23 (c 1, Me_2NCHO).** Suspend the hydrazide in ice-water (100mg/ml), stand overnight at 4°, filter and dry the solid in a vacuum. Recrystallise it from isoPrOH. Its solubility in DMSO is ~25mg/ml at ~25°. R_F is 0.26 on SiO_2 plate using $CHCl_3$/MeOH (7:3) as eluent. [O'Shannessy et al. *Anal Biochem* **163** 204 *1987*, DOI: 10.1016/0003-2697(87)90114-X.]

N-(+)-Biotinyl-L-lysine* (Biocytin)** *[576-19-2]* **$C_{16}H_{28}N_4O_4S$, M 372.5,** has **m 228.5°, 228-230° (dec), 241-243°, 245-252° (dec, sintering at 227°), $[\alpha]_D^{25}$ +53 (c 1.05, 0.1 N NaOH).** Recrystallise biocytin rapidly from dilute MeOH or Me_2CO. It can also be recrystallised from H_2O by slow evaporation or by dissolving in the minimum volume of H_2O and adding Me_2CO until a solid separates. It is freely soluble in H_2O and AcOH but insoluble in Me_2CO. [Wolf et al. *J Am Chem Soc* **74** 2002 *1952*, DOI: 10.1021/ja01128a039; **72** 1048 *1950*, DOI: 10.1021/ja01158a534.] It has been purified by chromatography on superfiltrol-Celite, Al_2O_3 and by countercurrent distribution and then recrystallised [IR: Peck et al. *J Am Chem Soc* **74** 1999 *1952*, DOI: 10.1021/ja01128a038]. The ***hydrochloride crystallises from aqueous Me_2CO/HCl and has **m 227°(dec)**. [*Beilstein* **27** III/IV 7984.] Intermediate in biotin metabolism found in serum and urine. I, M 317.2, m 171-174°, 173-176°.** Recrystallise S-butyryl thiocholine iodide from propan-1-ol and dry it *in vacuo*; store it in the dark under N_2. The ***bromide*** has **m 150°** (from Me_2CO) or **m 140-143°** (from butan-1-ol). [Gillis *Chem Ind (London)* 111 *1957*, Hansen *Acta Chem Scand* **11** 537 *1957*, DOI: 10.3891/acta.chem.scand.11-0537; *Beilstein* **4** IV 1586.]

Carbamazepine (Tegretol, 5*H*-dibenzo[*b*,*f*]azepine-5-carboxamide) *[298-46-4]* **$C_{15}H_{12}N_2O$, M 236.3, m 189-192°, 190-193°, 191-192°, 204-206°.** Recrystallise from EtOH/*C_6H_6, and dry *in vacuo*, or recrystallise it from EtOH then from *C_6H_6. It is soluble in Me_2CO EtOH and propylene glycol, but not in H_2O. Schindler [**US 2948718,** *1960* to Geigy] prepared it **in an efficient fume cupboard** from 5*H*-dibenzo[*b*,*f*]azepine (19.3 g, *[256-96-2]*) and phosgene (**suffocating and poisonous**) in toluene to give ***5H-dibenzo[b,f]azepine-5-carbonyl chloride*, m 168-169°**. **Also in an sufficient fume cupboard**, the acid chloride in absolute EtOH and NH_3 gas provides the desired ***azepine*, m 204-206°**, after washing with H_2O an recrystallising from absolute EtOH then from *C_6H_6. Its UV has λ_{max} (MeOH) at 237and 285nm; the IR has ν_{max} (KBr) at 1678, 1594, 1298, 800, 787, 769 cm^{-1}. It is an ***anticonvulsant*** and ***Na^+ channel inhibitor***. [Stenger & Roulet *Med Exp Int J Exp Med* **11** 191 *1964*, ISSN/ISBN: 0258-2589.] It is used in ***epilepsy*** [Livingston et al. *JAMA* **200** 204 *1967*, DOI: 10.1001/jama.1967.03120160070009] and pain associated with neuralgia [Scott in 'Carbamazepine' in The History of Epileptic Therapy, History of Medicine Series. CRC Press, *1993*, ISBN 9781850703914; Sidebottom & Maxwell *J Clin Pharm Ther* **20** 31 *1995*, PMID: 7775611.]

Cation exchange resins. These should be conditioned before use by successive washing with water, EtOH and water, and taken through two H^+-OH^--H^+ cycles by successive M HCl, water, M NaOH, water and M HCl treatment, then washed with water to give the ***H^+ form***. (See commercial catalogues on ion exchange resins).

Cephalosporin C potassium salt *[28240-09-7]* **$C_{16}H_{22}N_3O_2S.H_2O$, M 453.5 (nhydrous), $[\alpha]_D^{20}$ +103 (H_2O), pK_1 <2.6, pK_2 3.1, pK_3 9.8.** Purify the salt by dissolving it in the minimum volume of H_2O (filter) and adding EtOH until separation of solid is complete. A solution is stable in the pH range 2.5-8. It has UV with λ_{max} at 260nm (log ε 3.95) in H_2O. The ***Ba salt*** has $[\alpha]_D^{20}$ +80 (c 0.57, H_2O) [Woodward et al. *J Am Chem Soc* **88** 852 *1966,* DOI: 10.1021/ja00956a051; Abraham & Newton *Biochem J* **79** 377 *1961*, DOI: 10.1042/bj0790377; Hodgkin & Maslen *Biochem J* **79** 393 *1961*, DOI: 10.1042/bj0790393; see also Abraham *Quarterly Reviews London* **21** 231 *1967*, DOI: 10.1039/QR9672100231]. [*Beilstein* **27** III/IV 5902.] Antibiotic similar to penicillin.

Chlorambucil [Leukeran, 4-{bis(2-chloroethyl)amino)-phenylbutyric acid] *[305-03-3]* **$C_{14}H_{19}Cl_2NO_2$, M 304.2, m 64-66°, pK_1 5.8 (6.0 at 66°, 50% aqueous Me_2CO), pK_2 8.0.** Chlorambucil is recrystallised from petroleum ether (flat needles) and has a solubility at 20° of 66% in EtOH, 40% in $CHCl_3$, 50% in Me_2CO but is insoluble in H_2O [Everett et al. *J Chem Soc* 2386 *1953*, DOI: 10.1039/JR9530002386]. [As a substrate for the human glutathione transferase P1-1 see Parker et al. *J Mol Biol* **380**(1) 131 *2008*, DOI: 10.1016/j.jmb.2008.04.066; *Beilstein* **14** IV 1715.] It is a ***chemotherapeutic*** drug for treating chronic lymphocytic leukemia, low grade Hodgkin and non-Hodgkin lymphoma. **CARCINOGEN**.

Chloramphenicol [Amphicol, 1*R*,2*R*-(-)-2-{2,2-dichloroacetylamino}-1-{4-nitrophenyl}-propan-1,3-diol] *[56-75-7]* **$C_{11}H_{12}Cl_2N_2O_5$, M 323.1, m 149-151°, 150-151°, 151-152°, $[\alpha]_D^{20}$ +20.5 (c 3, EtOH), $[\alpha]_D^{25}$ -25.5 (EtOAc).** Purify this broad-spectrum antibiotic by recrystallisation from H_2O (solubility is 2.5mg/ml at 25°) or ethylene dichloride as needles or long plates, and by sublimation at high vacuum. It has $A_{1cm}^{1\%}$ 298 at λ_{max} 278nm, and it is slightly soluble in H_2O (0.25%) and propylene glycol (1.50%) at 25° but is freely soluble in MeOH, EtOH, BuOH, EtOAc and Me_2CO. [Rebstock et al. *J Am Chem Soc* **71** 2458 *1949*, DOI: 10.1021/ja01175a065; Controulis et al. *J Am Chem Soc* **71** 2463 *1949*, DOI: 10.1021/ja01175a066; Long & Troutman *J Am Chem Soc* **71** 2469, *1949*, DOI: 10.1021/ja01175a067; 2473 *1949*, DOI: 10.1021/ja01175a068; Ehrhart et al. *Chem Ber* **90** 2088 *1957*, DOI: 10.1002/cber.19570900957; *Beilstein* **13** IV 2742.] It inhibits bacterial protein synthesis. ***Chloramphenicol palmitate*** **(Vetranal)** *[530-43-8]* **$C_{27}H_{42}Cl_2N_2O_6$, M 561.5,** has **m 90°, $[\alpha]_D^{26}$ +24.6 (c 5, EtOH).** The palmitate crystallises from *benzene or xylene with **m 105-106°** and $[\alpha]_D^{21}$ –39.5 (c 2, Et_2O), λ_{max} 267.3nm. [Edgerton et al. *J Am Chem Soc* **77** 27 *1955*, DOI: 10.1021/ja01606a007; *Beilstein* **13** IV 2753.]

2-Chloroadenosine *[146-77-0]* **$C_{10}H_{12}ClN_5O_4$, M 301.7, m 145-146°(dec), 147-149°(dec), $pK_{Est(1)}$~ 0.5, $pK_{Est(2)}$~ 7.6.** Purify 2-chloroadenosine by recrystallisation from H_2O (~1% in cold), and it has UV with λ_{max} at 264 nm (pH 1 and 7) and 265 nm (pH 13) in H_2O. [Brown & Weliky *J Org Chem* **23** 125 *1958*, DOI: 10.1021/jo01095a626; Schaeffer & Thomas *J Am Chem Soc* **80** 3738 *1958*, DOI: 10.1021/ja01547a068; IR: Davoll & Lowy *J Am Chem Soc* **74** 1563 *1952*, DOI: 10.1021/ja01126a066; *Beilstein* **26** III/IV 3725.] It is a selective adenosine A_1 receptor agonist.

Chlorophyll *a* *[479-61-8]* **$C_{55}H_{72}MgN_4O_5$, M 983.5, m 117-120°, 150-153°, ~152.3°(dec), 178-180° (sinters at ~150°), $[\alpha]_D^{20}$ -262 (Me_2CO).** It forms green crystals from Me_2CO, Et_2O/H_2O, Et_2O/hexane/H_2O or Et_2O/pentane /H_2O. It is sparingly soluble in MeOH and insoluble in petroleum ether. In alkaline solution it gives a blue-green colour with deep red fluorescence. A very crude chlorophyll mixture has been purified by chromatography on low melting polyethylene (MI 0.044; 'Dow' melting index MI <2) and developed with 70% aqueous Me_2CO. The order of effluent from the bottom of the column is: xanthophylls, chlorophyll *b*, chlorophyll *a*, phaeophytins and carotenes. A mixture of chlorophylls *a* and *b* is best separated by chromatography on sugar, and the order is chlorophyll *b* elutes first followed by chlorophyll *a*. To an Me_2CO/H_2O solution of chlorophylls 200ml of iso-octane are added, and the mixture shaken in a separating funnel and the H_2O is carefully removed. The iso-octane layer is dried (Na_2SO_4) and applied onto a glass column (5cm diameter) dry packed with 1000ml of powdered sucrose which has been washed with 250ml of iso-octane. Elution with 0.5% of isopropanol in iso-octane gives chlorophyll *a*. Keeping the eluate overnight at 0° yields micro crystals which are collected by filtration or centrifugation (Yield 40mg). It is insoluble in H_2O but soluble in many organic solvents. The UV_{EtOH} has λ_{max} **660**, 613, 577, 531, 498, **429** and 409 nm. ***Note*** that ***anhydrous*** chlorophylls can be easily enolised, epimerised or allomerised in dry polar organic solvents. [Anderson & Calvin *Nature* **194** 285 *1962*, DOI: 10.1038/194285a0; Stoll & Weidemann *Helv Chim Acta* **16** 739 757 *1933*, DOI: 10.1002/hlca.193301601100; NMR: Katz et al. *J Am Chem Soc* **90** 6841 *1968*, DOI: 10.1021/ja01026a050; **85** 3809 *1963*, DOI: 10.1021/ja00906a020; for *a* and *b* ORD see Wolf et al. *Justus Liebigs Ann Chem* **704** 208 *1967*, DOI: 10.1002/jlac.19677040123; Willstätter & Isler *Justus Liebigs Ann Chem* **390** 269 *1912*, DOI: 10.1002/jlac.19123900302; *Beilstein* **26** III/IV 3243.] ***Chlorophyll b*** *[519-62-0]* **$C_{55}H_{70}MgN_4O_6$, M 907.52, sinters at 86-92°, sinters at 170°, dec at 160-170°,** has **m 183-185°**, **190-195°, $[\alpha]_D^{20}$ -267 (Me_2CO/MeOH), $[\alpha]_{720}^{25}$ -133 (MeOH/Pyridine 95:5).** See purification of chlorophyll *a*, and is separated from '*a*' by chromatography on sucrose [UV, IR: Stoll & Weidemann *Helv Chim Acta* **42** 679, 681 *1959*, DOI: 10.1002/hlca.19590420307]. It forms red-black hexagonal bipyramids or four-sided plates from dilute EtOH and has been recrystallised from $CHCl_3$/MeOH. It is insoluble in H_2O, but soluble in MeOH, EtOH, EtOAc and insoluble in petroleum ether. [Dougherty et al. *J Am Chem Soc* **88** 5037 *1966*, DOI: 10.1021/ja00973a056; *Beilstein* **26** III/IV 3787.] These are plant pigments in the light-energy harvesting system.

6-Chloropurine riboside (6-chloro-9-β-D-ribofuranosyl-9*H*-purine) *[2004-06-0, 5399-87-1]* **$C_{10}H_{11}ClN_4O_4$, M 286.7, m 158-162°(dec), 165-166°(sintering at 155°), 168-170°(dec), $[\alpha]_D^{26}$ -45 (c 0.8, H_2O).** Purify the riboside by suspending the dry solid (~12 g) in hot MeOH (130 ml) and then adding enough hot H_2O (~560ml) to cause solution, filter and set aside at 5° overnight. The colourless crystals of the riboside are filtered off, washed with Me_2CO, Et_2O and dried at 60°/0.1mm. More materialcan be obtained by evaporat-

ing the filtrate to dryness and recrystallisation of the residue from MeOH/H_2O (2:1) (15ml/g). It has UV with λ_{max} at 264nm (ε 9140) in H_2O. [Robins *Biochemical Preparations* **10** 145 *1963*, Baker et al. *J Org Chem* **22** 954 *1957*, DOI: 10.1021/jo01359a027.] It is a substrate for adenosine deaminase.

Chromomycin A_3 *[7059-24-7]* **$C_{57}H_{82}O_{26}$, M 1183.3, m 185°dec, $[\alpha]_D^{23}$ -57 (c 1, EtOH).** Dissolve the anthraquinone glycoside antibiotic (10g) in EtOAc and add to a column of Silica Gel (Merck 0.05-0.2microns, 4x70cm) in EtOAc containing 1% oxalic acid. Elute with EtOAc+1% oxalic acid and check fractions by TLC. Pool the fractions, wash with H_2O thoroughly, dry and evaporate. Recrystallise the residue from EtOAc. The ***heptaacetate*** has **m** 214°, $[\alpha]_D^{23}$ -20 (c 1, EtOH). [Miyamoto et al. *Tetrahedron* **23** 421 *1967*, DOI: 10.1016/S0040-4020(01)83328-7; Harada et al. *J Am Chem Soc* **91** 5896 *1969*, DOI: 10.1021/ja01049a047; *Beilstein* **17/5** V 673.] It is a fluorescent DNA-binding dye specific for GC residues.

8*S*,9*R*-(-)-Cinchonidine *[485-71-2]* **$C_{19}H_{22}N_2O$, M 294.4, m 204-205°, 210.5°, $[\alpha]_{546}^{20}$ -127.5 (c 0.5, EtOH), $[\alpha]_D^{20}$ -109.2 (EtOH), pK_1^{15} 4.17, pK_2^{15} 8.4, pK_1^{20} 5.80, pK_2^{20} 10.03.** Crystallise cinchonidine from aqueous EtOH (prisms or plates). It is a strong base and readily forms a ***mono-*** and ***di- hydrochloride*** and other stable salts. Slightly soluble in Et_2O, but very soluble in EtOH and $CHCl_3$. For ***N-benzylcinchonidinium chloride*** see *[69257-04-1]*. Coenzyme Q_o (Ubiquinone, 2,3-dimethoxy-5-methyl-1,4-benzoquinone, 3,4-dimethoxy-2,5-toluquinone, fumigatin methyl ether) *[605-94-7]* **$C_9H_{10}O_4$, M 182.2, m 56-58°, 58-60°, 59°, 59-60°.** It crystallises in red needles from petroleum ether (b 40-60°) and sublimes at high vacuum at a bath temperature of 46-48° [Anslow et al. *J Chem Soc* 439 *1938*, DOI: 10.1039/JR9380000439; UV in EtOH: Vischer *J Chem Soc* 815 *1953*, DOI: 10.1039/JR9530000815; for UV in cyclohexane see Morton et al. *Helv Chim Acta* **41** 2343 *1958*, DOI: 10.1002/hlca.19580410745; Aghoramurthy et al. *Chem Ind (London)* 1327 *1954*]. [*Beilstein* **8** IV 2721.]

Coenzyme Q_4 (Ubiquinone-4, 2,3-dimethoxy-5-methyl-6-[3,7,11,15-tetramethyl-hexadeca-2*t*,6*t*,10*t*,14-tetraenyl]-1,4-benzoquinone) *[4370-62-1]* **$C_{29}H_{42}O_4$, M 454.7, m 30°, 33-45°.** It is a red oil which can be purified by chromatography on SiO_2 plates and eluted with Et_2O/hexane. The purity is checked by HPLC (silica column using 7% Et_2O/hexane). It has UV with λ_{max} at 270 nm (ε 14,800) in petroleum ether. [NMR and MS: Naruta *J Org Chem* **45** 4097 *1980,* DOI: 10.1021/jo01309a006; cf. Morton *Biochemical Spectroscopy* (Adam Hilger, London, *1975*) p 491]. It has also been dissolved in MeOH/EtOH (1:1 v/v) and kept at 5° until crystals appear [Lester et al. *Biochim Biophys Acta* **32** 492 *1958*, DOI: 10.1016/0006-3002(59)90624-9; Belogrudov et al. *Arch Biochem Biophys* **392**(1) 48 *2001*, DOI: 10.1006/abbi.2001.2448, PMID: 11469793]. It is an essential component of cellular electron transport.

Coenzyme Q_9 (Ubiquinone-9, 2,3-dimethoxy-5-methyl-6-[3,7,11,15,19,23,27,31,35-nonamethylhexatriaconta-2*t*,6*t*,10*t*,14*t*,18*t*,22*t*,26*t*,30*t*,34-nonaenyl]-1,4-benzoquinone) *[303-97-9]* **$C_{54}H_{82}O_4$, M 795.3, m 40.5-42.5°, 44-45°, 45°.** The yellow crystals are purified by recrystallisation from petroleum ether and by chromatography on SiO_2 plates and eluted with Et_2O/hexane. The purity can be checked by HPLC (silica column using 7% Et_2O/hexane). It has UV with λ_{max} at 270nm (ε 14,850) in petroleum ether. [NMR and MS: Naruta *J Org Chem* **45** 4097 *1980,* DOI: 10.1021/jo01309a006; Lester et al. *Biochem Biophys Acta* **32** 492 *1958*, DOI: 10.1016/0006-3002(59)90624-9; cf. Morton *Biochemical Spectroscopy* (Adam Hilger, London, 1975) p 491, IR: Lester et al. *Biochim Biophys Acta* **33** 169 *1959*, DOI: 10.1016/0006-3002(59)90511-6; UV: Rüegg et al. *Helv Chim Acta* **42** 2616 *1959*, DOI: 10.1002/hlca.19590420733; Shunk *J Am Chem Soc* **81** 5000 *1959*, DOI: 10.1021/ja01527a062; *Beilstein* **8** IV 3313.] A membrane component of proton/electron transport.

Coenzyme Q_{10} $C_{59}H_{90}O_4$, M 863.4, (Ubiquinone-10, 2,3-dimethoxy-5-methyl-6-[3,7,11,15,19,23,27,31,35,-39-decamethyltetra-conta-2*t*,6*t*,10*t*,14*t*,18*t*,22*t*,26*t*,30*t*,34*t*,38-decaenyl]-1,4-benzoquinone) *[303-98-0]* **M 795.3, m 48-49°,49°, 49.5-50.5°, 50°, 48-52°.** Purify this yellow-orange solid by recrystallisation from EtOH,

EtOH/Me_2CO or Et_2O/EtOH and by chromatography on silica gel using isoPrOH/Et_2O (3:1) to give orange crystals. It has UV with λ_{max} at 270nm (ε 15,170) in petroleum ether. [Terao et al. *J Org Chem* **44** 868 *1979*, DOI: 10.1021/jo01319a051; for NMR and MS see Naruta et al. *J Org Chem* **45** 4097 *1980*, DOI: 10.1021/jo01309a006; for properties of the coenzyme Q compounds see Lester et al. *Biochem Biophys Acta* **33** 169 *1959*, DOI: 10.1016/0006-3002(59)90511-6; NMR: Planta et al. *Helv Chim Acta* **42** 1278 *1959*, DOI: 10.1002/hlca.19590420423; Morton *Biochemical Spectroscopy* (Adam Hilger, London, 1975) p 491].

Colcemid {Demecolcine, (7S)-6,7-dihydro-1,2,3,10-tetramethoxy-7-(methylamino)-benzo[a]heptalen-9(5H)-one} *[477-30-5]* **$C_{21}H_{25}NO_5$, M 371.4, m 182-185°, 183-185°, 186°, $[\alpha]_D^{20}$ -129 (c 1, $CHCl_3$).** Colcemid is purified by chromatography on silica and eluting with $CHCl_3$/MeOH (9:1), and by recrystallisation from EtOAc/Et_2O to form yellow prisms. Store it at -20°. Its UV in EtOH has λ_{max} at 243nm (ε 30,200) and 350nm (ε 16,3000). [Synthesis, IR, NMR, MS: Capraro & Brossi *Helv Chim Acta* **62** 965 *1979*, DOI: 10.1002/hlca.19790620406; *Beilstein* **8** IV 3319.] It is less toxic than colchicine (see below), and an antineoplastic agent affecting the mitotic cycle: Rieder & Palazzo *J Cell Sci* **102** 387 *1992*, PMID: 1506421.

Colchicine {*N*-[(7*S*)-1,2,3,10-tetramethoxy-5,6,7,9-tetrahydro-9-oxo-benzo[*a*]heptalen-7-yl]-acetamide} *[64-86-8]* **$C_{22}H_{25}NO_6$, M 399.5, m 150-160° (dec), 155-157°(dec), 156-157°, $[\alpha]_{546}^{20}$ -570 (c 1, H_2O), $[\alpha]_D^{20}$ -443 (c 1.7, H_2O), $[\alpha]_D^{20}$ -120 (c 1, $CHCl_3$), pK^{20} 1.85 and 12.4.** Commercial material contains up to 4% desmethylcolchicine. Purify colchicine by chromatography on alumina and eluting with $CHCl_3$ [Ashley et al. *J Chem Soc* 677 *1944*, DOI: 10.1039/JR9440000677]. *Alternatively*, an acetone solution on alkali-free alumina has been used, and eluting with acetone [Nicholls & Tarbell *J Am Chem Soc* **75** 1104 *1953*, DOI: 10.1021/ja01101a028]. It crystallises as yellow needles from EtOAc or $CHCl_3$ with solvent of crystallisation which can be removed at ~70°. It is soluble in Et_2O (0.5%), $*C_6H_6$ (1%) and H_2O (4%). It is sold as '**Colgout**' for the treatment of gout and ***binds to tubulin***. [Schreiber et al. *Helv Chim Acta* **44** 540 *1961,* DOI: 10.1002/hlca.19610440225; Scott et al. *Tetrahedron* **21** 3605 *1965*, DOI: 10.1016/S0040-4020(01)96977-7; van Tamelen et al. *Tetrahedron* **14** 8 *1961*, DOI: 10.1016/0040-4020(61)80083-5; *Beilstein* **14** IV 946.]

Compactin [Mevastatin, 1*S*,7*R*,8*S*,8a*R*)-8-{2-[(2*R*,4*R*)-4-Hydroxy-6-oxotetrahydro-2*H*-pyran-2-yl]ethyl}-7-methyl-1,2,3,7,8,8a-hexahydronaphthalen-1-yl (2*S*)-2-methylbutanoate] *[73573-88-3]* **$C_{23}H_{34}O_5$, M 390.5, m 151-153°, 152°, $[\alpha]_D^{22}$ +283 (c 0.48, acetone).** Purify compactin by recrystallisation from aqueous EtOH. Its UV (EtOH) has λ_{max} at 230, 237 and 246nm (log ε 4.28, 4.30 and 4.11); and its IR (KBr) has ν_{max} 3520, 1750 (lactone CO) and 1710 (CO ester) cm^{-1}. [Clive et al. *J Am Chem Soc* **110** 6914 *1988* DOI: 10.1021/ja00228a067; Review: Rosen & Heathcock *Tetrahedron* **42** 4909 *1986*, DOI: 10.1016/S0040-4020(01)88045-5; IR, NMR, MS: Brown et al. *JCS Perkin Trans 1* 1165 *1976*, DOI: 10.1039/P19760001165.] It is a ***statin*** and a ***potent inhibitor of 3-hydroxy-3-methylglutaryl-CoA reductase*** (HMG-CoA reductase) which inhibits cholesterol biosynthesis, and lowers cholesterol levels [Brown et al. *J Biol Chem* **253** 1121 *1978*, PMID: 624722; Nakamura & Abeles *Biochemistry* **24** 1364 *1985*, DOI: 10.1021/bi00327a014; *Beilstein* **18/3** V 145].

Creatinine [2-amino-1-methylimidazolidin-4-one, 2-imino-1-methyl-4(3*H*)-oxoimidazolidine] *[60-27-5]* **$C_4H_7N_3O$, M 113.1, m 295°(dec), ~305°(dec), pK_1^{25} 4.80, pK_2^{25} 9.2.** Likely impurities are creatine and ammonium chloride. Dissolve it in dilute HCl, then neutralise with ammonia. Recrystallise it from H_2O by adding excess of Me_2CO. The ***picrate*** crystallises from 23 volumes of boiling H_2O and has **m** 220-221°(dec). [King *J Chem Soc* 2377 *1930*, DOI: 10.1039/JR9300002374; *Beilstein* **25** III/IV 3543.] Serum creatinine is an important indicator of renal function. The ratio of creatinine in blood to that in urine allows calculation of the ***GFR*** (glomerular filtration rate), an indication of renal health. [Taylor *Clinical Chemistry* John Wiley & Sons, NY. pp. 4, 58–62 *1989*; Shemesh et al. *Kidney Int*. **28**(5) 830 *1985*, DOI: 10.1038/ki.1985.205. PMID: 2418254

Crotaline (monocrotaline, 12,13-dihydroxy-(13β-14β*H*)-14,19-dihydro-20-norcrotalanan-11,15-dione) *[315-22-0]* **$C_{16}H_{23}NO_6$, M 325.4, m 196-197°(dec), 197-198°(dec), 203°(dec), 204°(dec), $[\alpha]_D^{20}$ -55 (c 1, EtOH).** Crotaline (a pyrrolizidine alkaloid) forms prisms from absolute EtOH and crystallises also from $CHCl_3$. Its UV(96% EtOH) has λ_{max} at 217nm (log ε 3.32). [Adams et al. *J Am Chem Soc* **74** 5612 *1952*, DOI: 10.1021/ja01142a021; Culvenor & Smith *Aust J Chem* **10** 474 *1957*, DOI: 10.1071/CH9570474.] The ***hydrochloride*** has **m 212-214°** (from MeOH/Et_2O) and $[\alpha]_D^{28}$ -38.4 (c 5, H_2O) [Adams & Gianturco *J Am Chem Soc* **78** 1922 *1956*, DOI: 10.1021/ja01590a041]. The ***picrate*** has **m 230-231.5°(dec)** [Adams et al. *J Am Chem Soc* **74** 5612 *1952*, DOI: 10.1021/ja01142a021]. [*Beilstein* **27** III/IV 6660.] Present in ***Crotalinae*** **snakes** (pit

vipers, rattlesnakes, copperhead, cottonmouth, adders), and as alkaloids in Seneceae (***Polygala* senega**) and Retrorseae plants. [Ruan et al. *Chem Res Toxicol* **6** 16 *2014*, PMID: 24836403; Culvenor et al. *Ann NY Acad Sci* **163** 837 *1969*, DOI: 10.1111/j.1749-6632.1969.tb24903.x].

Curcumin [bis(4-hydroxy-3-methoxycinnamoyl)methane, 1,7-bis(4-hydroxy-3-methoxyphenyl)(1*E*,6*E*)-1,6-heptadiene-3,5-one] *[458-37-7]* **$C_{21}H_{20}O_6$, M 368.4, m 182°, 183°, 184-195°, 184-186°, pK^{25} 9.30 (50% v/v aqueous EtOH), pK$_1$ 7.80, pK$_2$ 8.5 and pK$_3$ 9.0 (H_2O).** Purify curcumin (principal cucuminoid of turmeric) by recrystallising it from MeOH, EtOH or acetic acid (yellow, orange-yellow prisms) and drying it *in vacuo*. It is best separated from related compounds by HPLC (see refs below). It is sparingly soluble in H_2O but soluble in AcOH and in alkaline buffer. In solution at pH 1-7 the colour is yellow and at pH 7-9 the colour is brownish-red or deep red. It was commercialised as a pH indicator under the name of '***curcuma paper***'. Curcumin is a phenolic substance which occurs naturally in ***Curcuma domestica***, ***C. xanthorrhiza***, ***C. aromatica***, ***C. longa***, and is used in Indian curry cooking as ***turmeric***. It has many physiological properties including anti-oxidant, anti-inflammatory, potent anti-tumour, and is an inhibitor of several enzymes (EGFR tyrosine kinase, IkB kinase, nitric oxide synthase, cyclooxygenase, lipoxygenase). It penetrates cell membranes accumulating in plasma membranes, nuclear envelope and endoplasmic reticulum. Its UV-VIS has λ_{max} (log ε)(EtOH) at 268 (4.09) and 430nm (4.74), (dioxane) at 265 (4.18) and 420nm (4.37) and (40% aqueous THF) at 429nm (4.780), with fluorescence maxima at λ_{excit} 433nm and λ_{emis} 511nm in 40% aqueous THF. Its IR (KBr) has ν_{max} at 3400 (br), 1625, 1600, 1500, 1275, 1025, 960 cm^{-1}. The ^{1}H NMR [400MHz, $CDCl_3$] has δ at 6.06 (1H, s, H-4), 16.41 (1H, br s, OH), 7.57 (2H, d, *J* = 16.0Hz, H-2,6), 6.75 (2H, d, *J* = 16.0Hz, H-1,7), 7.32 (2H, d, *J* = 2.0Hz, H-2',2"), 9.64 (2H, s, OH-4',4"), 6.85 (2H, d, *J* = 8.1Hz, H-5',5"), 7.16 (2H, dd, *J* = 2.0, 8.1Hz, H-6',6"), 3.85 (6H, s, 3',3" OMe) (from TMS); and the ^{13}C NMR [100MHz, $CDCl_3$] has δ at 100 (C-4), 183.2 (C-3,5), 121.1 (C-2,6), 140.7 (C-1,7), 126.4 (C-1',1"), 111.5 (C-2',2"), 148.0 (C-3',3"), 149.4 (C-4',4"), 115.8 (C-5',5"), 123.0 (C-6',6"), 55.7 (O***C***H_3) (from TMS). It ***complexes*** strongly with boron, iron, copper and nickel, but weakly with calcium and magnesium. As a 0.1% solution in AcOH it is used for the spectrophotometric determination of Boron as a complex with λ_{max} 550nm (ε180,000). [Dyrssen et al. *Analyt Chim Acta* **60** 139 *1972*, DOI: 10.1016/S0003-2670(01)81893-6; Spicer & Strickland *Analyt Chim Acta* **18** 231 *1958*, DOI: 10.1016/S0003-2670(00)87133-0; Roughley & Whiting, *JCS Perkin Trans I* 2379 *1973*, DOI: 10.1039/P19730002379; Zsila et al. *Tetrahedron Asymm* **14** 2433 *2003*, DOI: 10.1016/S0957-4166(03)00486-5; cf. The ***dimethyl derivative*** [***1,7-bis(3,4-dimethoxyphenyl)(1E, 6E)-1,6-heptadiene-3,5-one***] has **m 128-130°, M 396.2;** the UV has λ_{max} at 427nm, and the ^{1}H NMR [200MHz, $CDCl_3$] has δ at 3.92 (6H, s, 2 x CH_3O-Ph), 3.93 (6H, s, 2 x CH_3O-Ph), 5.82 (1H, s, H-4), 6.45 (2H, d, *J* = 13Hz, H-1,2), 6.86 (6H, m, Arom-H), 7.57 (2H, d, *J* = 13Hz, H-6,7) [Nurfina et al. *Eur J Med Chem* **32** 321 *1997*, DOI :10.1016/S0223-5234(97)89084-8].

5'-Methoxycurcumin [1-(4-hydroxy-3,5-dimethoxyphenyl)-7-(4-hydroxy-3-methoxyphenyl)-(1*E*,6*E*)-1,6-hepta-diene-3,5-one] **M 398.4**, has **m 145-146°** (from MeOH), and was isolated as a yellow powder from *C. **xanthorrhiza*** with UV λ_{max} at 429nm in MeOH.

1-Hydroxycurcumin [1-hydroxy-1,7-bis(4-hydroxy-3-methoxyphenyl)-(6*E*-6-heptene-3,5-dione] **m 84-88°** was isolated from the same source, had UV with λ_{max} at 372nm in MeOH and had a weaker antioxidant activity than the other curcumins towards the autoxidation of linoleic acid in a water-alcohol system [Masuda et al. *Phytochemistry* **31** 3645 *1992*, DOI: 10.1016/0031-9422(92)83748-N]. An optically active form, **(1ξ)-1-hydroxy-1,7-bis(4-hydroxy-3-methoxyphenyl)-(1*E*,6*E*)-1,6-heptadiene-3,5-one**, has **m 92.0-96.0°**, with **$[\alpha]_D$ +12.2 (c 0.06, EtOH, configuration unknown)**, **M 386.4**. Its UV has λ_{max} nm (ε)(MeOH) at 230 (sh), 260 (21000), 283 (18000), 370 (56000); and its IR ($CDCl_3$) has ν_{max} at 965, 1000, 1120, 1260, 1325, 1375, 1460, 1560, 1600, 1620, 1650, 2850, 2900, 3525 cm^{-1}. Its ^{1}H NMR [270MHz, $CDCl_3$] has δ at 2.65(1H, dd, *J* = 17, 3.5Hz), 2.93 (1H, dd, *J* = 17, 14Hz), 3.93 (3H, s), 3.95 (3H, s), 5.39 (1H. dd, *J* = 14, 3.5Hz), 5.60 (1H, s), 5.80 (1H, br s, disappeared on addition of D_2O), 5.86 (1H, br s, disappeared on addition of D_2O), 6.44 (1H, d, *J* = 16Hz), 6.90 (1H, d, *J* = 8Hz), 7.00 (4H, br s), 7.03 (1H, dd, *J* = 8, 2Hz), 7.30 (1H, d, *J* = 16Hz) and R_F (Silica gel 60 F_{254}, C_6H_6*/EtOAc 1:1) of 0.2. When this ***hydroxyheptadiene*** was heated at 130°/<15mmHg/10 hours it gave ***curcumin*** in 79% yield. ***(3S,5S)-1,7-Bis(4-hydroxy-3-methoxyphenyl)heptane-3,5-diol*** [colourless needles **m 132-134°**, with **$[\alpha]_D$ -18.5 (c 0.26, EtOH)**, R_F 0.1] was also isolated from the rhizomes of *C. **xanthorrhizia*** (Zingiberaceae) and characterised; and ***(3R,5R)-1-(4-hydroxyphenyl)-7-phenylheptane-3,5-diol***

[colourless needles **m 109-111°**, with **$[\alpha]_D$ +8.3 (c 0.06, $CDCl_3$)**, R_F 0.3] was isolated from the rhizomes of ***Alpinia officinarum*** (Zingiberaceae) and characterised; the absolute configurations were determined from the circular dichroism (CD) spectra of the 3,5-bis-*p*-dimethylaminobenzoate esters of their methylated derivatives, and applying the ***exciton chirality rule*** [Uehara et al. *Chem Pharm Bull Jpn* **35** 3298 1987, DOI: org/10.1248/cpb.35.3298].

Desmethoxycurcumin *[22608-11-3]* **$C_{20}H_{18}O_5$, M 338.3, m 173-175°** (also reported are **168°** and **172°**) is a contaminant of curcumin, isolated from the same source as curcumin, and best purified by HPLC and crystallises from EtOH as an orange-yellow powder. Its UV-VIS has λ_{max} (log ε)(MeOH) at 419nm (4.706) and (40% aqueous THF) 425nm (4.806) with fluorescence maxima at λ_{excit} 428nm and λ_{emis} 505nm in 40% aqueous THF. The ^{1}H NMR [400MHz, $CDCl_3$] has δ at 5.97 (1H, s, H-4), 7.60 (2H, d, *J* = 16.0Hz, H-2,6), 6.69 (1H, d, *J* = 16.0Hz, H-1 or 7), 6.64 (1H, d, *J* = 16.0Hz, H-7 or 1), 7.34 (1H, d, *J* = 1.7Hz, H-2' or 2"), 6.90 (1H, d, *J* = 8.0Hz, H-2"or 2'), 7.56 (1H, d, *J* = 8.0Hz, H-5'), 6.88 (1H, d, *J* = 8.0Hz, H-5"), 7.27 (1H, dd, *J* = 8,1.7Hz, H-6'), 6.9 (1H, d, *J* = 8Hz, H-6"), 3.92 (3H, s, OCH_3) (from TMS); and the ^{13}C NMR [100MHz, $CDCl_3$] has δ at 101.6 (C-4), 184.4 and 184.5 (C-3,5), 121.1 and 122.3 (C-2,6), 141.4 and 141.0 (C-1,7), 128.2 and 127.7 (C-1',1"), 111.5 and 130.9 (C-2',2), 148.8 and 116.8 (C-3',3"), 150.0 and 160.5 (C-4',4"), 116.2 and 116.8 (C-5',5"), 123.8 and 130.9 (C-6',6"), 56.3 (O***C***H_3) (from TMS).

Similarly **bis-desmethoxy-curcumin** *[22608-12-4, 24939-16-0]* **$C_{20}H_{18}O_5$, M 308.3, m 224°** (also reported are **216-218°** and **222°**) is a contaminant of curcumin, occurring in the same source, best purified by HPLC and crystallises as the ***hydrate*** in yellow plates from EtOH. Its UV has λ_{max} (log ε)(MeOH) at 414nm (4.675) and (40% aqueous THF) 420nm (4.702) with fluorescence maxima at λ_{excit} 425nm and λ_{emis} 501nm in 40% aqueous THF. The ^{1}H NMR [400MHz, $CDCl_3$] has δ at 6.03 (1H, s, H-4), 16.4 (1H, br s, 3-OH), 7.56 (2H, d, *J* = 15.9Hz, H-2,6), 7.56 (2H, d, *J* = 15.9Hz, H-1,7), 6.84 (2H, d, *J* = 8.2Hz, H-2',2"), 7.56 (2H, d, *J* = 8.2Hz, H-3',3"), 10.03 (2H, s, 4',4"-OH), 7.56 (2H, d, *J* = 8.2Hz, H-5',5"), 8.64 (2H, d, *J* = 8.2Hz, H-6',6") (from TMS); and the ^{13}C NMR [100MHz, $CDCl_3$] has δ at 100.9 (C-4), 183.2 (C-3,5), 120.8 (C-2,6), 140.3 (C-1,7), 125.8 (C-1',1"), 130.3 (C-2',2"), 115.9 (C-3',3"), 159.8 (C-4',4"), 115.9 (C-5',5"), 130.3 (C-6',6") (from TMS). [Jayaprakasha et al. *J Agric Food Chem* **50** 3668 *2002*, DOI: 10.1021/jf025506a; Inoue et al. *J Agric Food Chem* **56** 9328 *2008*, DOI: 10.1021/jf801815n, (HPLC, UV, fluorescence) Rouseff *J Food Sci* **53** 1823 *1988*, DOI: 10.1111/j.1365-2621.1988.tb07851.x; (MS) Jiang et al. *Rapid Commun Mass Spectrom* **20** 1001 *2006*, DOI: 10.1002/rcm.2401; (HPLC, MS) Jiang et al. *J Chromatogr* A **1111** 21 *2006*, DOI: 10.1016/j.chroma.2006.01.103; (HPLC, MS) Hiserodt et al. *J Chromatogr* A **740** 51 *1996*, DOI: 10.1016/0021-9673(96)00103-3; (spectroscopy) Haukvik et al. *Pharmazie* **65** 600 *2010*, DOI: 10.1691/ph.2010.0048; (IR) Tanaka et al. *J Agric Food Chem* **56** 8787 *2008,* DOI: 10.1021/jf801338e; (spectroscopy) Péret-Almeida et al. *Food Research International* **38** 1039 *2005*, DOI: 10.1016/j.foodres.2005.02.021; (cytotoxicity) Ishida et al. *Bioorg Med Chem* **10** 3481 *2002*, DOI: 10.1016/S0968-0896(02)00249-3; (anti-inflammatory, antioxidant and anti-amyloid activity) Yang et al. *J Biol Chem* **280** 5892 *2005*, PMID: 15590663.]

The keto-enol tautomerism of curcumin derivatives was shown to be a property that can be employed for amyloid detection in ***Alzheimer's disease***, and may be exploited for the design of amyloid-binding agents for the therapy of the disease [Yanagisawa et al. *Biomaterials* **31** 4179 *2010*, DOI: 10.1016/j.biomaterials.2010.01.142]. Over the years, curcumin derivatives have been screened for a variety of diseases (see above) including anti-HIV, and although few have displayed very potent anticancer activity, they are still being considered for development as future anticancer agents. A review on their potential as anticancer agents has been published recently. [Agrawal & Mishra *Med Res Rev* **30** 818 *2010*, DOI: 10.1002/med.20188.] The above information under *Curcumin* was kindly supplied by Prof. Hiroyasu Taguchi, Shiga University of Medical Science, Molecular Neuroscience Research Centre, JAPAN.

Cytidine *[65-46-3]* **$C_9H_{13}N_3O_5$, M 243.2, m 210-220°(dec), 230° (dec), 251-252° (dec), $[\alpha]_{546}^{20}$ +37 (c 9, H_2O), $[\alpha]_D^{20}$ +29 (c 9, H_2O), pK^{25} 3.85.** Cytidine crystallises from 90% aqueous EtOH. It has also been converted to ***sulfate*** by dissolving (~200mg) in a solution of EtOH (10ml) containing H_2SO_4 (50mg), whereby the salt crystallises out. It is collected, washed with EtOH and dried for 5 hours at 120°/0.1mm. The ***sulfate*** has **m 225°**. The ***free base*** is obtained by shaking the salt solution with a weak ion-exchange resin, filtering, evaporating and recrystallising the residue from EtOH as before. [Fox & Goodman *J Am Chem Soc* **73** 3256 *1956*, DOI: 10.1021/ja01151a076; Fox & Shugar *Biochim Biophys Acta* **9** 369 *1952*, DOI: 10.1016/0006-3002(52)90181-9; see Prytsas & Sorm in *Synthetic Procedures in Nucleic Acid Chemistry* (Zorbach & Tipson Eds) **Vol 1** 404 *1973*.] [*Beilstein* **25** III/IV 3667.] It is a component of RNA.

Cytochalasin B (from dehydrated mould matter, Phomin) *[14930-96-2]* **$C_{29}H_{37}NO_5$, M 479.6, m 218-221°, 215-223°.** Purify it by MeOH extraction, reverse phase C18 silica gel batch extraction by selective elution with 1:1 v/v hexane/tetrahydrofuran, crystallisation, subjected to TLC and recrystallisation [Lipski et al. *Anal Biochem* **161** 332 *1987*, DOI: 10.1016/0003-2697(87)90459-3]. It is soluble in EtOH (3.6%), Me_2CO (1%), Me_2SO (37%) and Me_2NCHO (49%) at 24°, and can be recrystallised from the first two solvents. It interferes with cellular movement [Korn *Physiol Reviews* **62** 672 *1982*]. For synthesis see Haidle & Myers [*Proc Natl Acad Sci* **101**(33) 12048 *2004*, DOI: 10.1073/pnas.0402111101, PMID: 15208404]. **VERY TOXIC.**

Cytosine (4-amino-2-hydroxypyrimidine) *[71-30-7]* **$C_4H_5N_3O$, M 111.1, m 313° (hydrate, dec), 320-325° (anhydrous, dec), pK_1^{25} 4.6, pK_2^{25} 12.1.** Cytosine crystallises from H_2O as the ***monohydrate*** which loses water on heating above 100°. Its solubility in H_2O is 0.77%. Its UV has λmax at 267nm (ε 6,100) in H_2O pH 8.8 and 275nm (ε 10,400) in 0.1N HCl. [Hilbert & Johnson *J Am Chem Soc* **52** 1152 *1930*, DOI: 10.1021/ja01366a051; Hilbert et al. *J Am Chem Soc* **57** 552 *1935*, DOI: 10.1021/ja01306a050; *Beilstein* **25** III/IV 3654.]

Cytosine-1-β-*O*-arabinofuranoside (Cytarabine) *[147-94-4]* **$C_9H_{13}N_3O_5$, M 243.2, m ~220°(dec), 212-213.5°, $[\alpha]_D^{20}$ +155 (c 1, H_2O), pK^{25} 4.3.** Purify cytarabine by recrystallisation from aqueous EtOH or a large volume of H_2O (it solubility at ~20° is 5%). It has λ_{max} at 212 and 279nm at pH 2, and 272nm at pH 12. It is an acute ***leukaemic*** agent. (October 2007). It is used in myeloid leukemia chemotherapy [Pigneux et al. *Haematologica* **92**(10) 1327 *2007*, DOI: 10.3324/haematol.11068; PMID: 18024370]; and has ***antiviral activity*** in humans [Lauter et al. [*Antimicrob Agents Chemother* **6**(5) 598 *1974*, DOI: 10.1128/aac.6.5.598; PMID: 15825312; Walwick et al. *Proc Chem Soc (London)*73 84 *1959*, DOI: 10.1039/PS9590000073; *Beilstein* 25 III/IV 3669.]

Demeclocycline hydrochloride (7-chloro-6-demethyltetracycline hydrochloride, Clortetrin) *[127-33-3 (free base), 64-73-3 HCl]* **$C_{21}H_{21}N_2O_8$. HCl, M 501.3, m 174-178°(dec, for sesquihydrate), $[\alpha]_D^{25}$ -258 (c 0.5, 0.1N H_2SO_4), pK^{25} 4.45 [H_2O-Me_2NCHO (1:1)].** Crystallise the salt from EtOH/Et_2O or H_2O and dry it in air [McCormick et al. *J Am Chem Soc* **79** 4561 *1957*, DOI: 10.1021/ja01573a089; Dobrynin et al. *Tetrahedron Lett* 901 *1962*, DOI: 10.1016/S0040-4039(00)70561-2]. 156-158°, $[\alpha]_D^{20}$ +10.5 (c 2, H_2O), pK_{Est} ~2.8. Dissolve desthiobiotin in 0.5% Na_2CO_3, filter, acidify with HCl to Congo Red, concentrate to a small volume (2-3 ml) to give fine needles, filter it off and recrystallise it twice from H_2O, **m** 157-158°. It also crystallises from 95% EtOH. The ***methyl ester*** crystallises from MeOH and sublimes at 100°/high vacuum, **m 69-70°**, with $[\alpha]_D^{27.5}$ +2.6 (c 2, $CHCl_3$). [Melville et al. *Science* **98** 497 *1943*, DOI: 10.1126/science.98.2553.497; *J Am Chem Soc* **66** 1422 *1944*, DOI: 10.1021/ja01236a505; *Beilstein* **25** III/IV 1543.]

Di- and tri-carboxylic acids. These are separated by anion-exchange chromatography. [Bengtsson & Samuelson *Anal Chim Acta* **44** 217 *1969*, DOI: 10.1016/S0003-2670(01)81756-6.]

7,8-Dihydrofolic acid (7,8-dihydropteroyl-L-glutamic acid, DHFA) *[4033-27-6]* **$C_{19}H_{21}N_7O_6$, M 443.4, pK_1 2.0 (basic 10-NH), pK_2 2.89 (2-NH_2), pK_3 3.45 (α-CO_2H), pK_4 4.0 (basic 5N), pK_5 4.8 (γ-CO_2H), pK_6 9.54 (acidic 3NH).** DHFA is best purified by suspending (1g mostly dissolved)) in ice-cold sodium ascorbate (300ml of 10% at pH 6.0, prepared by adjusting the pH of 30g of sodium ascorbate in 150ml of H_2O by adding 1N NaOH dropwise using a glass electrode till the pH is 6.0). This gives a clear solution at pH ~5. While stirring at 0°, add N HCl dropwise slowly (0.1ml/min) until the pH drops to 2.8 when white birefringent crystals separate. These are collected by centrifugation (1000xg for 5 minutes), washed 3x with 0.001N HCl also by centrifugation and decantation. The residue is then dried in a vacuum (0.02mm) over P_2O_5 (change the P_2O_5 frequently at first) and KOH at 25° in the dark. After 24 hours the solid reaches constant weight.
For the ***assay*** of ***dihydrofolate reductases*** (see *[9002-03-3]* 'Proteins, Enzymes…' in this Chapter): suspend ~66.5mg of DHFA in 10ml of 0.001M HCl containing 10mM dithiothreitol (**DTT** stock made from 154mg in 10ml H_2O making 0.1M), shake well and freeze in 400μl aliquots. Before use, mix 400μl of this suspension with 0.1M **DTT** (200μl, also made in frozen aliquots), and the mixture is diluted with 200μl of 1.5M Tris-HCl pH 7.0 and 1.2ml of H_2O (making a total volume of ~2ml) to give a clear solution. To estimate the concentration of DHFA in this solution, dilute 20μl of this solution to 1ml with 0.1M Tris-HCl pH 7.0 and read the OD at 282nm in a 1cm path length cuvette. ε at 282nm is 28,000$M^{-1}cm^{-1}$. [Futterman *Methods Enzymol* **6** 801 *1963*, DOI: 10.1016/0076-6879(63)06252-2; Reyes & Rathod *Methods Enzymol* **122** 360 *1986*, DOI: 10.1016/0076-6879(86)22194-1; Beilstein **26** III/IV 3934.]

DL-*erythro*-Dihydrosphingosine (dl-*erythro*-2-aminooctadecan-1,3-diol) *[3102-56-5]* **$C_{18}H_{39}NO_2$, M 301.5, m 85-86°, 85-87°, pK_{Est} ~ 8.8.** Purify it by recrystallisation from petroleum ether/EtOAc or $CHCl_3$. The ***(±)-N-dichloroacetyl derivative*** has **m 142-144°** (from MeOH). [Shapiro et al. *J Am Chem Soc* **80** 2170 *1958*, DOI: 10.1021/ja01542a034; Shapiro & Sheradsky *J Org Chem* **28** 2157 *1963*, DOI: 10.1021/jo01043a514.] The ***D-isomer*** *[764-22-7]* crystallises from petroleum ether/Et_2O and has **m 78.5-79°**, $[\alpha]_{546}^{28}$ +6 ($CHCl_3$/MeOH, 10:1); its solubility in EtOH or in Me_2SO is 25mg/ml (warm). [Grob & Jenny *Helv Chim Acta* **35** 2106 *1952*, DOI: 10.1002/hlca.19520350641; Jenny & Grob *Helv Chim Acta* **36** 1454 *1953*, DOI: 10.1002/hlca.19530360632; *Beilstein* **4** I 448, **4** II 757, **4** III 854, **4** IV 1887.]

Dihydrostreptomycin sesquisulfate *[5490-27-7]* **$C_{21}H_{41}N_7O_{12}$. $3/2H_2SO_4$, M 730.7, m 250°(dec), 255-265°(dec), $[\alpha]_D^{20}$ -92.4 (c 1, H_2O), $pK_{Est(1)}$~ 9.5 (NMe), pK_{Est} ~ 13.4 (guanidino).** The antibiotic crystallises from H_2O, MeOH, *n*-BuOH or methyl ethyl ketone. The crystals are not hygroscopic like the amorphous powder; however, both forms are soluble in H_2O but the ***amorphous solid*** is about 10 times more soluble than the crystals. The ***free base*** *[128-46-1]* $C_{21}H_{41}N_7O_{12}$, M 583.6, also crystallises from H_2O/Me_2CO and has $[\alpha]_D^{26}$ -92 (a strong base, with aqueous solution pH 7.0, see pKa). [Solomons & Regna *Science* **109** 515 *1949*, DOI: 10.1126/science.109.2838.515; Wolf et al. *Science* **109** 515 *1949*, DOI: 10.1126/science.109.2838.515-a; McGilveray & Rinehart *J Am Chem Soc* **87** 4003 *1956*, DOI: 10.1021/ja01095a054; Gardin et al. *J Am Vet Med Assoc* **183**, 434 *1983*, PMID: 6618969]. [*Beilstein* **18** III/IV 7538.] Active against bacteria and mycoplasma.

2,4-Dihydroxyimidazole (hydantoin, imidazolin-2,4-dione) *[461-72-3]* **$C_3H_4N_2O_2$, M 100.1, m 215°, 218-220°, 220°, pK^{25} 9.15, pK^{18} 9.16.** Well over the past hundred years many syntheses of hydantoin have been reported involving the reaction of alloxanic acid with HI [Baeyer *Justus Liebigs Ann Chem* **119** 126 *1861*, DOI: 10.1002/jlac.18611190115; and **130** 129 159 *1864*, DOI: 10.1002/jlac.18641300202], the cyclisation of urea derivatives [Harries & Weiss *Chem Ber* **33** 3418 *1900*, DOI: 10.1002/cber.190003303122; and *Justus Liebigs Ann Chem* **327** 355 366 *1903*, DOI: 10.1002/jlac.19033270307], the cyclisation of ethyl *N*-carbamoylglycinate,

using NaOMe/MeOH in 85% yield [Kaválek et al. *Coll Czech Chem Commun* **51** 375 *1986*, DOI: org/10.1135/cccc19860375], and more recently by the acid catalysed condensation of glycine with KNCO [El-Deeb et al. *Eur J Med Chem* **45** 2516 *2010*, DOI: 10.1016/j.ejmech.2010.02.038]. In a later patent, glycine (75g, 1 mole) and urea (140g, 2.3 moles) in H_2O (120ml) were stirred under reflux for 12 hours. The mixture was acidified by careful addition of concentrated H_2SO_4 while cooled in an ice bath, then boiled for 1 hour, cooled to 0-5°, the crystals were filtered off, washed with cold H_2O and dried. Recrystallisation from AcOH (10 parts) gave ***pure hydantoin*** (71g, 70%) m 220-220°. [Alkaloida US patent 4647694 *1987*.] Also purified from 2.5 parts of hot H_2O (charcoal), filtering, acidifying to pH ~6, filtering again, collecting the solid, washing with ice cold H_2O, drying, and recrystallising from EtOH (needles) or 10 parts of AcOH. Its solubility is 39.7g/L in H_2O and 3.24g/L in EtOH at 25°. Its UV has λ_{max} (ε) at 215(400) and 245(60)nm in 0.01N EtOH/NaOH; 215(360) and 245(50)nm in EtOH/H^+; and IR has ν_{max} at 1697 (CO) and 1776 (CO) cm^{-1} in a paraffin mull [West *J Biol Chem* **34** 187 *1918*, http://www.jbc.org/ content/34/1/187; Crombie & Hooper *J Chem Soc* 3010 *1955*, DOI: 10.1039/JR9550003010; *Beilstein* **24** H 242, **24** I 287, **24** II 127, **24** III/IV 1034].

1,2-Dilauroyl-*sn*-glycero-3-phosphoethanolamine (±-dilauroyl-α-cephalin, 3-*sn*-phosphat-idylethanol-amine 1,2-didodecanoyl) *[59752-57-7]* **$C_{29}H_{58}NO_8P$, M 579.8, m 210°, $pK_{Est(1)}$~ 5.8 (PO_4H), $pK_{Est(2)}$~ 10.5 (NH_2).** Recrystallise it from EtOH or tetrahydrofuran. Dry it in a vacuum and store it at -20°. [Bevan & Malkin *J Chem Soc* 2667 *1951*, DOI: 10.1039/JR9510002667; IR: Bellamy & Beecher *J Chem Soc* 728 *1953*, DOI: 10.1039/JR9530000728; *Beilstein* **4** IV 1417.]

3,7-Dimethyl-2,6-dioxopurine (Theobromine) *[83-67-0]* **$C_7H_8N_4O_2$, M 180.2, m 337° (sublimes slowly at 290° and finally melts at ~351°), pK_1^{40} -0.16, pK_1^{25} 9.96.** Recrystallise it from hot H_2O (solubility in w/v% is 0.06 at 15°; 1.25 at 100°). Forms salts with heavy metals, is a diuretic, vasodilator and cardiac stimulant. [Lister *Purines Part II. Fused Pyrimidines, 1971*, J.Wiley NY, ISBN 047138205-1; *Beilstein* **26** III/IV 2336.]

The presence of H_2O raises its melting point to 40°. [Moore & Tabern *J Am Pharm Soc* **24** 211 *1935*, DOI: 10.1002/jps.3080240306.] The ***anhydrous base*** crystallises from dry ether [Fleming & Saunders *J Chem Soc* 4150 *1955*, DOI: 10.1039/JR9550004150]. It gradually decomposes on exposure to light and is best stored in an inert atmosphere in the dark (preferably at -20°). Its solubility in H_2O is 5%, in EtOH it is 1% and it is soluble in $CHCl_3$, Et_2O and mineral oils. It has pKa values in H_2O of 10.25 (0°) and 8.69 (60°) [Everett & Hyne *J Chem Soc* 1636 *1958*, DOI: 10.1039/JR9580001636; Prelog & Häfliger *Helv Chim Acta* **33** 2021 *1950*, DOI: 10.1002/hlca.19500330708] and pK_a^{23} 8.84 in 80% aqueous methoxyethanol [Simon *Helv Chim Acta* **41** 1835 *1958*, DOI: 10.1002/hlca.19580410639]. The ***hydrochloride*** has **m 220°** (from EtOH/Et_2O) and $[\alpha]_D^{20}$ -38.8 (c 2, EtOH). [IR: Chatten & Levi *Anal Chem* **31** 1581 *1959*, DOI: 10.1021/ac60153a045.] The ***anhydrous base*** crystallises from Et_2O [Fleming & Saunders *J Chem Soc* 4150 *1955*, DOI: 10.1039/JR9550004150]. [*Beilstein* **13** H 373, **13**, III 1720, **13** IV 1879.] It is a ***sympathomimetic*** amine. [Kobayashi, et al. *Anesth Analg* **97** 1239 *2003*, DOI: 10.1213/01.ANE.0000092917.96558.3C].

(+)-Ephedrine hydrochloride **(1*S*-2*R*-2-methylamino-1-phenylpropan-1-ol hydrochloride)** *[24221-86-1]* **$C_{10}H_{15}NO$. HCl, M 201.7,** has **m 216-219°, $[\alpha]_D^{20}$ +34 (c 11.5, H_2O).** Recrystallise the hydrochloride from EtOH/Et_2O. The ***free base*** crystallises from *C_6H_6 with **m 40-41°** (Skita et al. *Chem Ber* **66** 974 *1933*, DOI: 10.1002/cber.19330660713]. [*Beilstein* **13** H 254, **13** II 375, **13** III 1721, **13** IV 1879.]

(-)Ephedrine hydrochloride **(1*R*-2*S*-2-methylamino-1-phenylpropan-1-ol hydrochloride)** *[50-98-6]* has **m 218°, $[\alpha]_{546}^{20}$ -48 (c 5, 2M HCl).** It crystallises from water. See ***free base*** above. [*Beilstein* **13** H 254.]

α-Erythroidine (3*R*,5*S*,12*S*-1,2,6,7-Tetradehydro-12,17-dihydro-3β-methoxy-16(15H)-oxaerythrinan-15-one) *[466-80-8]* **$C_{16}H_{19}NO_3$, M 273.3, m 52-55°, 58-60°, $[\alpha]_D^{27}$ +136 (c 0.5, H_2O), $pK_{Est(3)}$~7.4** Recrystallise α-erythroidine from pentane. It is best prepared freshly from the more stable hydrochloride. The ***hydrochloride*** (1.3g) in H_2O (20ml) is basified with $NaHCO_3$ to pH ~8 and extracted with *C_6H_6 (6 x 10ml). The combined extracts are evaporated to a small volume and refrigerated. The ***free base*** separates as white hygroscopic crystals **m** 52-55°, which can be recrystallised from pentane. Although stable in solution, the crystals turn brown on exposure to air.

α-Erythroidine hydrochloride is best purified by dissolving 10g in H_2O (100ml), adjusting the pH to 8 with aqueous $NaHCO_3$, extracting with *C_6H_6 (4 x 20ml), evaporating to 20ml, passing through activated Al_2O_3 and eluting with *C_6H_6. The eluate is evaporated to a small volume and the crystals are collected, dissolved in EtOH and dry HCl gas is passed through to give the ***pure hydrochloride***. When recrystallised from EtOH, it has **m 226-228°(dec),** and **$[\alpha]_D^{32}$ +118 (c 0.5, H_2O).** It has UV with λ_{max} at 224nm (ε 35,500); compare with β-erythroidine hydrochloride below. [Boelkeleide & Grundon *J Am Chem Soc* **75** 2563 *1953*, DOI: 10.1021/ja01107a006; for conversion of ***α to β forms*** see Boekeleide & Morrison *J Am Chem Soc* **80** 3905 *1958*, DOI: 10.1021/ja01548a027; Hill & Schearer *J Org Chem* **27** 921 *1962*, DOI: 10.1021/jo01050a056; Boelkeleide & Wenzinger *J Org Chem* **29** 1307 *1964*, DOI: 10.1021/jo01029a008; *Beilstein* **27** III/IV 3569.]

β-Erythroidine (3*R*,5*S*) *[466-81-9]* **$C_{16}H_{19}NO_3$, M 273.3, m 97-99°, 99.5-100°, $[\alpha]_D^{25}$ +89 (c 0.5, H_2O).** Purify it like the ***α-isomer*** but recrystallise it from EtOH. The ***free base*** is unstable in air and light, but the hydrochloride is more stable and best stored as such. The ***methiodide*** has **m 211°** (prisms from EtOH).

β-Erythroidine hydrochloride can be obtained from the ***α-isomeric salt*** as follows: The α-hydrochloride (1.2g) in 10% aqueous NaOH (12ml) is refluxed for 3 hours under N_2, cooled in ice and concentrated HCl added to pH 2. After standing for 3 hours, $NaHCO_3$ is carefully added to pH 7, the solution is extracted with $CHCl_3$ (5x), and the extracts are dried, filtered, and concentrated to give an oil which on seeding gives β-erythroidine **m 97-99°**. When dissolved in EtOH and dry HCl gas is passed through the solution, the ***pure β-erythroidine hydrochloride*** crystallises out with **m 230.5-231.5°, $[\alpha]_D^{25}$ +10 (c 0.5, H_2O).** It is a ***muscle relaxant*** with a curare-like-action and is ***more active*** than the α-isomer. [Koniuszy & Folkers *J Am Chem Soc* **72** 5579 *1950*, DOI: 10.1021/ja01168a061; Boekelheide et al. *J Am Chem Soc* **75** 2550 *1953*, DOI: 10.1021/ja01107a004; Boekelheide & Morrison *J Am Chem Soc* **80** 3905 *1958*, DOI: 10.1021/ja01548a027; Boelkeleide & Wenzinger *J Org Chem* **29** 1307 *1964*, DOI: 10.1021/jo01029a008; Berger & Schwartz *J Pharmacol Exp Therap* **93** 362 *1948*, PMID: 18882142; *Beilstein* **4** IV 3568.]

Erythromycin A *[114-07-8]* **$C_{37}H_{67}NO_{13}$, M 733.9, m 133-135°(dec), 135-140°, 137-140°, $[\alpha]_D^{20}$ -75 (c 2, EtOH), pK^{25} 8.9.** It is recrystallised from H_2O to form ***hydrated*** crystals which melt at *ca* **135-140°**, resolidifiy and melt again at **190-193°**. The melting point after drying at 56°/8mm is that of the ***anhydrous*** material and is

at **137-140°**. Its solubility in H_2O is ~2mg/ml. The ***hydrochloride*** has **m 170°, 173°** (from aqueous EtOH, EtOH/Et_2O). [Flynn et al. *J Am Chem Soc* **76** 3121 *1954*, DOI: 10.1021/ja01641a005; constitution: Wiley et al. *J Am Chem Soc* **79** 6062 *1957*, DOI: 10.1021/ja01579a059]. [*Beilstein* **18/10** V 398.] A polyketide antibiotic [Washington & Wilson *Mayo Clinic Proceedings* **60** 189 *1985*, DOI: 10.1016/S0025-6196(12)60219-5].

Ethidium bromide *[1239-45-8]* **$C_{21}H_{20}N_3$. Br, M 394.3, m 260-262°.** Crystallise the purple-red solid from MeOH or EtOH [Lamos et al. *J Am Chem Soc* **108** 4278 *1986*, DOI: 10.1021/ja00275a007]. Its solubility in H_2O is 1%. Nucleic acid intercalating and colouring agent (used in gels). [*Beilstein* **22/11** V 352.] **CARCINOGEN.**

Ethyl 7-acetoxycoumarin-3-carboxylate *[13207-77-3]* **$C_{14}H_{12}O_6$, M 276.3, m 147-148°, 151°, 152°, 152-154°, pK^{25} 7.04.** Purify the ester by recrystallisation from EtOH or aqueous EtOH, dry it *in vacuo* and store it at 2-8°. It is a good ***fluorogenic substrate for esterases*** that hydrolyse it to the acid, which acts as an indicator. The fluorescence has λ_{ex} 386nm, λ_{em} 445nm in 0.1 M Tris buffer pH 8.0. It has been prepared by refluxing 2-imino-3-ethoxycarbonyl-7-hydroxy-2*H*-chromene with Ac_2O for 1 hour, evaporating and recrystallising the residue from aqueous MeOH [Yasuda & Midorikawa *Bull Chem Soc Jpn* **39** 1754 *1966*, DOI: 10.1246/bcsj.39.1754]. *Alternatively*, it can be prepared by acetylation of 7-hydroxy-3-carbethoxycoumarin by the Ac_2O/pyridine method, and crystallises from EtOH in plates, **m 152°**. An attempted Fries rearrangement by heating the ester with anhydrous $AlCl_3$ at 16-170° failed, but gave ***7-hydroxy-3-carboxycoumarin***, **m 271° (dec)** (from H_2O). [Shah & Shah *J Org Chem* **19** 1681 *1954*, DOI: 10.1021/jo01375a018; see also Boehm *Archiv der Pharmazie (Weinheim)* **271** 490 *1933*, DOI: 10.1002/ardp.19332710808].

Farnesol **(*trans-trans*-3,7,11-trimethyl-2,6,10-dodecatrien-1-ol)** *[106-28-5, 4602-84-0 (trans-trans, E,E)]* **$C_{15}H_{26}O$, M 222.4, b 111°/0.35mm, 126-127°/0.5mm, 142-143°/2mm, d_4^{20} 0.8871, n_D^{25} 1.4870.** The main impurity is the *cis-trans* isomer. Purify it by gas chromatography using a 4ft x 0.125in 3%OV-1 column at 150°. [Corey & Yamamoto *J Am Chem Soc* **92** 6637 *1970*, DOI: 10.1021/ja00725a044; Popjak et al. *J Biol Chem* **237** 56 *1962*, PMID: 14487886.] It has also been fractionated through a 14-in Podbielniak column at 11°/0.35mm. *Alternatively*, it has been purified by gas chromatography using SF96 silicone on Fluoropak columns or Carbowax 20M on Fluoropak or base-washed 30:60 firebrick (to avoid decomposition, prepared by treating the firebrick with 5N NaOH in MeOH and washed with MeOH to pH 8) at 210° with Helium carrier gas at 60 ml/min flow rate. It distils at high vacuum, and should be stored in sealed containers under N_2 in the dark. The ***diphenylcarbamoyl derivative*** has **m 61-63°** (from MeOH) and has an IR band at 3500 cm^{-1}. It has the scent of flowers. [Bates et al. *J Org Chem* **28** 1086 *1963*, DOI: 10.1021/jo01039a054; *Beilstein* **1** IV 2335.] ***Farnesyl acetate*** **(*trans-trans*-3,7,11-trimethyl-2,6,10-dodecatrien-1-yl acetate)** *[4128-17-0 (trans-trans, E,E); 29548-30-9 (isomeric mixture)]* **$C_{17}H_{28}O_2$, M 264.4,** has **b 115-125°/0.3mm, 167-169°/0.3mm, d_4^{20} 0.91, n_D^{20} 1.4870.** Purify and store farnesyl acetate as for the alcohol above. [*Beilstein* **2** II 154, **2** III 303.] Used in the perfumery. ***Farnesyl pyrophosphate*** *[13058-04-3, E,E: 372-97-4]* **$C_{15}H_{28}O_7P_2$, M 382.3,** has **$pK_{Est(1)}$~<2, $pK_{Est(2)}$~<2, $pK_{Est(3)}$~3.95, $pK_{Est(4)}$~6.26.** Purify the it by chromatography on Whatman No3 MM paper in a system of isopropanol-isobutanol/ammonia/water (40:20:1:30) (v/v). Store it as the Li or NH_4 salt at 0°. See geranyl-geranyl pyrophosphate below. Intermediate in the biosynthesis of terpenes, sterols and terpenoids substances.

Fenretinide [4-HPR, *N*-(4-hydroxyphenyl)retinamide] *[65646-68-6]* **$C_{26}H_{33}NO_2$, M 391.5.6, m 173-175°.** It is prepared from all-*trans*-retinoic acid [3.0g; see *302-79-4* above] and redistilled PCl_3 (0.92g) in dry $*C_6H_6$ (50ml) which are stirred for 2.5 hours, and during 20 minutes. This mixture is added to a solution of *p*-aminophenol (5.46g) in DMF (16ml) and Et_2O (2ml) with stirring under N_2 and ice-cooling, then stirred further at ~25°/3hrs followed by 50°/1hr. This is then diluted with Et_2O (150ml), the ethereal layer is extracted with cold 5% aqueous HCl (2 x 25ml), H_2O (25ml), dried (Na_2SO_4), filtered and evaporated to give a dark yellow solid which crystallises from MeOH (6ml/g), then 1:1.7 $CHCl_3$/*n*-hexane (8ml/g) to provide ***fenretinide*** **m 162-163°**. [Gander & Gurney US Patent 4190594 A to Johnson & Johnson 26 Feb *1980*]. ***Note*** that it is polymorphic and has various forms, e.g. from aqueous EtOH the crystals have **m 173-175°**, and from MeOH the crystals have **m 178-181°**. The UV has λ_{max} at 362nm (ε 47900) in MeOH, and 370nm (ε 44500) in $CHCl_3$. [Synthesis and properties: Shealy et al. *J Pharm Sci* **73** 745 *1984*, DOI: 10.1002/ jps.2600730610.] ***Fenretinide*** is a synthetic retinoid agonist agent, with anti-proliferative, anti-oxidant, anti-cancer activity with a ***long half life*** *in vivo*. Its ***apoptotic action*** appears different from that of *classical* retinoids. [Ulukaya & Wood *Cancer*

Treat Rev **25** 229 *1999*, DOI: 10.1053/ctrv.1999.0127.]

Fentanyl [*N*-(4-phenethyl-1-piperidinyl)-*N*-phenylpropionamide] *[437-38-7]* **$C_{22}H_{28}N_2O$, M 336.5, m 83-84°, 87.5°, pK^{25}_{Est} ~10.0.** The syntheses of this drug and related compounds are described in a patent by Janssen [USP 3164600 A, Jan 5 *1965*]. -Purify it by dissolving in di-*iso*-propyl ether, filtering several times until clear, concentrate to a small volume and cool (2hrs/~0°) whereby ***Fentanyl*** crystallises out. *Alternatively*, recrystallise from di-*iso*-propyl ether, hexone or petroleum ether. It is a ***strong organic base*** (see pKa) and is best kept as its salts. ***Fentanyl citrate*** *[990-73-8]* **$C_{22}H_8N_2O.C_6H_{28}O_2$, M528.6, m 149-151°**, has a solubility in H_2O at ~25° of 2.5g/100ml, and is soluble in MeOH, but poorly soluble in $CHCl_3$. It has a bitter taste and is sold under the trade name of ***Sublimaze***, among other names. It is a potent ***opioid analgesic***, ~80-100 times ***more potent than morphine*** *[57-27-2]* and ~40-50 times the potency of pure pharmaceutical grade ***heroin***. It is a ***controlled substance*** and a medical prescription. Used for severe trauma, strong chronic pain and apparently less addictive than morphine. Related useful analgesics are ***Alfentanil*** (ultra-short acting, 5-10min) and ***Sufentanil*** (5-10 times more potent than *Fentanil*). [Hess et al. *Eur J Clin Pharmacol* **4** 137 *1972*, DOI: 10.1007/BF00561135, PMID: 4655287; Stanley *J Pain Symptom Manage* **7** (3 Suppl, Issue 3) S3–7 *1992*, DOI: 10.1016/0885-3924(92)90047-L, PMID: 1517629; Black *J Med Chem*. **48** 1687 *2005*, DOI: 10.1021/jm040195b; PMID: 15771410.]

Flavin adenine dinucleotide (di-Na, $2H_2O$ salt, FAD) *[146-14-5, 84366-81-4 (anhydrous)]* **$C_{27}H_{33}N_9O_{15}P_2$, M 865.6 (free acid), 865.6, $[\alpha]_{546}$ -54 (c 1, H_2O), pK_a 1.13, pK_b 12.87.** Small quantities of FAD are purified by paper chromatography using *tert*-butyl alcohol/water, cutting out the main spot and eluting with water. Larger amounts can be precipitated from water as the ***uranyl complex*** by adding a slight excess of uranyl acetate to a solution at pH 6.0, dropwise and with gentle stirring. The solution is set aside overnight in the cold, and the precipitate is centrifuged off, washed with small portions of cold EtOH, then with cold peroxide-free diethyl ether. It is dried in the dark under vacuum over P_2O_5 at 50-60°. For **recovery**, the uranyl complex is suspended in water, and, after adding sufficient 0.01M NaOH to adjust the pH to 7, the precipitate of uranyl hydroxide is removed by centrifugation and the supernatant is lyophylised [Huennekens & Felton *Methods Enzymol* **3** 950 *1957*, DOI: 10.1016/S0076-6879(57)03484-9]. It can also be crystallised from water. It should be kept in the dark. More recently it was purified by elution from a DEAE-cellulose (Whatman DE 23) column with 0.1M phosphate buffer pH 7, and the purity was checked by TLC. [Holt & Cotton, *J Am Chem Soc* **109** 1841 *1987*, DOI: 10.1021/ja00240a039; *Beilstein* **26** III/IV 3632.] Cofactor of oxido-reductase enzymes.

Flavin mononucleotide (Na, $2H_2O$ salt, riboflavin-5'-phosphate [Na salt, $2H_2O$], FMN) *[130-40-5, 6184-17-4 (Na salt)]* **$C_{17}H_{21}N_4O_9P$, M 456.3 (free acid), 514.4, pK_1 2.1 (PO_4H_2), pK_2 6.5 (PO_4H^-), pK_3 10.3 (CONH), fluorescence λ_{max} 530nm (870nm for reduced form).** Purify FMN by paper chromatography using *tert*-butanol/water, cutting out the main spot and eluting it with water. It can also be purified by adsorption onto an apo-flavodoxin column, followed by elution and freeze drying. It crystallises from aqueous acidic solution. [Mayhew & Strating *Eur J Biochem* **59** 539 *1975*, DOI: 10.1111/j.1432-1033.1975.tb02480.x; *Beilstein* **26** III/IV 2555.] Prosthetic group for NADH(P) oxido-reductases.

5-Fluorouridine (5-FU, 5-fluoro-1-β-D-ribofuranosyl-1*H*-pyrimidine-2,4-dione) *[316-46-1, 77180-80-1]* **$C_9H_{11}FN_2O_6$, M 262.2, m 180-182°, 182-184°, $[\alpha]^{20}_D$ +18 (c 1, H_2O), $pK_{Est(1)}$~ 8.0, $pK_{Est(2)}$~ 13.** 5-Fluorouridine is recrystallised from EtOH/Et_2O and dried at 100° in a vacuum. It has UV with λ_{max} at 269nm (pH 7.2, H_2O), 270nm (pH 14, H_2O). [Liang et al. *Mol Pharmacol* **21** 224 *1982*, PMID: 6813676; *Beilstein* **24** III/IV 1231.] It is an antitumour agent.

Folic acid (FA, pteroyl-S-glutamic acid) *[59-30-3, 75708-92-8 ($2H_2O$)]* **$C_{19}H_{19}N_7O_6$, M 441.4, m >250°(dec), $[\alpha]^{25}_D$+23 (c 0.5, 0.1N NaOH), pK_1 2.35 (protonation N10), pK_2 2.75 (protonation N1), pK_3 3.49 (α-CO_2H), pK_4 4.65 (γ-CO_2H), pK_5 8.80 (acidic N3).** If paper chromatography indicates impurities, then recrystallise it from hot H_2O or from dilute acid [Waller et al. *J Am Chem Soc* **70** 19 *1948*, DOI: 10.1021/ja01181a006]. Impurities are removed by repeated extraction with *n*-BuOH of a neutral aqueous solution of folic acid (by suspending in H_2O and adding N NaOH dropwise till the solid dissolves, then adjusting the pH to ~7.0-7.5) followed by precipitation with acid, filtration, or ***better*** collected by centrifugation and recrystallistion from hot H_2O (fine yellow crystals). [Blakley *Biochem J* **65** 331 *1957*, DOI: 10.1042/bj0650331; Khalifa et al. *Helv Chim Acta* **61** 2739 *1978*, DOI: 10.1002/hlca.19780610742.]

Chromatography on cellulose followed by filtration through charcoal has also been used to obtain ***pure acid***. [Sakami & Knowles *Science* **129** 274 *1959*, DOI: 10.1126/science.129.3344.274.] Its UV has λ_{max} at 247 and 296nm (ε 12,800 and 18,700) in H_2O pH 1.0; 282 and 346nm (ε 27.600 and 7,200) in H_2O pH 7.0; 256, 284 and 366nm (ε 24600, 24,500 and 86,00) in H_2O pH 13 [Rabinowitz in *The Enzymes* (Boyer et al. Eds), **2** 185 *1960*]. [*Beilstein* **26** III/IV 3944.] It is an important ***food additive*** and essential vitamin precursor of the cofactor dihydrofolic acid, necessary for thymidine synthesis and DNA; and the development of the neuronal tube in foetuses where deficiency leads to incomplete sealing of the tube and subsequently ***Spina bifida***.

3-Formylchromone (4-oxo-4*H*-1-benzopyran-3-carbaldehyde) *[17422-74-1]* **$C_{10}H_6O_3$, M 174.2, m 151-153°, 152°, 152-153°.** This useful precursor for heterocyclic compounds [Sabitha *Aldrichim Acta* **29** 12 *1996*] is best prepared by a Vilsmeier-Haack reaction. Tetrachloropyrophosphate (80ml) is added dropwise to a solution of *o*-hydroxyacetophenone (25g, 0.184mole) in DMF (80ml) at -20° to 20° during 10 minutes. The mixture is stirred at ~25° for 13 hours, poured into ice-water and the solid is filtered off, washed with H_2O, then EtOH, dried *in vacuo*, and recrystallised from Me_2CO to give white crystals of ***pure 3-formylchromone*** (19.6g, 61%). *Alternatively*, DMF/$POCl_3$ is used. It has IR bands with ν_{max} at 1605 (CHO), 1650 (C=O) and 1620 (C=C) cm^{-1}, the ^1H NMR [60MHz, DMSO-d_6, TMS) has δ at 10.16 (s, C*H*O), 8.9 (s, H-2) and 8.3-7.4 (m, H-5,6,7 and 8), and the MS *m/z(%)* has peaks at 174(4), 147(10), **146**(100), 121(8), 120(24), 118(3), 105(6), **104**(34), 92(17), 90(13), 89(11), **76**(13), 64(12), 63(18), 53(24), fragments in bold are characteristic of the 4-oxo-4*H*-1-benzopyran-3-carbaldehyde molecule. A large number of substituted derivatives have been prepared in this way and some, particularly the ***6-bromo-derivative***, showed relatively ***strong anti-anaphylactic activity*** with low LD_{50}, and decreased gastric acid volume. [Nohara et al *Tetrahedron* **30** 3553 *1974*, DOI: 10.1016/S0040-4020(01)97034-6; Klutchko et al. US Pat 4,098,799 *1978*, *Chem Abs* **90** 22803 *1979*.]

Fructose-1,6-diphosphate (trisodium salt) *[38099-82-0]* **$C_6H_{11}Na_3O_{12}P_2$. xH_2O, M 406.1, pK_1^{25} 1.48, pK_2^{25} 6.14, pK_3^{25} 6.29, pK_4^{25} 6.93 (free acid).** Fructose-1,6-diphosphate is best purified *via* the acid strychnine salt which is stable for several months. To remove the strychnine, dissolve 5g in H_2O (150ml), and add 5N NaOH (or KOH to obtain the K salt) to pH 8.3 (phenolphthalein) with vigorous stirring. Remove the precipitate by centrifugation, wash with cold H_2O (2x 25ml), extract with $CHCl_3$ until the extract is free of strychnine (*ca* 8 to 10 times, Mandelein spot test). Freeze-dry the aqueous solution to give the Na salt which is ***hygroscopic***. It has been recrystallised from aqueous EtOH as the ***octahydrate***, **m 125°**, **$[\alpha]_D^{20}$ +2.6 (c 1, H_2O)**. A neutral solution of the salt keeps well in a frozen state for over several months. Store it at -20°. [Sable *Biochemical Preparations* **2** 52 *1952*, Stumpf *J Biol Chem* **182** 261 *1950*, http://www.jbc.org/content/182/1/261; for estimation of hexose diphosphate see Kahan *Arch Biochem Biophys* **48** 331 *1954*, DOI: 10.1016/0003-9861(54)90348-3]. The ***calcium salt*** can be partially purified by dissolving in ice-cold N HCl (1g per 10ml) and re-precipitating by dropwise addition of 2N NaOH: the precipitate and supernatant are heated on a boiling water bath for a short time, then filtered, and the precipitate is washed with hot water. The ***magnesium salt*** can be precipitated from a cold aqueous solution by adding four volumes of EtOH. The ***tetramethyl ester*** is an oil with **n_D^{10} 1.4648, $[\alpha]_D^{18}$ +20.2 (c 0.4, MeOH)**. [Schulbach & Rauchenberger *Chem Ber* **60** 1178 *1927*, DOI: 10.1002/cber.19270600536; *Beilstein* **1** IV 4424.]

Fructose-6-phosphate (Neuberg ester, β-D-form) *[643-13-0]* **$C_6H_{13}O_9P$, M 260.1, $[\alpha]_D^{21}$ +2.5 (c 3, H_2O), pK_1^{21} 0.97, pK_2^{21} 6.11, (pK_2^{25} 5.84).** Crystallise fructose-6-phosphate as the ***barium salt*** from water by adding 4-volumes of EtOH. The barium can be removed by passage through the H^+ form of a cation exchange resin, and the ***free acid*** is collected by freeze-drying. *Alternatively*, the Ba salt is dissolved in H_2O, and one equivalent of Na_2SO_4 is added in small portions with stirring, filter off $BaSO_4$ and freeze dry to give the ***Na salt***. The 6-phosphate hydrolyses more slowly than the 1-phosphate and considerably slower than pyrophosphoric acid (10^2 times) and triphosphoric acid (10^3 times). [For hydrolysis see Friess *J Am Chem Soc* **74** 5521 *1954*, DOI: 10.1021/ja01141a510; Tankó & Robinson *Biochem J* **29** 961 *1935*, DOI: 10.1042/bj0290961; Neuberg *Biochem Zeitschrift* **88** 432 *1918*, pKa: Meyerhof & Lohmann *Biochem Zeitschrift* **185** 113, 131 *1927*, Neuberg et al. *Arch Biochem* **3** 33, 40 *1944*, *Beilstein* **1** I 464, **1** IV 4423, H **31** 537.]

Gangcyclovir **[9-{(1,3-dihydroxy-2-propoxy)methyl}guanine; 2-amino-1,9-{(2-hydroxy-1-hydroxy-methyl)-ethoxymethyl}-6*H*-purin-6-one; Cytovene; Cymeva(e)n(e)]** *[82410-32-0]* **$C_9H_{13}N_5O_4$, M 255.2,**

m >290°(dec), >300°(dec), monohydrate m 248-249°(dec), $pK_{Est(1)}$~ -1.1, $pK_{Est(2)}$~ 4.1, $pK_{Est(3)}$~ 9.7. Recrystallise gangcyclovir from MeOH. *Alternatively*, dissolve ~90g of it in 700ml of H_2O, filter and cool (*ca* 94% recovery). It has UV with λ_{max} (MeOH) at 254nm (ε 12,880), 270sh nm (ε 9,040); its solubility in H_2O at 25° is 4.3mg/ml at pH 7.0. [Ogilvie et al. *Can J Chem* **60** 3005 *1982*, DOI: 10.1139/v82-430; Ashton et al. *Biochem Biophys Res Commun* **108** 1716 *1982*, DOI: 10.1016/S0006-291X(82)80109-5; Martin et al. *J Med Chem* **26** 759 *1983*, DOI: 10.1021/jm00359a023.] It is an antiviral drug.

Geraniol (*trans*-3,7-Dimethyl-2,6-octadien-1-ol) *[trans, E-form 106-24-1]* **$C_{10}H_{18}O$, M 154.2, b 114-115°/12mm, 229-230°/757mm, d_{15}^{15} 0.889, n_D^{20} 1.4628.** Purify geraniol by fractional distillation preferably at high vacuum. It has a sweet rose odour when pure, and the UV has λ_{max} at 190-195nm (ε 18,000). [*Beilstein* **1** H 457, **1** IV 2277.] It is an important biosynthetic intermediate, is present in rose, geranium, lemon and other essential oils, used in perfumery and as a flavouring agent.

Geranyl acetate *[trans, E-form 105-87-3; 16409-44-2]* **$C_{12}H_{20}O_2$, M 196.3, m <25°, b 118°/12mm, 138°/25mm, 236-242°/760mm(dec), d_{15}^{15} 0.9174, n_D^{15} 1.4766.** Purify the fragrant smelling geranyl acetate by fractional distillation at as high a vacuum as possible. It is very soluble in EtOH but insoluble in H_2O. [*Beilstein* **2** H 140, **2** I 65, **2** II 153, **2** III 299, **2** IV 204.] It has the scent of flowers and is used in food and cosmetics see *Food and Cosmetics Toxicology* **12** 885 *1974*, DOI: 10.1016/0015-6264(74)90167-9.

Geranylgeranyl pyrophosphate *[6699-20-3 (NH_4 salt), 64732-91-8]* **$C_{20}H_{36}O_7P_2$, M 450.5, $pK_{Est(1)}$~<2, $pK_{Est(2)}$~<2, $pK_{Est(3)}$~3.95, $pK_{Est(4)}$~6.26.** Purify the pyrophosphate by countercurrent distribution between two phases of a butanol/isopropyl ether/ammonia/water mixture (15:5:1:19) (v/v), or by chromatography on DEAE-cellulose (linear gradient of 0.02M KCl in 1mM Tris buffer, pH 8.9). *Alternatively*, purify it through a column of Dowex 1-x8 (formate form previously washed with MeOH) and eluted with a linear gradient of 0.053—0.43M ammonium formate in a total volume of 300ml of MeOH. The purity can be checked by TLC on Silica gel G on buffered plates (pH 6.5), eluted with $CHCl_3$/MeOH/H_2O (60:40:9) and developed with I_2 vapour. Store it as a powder at 0°. [Altman et al. *J Am Chem Soc* **94** 3257 *1972,* DOI: 10.1021/ja00764a073.] It is more stable as the ***di(tri-n-butylammonium)hydrogen phosphate salt*** which can be obtained from the acid by evaporation in a rotary evaporator below 32° [Upper & West *J Biol Chem* **242** 3285 *1967*, PMID: 4291475]. [Gregonis & Rilling *Biochemistry* **13** 1538 *1974*, DOI: 10.1021/bi00704a033; Gregonis & Rilling *Biochem Biophys Res Commun* **54** 449 *1973*, DOI: 10.1016/0006-291X(73)90942-X; for medical aspects see Wiemer et al. [*Clin Pharmacol Therap* **90**(6) 804 *2011*, DOI: 10.1038/clpt.2011.215. PMID: 22048229].

Geranyl pyrophosphate *[E-form 763-10-0 tri-(NH_4 salt), Z-form 16751-02-3]* **$C_{10}H_{20}O_7P_2$, M 314.2, $pK_{Est(1)}$~<2, $pK_{Est(2)}$~<2, $pK_{Est(3)}$~3.95, $pK_{Est(4)}$~6.26.** Purify the pyrophosphate by paper chromatography on Whatman No 3 MM paper in a system of isopropyl alcohol/isobutyl alcohol/ammonia/water (40:20:1:39), R_F 0.77-0.82. Store it in the dark as the ***ammonium salt*** at 0°. The *E*-form crystallises in platelets from aqueous Me_2CO, **m** ~120°. It dissolves in dry MeCN. *Alternatively*, purify it through a column of Dowex AG 1x8(200-400mesh) equilibrated with 50mM NH_4 formate, and elute with MeOH/H_2O/NH_4OH (95:5:05), then freeze-dry. [Dixit et al. *J Org Chem* **46** 1967 *1981*, DOI: 10.1021/jo00322a060; *Beilstein* **1** IV 3580.] It is an intermediate in the HMG-CoA reductase pathway.

Gliotoxin (3*R*-6*t*-hydroxy-3-hydroxymethyl-2-methyl-(5*at*)-2,3,6,10-tetrahydro-5*aH*-3,10*ac*-epidisulfido-[1,2-*a*]-indol-1,4-dione) *[67-99-2]* **$C_{13}H_{14}N_2O_4S_2$, M 326.4, m 191-218°(dec), 220°(dec), 221°(dec), $[\alpha]_D^{20}$ -254 (c 0.6, $CHCl_3$), $[\alpha]_D^{25}$ -270 (c 1.7, pyridine).** Purify gliotoxin by recrystallisation from MeOH. Its solubility in $CHCl_3$ is 1%. The ***dibenzoyl derivative*** has **m 202°** (from $CHCl_3$/MeOH). [Glister & Williams *Nature* 153 651 *1944*, DOI: 10.1038/153651a0; Elvidge & Spring *J Chem Soc* Suppl 135 *1949*, DOI: 10.1039/JR949000S135; Johnson et al. *J Am Chem Soc* **65** 2005 *1943*, DOI: 10.1021/ja01250a051; Bracken & Raistrick *Biochem J* **41** 569 *1947*, DOI: 10.1042/bj0410569; for a review see Waring & Chai *Aust J Chem* **68** 178 *2015*, DOI; 10.1071/CH14482.] It is a highly bioactive mycotoxin produced by various fungi.

Glucose-1-phosphate (G-1-P) (Cori ester) *[59-56-3]* **$C_6H_{13}O_9P$, M 260.1, $[\alpha]_D^{25}$ +120 (c 3, H_2O), $[\alpha]_D^{20}$ +78 (c 4, H_2O of di-K salt), pK_1 1.11, pK_2 6.13 [pK^{25} 6.50].** Two litres of a 5% aqueous solution of the phosphate are purified by adjusting the pH to 3.5 with glacial acetic acid (+ 3g of charcoal) and filtering. An

equal volume of EtOH is added, the pH is adjusted to 8.0 (glass electrode) and the solution is stored at 3° overnight. The precipitate is filtered off, dissolved in 1.2L of distilled water, filtered and an equal volume of EtOH is added. After standing at 0° overnight, the crystals are collected at the centrifuge and washed with 95% EtOH, then absolute EtOH, ethanol/diethyl ether (1:1), and diethyl ether. [Sutherland & Wosilait, *J Biol Chem* **218** 459 *1956*, PMID: 13278353.] Its ***barium salt*** can be crystallised from water and EtOH. Heavy metal impurities are removed by passage of an aqueous solution (*ca* 1%) through an Amberlite IR-120 column (in the appropriate H^+, Na^+ or K^+ forms). ***Di-K salt*** crystallises as a ***dihydrate*** from EtOH. [see McGready *Biochemical Preparations* **4** 63 *1955*.] [*Beilstein* **17/8** V 247.] This is the **α**–form, the **β**–form occurs in microbes.

Glucose-6-phosphate (G-6-P) (Robison ester) *[acid 56-73-5; Ba salt 58823-95-3; Na salt 54010-71-8]* **$C_6H_{13}O_9P$, M 260.1, m 205-207°(dec) mono Na salt, $[\alpha]_{546}^{20}$ +41 (c 5, H_2O), pK_1 1.65, pK_2 6.11, pK_3^{25} 11.71 [$-C_1(OH)O^-$].** It can be freed from metal impurities as described for glucose-1-phosphate. The solubility of the Na salt is 5% in H_2O at 20°. Its ***barium salt*** can be purified by solution in dilute HCl and precipitation by neutralising the solution. The precipitate is washed with small volumes of cold water and dried in air. *Alternatively*, the barium salt is dissolved in H_2O, 4 volumes of EtOH are added, the precipitate is collected, washed with 90% EtOH, absolute EtOH, 75% EtOH/25% Et_2O, 25% EtOH/75% Et_2O and finally dry Et_2O. The ***dry pure Barium salt*** has $[\alpha]_D^{25}$ +17.9° (c 1, H_2O). [*Beilstein* **1** IV.] **G-6-P** is relatively more stable to hydrolysis (12% hydrolysis in N HCl/100° in 4 hours) than G-1-P (45% hydrolysis in N HCl/20° in 20 hours). [Lardy & Fischer *Biochemical Preparations* **2** 39 *1952*.]

L-α-Glycerol phosphocholine (Cadmium Chloride)$_x$ complex *[64681-08-9]* **$C_8H_{20}NO_6P.CdCl_2$. M 257.2 + (183.3)$_x$, pK_{Est} ~ 5.5.** Glycerol phosphocholine is purified *via* the $CdCl_2$ complex which is recrystallised four times from 99% EtOH by standing at 0° for 1 hour. The white precipitate is collected, washed with EtOH, Et_2O and dried in a vacuum. The amorphous Cd complex can be converted to the crystalline form ***[$C_8H_{20}O_6NP.CdCl_2.3H_2O$]*** by dissolving 34.4g in H_2O (410ml), and 99% EtOH (1650ml total) is added slowly with stirring and allowing the clear solution to stand at 25° for 12 hours, then at 5° for 12 hours. The crystalline complex is filtered off, washed with cold 80% EtOH and dried in air. ***Glycerol phosphocholine*** is be recovered from the complex by dissolving in H_2O (2% solution) and passing it through an ion-exchange column (4.9 x 100cm, of 1 volume IRC-50 and 2 volumes of IR-45). The effluent is concentrated to a thick syrup at 45°. It is dried further at 50°/P_2O_5/48 hours. The vitreous product (~8.25g) is then dissolved in 99% EtOH (50ml), and the clear solution is cooled to 5°, whereby crystals begin to appear, and crystallisation is completed at -15°/16 hours. The crystals are filtered off, washed with 99% EtOH, and Et_2O then dried at 50° *in vacuo* over P_2O_5. It can be recrystallised from 99.5% EtOH (long prisms). It is ***hygroscopic*** and must be handled in a H_2O-free atmosphere [Tattrie & McArthur *Biochemical Preparations* **6** 16 *1958*, Baer & Kates *J Am Chem Soc* **70** 1394 *1948*, DOI: 10.1021/ja01184a031; Abrahamsson & Pascher *Acta Cryst* **21** 79, 87 *1966*, DOI: 10.1107/S0365110X66002366].

Hematin (ferrihaeme hydroxide) *[15489-90-4]* **$C_{34}H_{33}N_4O_5Fe$, M 633.5, m 200°(dec), pK_{Est} ~ 4.** Crystallise the bluish-black or brownish-black solid from pyridine. Dry it at 40° *in vacuo*. It is soluble in dilute aqueous NaOH or KOH and has λ_{max} (2.5N NaOH) at 580nm (**ε** 10500). [*Beilstein* **26** III/IV 3047.]

Hesparin IX (8,13-bis(1-hydroxyethyl)-3,7,12,17-tetramethyl-21*H*-23*H*-porphin-2,18-dipropionic acid, 3,3'-[7,12-bis-(1-hydroxyethyl)-3,8,13,17-tetramethyl-porphyrin-2,18-diyl]-dipropionic acid) *[14459-29-1]* **$C_{34}H_{38}N_4O_6$, M 598.7, pK_{Est} ~4.8, 3.67.** Purify it by dissolving it in EtOH and adding H_2O or Et_2O to give deep red crystals. It has also been recrystallised from MeOH. Its UV has λ_{max} at 615.5, 565, 534.4 and 499.5nm in 0.1N NaOH, and 597, 619, 634, 653, 683 and 701nm in 2N HCl [Falk *Porphyrins and Metalloporphyrins* Elsevier, NY, p 175 *1964*, LCCCNo 63-19821.] It is used in the affinity chromatographic purification of Heme proteins [Olsen *Methods Enzymol* 123 324 *1986*, DOI: 10.1016/S0076-6879(86)23038-4]. The ***dihydrochloride*** *[17696-69-4]* **M 671.6,** crystallises from EtOH/HCl/Et_2O and is partly soluble in H_2O and 5w/v% in pyridine. The ***O-methyl-dimethyl ester*** has **m 203-206°** (from $CHCl_3$/MeOH), and the ***O,O'-dimethyl-dimethyl ester*** has **m** 145° (from $CHCl_3$/MeOH). [Paul *Acta Chem Scand* **5** 389 *1951*, DOI: 10.3891/acta.chem.scand.05-0389; *Beilstein* **26** III/IV 3157, and 3158 for the HCl.] ***Hematoporphyrin dimethyl ester*** *[33070-12-1, 5594-29-6]* **$C_{36}H_{42}N_4O_6$, M 626.7,** has **m 212°, 212.2-217.2°.** It crystallises from $CHCl_3$/MeOH [*Beilstein* **26** III/IV 3157.]

Hematoxylin (±-11*bc*-7,11*b*-dihydroindeno[2,1-*c*]-chromen-3,4-6*ar*-9,10-pentaol) *[517-28-2]* **$C_{16}H_{14}O_6$, M 302.3, m 200°(dec), 210-212°(dec).** Hematoxylin crystallises from H_2O (as ***trihydrate***) in white-yellow crystals which become red on exposure to light and then melt at 100-120°. It can be recrystallised from $Me_2CO/*C_6H_6$. It has also been recrystallised from dilute aqueous $NaHSO_3$ until colourless and is soluble in alkali, borax and glycerol. Store it in the dark below 0°. [Morsingh & Robinson *Tetrahedron* **26** 281 *1970*, DOI: 10.1016/0040-4020(70)85029-3; Dann & Hofmann *Chem Ber* **98** 1498 *1965*, DOI: 10.1002/cber.19650980524; *Beilstein* **17/8** V 469.] Used extensively for staining plant and animal tissue. [Puchtler et al. *Histochemistry* **85** 353 *1986*, DOI: 10.1007/ BF00982665.] It has one more phenolic group than *Brazilin (474-07-7, Brazilein)*.

Hemin (ferriproptoporphyrin IX chloride) *[16009-13-5]* **$C_{34}H_{32}ClN_4O_4Fe$, M 652.0, m sinters at 240°, pK_{Est} ~4.8.** Hemin is purified by recrystallisation from AcOH. Also, hemin (5g) is shaken in pyridine (25ml) till it dissolves, then $CHCl_3$ (40ml) is added, the container is stoppered and shaken for 5 minutes (releasing the stopper occasionally). The solution is filtered under slight suction, and the flask and filter are washed with a little $CHCl_3$ (15ml). During this period, AcOH (300ml) is heated to boiling, and saturated aqueous NaCl (5ml) and concentrated HCl (4ml) are added. The $CHCl_3$ filtrate is poured in a steady stream, with stirring, into the hot AcOH mixture and set aside for 12 hours. The crystals are filtered off, washed with 50% aqueous AcOH (50ml), H_2O (100ml), EtOH (25ml), Et_2O and dried in air. [Fischer *Org Synth* Coll Vol **3** 442 *1955*, DOI: 10.15227/orgsyn.021.0053; *Beilstein* **26** III/IV 3048.] It is used in the treatment of ***porpheria***.

α-1,2,3,4,5,6-Hexabromocyclohexane (NSC 7908, Jak2 inhibitor, α-1r,2t,3t,4c,5t,6c-hexabromocyclohexane) *[1837-91-8]* **$C_6H_6Br_6$, M 557.5, m 222°, 216-218°, 218-223°, 224-225°, b 388.9° /760mm (predicted), d ^{25} 2.90g/cm^3, n $^{20}_{D}$ 1.70.** Although eight stereoisomers are possible, the least adaptable isomers should be the ones where 1,3-diaxial bromine atoms in the cyclohexane ring, which would be dis-favoured due to strong non-bonded interactions. The most favourable configuration, and consequently more stable, is the one where the cyclohexane ring is in the *chair* conformation with all the six bromine atoms holding *equatorial* orientations. α-*1,2,3,4,5,6-Hexabromocyclohexane* has been prepared in 86% yield by prolonged exposure of Br_2 (50g, 16ml) in $*C_6H_6$ (100ml) to sunlight and isolating successive crops, combining them and recrystallising them from toluene to give white cubes with **m 216-218°**. The yield is affected by the light source and strength — stronger light greatly decreases the yield. A series of reactions occur here and were uravelled by Bolton et al. [*JCS Perkin Trans 1* 893 *1984*, DOI: 10.1039/P19840000893.] who showed that it was the isomer where four Br atoms on consecutive carbon atoms of the cyclohexane ring are in the *equatorial* orientation, while the fifth and sixth adjacent Br atoms are in the *axial* configuration. It used to be referred to as 'α-benzene hexabromide' and its structure was confirmed by X-ray crystallography (130K), and by ^{1}H and ^{13}C NMR spectroscopy to be r-*1*, t-*2*, t-*3*, c-*4*, t-*5*, c-*6-hexabromocyclohexane* (where r = reference point, t = trans and c = cis) [Carman et al. *Aust J Chem* **47** 1395 *1994*, DOI: 10.1071/CH9941395].

β-1,2,3,4,5,6-Hexabromocylohexane *[87-82-1, 3015-41-0]* is apparently the thermodynamically stable isomer which has been known for some time. It was prepared by Orndorff and Howells [*J Am Chem Soc* **18** 312 *189*], and repeated by Hendricks and Bilicke [*J Am Chem Soc* **48** 3007 *1928*, DOI: 10.1021/ja01691a001] who added slowly, and successively, small amounts of Br_2 to a layer of $*C_6H_6$ floating on a 1% solution of NaOH at a temperature near 0°. The ***α- and β- isomers*** were isolated from the solid that separated from the lower layer by boiling with EtOH in which they have limited solubility. The ***α- form*** was separated by extraction with $CHCl_3$ leaving the ***β-form*** behind. The latter was recrystallised from boiling xylene which gave a 0.1% yield of small crystals, 1mm thick, which showed a crystal development of [111] and [110]. These crystals had a sharp **melting point** at **253°**. The latter authors have determined the X-ray structure of the crystals of this ***β-isomer*** which showed that they are of the point group $\mathbf{C_{3i}}$, which require a three-fold axis and a centre of symmetry, consistent with a cyclohexane ring with ***all the bromine atoms*** in the ***equatorial*** orientation.

α-1,2,3,4,5,6-Hexabromocyclohexane has limited solubility in most solvents but can be recrystallised from toluene and is extractable from the ***β-isomer*** with hot $CHCl_3$ (see above). To obtain higher solubility make a solution in DMSO (5mg/ml) by warming at 37° with shaking in an ultrasonic bath for several minutes. This stock solution can be stored below -20° for several months. The ***enantiomers*** of this isomer have been separated by gas chromatography (see Kallenborn et al. *ChemInform Abstract* **22** (Issue 20) page no, May 21, 1991, on line 23 Aug *2010*, DOI: 10.1002/chin.199120281].

Sayeski and coworkers [Sandberg et al. *J Med Chem* **48** 2526 *2005*, DOI: 10.1021/jm049470k, PMID: 15801842] have identified this ***α-isomer*** as a small molecule inhibitor of Jak2 tyrosine kinase autophosphor-

ylation which specifically ***inhibits*** ligand-dependent Jak2 activation.

(+)-Hydroquinidine anhydrous (9*S*-6'-methoxy-10,11-dihydrocinchonan-9-ol) *[1435-55-8]* **$C_{20}H_{26}N_2O_2$, M 326.4, m 168-169°, 169°, 169-170°, 171-172°, $[\alpha]_D^{20}$ +231 (c 2, EtOH), +299° (c 0.82, 0.1N H_2SO_4), pK_{Est} ~ 8.8.** (+)-Hydroquinidine forms needles from EtOH and plates from Et_2O. It is slightly soluble in Et_2O and H_2O but readily soluble in hot EtOH. The ***hydrochloride*** *[1476-98-9]* has **m 273-274°** (**dec**, darkening at ~270°), and $[\alpha]_D^{26}$ +183.9 (c 1.3, MeOH); and is very soluble in MeOH and $CHCl_3$, but less soluble in H_2O, EtOH and still less soluble in dry Me_2CO. [Heidelberger & Jacobs *J Am Chem Soc* **41** 817 *1919*, DOI: 10.1021/ja02226a015; King *J Chem Soc* 523 *1946*, DOI: 10.1039/JR9460000523.] [Kyker & Lewis *J Biol Chem* **157** 707 *1945*, http://www.jbc.org/content/157/2/707; Emde *Helv Chim Acta* **15** 557 *1932*, DOI: 10.1002/hlca.19320150156; *Beilstein* **23/13** V 340.] It is a useful base for ***optical resolutions*** of chiral acids.

Hydroquinine [(8α,9*R*)-10,11-dihydro-6′-methoxycinchonan-9-ol] *[522-66-7]* **$C_{20}H_{26}N_2O_2$, M 326.4, m 168-171°, 171.5°, $[\alpha]_D^{16}$-143.5 (-148) (c 1.1, EtOH), pK^{15} 5.33 and 8.87.** Recrystallise hydroquinine from EtOH, Et_2O or $*C_6H_6$. The ***hydrochloride*** *[1668-97-9]* $C_{20}H_{26}N_2O_2$. HCl. $0.5H_2O$, crystallises from H_2O and decomposes at **206-208°** (after initial rapid heating to 200°). It is soluble in H_2O, EtOH and Me_2CO and has $[\alpha]_D^{21}$ -123.9 (c 1.11 H_2O). [Rabe & Schultz *Chem Ber* **66** 120 *1933*, DOI: 10.1002/cber.19330660208; for synthesis see Heidelberger & Jacobs *J Am Chem Soc* **41** 817 *1919*, DOI: 10.1021/ja02226a015; *Beilstein* **23** III/IV 3193, **23/13** V 340.] It is a useful base for ***optical resolutions*** of chiral acids. The ***racemate*** has **m 175-175.5°** (from EtOH and drying at 100°/0.1mm).

5-Hydroxycreatinine (creatol, CTL, 2-amino-5-hydroxy-1-methylimidazolidin-4-one) *[133882-98-1]* **$C_4H_7N_3O_2$, M 129.1, m 190° (191°, dec) for the hydrochloride, pK^{25} 4.2.** Creatol is one of three metabolites of creatinine *[60-27-5]* which was isolated from inflamed rabbit skin tissues [Ienaga et al. *Tetrahedron Lett* **28** 4587 1987, DOI: 10.1016/S0040-4039(00)96571-7], and the urine of uraemic rats (adenine induced chronic renal failure) and uraemic patients. The other two metabolites are 1-methylhydantoin (1-methylimidazolidine-2,4-dione *[616-04-6]*) and 5-hydroxy-1-methylhydantoin [1-methyl-5-hydroxyimidazolidine-2,4-dione *[84210-26-4]*. [Ienaga et al. *JCS Chem Commun* 509 *1991*, DOI: 10.1039/C39910000509.] Urine from uraemic rats (44ml, collected after 24 hours of administration of creatinine) was applied onto a PK216 ion exchange column (H^+ form) that was washed with H_2O, then eluted with aqueous NH_3 (2mol dm^{-3}) and evaporated *in vacuo*. The residue, in H_2O, was applied onto a Biolex-70 ion exchange column (H^+ form) that was washed with H_2O, then eluted with aqueous AcOH (0.1mol dm^{-3}), and the eluate was evaporated *in vacuo* to give ***creatol*** (0.66mg, 0.11%, purity checked by ODS reverse phase HPLC). [The H_2O wash from the PK216 column gave the other two metabolites (1.5mg, 0.35 and 0.87mg, 0.15% respectively) which were separated on a silica gel column with EtOAc elution. ***Creatol*** has ^1H NMR (D_2O, *tert*-BuOH as internal standard) with δ at 3.11 (s, in $N^{12}CH_3$ creatol; but d, in $N^{13}CH_3$ labelled creatol with J = 143 Hz) and 5.11 (s, H-5); and ^{13}C NMR (D_2O, dioxane as internal standard) with δ at 30 (NCH_3), 81 (*C*-5), 160 (*C*-2) and 174 (*C*-4). [Ienaga et al. *JCS Chem Commun* 509 *1991*, DOI: 10.1039/C39910000509.] The ***natural enantiomer*** most probably has the ***S configuration*** at C-5 [see Ienaga et al. *JCS Chem Commun* 509 *1991*, DOI: 10.1039/C39910000509]. [Nakamura & Ienaga, Glycocyamidine derivatives, *Japanese Kokai Tokkyo Koho*, JP 2957217 *1989*, US patent 4957936 *1990*.] A urinary metabolite indicator of renal disfunction. Data kindly supplied by Dr Kazu Ienaga, Nippon Zoki Pharmaceutical Co Ltd, Osaka, Japan.

R*-(-)-2-Hydroxy-3,3-dimethyl-γ-butyrolactone (3-hydroxy-4,4-dimethyl-4,5-dihydrofuran-2-one, D-pantolactone)** *[599-04-2]* **$C_6H_{10}O_3$, M 130.1, m 89-91°, 90.5-91.5°, 91°, 92-93°, b 120-122°/15mm, $[\alpha]_D^{20}$ -28° (c 5, MeOH), $[\alpha]_D^{20}$ -51 (-49.1) (c 3, H_2O).** Recrystallise the lactone from Et_2O/petroleum ether, diisopropyl ether or $*C_6H_6$/petroleum ether and sublime it at 25°/0.0001mm. It hydrolyses readily to the hydroxy-acid and racemises when heated above 145°. Store at 2-8°. The ***Brucine salt has **m 211-212°** (from EtOH). [Kuhn & Wieland *Chem Ber* **73** 1134 *1940*, DOI: 10.1002/cber.19400731020; and Stiller et al. *J Am Chem Soc* **62** 1779 *1940*, DOI: 10.1021/ja01864a037; Beutel & Tishler *J Am Chem Soc* **68** 1463 *1946*, DOI: 10.1021/ja01212a020; *Beilstein* **18/1** V 22.] The ***racemate*** *[79-50-5]*, **m 74-78°**, **80°**, **b 130°/18mm**, purified in the same way, is ***hygroscopic*** and its ***resolution*** has been described [Major & Finkelstein *J Am Chem Soc* **63** 1368 *1941*, DOI: 10.1021/ja01850a068; see also preceding references].

(±)-5-Hydroxy-1-methyl-imidazolidine-2,4-dione (HMH) *[84210-26-4]* **$C_4H_6N_2O_3$, M 130.1, m 138°, pK 8.64.** The racemic compound was obtained by oxidation of *N*-1-methylhydantoin with $Pb(OAc)_4$ in $*C_6H_6$ (60°, 24 hours), isolation of the 5-acetoxy derivative (*via* a short silica-gel column chromatography; eluting with $*C_6H_6$/hexane), followed by hydrolysis with aqueous 0.3M H_2SO_4 (~25°, 40 minutes). Neutralisation, followed by evaporation, and silica-gel TLC (EtOAc) provided pure ***racemate*** **m 138°**, (64% yield) with the expected ^{1}H NMR spectrum, EI MS and elemental analysis. It is a ***plant growth regulator*** affecting the flowering period of cut white chrysanthemums at concentrations as low as 10^{-6} M. [Ienaga et al. *Tetrahedron Lett* **28** 4587 *1987*, DOI: 10.1016/S0040-4039(00)96571-7.] The ***natural metabolite*** **N-1-methylhydantoin** (**MH** *[616-04-6]*, see below) was isolated from rabbit urine by diluting the urine two-fold with MeOH and evaporating. The residue was extracted with MeOH/EtOAc (1:6), filtered, the filtrate was concentrated, subjected to silica-gel column chromatography and eluted with MeOH/$CHCl_3$ (1:9). The first eluate gave the pure crystalline ***5-hydroxy compound*** (**HMH**, 28% of total) that had **m 147-150°** and $[\alpha]_D^{25}$ **-**5.1 (c 1.0, MeOH). The expected ^{1}H NMR [Eu(tfc)$_3$] spectrum indicated that its enantiomeric excess was 56% (i.e. a 78:22 mixture). Some racemisation of the 5-hydroxy compound may well have occurred during isolation. The synthetic ***racemate*** was resolved by conversion into the diastereoisomeric Bz-L-proline ester (1:1, *R*:*S*) [with 1-(3-diethylaminopropyl)-3-ethylcarbodiimide HCl in the presence of DMAP in MeCN at 0°/2 hours) followed by purification through a silica-gel column and eluting with EtOAc/hexane (7:3)] in 56% yield. Fractional recrystallisation from Me_2CO gave pure 5-(*R*)-(*N*-Bz-L-prolyloxy)-1-methylimidazolidine-2,4-dione (30%), **m 189-192°,** $[\alpha]_D^{25}$ **–**2.1 (c 1.0, MeOH) {^{1}H NMR, DMSOd_6 has δ at 1.8-2.0 (m, 3H), 2.2-2.4 (m, 1 H), [2.52 (s) + 2.75 (s), 3H], 3.4-3.55 (m, 2 H), [4.35 (dd, *J* = 4, 9 Hz) + 4.46 (dd, *J* = 4, 9 Hz) 1H], [5.03 (s) + 5.10 (s) 2H] , [6.90 (s) + 6.10 (s) 1H], 7.25-7.45 (m, 5H, aromatic) and 11.21 (br s, NH)}; and when these crystals were subjected to X-ray crystallography they revealed that the absolute configuration at C5 of the *imidazolidine-2,4-dione* part of the molecule was ***R***, and that C5 of the *natural metabolite* was therefore ***S*** when a comparison of the HPLC of the mixture of prolyl-esters from the natural metabolite was made. The residue from evaporation of the mother liquors was recrystallised from EtOAc and gave the diastereoisomeric ***5-(S)-N-Bz-L-prolyl ester*** (8%) with **m 147-150°,** and $[\alpha]_D^{25}$ **–**68.9 (c 1.0, MeOH) {^{1}H NMR, DMSOd_6 has δ at 1.7-2.0 (m, 3H), 2.2-2.4 (m, 1 H), [2.63 (s) +2.73(s), 3H], 3.35-3.55 (m, 2 H), [4.36 (dd, *J* = 4, 9 Hz) + 4.47 (dd, *J* = 4, 9 Hz) 1H], [5.04 (d, *J* = 13Hz) + 5.07 (d, *J* = 13Hz) 1H], [5.07 (d, *J* = 13Hz) + 5.13 (d, *J* = 13Hz) 1H], [6.05 (s) + 6.12 (s) 1H], 7.25-7.45 (m, 5H, aromatic) and 11.25(br s, NH)}. Hydrolysis of these esters gave ***racemic*** 5-hydroxyimidazoline-2,4-dione, however, owing to facile racemisation. [Ienaga et al. *JCS Perkin Trans I* 1153 *1989*, DOI: 10.1039/P19890001153.] The ***racemate*** and the ***optically active*** form of ***5-hydroxy-1-methylhydantoin*** have the same ^{1}H NMR (400MHz, Me_2CO-d_6, TMS) with δ at ~5.1 (d, C-5) and ~5.9 (d, 1-NMe). Data kindly supplied by Dr Kazu Ienaga, Nippon Zoki Pharmaceutical Co Ltd, Osaka, Japan. These are urinary metabolites and ***indicators of renal health***.

(-)-Inosine **{9-[(2*R*,3*R*,4*S*,5*R*)-3,4-dihydroxy-5-(hydroxymethyl)oxolan-2-yl]-6,9-dihydro-3*H*-purin-6-one}** *[58-63-9]* **$C_{10}H_{12}N_4O_5$, M 268.2, m 90° (dihydrate), 218° (dec, anhydrous), $[\alpha]_{546}^{20}$ -76 (c 1, 0.1M NaOH), pK_1^{25} 1.06, pK_2^{25} 8.96, pK_3^{25} 11.36.** (-)-Inosine forms ***anhydrous*** crystals from aqueous 80% EtOH but the *dihydrate* from H_2O. [*Beilstein* **31** H 25, **26** III/IV 2087.] Inosine is commonly found in tRNAs.

myo*-Inositol (cyclohexane[1*r*,2*c*,3*c*,4*t*,5*c*,6*t*]-hexol)** *[87-89-8]* **$C_6H_{12}O_6$, M 180.2, m 218° (di-hydrate), 225-227°, 226-230°.** Recrystallise *myo*-inositol from aqueous 50% ethanol or H_2O forming a ***dihydrate, or ***anhydrous*** crystals from AcOH. The dihydrate is ***efflorescent*** and becomes anhydrous when heated at 100°. The anhydrous crystals are not hygroscopic. Its solubility in H_2O at 25° is 14%, at 60° it is 28%; it is slightly soluble in EtOH but insoluble in Et_2O. [Ballou & Anderson *J Am Chem Soc* **75** 648 *1953*, DOI: 10.1021/ja01099a039; Anderson & Wallis *J Am Chem Soc* **70** 2931 *1948*, DOI: 10.1021/ja01189a030; *Beilstein* **6** II 1157, **6** IV 7919.] Combined GC-MS study of many organic-rich marine sediments identified *myo*-inositol, *chiro*-inositol and *scyllo*-inositol, with the *myo*-isomer as the most abundant. [White & Miller *Science* **193** (issue 4256) 885 *1976*, DOI: 10.1126/science.193.4256.885]. *myo*-Inositol is useful in the treatment of several medical problems, e.g. bulimia, panic disorder, obsessive compulsive disorder (OCD), unipolar and bipolar depression, and is used as a food supplement [Clemments & Damell *Am J Clin Nutr* **33**(9) 1954 *1980*, PMID: 7416064].

Inositol monophosphate *[15421-51-9]* **$C_6H_{13}O_9P$, M 260.1, m 195-197°(dec).** Crystallise the phosphate from

water, and EtOH. Recrystallise 1g by dissolving it in 3ml of H_2O and adding slowly 15ml of commercial EtOH, filter the crystals, wash with a little EtOH then Et_2O and dry it in a vacuum. Although hydrolysed by boiling 6N HCl (~14 hours), it is rather resistant to boiling strong alkali. [McCormick & Carter *Biochemical Preparations* **2** 65 *1952*, Posternak *Helv Chim Acta* **12** 1165 *1929*, DOI: 10.1002/hlca.192901201125] It is involved in ***trans-membrane signaling*** when bound to lipids.

5-Iodouridine (5-iodo-1-[β-D-ribofuranosyl]-pyrimidine-2,4(1*H*)-dione) *[1024-99-3]* **$C_9H_{11}IN_2O_6$, M 370.1, m 205-207°(dec), 205-208°(dec), 210-215°(dec), $[\alpha]_D^{20}$ -23.5 (c 1, H_2O), pK^{20} 8.5.** Recrystallise 5-iodouridine from H_2O and dry it *in vacuo* at 100°. Its UV has λ_{max} at 289nm (0.01N HCl) and 278nm (0.01N NaOH). [Prusoff et al. *Cancer Res* **13** 221 *1953*, *Beilstein* **24** III/IV 1235.] It can be incorporated into RNA and used for X-ray crystallography of the RNA [Golden et al. *RNA* **2** 1295 *1996*, PMID: 8972777].

Isopentenyl pyrophosphate *[358-71-4]* **$C_5H_{12}O_7P_2$, M 246.1, $pK_{Est(1)}$~<2, $pK_{Est(2)}$~<2, $pK_{Est(3)}$~3.95, $pK_{Est(4)}$~6.26.** Purify the pyrophosphate by chromatography on Whatman No 1 paper using *tert*-butyl alcohol/formic acid/water (20:5:8, R_F 0.60) or 1-propanol/ammonia/water (6:3:1. R_F 0.48). *Alternatively*, purify it by chromatography on a DEAE-cellulose column or a Dowex-1 (formate form) ion-exchanger using formic acid and ammonium formate as eluents. A further purification step is to convert it to the ***monocyclohexylammonium salt*** by passage through a column of Dowex-50 (cyclohexylammonium form) ion-exchange resin. Also converted into its ***lithium salt***. It is the primary compound in mevalonate biosynthesis. [Wiemer et al. *Current topics in medicinal chemistry* **10**(18) 1858 *2010*, PMID: 20615187.]

Kanamycin B (Bekanamycin, 4-*O*-[2,6-diamino-2,6-dideoxy-α-D-glucopyranosyl]-6-*O*-[3-amino-3-deoxy-α-D-glucopyranosyl]-2-deoxystreptamine) *[4696-76-8, 29701-07-3 (sulfate salt)]* **$C_{18}H_{37}N_5O_{10}$·H_2SO_4, M 483.5 (free base), 587.6 (salt), m 170-179°(dec), 178-182°(dec), $[\alpha]_D^{18}$ +130 (c 0.5, H_2O), pK^{25} 7.2.** A small quantity of kanamycin B (24mg) can be purified on a small Dowex-1 x 2 column (6 x 50mm); the required fraction is evaporated to dryness and the residue crystallised from EtOH containing a small amount of H_2O. [Umezawa et al. *Bull Chem Soc Jpn* **42** 537 *1969*, DOI: 10.1246/bcsj.42.537.] It has been crystallised from H_2O by dissolving ~1g in H_2O (3ml), adding Me_2NCHO (3ml) and setting aside at 4° overnight. The needles are collected and dried to constant weight at 130°. It has also been recrystallised from aqueous EtOH. It is slightly soluble in $CHCl_3$ and isoPrOH. [IR: Wakazawa et al. *J Antibiot* **14A** 180, 187 *1961*, Ito et al. *J Antibiot* **17 A** 189 *1964*; for total synthesis of aminoglycosides see *J Antibiot* **66** 107 *2013*, DOI: 10.1038/ja.2012.126; *Beilstein* **18** III/IV 7631.] Antibiotic, potent against Gram-positive bacteria, affecting ribosomal RNA synthesis.

Ketamine [2-(2-chlorophenyl)-2-(methylamino)cyclohexanone)] *[6740-88-1]* **$C_{13}H_{16}ClNO$, M 237.7, m 92-93°, pK^{25} 7.50.** Its preparation has been described by Stevens [US patent 3254124 A to Parke Davis & Co, May 31 *1966*] which required a rearrangement with ring expansion. The steps in one variant of the synthesis involved preparing *o*-chlorophenyl 1-hydroxycyclopentyl ketone *N*-methylimine [from cyclopentylMgBr + *o*-chlorobenzonitrile → *o*-chhlorophenyl cyclopentyl ketone, b 96-97°/0.3mm, n_D^{20} 1.5452 → *o*-chlorophenyl 1-bromocyclopentyl ketone, b 111-114°/0.1mm + $MeNH_2$ at 50°/1hr in a bomb → *o*-chlorophenyl 1-hydroxycyclopentyl ketone *N*-methylimine, m 62°) and heating it in excess $MeNH_2$ in an autoclave at ~200°/5hrs, evaporating to dryness (fume cupboard, and absorb $MeNH_2$ in aqueous HCl), adding *iso*-PrOH/HCl and isolating ***ketamine hydrochloride*** *[1867-66-9]* **M 274.2**, as white crystals **m 262-263°** after recrystallisation from EtOH-Et_2O. Its solubility in H_2O is 20w/v% at ~25°. ***Ketamine*** is obtained by basifying the hydrochloride with dilute aqueous NaOH (~0.5N, to pH >10), extracting with Et_2O, drying, evaporating and recrystallising the residue from pentane-Et_2O. The UV of the neutral species (0.01N NaOH in 95% MeOH, see pKa above) has λ_{max}(nm)($E^{1\%}_{cm}$) at 261(10.7), 268(9.8), 276(7.0) and 301(5.0). [For rearrangement of α-aminoketones see Stevens *J Am Chem Soc* **84** 2272 *1962*, DOI: 10.1021/ja00870a062].

Optical resolution: Ketamine has one asymmetric centre and has been resolved into its optical isomers ***S*(-)-ketamine (Esketamine)** *[33643-46-8] and* ***R*(+)-ketamine (Arketamine)** *[33643-49-1]* which is described by Steiner et al. [patent DE 1961665 A1 to Uetikon Chemie Gmbh, Nov 20, 1997; see also Hudyama et al. German Patent 2,062,620 *1970*, *Chem Abstr* **75** 119119x *1971*]. Only the preparation of ***Esketamine*** is provided here because it is ~3 times more active than its enantiomer, 2 times more active than the ***racemate*** and is available commercially; the *R*-enantiomer has not been marketed as an enantio pure drug for clinical use. Thus *RS*-ket-

amine (50g, 0.21 mol) in boiling Me_2CO (613ml) is treated with L(+)-tartaric acid (31.5g, 0.21 mol), and to obtain a clear solution H_2O (40ml) is added at the boiling point and the hot solution is filtered, After seeding, the solution is cooled to ~25°, the crystals are filtered off, dried first at ~25° then at 50-60° to give the crude (-)-base-(+) acid diasteriomeric tartrate [**m 161°**, $[\alpha]_D^{20}$ +26.1 (c 2, H_2O)]. This is recrystallised from a hot Me_2CO (1226ml) and H_2O (90ml) mixture, which on cooling to ~25° with stirring for 4 hours gives pure diasteriomeric tartrate (38.8g, 95%) after drying as before, which has m 175.3°, $[\alpha]_D^{20}$ +68.9 (c 2, H_2O). The (-)-base-(+) acid salt (38.8g) in aqueous NaOH (420ml, pH>10) is stirred with Et_2O (540ml), the ethereal extract is washed with H_2O and brine, dried (Na_2SO_4), filtered and evaporated to dryness to give colourless crystals [21.5g, 86%; m **118.9°**, $[\alpha]_D^{20}$ -55.8 (c 2, H_2O)]. The crystals (10.75g) are recrystallised from hot cyclohexane (43ml), which after stirring with cooling at 10° during 1 hour gave pure ***S(-)-ketamine*** (10.3g, 96%) with **m 120°** (also **120-122°**) and **$[\alpha]_D^{20}$ -56.8 (c 2, EtOH)**.

When ***S(-)-ketamine*** (5g) is dissolved in *iso*-PrOH (50ml) at ~50°, filtered through kieselguhr, then HCl gas is passed through the solution at 50-60° until the pH is 0-1 and cooled to ~20°; the crystals are collected washed with cold *iso*-PrOH (5ml), dried overnight in an oven at 50° provided ***pure S(+)-ketamine hydrochloride*** *[33795-24-3]* (5.09g, 88%) **$[\alpha]_D^{25}$ +92.5 (c 2, H_2O).** [***Note*** change in sign of the optical rotation].

R*(+)-ketamine** and ***R(-)-ketamine hydrochloride *[33795-24-3]* can be obtained in a similar way but using D(+)-tartaric acid. There is much confusion in the literature about the absolute configuration most probably because the free base has the opposite sign of rotation from that of its hydrochloride, and because it is the (+)-hydrochloride that is generally used as the drug since it is 3 times more active than the (-)-hydrochloride. Also when the name Ketamine is used, it is the ***hydrochloride drug*** that is usually intended. This was put to rest when Groth and coworkers [Ratti-Moberg *Acta Chem Scand* **45** 108 *1991*, DOI: 10.3891/acta.chem.scand.45-0108] determined the crystal structure of the *R,R*-tartrate salt of levo-ketamine showing that (-)-ketamine has the *S*- absolute configuration, and that its hydrochloride has a positive rotation for the sodium D line(s) at ~25°.

Ketamine is a controlled anti-depressant drug that requires a medical prescription for use. It is an anaesthetic (dissociative) and a ***non-competitive NMDA*** (*N*-methyl-D-Aspartate) ***receptor antagonist***, with the *S(+)*-HCl having three times the activity of its enamtiomer. [Hashimoto in Zhang et al. *Pharmacol Biochem Behavior* **116** 137 *2014*, DOI: 10.1016/j.pbb.2013.11.033; review: Morgan et al. *Addiction* **107** 27 *2012*, DOI: 10.1111/j.1360-0443.2011.03576.x; Anis et al. *Br J Pharmacol* **79** 565 *1983*, PMCID: 2044888; Liu et al. *Anesth Analg* **92** 1173 *2001*, PMID: 11323343.]

Lansoprazole {2-[4-(2,2,2-trifluoroethoxy)-3-methyl-2-pyridylmethylsulfinyl)]-1*H*-benzimidazole, Zoton, Takepron) *[103577-45-3]* $C_{16}H_{14}F_3N_3O_2S$, M369.4, m 178-182°(dec), pKa similar to Omeprazole.

It is a drug related to ***Omeprazole*** (see below) with similar structure except that the 5-methyl group is missing, the 4-methoxygroup is replaced by a 2,2,2-trifluoroethoxy group in the pyridine ring and the 5-methoxy group is missing in the benzimidazole ring. Although it exhibits similar properties to Omeprazole, Katsuki et al. [*Pharm Res* **13** 611-615 *1996*, DOI: 10.1023/A:1016062508580] found that the enantiomers of Lansoprazole show different pharmacokinetic profiles in humans. The *R*-(+) isomer is more effective as a ***proton pump inhibitor*** due to its higher bioavailability and less adverse side effects.

Racemic Lansoprazole can be optically resolved, *via* the *diasteriomeric* (1:2) inclusion compounds with *R*-(+)-1,1,2-triphenyl-1,2-ethane diol. Thus, according to the procedure of Sun Young Jan et al. [WO2010068049 A2, *2010*], a mixure of (±)-Lansoprazole (40.0g, 1mol) and *R*-(+)-1,1,2-triphenyl-1,2-ethane diol (**TED**, *[9506-46-4]* 62.9g, 2mol) suspended in $CHCl_3$ (640ml) are boiled under reflux until a clear solution is formed, then slowly cooled to ~25° followed by stirring for 4 hours. The precipitate formed is filtered off, washed with cold $CHCl_3$, and dried at 40° to give the ***(+)(+)-1:2-inclusion complex*** (41.1g 80%, 97.2%ee) as a white crystalline powder, **m 147.8-149.9°**, **$[\alpha]_D^{25}$ +174.32 (c 1, MeOH)** 97.2% optical purity. Purification to >99.9% optical purity can be achieved by suspending the product (15g) in $CHCl_3$ (120ml) refluxing until clear, then hexane (180ml) is added, cooled slowly to ~25°, stirred for 1 hour, and the precipitate is collected, and dried at 40° to give ***pure (+)(+)-1:2-inclusion complex*** (13g, 87%, 99.9%ee) as a white crystalline powder, **m 149.8-151.5°, $[\alpha]_D^{25}$ +182.76 (c 1, MeOH)**. Its IR (KBr) and ^{1}H NMR ($CDCl_3$) have been reported. Other solvents used for complex formation are MeOH/di-disopropyl ether (20:10, yield 70%, 96%ee), EtOH/di-disopropyl ether (20:10, yield 76%, 94.5%ee), MeOH/H_2O (25:5, yield 62%, 97.3%ee), isoPrOH/H_2O (25:5, yield 78%, 94.5%ee), Me_2CO/H_2O (20:5, yield 70%, 95.2%ee), and MeCN/H_2O (20:5, yield 62%, 95.5%ee).

***R*-(+)-Lansoprazole** is obtained from the (+)(+)-inclusion complex above (10.0g, 10.5mmol, >99.9%ee) by dis-

solving in CH_2Cl_2 (155ml), adding 0.2N KOH (105ml, 21.0mmol) and stirring. The aqueous layer is collected, diluted with MeOH (50ml) and the pH of the mixture is adjusted to 6.5 with AcOH, then stirred for 2 hours at ~25°. The precipitate is collected, washed with H_2O, then dissolved in EtOAc (80ml); hexane (80ml) is added, stirred for 1hr and the crystalline precipitate is collected, dried at 40° to give ***pure R-(+)-Lansoprazole 1.5H_2O*** (3.4g, 89%, 99.9%ee). This has **m 80-90°, $[\alpha]_D^{25}$ +154.7 (c 1, $CHCl_3$)** [H_2O content 6.8%]; and its IR (KBr) and ^1H NMR ($CDCl_3$) have been reported. Also *R*-(+)-TED can be recovered by washing the above CH_2Cl_2 layer with H_2O (100ml), drying (anhydrous $MgSO_4$), filtering, evaporating the solvent to dryness and recrystallising the residual solid from EtOAc/hexane (1:10 v/v) to give *R*-(+)-1,1,2-triphenyl-1,2-ethanediol (5.5%, 90% recovery), **m 127-130°, $[\alpha]_D^{25}$ +205.5 (c 1, MeOH, 99.8%ee)**; its IR (KBr) have been reported.
Alternatively, to obtain the ***anhydrous*** drug, the (+)(+)-inclusion complex (10.0g, 10.5mmol, >99.9%ee) is dissolved in CH_2Cl_2 (155ml), stirred with 0.25N NaOH (105ml, 21.0mmol), the aqueous layer is isolated, mixed with EtOAc (200ml), the pH of the mixture is adjusted to 7.0 with hydrochloric acid whereby the neutral species remain in the EtOAc layer which is washed with brine (50ml), dried ($MgSO_4$), and evaporated to provide the ***anhydrous R-(+)-drug*** (3.5g, 91%) as an ***amorphous powder*** **m 76.8-77.2°, $[\alpha]_D^{25}$** ~+156 (c 1, MeOH, 99.9%ee).
NOTE: that from the original resolution the (-)(+)-inclusion complex of high optical purity can be isolated, and optically ***pure S-(-)-Lansoprazole*** can be obtained; ***OR better***, by using the *S*-(-)-1,1,2-triphenyl-1,2-ethanediol *[108998-83-0]* **$C_{20}H_{18}O_2$,** M 290.4, **m 125-127°, $[\alpha]_D^{20}$ -214 (c 1, EtOH)** as resolving agent, the ***(-)(-)-1;2-inclusion complex*** can be produced from which the ***S-(-)-drug*** can be obtained using exactly the same quantities of reagents and solvents as used for their antipodes above, without the necessity of exploring new reagents and solvents.
[For mechanism of action of Lansoprazole see also Nagaya et al. *J Pharmacol Exp Ther* **252** 1289 *1990*, PMID: 2156997; for the synthesis of the (±)-drug see Nohara & Maki to Takeda US Pat 4628098 A and EP 174726; and Clarke & Slemon US Pat 5470983 A *1995* above; and for the process of preparing *R*-(+)-1,1,2-triphenyl-1,2-ethane diol see Sun et al. to Hanmi Pharm Co WO 2010068049 A2 and A3 *2010*.]

Lecithin (1,2-diacylphosphatidylcholine mixture) *[8002-43-5]* **M ~600-800, amorphous**. Lecithin from hen egg white is purified by solvent extraction and chromatography on alumina. It is suspended in H_2O and kept frozen until required [Lee & Hurst *J Am Chem Soc* **106** 7411 *1984*, DOI: 10.1021/ja00336a020; Singleton et al. *J Am Oil Chem Soc* **42** 53 *1965*, DOI: 10.1007/BF02558256]. For purification of commercial egg lecithin, see Pangborn [*J Biol Chem* **188** 471 *1951*, http://www.jbc.org/content/188/2/471; PMID: 14824134].

Leucopterin (2-amino-5,8-dihydropteridine-4,6,7(1*H*)-trione) *[492-11-5]* **$C_6H_5N_5O_3$, M 195.1, m >300° (dec), pK_1^{20} -1.66, pK_2^{20} 7.56, pK_3^{20} 9.78, pK_4^{20} 13.6.** Leucopterin is purified by dissolving in aqueous NaOH, stirring with charcoal, filtering and precipitating by adding aqueous HCl, then drying at 100° in a vacuum. It separates with 0.5 mole of H_2O. Its solubility in H_2O is 1g/750 litres [Albert et al. *J Chem Soc* 4219 *1952*, DOI: 10.1039/JR9520004219; Albert & Wood *J Appl Chem* (*UK*) **2** 591 *1952*, DOI: 10.1002/ jctb.5010021005; Pfleiderer *Chem Ber* **90** 2631 *1957*, DOI: 10.1002/cber.19570901129]. [*Beilstein* **26** III/IV 4017.]

DL-α-Lipoamide (±-6,8-thioctic acid amide, 5-[1,2]-dithiolan-3-ylvaleric acid amide) *[940-69-2; 3206-73-3]* **$C_8H_{15}NOS_2$, M 205.3, 242.2, m 124-126°, 126-129°, 130-131°.** DL-α-Lipoamide is recrystallised from EtOH and has UV with λ_{max} at 331nm in MeOH. [Reed et al. *J Biol Chem* **232** 143 *1958*, PMID: 13549405; IR: Wagner et al. *J Am Chem Soc* **78** 5079 *1956*, DOI: 10.1021/ja01600a069; *Beilstein* **19/7** V 238.] **IRRITANT**.

DL-α-Lipoic acid (±-6,8-thioctic acid, 5-[1,2]-dithiolan-3-ylvaleric acid) *[1077-28-7]* **$C_8H_{14}O_2S_2$, M 206.3, m 59-61°, 60.5-61.5° and 62-63°, b 90°/10^{-4}mm, 150°/0.1mm, pK^{25} 4.7.** It forms yellow needles from cyclohexane or hexane, has been distilled at high vacuum, and sublimes at ~90° and very high vacuum. It is insoluble in H_2O but dissolves in alkaline solution. [Lewis & Raphael *J Chem Soc* 4253 4263 *1962*, DOI: 10.1039/JR9620004253; Soper et al. *J Am Chem Soc* **76** 4109, DOI: 10.1021/ja01645a016; Reed & Niu *J Am Chem Soc* **77** 416 *1955*, DOI: 10.1021/ja01607a057; Tsuji et al. *J Org Chem* **43** 3606 *1978*, DOI: 10.1021/jo00412a044; Calvin *Fed Proc USA* **13** 697 *1954*, PMID: 13210461.] The ***S-benzylisothiuronium salt*** has **m 153-154°** (evacuated capillary, from MeOH), 132-134°, 135-137° (from EtOH). The ***d- and l- forms*** have **m 45-47.5°** and **$[\alpha]_D^{23}$ ±113 (c 1.88, *C_6H_6)**; and have UV in MeOH with λ_{max} at 330nm (ε 140). [*Beilstein* **19/7** V 237.] The reduced form, ***(±)-6,8-dimercaptooctanoic acid***, *[7516-48-5]* **M 208.3**, is a light

yellow liquid which is sold in sealed ampoules.

D-Luciferin (firefly luciferin, *S*-2[6-hydroxybenzothiazol-2-yl]-4,5-dihydrothiazol-4-carboxylic acid), *[2591-17-5]* **$C_{11}H_{18}N_2O_3S_2$, M 280.3, m 189.5-190°(dec), 196°(dec), 201-204°, 205-210°(dec, browning at 170°), $[\alpha]_D^{22}$ -36 (c 1.2, DMF), $pK_{Est(1)}$~ 1.2 (benzothiazole-N), $pK_{Est(2)}$~ 1.6 (thiazolidine-N), $pK_{Est(3)}$~ 6.0 (CO_2H), $pK_{Est(4)}$ 8.5 (6OH).** D-Luciferin crystallises as pale yellow needles from H_2O, or MeOH (83mg/7ml). It has UV with λ_{max} at 263 and 327nm (log ε 3.88 and 4.27) in 95% EtOH; and fluorescence (H_2O) with λ_{ex} 328nm and λ_{em} 532nm. The ***Na salt*** has a solubility of 4mg in 1 ml of 0.05M glycine. Store it at -20°. [White et al. *J Am Chem Soc* **83** 2402 *1961*, DOI: 10.1021/ja01471a051; **85** 337 *1963*, DOI: 10.1021/ja00886a019; for UV and IR see Bitler & McElroy *Arch Biochem* **72** 358 *1957*, DOI: 10.1016/0003-9861(57)90212-6; Review: Cormier et al. *Fortschr Chem Org Naturst* **30** 1 *1973*, PMID: 4156520; *Beilstein* **27** III/IV 8934.] It is a substrate for ***firefly luciferase*** (Km ~2μM) being involved in bioluminescence, and is a useful biological tag.

Lumichrome (7,8-dimethylalloxazine) *[1086-80-2]* **M 242.2, m >290°, $pK_{Est(1)}$ ~ -0.1 (basic), $pK_{Est(2)}$ ~9.9 (acidic).** Recrystallise lumichrome twice from glacial AcOH and dry it at 100° in a vacuum. [Cresswell & Wood *J Chem Soc* 4768 *1960*, DOI: 10.1039/JR9600004768; *Beilstein* **26** III/IV 2538.]

Lumiflavin (7,8,10-trimethylbenzo[*g*]pteridine-2,4(3*H*,10*H*)-dione) *[1088-56-8]* **$C_{13}H_{12}N_4O_2$, M 256.3, m 330°(dec), 340°(dec), pK^{25} 10.2.** Lumiflavin forms orange crystals upon recrystallisation from 12% aqueous AcOH, or from formic acid. It sublimes at high vacuum. It is freely soluble in $CHCl_3$, but not very soluble in H_2O and most organic solvents. In H_2O and $CHCl_3$ it has a green fluorescence. Its UV has λ_{max} at 269, 355 and 445nm (ε 38,800, 11,700 and 11,800, respectively) in 0.1N NaOH, and 264, 373 and 440nm (ε 34,700, 11,400 and 10,400, respectively) in 0.1N HCl, while the UV in $CHCl_3$ has λ_{max} at 270, 312, 341, 360, 420, 445 and 470nm. [Hemmerich et al. *Helv Chim Acta* **39** 1242 *1956*, DOI: 10.1002/hlca.19560390511; Holiday & Stern *Chem Ber* **67** 1352 *1934*, DOI: 10.1002/cber.19340670812; Yoneda et al. *Chem Pharm Bull Jpn* **20** 1832 *1972*, DOI: org/10.1248/cpb.20.1832; Birch & Moye *J Chem Soc* 2622 *1958*, DOI: 10.1039/JR9580002622; Kuhn & Moruzzi *Chem Ber* 67 888 *1934*, DOI: 10.1002/cber.19340670539; *Beilstein* **26** III/IV 2539.]

Magnesium protoporphyrin dimethyl ester *[14724-63-1]* **$C_{36}H_{36}N_4O_4Mg$, M 580.7, m 214-217° (others found m 228-230°).** The Mg complex can be prepared from protoporphyrin dimethyl ester (see below) and $Mg(ClO_4)_2$ in boiling pyridine under N_2 for 3-4 hours until the band at 630nm (free porphyrin) is absent. Filter, wash the insolubles with Et_2O until the filtrate is colourless. Evaporate the solvent *in vacuo* at 50-60° to a very small volume, then add excess peroxide free Et_2O in a separating funnel, shake with H_2O (2x), evaporate the Et_2O, and remove the H_2O and pyridine by evaporating (azeotropically) with $*C_6H_6$ (4x). Purify the residue by dissolving the Mg complex in as little hot $*C_6H_6$ (50ml for 800mg) as possible, and add cold petroleum ether (b 30-60°), leave at room temperature until crystallisation begins, then further in a refrigerator to give twinned prisms, **m** >330°. Its IR has ν_{max} at 3080(w CH=CH_2), 1610, 1698, 1740 (s CO_2Me) cm^{-1}, but no NH. Its UV (Et_2O) has λ_{max} (ε) at 588nm (19,000), 550nm (19,300), 417nm (Soret, 252,000) [and 340nm (20,550)]. [Ramsey *Biochemical Preparations* **3** 39 *1953*, Fuhrhop & Granick *Biochemical Preparations* **13** 55 *1971*.] Even when pure, Mg protoporphyrin dimethyl ester is difficult to crystallise although crystals can be found to form on a glass slide under a microscope. For analysis, a portion of the pink powder is washed on the filter with dry Et_2O. The filtrate consists of a colloidal solution (a slight residue remains on the filter paper). To the filtrate is now added low boiling light petroleum and a precipitate of plates and highly twinned crystals results. These are centrifuged down, washed with this petroleum ether and dried *in vacuo*. The UV of the red solution in Et_2O is the same as above. [Granick *J Biol Chem* **175** 333 *1948*, PMID: 18873307.]

6-Mercaptopurine-9-β-D-ribofuranoside *[574-25-4]* **$C_{10}H_{12}N_4O_4S$, M 284.3, m 208-210°(dec), 210-211°(dec), 221-223°(dec), 220-223°(dec), 222-224°(dec), $[\alpha]_D^{25}$ -73 (c 1, 0.1N NaOH), pK^{25} 7.56.** Recrystallise the riboside from hot H_2O or EtOH. It has UV with λ_{max} (H_2O) at 322nm (pH 1), 320 nm (pH 6.7) and 310nm (pH 13). It is soluble in DMSO. [IR: Johnson et al. *J Am Chem Soc* **80** 699 *1958*, DOI: 10.1021/ja01536a044; UV: Fox et al. *J Am Chem Soc* **80** 1669 *1958*, DOI: 10.1021/ja01540a041; *Beilstein* **26** III/IV 2100.] It is a substrate for adenosine deaminase.

R*-(-)-Methadone (Levomethadone, 6-dimethylamino-4,4-diphenylheptan-3-one)** *[125-58-6]* **$C_{21}H_{27}NO$, M 309.4, m 98-100°, $[\alpha]_D^{20}$ -32 (c 1.8, EtOH), see below for pKa.** This pharmacologically active (against narcotic addiction) enantiomer was obtained by optical resolution (using D-tartaric acid) of the racemate, and was purified by precipitation of the hydrochloride from aqueous solution at pH <6, dried and recrystallised from propan-2-ol. The ***R*-hydrochloride** *[5967-73-7]*, when recrystallised from propan-2-ol, has **m 245-246°**, and $[\alpha]_D^{20}$ -169 (c 2, EtOH). The ***S*-(+)-*enantiomer *[5653-8-5]* also recrystallises from propan-2-ol and has a recorded **m** of **100-101°**, and $[\alpha]_D^{25}$ + 26 (c 1.2, H_2O). The ***S*-hydrochloride** *[15284-15-8]*, when crystallised from propan-2-ol, has **m 243-244°**, and $[\alpha]_D^{20}$ +169 (c 2, EtOH). [Larsen et al. *J Am Chem Soc* **70** 4194 *1948*, DOI: 10.1021/ja01192a065; Brode & Hill *J Org Chem* **13** 191 *1948*, DOI: 10.1021/jo01160a004; Schultz et al. *J Am Chem Soc* **69** 2454 *1947*, DOI: 10.1021/ja01202a061; Easton et al. *J Am Chem Soc* **69** 2941 *1947*, DOI: 10.1021/ja01204a006; Winter & Flataker *J Pharmacol Exp Ther* **98** 305 *1950*, PMID: 15428991; *Beilstein* **14** III 278, **14** III/IV 300.] [Strain & Stitzer *The Treatment of Opioid Dependence* JHU Press p 63 *2005*, ISBN 978-0-8018-8303-3].

***(±)-Methadone hydrochloride* (6-dimethylamino-4,4-diphenylheptan-3-one HCl)** *[1095-90-5]* **$C_{21}H_{27}NO$. HCl, M 345.9,** has **m 241-242°, pK_1^{25} 8.94, pK_2^{20} 10.12 (free base).** The salt (see above) crystallises from EtOH, or EtOH/Et_2O. [see methadone references.]

Methoxantin coenzyme (PQQ, pyrrolo quinoline quinone, 2,7,9-tricarboxy-1*H*-pyrrolo-[2,3-*f*]-quinoline-4,5-dione, 4,5-dihydro-4,5-dioxo-1*H*-pyrrolo[2,3-*f*]quinoline-2,7,9-tri-carboxylic acid) *[72909-34-3]* **$C_{14}H_6N_2O_8$, M 330.2, m 220°(dec).** Efflorescent yellow-orange needles of PQQ are formed on recrystallising from H_2O by addition of Me_2CO, or better from a supersaturated aqueous solution, as it forms an ***acetone adduct***. [Salisbury et al. *Nature* **280** 843 *1979*, DOI: 10.1038/280843a0.] It has also been purified by passage through a C-18 reverse phase silica cartridge or a silanised silica gel column in aqueous solution whereby methoxantin remains behind as a ***red-orange band*** at the origin. This band is collected and washed thoroughly with dilute aqueous HCl (pH 2) and is then eluted with MeOH/H_2O (7:3) and evaporated *in vacuo* to give the coenzyme as a red solid. It has also been purified by dissolving it in aqueous 0.5M K_2CO_3 and acidifying to pH 2.5 whereby PQQ precipitates as a deep red solid which is collected and dried *in vacuo*. Methoxantin elutes at 3.55 retention volumes from a C18 μBondapak column using H_2O/MeOH (95:5) + 0.1% AcOH pH 4.5. It has UV with λ_{max} at 247 and 330nm (shoulder at 270nm) in H_2O, and λ_{max} at 250 and 340nm in H_2O at pH 2.5. With excitation at λ_{ex} 365nm it has a λ_{em} at 483nm. The ^{13}C NMR has δ: 113.86, 122.76, 125.97, 127.71, 130.68, 137.60, 144.63, 146.41, 147.62, 161.25, 165.48, 166.45, 173.30 and 180.00.

When ***dissolved in*** a solution of 10% aqueous MeCO and adjusted to pH 9 with aqueous NH_3 then kept at 25° for 30 minutes, the ***acetone adduct*** is formed, which has UV with λ_{max} at 250, 317 and 360nm (H_2O, pH 5.5), and with λ_{ex} at 360nm it fluorescence with λ_{em} at 465nm; and the ^{13}C NMR [$(CD_3)_2SO$, TMS] has been reported. It also forms a ***methanol adduct***.

When it is reacted with Me_2SO_4/K_2CO_3 in dry Me_2NCHO at 80° for 4 hours, it forms the ***trimethyl ester*** which has **m 265-267°(dec)** [**260-263°(dec)** also reported] and after recrystallisation from hot MeCN it forms orange crystals with UV that has λ_{max} at 252 and 344nm (H_2O), and 251, 321 and 373nm (in MeOH; MeOH adduct ?). 5-Methyltetrahydrofolic acid disodium salt (prefolic A) *[68792-52-9]* **$C_{20}H_{23}N_7O_6$. 2Na, M 503.4, pK_1 2.4 (N10 protonation), pK_2 2.7 (pyrimidine N1 protonation), pK_3 3.5 (α-CO_2H), pK_4 4.9 (γ-CO_2H), pK_5 5.6 (N5-Me) , pK_6 8.5 (3NHCO acidic).** First check the purity by measuring the UV at pH 7.0 (use phosphate buffer), and it should have λ_{max} at 290nm and λ_{min} at 245nm with a ratio of A_{290}/A_{250} of 3.7. This ratio goes down to 1.3 as oxidation to the dihydro derivative occurs. The latter can be reduced back to the tetrahydro compound by reaction with 2-mercaptoethanol at room temperature. If oxidation has occurred, then the compound should be chromatographed on DEAE-cellulose (~0.9 milliequiv/g, in AcO^- form) in $(NH_4)_2CO_3$ (1.5 M) and washed with 1M NH_4OAc containing 0.01M mercaptoethanol till free from UV absorption and then washed with 0.01M mercaptoethanol. All is done in a nitrogen atmosphere. The reduced folate is then eluted with a gradient between 0.01M mercaptoethanol and 1M NH_4OAc containing 0.01M mercaptoethanol, and the fractions with absorption at 290nm are collected. These are evaporated under reduced pressure at 25°, and traces of NH_4OAc and H_2O are removed at high vacuum/25° (~24-48 hours). The residue is dissolved in the minimum volume of 0.01M mercaptoethanol, and an equivalent of NaOH is added to convert the acid to the diNa salt and evaporated to dryness at 25°/high vacuum. The ***pure product*** has λ_{max} 290nm (ε 32,000) in pH 7.0 buffer. [Sakami *Biochemical Preparations* **10** 103 *1963*; for a convenient preparation of (±)-5-MeTHF and it Ca and Ba salts in quantity see Blair & Saunders *Analyt Biochem* **34** 376 *1970*, DOI: 10.1016/0003-2697(70)90122-3] It is a biological methylating agent [Banerjee & Snyder *Science* **182** 74 *1973*, DOI: 10.1126/science.182.4107.74].

Metoclopramide [Reglan, 4-amino-5-chloro-2-methoxy-*N*-(β-diethylaminoethyl)benzamide] *[364-62-5]* **$C_{14}H_{22}ClN_3O_2$, M 299.8, m 146.5-148°, 147.3°, pK_1 0.6 (ArNH), pK_2 9.3 (Alkyl-*tert*-N).** It can be prepared from 5-chloro-2-methoxy-4-nitrobenzoic acid (*[35633-81-4]*, in several steps from *o*-toluidine, see e.g. Büchi et al. *Helv Chim Acta* **34** 1002 *1951*, DOI: 10.1002/hlca.19510340404). It is converted to the acid chloride which is reacted with *N,N*-diethylethylenediamine to give the respective *N*-(diethylaminoethyl) 5-chloro-2-methoxy-4-nitrobenzamide which is reduced catalytically to ***Metoclopramide***. [Thominet US Patent 3177252, *1965* to Soc d'Etudes Sci Ind de l'Ile-de-France.] This base is purified by recrystallisation from aqueous EtOH containing a small amount of NH_3 in order to avoid contact with CO_2 (to form a carbonate salt as it is a strong base) and drying in a dessicator over solid KOH. The solubilty of the ***free base*** in w/v at ~25° in H_2O is 0.01%, in $*C_6H_6$ is 0.10%, in absolute EtOH is 1.90%, in 95% aq EtOH is 2.30% and in $CHCl_3$ is 6.60%. It is best to convert it into the ***monohydrochloride monohydrate*** **(Clopromate, Maxolon, Meclopran)** *[54143-57-6]* which is a white crystalline solid **m 182.5-184°** obtained by dissolving the ***free base*** in EtOH (3 volumes) to which is added 5N alcoholic HCl (1.5 equivalents), filtering off the salt and drying it in a vacuum dessicator over KOH. Similarly, the ***dihydrochloride monohydrate*** **(Emetid, Gastronerton, Primperan)** *[7232-21-5]* **m 145°(dec),** is prepared as for the ***monohydrochloride*** except that a large excess of HCl is added. It is stable in acidic media but unstable in strong alkaline solutions. The solubilty in w/v at ~25° in $CHCl_3$ is 0.10%, in $*C_6H_6$ is 0.10%, in absolute EtOH is 6.0%, in 95% aqueous EtOH is 9.0% and in H_2O it is 48.0%.
Metoclopramide is a useful ***anti-emetic***, and used for alleviating nausea (also in radiation sickness), vomiting and gastric reflux. It appears to bind to dopamine D_2 receptors with nanomolar affinity (Ki 28.8 nM), and is a ***mixed 5-HT_3 receotor antagonist/5-HT_4 receptor agonist***. [Justin-Besançon & Laville *Comptes Rendus des Séances de la Société de Biologie et de ses Filiales* (in French) **158** 723 *1964*. (±)-Mevalonic acid lactone *[674-26-0]* **$C_6H_{10}O_3$, M 130.2, m 28°, b 145-150°/5mm.** Purify the lactone *via*

the ***dibenzyl-ethylenediammonium salt*** (**m** 124-125°) [Hofmann et al. *J Am Chem Soc* **79** 2316 *1957*, DOI: 10.1021/ja01566a080], or by chromatography on paper or on a Dowex-1 (formate) column. [Bloch et al. *J Biol Chem* **234** 2595 *1959,* PMID: 13801508.] Store it as the *N,N'*-dibenzylethylenediamine (DBED) salt, or as the lactone in a sealed container at 0°. [*Beilstein* **18/1** V 19.]

Mevalonic acid 5-phosphate *[1189-94-2]* **$C_6H_{13}O_7P$, M 228.1, $pK_{Est(1)}$~ 1.5 (PO_4H_2), $pK_{Est(2)}$~ 4.4 (CO_2H), $pK_{Est(3)}$~ 6.31 (PO_4H^-).** Purify the acid by conversion to the ***tricyclohexylammonium salt*** (**m 154-156°**) by treatment with cyclohexylamine. Recrystallise the salt from water/acetone at -15°. *Alternatively*, the phosphate is chromatographed through an ion-exchange resin or paper (Whatman No 1) in a system of isobutyric acid/ammonia/water (66:3:30; R_F 0.42). See following entry. Store it as the cyclohexylammonium salt.

Mevalonic acid 5-pyrophosphate *[1492-08-6]* **$C_6H_{14}O_{10}P_2$, M 308.1, $pK_{Est(1)}$~<2, $pK_{Est(2)}$~<2, $pK_{Est(3)}$~3.95 (PO_4), $pK_{Est(4)}$ 4.4 (CO_2H), $pK_{Est(5)}$ ~6.26 (PO_4).** Purify the pyrophosphate by ion-exchange chromatography on Dowex-1 formate [Bloch et al. *J Biol Chem* **234** 2595 *1959*, PMID: 13801508], DEAE-cellulose [Skilletar and Kekwick, *Anal Biochem* **20** 171 *1967*, DOI: 10.1016/0003-2697(67)90275-8], or by paper chromatography [Rogers et al. *Biochem J* **99** 381 *1966*, DOI: 10.1042/bj0990381]. Likely impurities are ATP and mevalonic acid phosphate. Store it as a dry powder or in a slightly alkaline (pH 7-9) solution at -20°.

Mexiletine hydrochloride [Mexitil, MEX, 1-(2,6-dimethylphenoxy)-2-proanamine hydrochloride] *[5370-01-4]* **$C_{11}H_{17}NO$. HCl, M 215.7, m 203-205°, pKa 9.0.** The synthesis of the ***racemate*** is described in a patent by Köppe et al. [US 3954872 *1976* to Boehringer] where starting from 2,6-dimethylphenol, the 1-(2,4-dimethylphenoxy)propan-2-one oxime is obtained and reduced catalytically with Raney Ni in MeOH at 60°/5 atmospheres in a pressure bomb until the desired volume of H_2 is absorbed, cooled, filtered and evaporated to dryness to give the ***free base*** *[31828-71-4]* as an oil. This oil is dissolved in EtOH and acidified with ethereal HCl and cooled; the solid is collected and recrystallised by dissolving in the minimum volume of hot EtOH and adding excess dry Et_2O to give ***Mexiletine hydrochloride*** **m 203-205°** (51.5% yield) as off-white crystals with ^{1}H NMR (200MHz, DMSOd_6, TMS) which has δ at 1.35 (d, 3H, *J* = 6.6Hz, CH_3-CH), 2.23 (s, 6H, 2 CH_3-Ar), 3.5-3.58 (m, 1H, CH_2-C*H*-CH_3), 3.81 (d, 2H, *J* = 5.2Hz, O-CH_2-CH), 6.87-7.04 (m, 3H, Ar-H), 8.49 (br s, 3H, NH_3^+) ppm [from *Chirality* **6** 590 *1994*, DOI: 10.1002/chir.530060713]. The compound has one asymmetric centre and could be resolved into its optical antipodes using di-*O*-benzoyl-L-tartaric acid or D-3-bromocamphor-8-sulfonic acid. The ***(-)-R-mexiletine*** has been found to be more potent than the ***(+)-S-enantiomer*** in ***experimental arrhythmias*** [Turgeon et al. *J Pharm Pharmacol* **43** 630 *1991,* DOI: 10.1111/j.2042-7158.1991.tb03552.x], in binding studies on cardiac sodium channels [Hill et al. *Mol Pharmacol* **34** 659 *1988*, PMID: 2848186], and a more potent blocker of Na currents in adult frog skeletal muscle fibres [De Luca et al. Naunyn Schmiedeberg's *Arch Pharmacol* **352** 653 *1995*, DOI: 10.1007/BF00171325; Luca et al. Naunyn Schmiedeberg's *Arch Pharmacol* **356** 777 *1997*, PMID: 9453464]. However, the reverse is true where the ***(+)-S-enantiomer*** is more effective than the ***(-)-R-enantiomer*** as an ***inhibitor of*** **c**hlorglycine-**r**esistant **a**mine **o**xidase (***CRAO***) [Clarke et al. *Biochem Pharmacol* **31** 27 *1982*, DOI: 10.1016/0006-2952(82)90231-3], and in the treatment of ***allodynia*** [Zeitlin US Patent 97,7867,49, *1999*, *Chem Abstr* **129** 153250 *1999*]. Various methods have been devised to obtain the two enantiomers: the procedure of G. Lentini and coworkers [Carocci et al. *Chirality* **12** 103 *2000*, DOI: 10.1002/(SICI)1520-636X] requires three steps starting from commercially available *S*(-)- and *R*(+)- propylene oxides in acceptable overall yields (24-34%) with 96% 'ee' and 93% 'ee' respectively, and checked by TLC on Kieselgel 60F_{254}) with $[\alpha]_D^{20}$ -1.1 (c 5, $CHCl_3$), and by the ^{1}H NMR and MS which has *m/z* 180 M^+ (26), 122 (100). Smilarly *R*(+)-propylene oxide gives ***R(+)-1-(2,6-dimethylphenoxy)-2-propanol*** in 57% yield with $[\alpha]_D^{20}$ +0.9 (c 5, $CHCl_3$) with the same spectra. ***S(-)-1-(2,6-dimethylphenoxy)-2-propanol***, phthalimide and PhP_3 in THF under N_2 is treated dropwise with a solution of DEAD in THF, stirred overnight, concentrated *in vacuo*, Et_2O is added to the residue, the solid is filtered off and the filtrate is evaporated *in vacuo*, followed with purification by flash chromatography to give ***R(-)-1-(2,6-dimethylphenoxy)-2-propyl* N-*phthalimide*** (68% yield: ***NOTE*** inversion of configuration at asymmetric centre) with $[\alpha]_D^{20}$ -55 (c 2.2, $CHCl_3$) and ^{1}H NMR (90MHz, $CDCl_3$ TMS) has δ at 1.55 (d, 3H, *J* = 7.5Hz, CH_3-CH), 2.2 (s, 6H, 2 CH_3-Ar), 3.9 (dd, 1H, *J* = 9Hz, *J* = 6Hz, OC*H*H), 4.39 (apparent t, 1H, *J* = 6Hz, OC*H*H), 4.85 (apparent br sextet, 1H, *J* = 7.5Hz, CH_3C*H*), 6.9 (br s, 3H, PhO), 7.6-8.0 (m, 4H, Ar) ppm; and

MS has *m/z* 309 M^+ (5), 188 (100). Similarly, the ***S(+)-1-(2,6-dimethylphenoxy)-2-propyl* N-*phthalimide*** (with inversion of configuration) is obtained in 84% yield with $[\alpha]_D^{20}$ +55 (c 2.5, $CHCl_3$) and same spectra as its enantiomer. Removal of the phthalimido group is achieved in the usual way, e.g. to the *R(-)*-phthalimide derivative in MeOH are added 2 equivalents of AcOH and 2 equivalents of $NH_2NH_2.H_2O$, stirred for 6 hours, the phthalazine-1,4-dione that separated is filtered off, washed twice with EtOAc, the combined filtrates are dried (Na_2SO_4), filtered, and evaporated to provide *R*(-)-***Mexiletine*** *[81771-86-0]* in 66% yield as a colourless oil with **$[\alpha]_D^{20}$ -2.7 (c 4.7, $CHCl_3$),** MS: *m/z* 179 M^+ (10), 44 (100). ***R(-)-Mexiletine hydrochloride*** **m 204-205°, $[\alpha]_D^{20}$ -2.5 (c 5, MeOH),** is prepared by dissolving the ***free base*** in a small volume of aqueous 1M HCl, removing the H_2O azeotropically (e.g. with toluene) and the crude salt is recrystallised from EtOH-Et_2O to give analytically pure ***hydrochloride***. The enantiomeric excess ('ee') is determined by HPLC analysis of ***N-acetyl-R(-)-Mexiletine***. The acetate is prepared by treating a solution of the ***free base*** in dry THF with 2-equivalents of Ac_2O and 2-equivalents of Et_2N, stirring at ~25° for 8 hours, evaporated *in vacuo*, the residue is dissolved in EtOAc, washed with $NaHCO_3$ then brine, dried (Na_2SO_4), filtered and evaporated. The ***acetate*** is shown by HPLC (CSP: on CHIRACEL OD/R, with 9:1 MeOH-H_2O mobile phase at 0.4ml/min flow rate) to have 96% ee purity. Similarly ***S(+)-Mexiletine*** *[9491-72-7]* **$[\alpha]_D^{20}$ +2.5 (c 4.9, $CHCl_3$),** and the ***S*(+)-*Mexiletine hydrochloride*** **$[\alpha]_D^{20}$ +2.2 (c 5, MeOH)**, are obtained; and the ***S*(+)-*Mexiletine acetate*** that is obtained in this case crystallised from 1:1 EtOAc-petroleum ether, and had ^{1}H NMR (200MHz, $CDCl_3$, TMS) with δ at 1.38 (d, 3H, *J* = 6.8Hz, C*H*$_3$-CH), 2.01 (s, 3H, C*H*$_3$-CO), 2.24 (s, 6H, 2 C*H*$_3$-Ar), 3.65-3.80 (d, 2H, O-C*H*$_2$-CH), 4.35 (m, 1H, CH_2-*C*H*-CH_3), 6.15 (br s, 1H, N*H*-acetyl) ppm with 96% 'ee' purity as determined by using the Eu(hfc)$_3$ chemical shift reagent and by CSD HPLC (see above). An earlier different synthesis of chiral *Mexiletine* by Franchini and coworkers [*Chirality* **6** 590 *1994*, DOI: 10.1002/chir.530060713] starts with the reaction of *S*(+)-3-bromo-2-methyl-1-propanol, of known absolute configuration, and sodium 2,6-dimethylphenolate. It provides ***R*(-)-*Mexiletine hydrochloride*** in four further steps without involving the chiral centre. It also establishes the absolute configuration of the drug, which is further confirmed by X-ray crystallographic analysis of the related ***S*(+)-*Mexiletine hydrobromide*** prepared from an optical resolution of racemic *Mexiletine* L(-)-dibenzoyl-tartrate. For optical resolution of Mexiletine enantiomers using di-O-*p*-toluoyltartrate salts see Turgeon et al. [*J Pharm Pharmacol* **43** 630 *1991,* DOI: 10.1111/j.2042-7158.1991.tb03552.x]. The syntheses and pharmacological evaluation as selective Na^+ channel blockers of a variety of optically active Mexiletine analogues have been described [Franchini et al. *J Med Chem* **46** 5238 *2003*, DOI: 10.1021/ jm030865y]. ***R*(-)-*Mexiletine*** *[81771-86-0]* {with reported IR, ^{1}H NMR (200MHz, $CDCl_3$, TMS) and MS reported} has also been prepared enantiomerically pure (ee 98%, by DIACEL CHIRACEL HPLC of the *N*-acetyl derivative, see above) using a ***hydrolytic kinetic resolution*** of **(±)-*2-[(2,6-dimethylphenoxy)methyl]oxirane*** with Jacobsen's catalyst *R,R*-Salen-Co(III) (see 'Catalysts Part-2' in Chapter 5) [Sasikumar et al. *Tetrahedron*: *Asymmetry* **20** 2814 *2009*, DOI: 10.1016/j.tetasy.2009.11.014].
Mexiletine is an ***antiarrhytmic (Class 1B) drug*** that is also used to treat ***refractory pain*** and ***muscle stiffness*** from ***myotonic dystrophy*** (Steinert's disease) or ***congenital mitonia*** (Thomsen disease).

Mithramycin A (Aureolic acid, Plicamycin) *[18378-89-7]* **$C_{52}H_{76}O_{24}$, M 1085.2, m 164-167°, 180-183°, $[\alpha]_D^{20}$ -51 (c 0.3, EtOH), pK_{Est} ~ 9.2.** Purify the antibiotic *mithramycin A* by crystallisation from $CHCl_3$. It is soluble in MeOH, EtOH, Me_2CO, EtOAc, Me_2SO and H_2O, and moderately soluble in $CHCl_3$, but is slightly soluble in $*C_6H_6$ and Et_2O. It is a fluorescent antitumour agent used in flow cytometry. Store it at -20°. [Thiem & Meyer *Tetrahedron* **37** 551 *1981*, DOI: 10.1016/S0040-4020(01)92428-7; for NMR see Yu et al. *Nature* **218** 193 *1968*, DOI: 10.1038/218193a0; *Beilstein* **17/1** V 672.] It is an ***inhibitor of DNA/RNA***

Mitomycin C {[1a*S*-(1aα,8β,8aα,8bα]-6-amino-8-[[(aminocarbonyl)oxy]methyl]-1,1a,2,8,8a,8b-hexahydro-8a-methoxy-5-methylzirino[2',3':3,4]pyrrolo[1,2-*a*]indole-4,7-dione} *[50-07-7]* **$C_{15}H_{18}N_4O_5$, M 334.4, m >360°, $pK_{Est(2)}$~ 8.0.** Mitomycin C forms blue-violet crystals from $*C_6H_6$/petroleum ether and is soluble in Me_2CO, MeOH and H_2O, moderately soluble in $*C_6H_6$, CCl_4 and Et_2O but insoluble in petroleum ether. It has UV with λ_{max} at 216, 360 and a weak peak at 560nm in MeOH. [Stevens et al. *J Med Chem* **8** 1 *1965*, DOI: 10.1021/jm00325a001; Shirahata & Hirayama *J Am Chem Soc* **105** 7199 *1983*, DOI: 10.1021/ja00362a046; *Beilstein* **25** III/IV 516.] **Anticancer agent** [see 'Effect of Mitomycin C on Bladder Cancer: A 7 Years of Followup' Tolley et al. *J Urology* **155** 1233 *1996*, DOI: 10.1016/S0022-5347(01)66226-8].

(-)-Morphine (H_2O) (5α,6α)-7,8-didehydro-4,5-epoxy-17-methyl-3,6-diol) *[57-27-2]* **$C_{17}H_{19}NO_3.H_2O$, M**

285.3 (anhydrous), 302.2, m 230°(dec), 254°(dec, rapid heating), 255°, 260°(Kofler block), d $_4^{20}$ 1.32, [α] $_D^{23}$ -130.9 (MeOH), [α] $_D^{25}$ -133 (MeOH), pK$_1$ 8.31 (NMe), pK$_2$ 9.51 (OH). Morphine is among the three more abundant (9-14% depending on source) narcotic alkaloids isolated from opium poppy seed pods; the other two being ***codeine*** (3-methoxymorphine, 1-3%) and ***thebaine*** (3,6-dimethoxy derivative of morphine with double bonds at C_5=C_6 and C_8=C_{14}, 0.3 to 1.5%) [Robinson & Gulland numbering see Bergel & Morrison *Quart Rev Chem Soc* **2** 349 *1948*, DOI: 10.1039/QR9480200349]. Crystallise the narcotic from MeOH or anisole (short orthorhombic crystals). It ***dehydrates*** at 130°, and sublimes at bath temperature 190-200°/0.2mm. A ***metastable form*** melts at ~197°. Its solubility in H_2O is 0.2g/L at 20° and 0.9g/L at 100°; 60g/L in dilute HCl or H_2SO_4 at 20°; and in EtOH it is 5g/L at 20° and 10g/L on boiling. The solubility (w/v) at ~25° in $CHCl_3$ is 0.08%, in Et_2O is 0.016%, in amyl alcohol is 0.7%, and in boiling EtOAc is 10%. Store it away from light as it darkens in its presence, but with little loss of activity. It is basic due to the 'aliphatic type' NMe group and acidic due to its phenolic OH group (see pKa's), forms salts readily and is useful for the ***optical resolution*** of acids. The ***styphnate*** has **m 189°** (from aqueous EtOH).

Morphine sulfate* (2:1)** *[anhydrous 64-31-3; $5H_2O$ 6211-15-0]* **[$C_{17}H_{19}NO_3]_2$ $5H_2SO_4$, M 668.8,** has **[α] $_D^{25}$ -109 (c 4** anhydr**, H_2O).** The ***pentahydrate crystallises from hot H_2O (solubility is 6.5w/w% at ~25°, 143w/w% at 80°) and loses $1H_2O$ at ~25°, $3H_2O$ at 100°, all H_2O at 130°, and decomposes at ~250°. Its solublity in EtOH is 0.18w/w% at ~25° and 0.42w/w% at 60°. Store away of light as it darkens, but without loss of activity.

Morphine acetate has **[α] $_D^{15}$ -77 (H_2O)** forms a ***trihydrate*** from H_2O (solubility w/v is 40% at 100°), and the solubility in EtOH is 4.5w/v% at ~25°, 50w/v% at 60°, and in $CHCl_3$ it is 0.21w/v% at ~25°. ***Morphine hydrochloride*** *[52-26-6]* **[α] $_D^{25}$ -113 (c 2.2** anhydr**, H_2O)** crystallises as a ***trihydrate*** from H_2O which loses H_2O, becomes yellow and melts at ~200°(dec). [*Beilstein* **27** II 118, **27** III/IV 2223.]

Morphine and its salts are strong ***analgesic*** substances, are ***addictive narcotics*** with ***strong withdrawal effects***, rapid acting, cause respiratory depression and death when used in excess, and are ***controlled drugs*** that require a medical prescription for use [*Narcotic Drugs 2014 INTERNATIONAL NARCOTICS CONTROL BOARD. 2015*, ISBN 9789210481571].

The *second* abundant opiate alkaloid in poppy seedpods is ***Codeine (3-methylmorphine,* 5α,6α)-7,8-didehydro-4,5-epoxy-3-methoxy-17-methyl-6-ol)** *[76-57-3]* **$C_{18}H_{21}NO_3$, M 299.4, m 151-154°, 154-156°, d $_4^{20}$ 1.32, [α] $_D^{15}$ -112 (c 2** anhydr**, $CHCl_3$), [α] $_D^{15}$ -136 (c 2** anhydr**, EtOH), pK^{25} 8.21.** Purify it by recrystallisation from H_2O or aqueous EtOH (rods or octahedral plates) to give the ***monohydrate*** **m 157-158.5°**, which has [α] $_D^{25}$ -136 (c 2.8, EtOH), and is dried at 80°. The dried base sublimes at bath temperature 140-150°/~1.5mm. If it contains morphine (which has a phenolic group see pKa above) then dissolve it in *C_6H_6 (solubility of codeine is 7.7w/v% at ~20°) extract this impurity into aqueous Na_2CO_3, dry the organic extract, evaporate and recrystallise. Its solubility (w/v) in H_2O is 0.83%(20°) and 1.67%(80°); in EtOH it is 50%(25°) and 83.3%(~78°); in Et_2O it is 5.6%(~25°); and is very soluble in $CHCl_3$ (200% at ~25°). Evaporation of a $CHCl_3$ extract gives a colourless glass which crystallises on scratching. ***Codeine hydrobromide*** *[125-25-7]* crystallises in needles from H_2O as the ***dihydrate*** (PubChem CID 517281), and ***effervesces*** at **151-160°** (**m 190-192°** also reported) solidifies and remelts with extensive decomposition at 273-278°. It sublimes at 100°/0.03mm. [Gates *J Am Chem Soc* **75** 4340 *1953*, DOI: 10.1021/ja01113a511; Dauben et al. *J Org Chem* **44** 1567 *1979*, DOI: 10.1021/jo01323a045; *Beilstein* **27** II 136, **27** III/IV 2228.] ***Codeine hydrochloride*** *[1422-07-7]* crystallises in small needles from H_2O (solubility in w/v is 5% at ~25° and 100% at boiling) as the ***dihydrate*** with **m ~287°(dec)** and has **[α] $_D^{15}$ -108.2 (H_2O)**. Its solubility in EtOH is 0.56w.v% at ~25°. ***Codeine sulfate*** *[1420-53-7]* **[$C_{18}H_{21}NO_3]_2$. H_2SO_4,** crystallises in small crystals from H_2O (solubility in w/v is 3.3% at ~25° and 14.7% at 80°) as the ***pentahydrate*** with **m 278°(anhydrous)** and has **[α] $_D^{15}$ -100.9 (c 3, H_2O)**. Its solubility in EtOH is very low at 0.076w/v% at ~25°. Like morphine and its salts, **codeine** and its salts are ***light sensitive*** and darken, although their activity is barely diminished. They should be stored in the dark. ***Codeine*** is also an ***opiate analgesic*** but much milder than morphine and less addictive, so much so that in some countries it is dispensed without a medical prescription. It is used in cough medicines and sometimes mixed with ***paracetamol*** or ***ibuprofen***, and is a ***muscle relaxant***. Its apparently weaker action is because it is demethylated to morphine during metabolism and poeple who do not have the required demethylating enzymes suffer from morphine side effects. See below for chemical syntheses

The *third* abundant opiate alkaloid in poppy seedpods (see above) is ***Thebaine (6,7,8,14-tetradehydro-4.5α-epoxy-3,6-dimethoxy-17-methylmorphinan, Paramorphine)*** *[115-37-7]* **$C_{19}H_{21}NO_3$, M 311.4, m ~193°(rapid heating), [α] $_D^{23}$ -230 (c 2, $CHCl_3$), [α] $_D^{15}$ -219 (c 2, EtOH), pK^{25} 8.15.** Purify by sublimation at 170-180°/atm or in a vacuum to give rectangular plates. It is poorly soluble in H_2O (solubility is 0.068w/v% at

15°), but is more soluble in $CHCl_3$ (7.7w/v% at ~25°), EtOH (6.7w/v% at boiling), *C_6H_6 (4.0w/v% at ~25°), and Et_2O (0.5w/v% at ~25°). ***Thebaine hydrochloride*** *[850-57-7]* **$C_{19}H_{21}NO_3$. HCl, M 347.8, decomposes on heating emitting toxic NO_x and HCl fumes, $[\alpha]_D^{23}$ -164 (c 2, EtOH).** Purify by recrystallisation from EtOH (colourless prisms). Its solubility in H_2O is 8.3w/v% at ~25°. Unlike morphine and its compounds, ***thebaine compounds*** are ***opiates*** with stimulatory rather than depressant effects on the nervous system, and at ***high doses cause convulsions*** not unlike strychnine. The synthestic ***(+)-thebaine exhibits analgesic effects*** unlike the natural (-)-thebaine which is inactive in this respect. It is not used therapeutically but is important commercially as it is used for preparing several physiologically active compounds such as ***oxycodone*** *[76-42-2]* and ***naloxone*** *[465-65-6]*. Many ***chemical syntheses*** of natural (-)-morphine, its enantiomer (+)- morphine as well as the racemate (see below) have been reported, but none are cheaper to produce than the drug from natural sources. [Beyerman et al. 'A convenient synthesis of codeine and morphine' *Recl Trav Chim Pays-Bas* **95** 24 *1976*, DOI: 10.1002/recl.19760950107; Beyerman et al. Muramic acid [*R*-2(2-amino-2-deoxy-D-glucose-3-yloxy)-propionic acid] *[1114-41-6]* **$C_9H_{17}NO_7$, M 251.2, m 145-150°(dec), 152-154°(dec), 155°(dec), $[\alpha]_D^{25}$ +109 (c 2, H_2O), +165.0° (extrapolated to 0 time) → +123° [after 3 hours (c 3, H_2O)], $pK_{Est(1)}$~ 3.8 (CO_2), $pK_{Est(2)}$~ 7.7 (NH_2).** Muramic acid crystallises from H_2O or aqueous EtOH as the ***monohydrate*** which loses H_2O at 80° *in vacuo* over P_2O_5. It sometimes contains some NaCl. It has been purified by dissolving 3.2g in MeOH (75ml), filtering from some insoluble material, concentrating to ~10ml and refrigerating. The colourless crystals are washed with absolute MeOH. This process does not remove NaCl; to do so, the product is recrystallised from an equal weight of H_2O to give a low recovery yield of ***very pure acid*** (0.12g). On paper chromatography 0.26μg give one ninhydrin positive spot after development with 75% phenol (R_F 0.51) or with *sec*-BuOH/HCO_2H/H_2O (7:1:2) (R_F 0.30). [Matsushima & Park *Biochemical Preparations* **10** 109 *1963*, *J Org Chem* **27** 3581 *1962*, DOI: 10.1021/jo01057a045.] The acid has also been purified by dissolving 990mg in 50% aqueous EtOH (2ml), cooling, collecting the colourless needles on a sintered glass funnel and drying over P_2O_5 at 80°/0.1mm to give the ***anhydrous acid***. [Lambert & Zilliken *Chem Ber* **93** 2915 *1960*, DOI: 10.1002/cber.19600931224.] *Alternatively*, the acid is dissolved in a small volume of H_2O, neutralised to pH 7 with ion-exchange resin beads (IR4B in OH^- form), filtered, evaporated and dried. The residue is recrystallised from 90% EtOH (v/v) and dried as above for 24 hours. [Strange & Kent *Biochem J* **71** 333 *1959*, DOI: 10.1042/bj0710333.] The ***N-acetyl derivative*** **(NAMA, *R*-2-(acetylamino)-3-*O*-(1-carboxyethyl)-2-deoxy-D-glucose, *R*-2(2-acetylamino-2-deoxy-D-glucose-3-yloxy)-propionic acid)** *[10597-89-4]*, M 292.3, has **m ~125° (dec)** and $[\alpha]_D^{20}$ +41.2 after 24 hours (c 1.5, H_2O), pK_{Est} ~ 3.6. [Watanabe & Saito *J Bacteriol* **144** 428 *1980*, PMID: 7419493; *Beilstein* **4** IV 2029.] It is a component of bacterial cell walls.

Muscimol (pantherine, 5-aminoethyl-3[2*h*]-isoxazolone) *[2763-96-4]* **$C_4H_6N_2O_2$, M 114.1, m 170-172°(dec), 172-174°(dec), 172-175°, 175°, 176-178°(dec), 184-185°, $pK_{Est(1)}$~ 6 (acidic, ring 2-NH), $pK_{Est(2)}$~ 8 ($CH_2CH_2NH_2$).** Recrystallise muscimol from MeOH/tetrahydrofuran or EtOH and sublime it at 110-140° (bath) at 10^{-4} mm to give a yellow spot with ninhydrin which slowly turns purple [for NMR see Bowden et al. *J Chem Soc (C)* 172 *1968*, DOI: 10.1039/J39680000172]. It can also be purified by dissolving in the minimum volume of hot H_2O and adding EtOH dropwise until cloudy, cool, and colourless crystals separate; its IR has ν_{max} at 3445w, 3000-2560w br, 2156w, 1635s and 1475s cm^{-1}. [For NMR see Jager & Frey *Justus Liebigs Ann Chem* 817 *1982*, DOI: 10.1002/jlac.198219820423.] *Alternatively*, it has been purified by two successive chromatographic treatments on Dowex-1 x 8, with the first elution with 2M AcOH and a second with a linear gradient between 0—2M AcOH, evaporating the desired fractions and recrystallising the residue from MeOH. [McCarry & Savard *Tetrahedron Lett* **22** 5153 *1981*, DOI: 10.1016/S0040-4039(01)92445-1; Nakamura *Chem Pharm Bull Jpn* **19** 46 *1971*, DOI: org/10.1248/cpb.19.46.] It is a psychoactive ingredient of a poisonous mushroom (*Amanita muscaria*).

Mycophenolic acid (6-[1,3-dihydro-7-hydroxy-5-methoxy-4-methyl-1-oxoisobenzofuran-6-yl]-4-methylhex-4-enoic acid) *[24280-93-1]* **$C_{17}H_{20}O_6$, M 320.3, m 141°, 141-143°, $pK_{Est(1)}$~ 2.5 (CO_2H), $pK_{Est(2)}$~ 9.5 (phenolic OH).** Purify the acid by dissolving it in the minimum volume of EtOAc, applying onto a silica gel column (0.05-0.2 mesh) and eluting with a mixture of EtOAc/$CHCl_3$/AcOH (45:55:1) followed by recrystallising from heptane/EtOAc, from aqueous EtOH or from hot H_2O and drying *in vacuo*. It is a weak dibasic acid, moderately soluble in Et_2O, $CHCl_3$ and hot H_2O but weakly soluble in $*C_6H_6$ and toluene. [Birch & Wright *Aust J Chem* **22** 2635 *1969*, DOI: 10.1071/CH9692635; Canonica et al. *JCS Perkin Trans 1* 2639 *1972*, DOI: 10.1039/P19720002639; Birkinshaw et al. *Biochem J* **50** 630 *1952*, DOI: 10.1042/bj0500630; *Beilstein* **18** II 393, **18** III/IV 6513.] It is an immunosuppressive agent of use in organ transplant.

Myricetin (Cannabiscetin, 3,3',4',5,5',7-hexahydroxyflavone) *[529-44-2]* **$C_{15}H_{10}O_8$, M 318.2, m >300°, 357°(dec) (polyphenolic pK_{Est}~8-11).** Recrystallise myricetin from aqueous EtOH (**m 357° dec**, as ***monohydrate***) or Me_2CO (**m 350° dec**, with one molecule of Me_2CO) as yellow crystals. It is almost insoluble in $CHCl_3$ and AcOH. The ***hexaacetate*** has **m 213°**. [Hergert *J Org Chem* **21** 534 *1956*, DOI: 10.1021/jo01111a013; Spada & Cameroni *Gazzetta* **86** 965, 975 *1956*, Kalff & Robinson *J Chem Soc* **127** 181 *1925*, DOI: 10.1039/CT9252700181; *Beilstein* **18/5** V 670.] This is a polyphenolic flavonoid antioxidant.

Nalidixic acid (1-ethyl-7-methyl-1,8-naphthyridin-4-one-3-carboxylic acid) *[389-08-2]* **$C_{12}H_{12}N_2O_3$, M 232.3, m 226.8-230.2°, 228-230°, 229-230°, pK^{25} 6.0.** Nalidixic acid crystallises from H_2O or EtOH as a pale buff powder. It is soluble at 23° in $CHCl_3$ (3.5%), toluene (0.16%), MeOH (0.13%), EtOH (0.09%), H_2O (0.01%) and Et_2O (0.01%). It inhibits nucleic acid and protein synthesis in yeast [Lesher et al. *J Med Chem* **5** 1063 *1962*, DOI: 10.1021/jm01240a021] and is a synthetic quinolone antibiotic.

Naloxone hydrochloride hydrate $C_{19}H_{21}NO_4$. HCl. H_2O, (Narcan, 1-*N*-propenyl-7,8-dihydro-14-hydroxymorphinan-6-one hydrochloride) *[357-08-4 anhydrous, 51481-60-8 hydrate]* **M 399.9, m 200-205°, $[\alpha]_D^{20}$ -164 (c 2.5, H_2O), $pK_{Est(1)}$~ 6 (N-propenyl), $pK_{Est(2)}$~ 9.6 (phenolic OH).** This opiate antagonist has been recrystallised from EtOH/Et_2O or H_2O. It is soluble in H_2O (5w/v%) and EtOH but insoluble in Et_2O. The ***free base*** *[465-65-6]* has **m 184°** (**177-178°** also reported) after recrystallisation from EtOAc, and $[\alpha]_D^{20}$ -194.5 (c 0.93, $CHCl_3$). [Olofson et al. *Tetrahedron Lett* 1567 *1977*, DOI: 10.1016/S0040-4039(01)93104-1; Gold et al. *Med Res Rev* **2** 211 *1982*, DOI: 10.1002/med.2610020302.] It blocks the effects of opioids when overdosed.

Naltrexone hydrochloride dihydrate (1-*N*-cyclopropylmethyl-7,8-dihydro-14-hydroxy-morphinan-6-one hydrochloride) *[16676-29-2]* **$C_{20}H_{23}NO_4$. HCl. $2H_2O$, M 413.9, m 274-276°, $[\alpha]_D^{20}$ -173 (c 1, H_2O), $pK_{Est(1)}$~ 6 (N-cyclopropylmethyl), $pK_{Est(2)}$~ 9.6 (phenolic OH).** This narcotic antagonist has been purified by recrystallisation from MeOH and dried in air. The ***free base*** *[465-65-6]* has **m 168-170°** after recrystallisation from Me_2CO. [Cone et al. *J Pharm Sci* **64** 618 *1975*, DOI: 10.1002/jps.2600640409; Gold et al. *Med Res Rev* **2** 211 *1982*, DOI: 10.1002/med.2610020302.] Blocks the effect of opioids.

1-Naphthyl phosphate disodium salt *[2183-17-7, 207569-06-0]* **$C_{10}H_7O_4P$. 2Na, M 268.1, pK_1^{26} 0.97, pK_2^{26}**

5.85 (for free acid). Purify the salt through an acid ion-exchange column (in H^+ form) to give the ***free acid*** *[1136-89-6]*, M 224.2, which is obtained by freeze drying and recrystallising from $Me_2CO/*C_6H_6$, or by adding 2.5 volumes of hot $CHCl_3$ (or 20 parts of boiling $*C_6H_6$) to a hot solution of 1 part acid and 1.2 parts Me_2CO and cooling (**m 155-157°**, **157-158°**). The acid is dissolved in the minimum volume of H_2O to which 2 equivalents of NaOH are added and then freeze dried, or by adding the equivalent amount of MeONa in MeOH to a solution of the acid in MeOH and collecting the ***Na salt***, washing with cold MeOH, then Et_2O, and drying in a vacuum. [Friedman & Seligman *J Am Chem Soc* **72** 624 *1950*, DOI: 10.1021/ja01157a505; Chanley & Feageson *J Am Chem Soc* **77** 4002 *1955*, DOI: 10.1021/ja01620a015.] The ***monosodium salt*** *[1136-89-6]* is similarly prepared but with 1 equiv of NaOH. The phosphate group hydrolyses at pH 1.1-5.85 at 70°. [*Beilstein* **6** IV 4226.] A ***substrate*** for ***alkaline phosphatase*** [Gomori *Methods Enzymol* **4** 381 *1957*, DOI: 10.1016/0076-6879(57)04066-5; **128** 212 *1968*], and ***prostatic phosphatase*** [Babson *Clin Chem* **30** 1418 *1984*, PMID: 6744605].

2-Naphthyl phosphate monosodium salt *[14463-68-4]* **$C_{10}H_8O_4P$. Na, M 246.2, m 177-178°, 296° (sintering at 228°), pK_1^{26} 1.28, pK_2^{26} 5.53, pK_3^{26} 6.57 (for free acid).** The ***free acid*** *[41845-15-2]* is purified as for the preceding 1-isomer and has **m 176-177°** (also **177-178°**) after several recrystallisations by adding 2.5 volumes of hot $CHCl_3$ to a hot solution of 1 part of acid in 1.3 volumes of Me_2CO as for the 1-isomer above. It is neutralised with one equivalent of NaOH and freeze dried or prepared as the 1-isomer above. Its solubility in H_2O is ~5%. It also forms a ***0.5 Na. 1 H_2O salt*** which has **m 203-205°** (**244°** also reported). [Friedman & Seligman *J Am Chem Soc* **72** 624 *1950*, DOI: 10.1021/ja01157a505; Chanley & Fegeason *J Am Chem Soc* **77** 4002 *1955*, DOI: 10.1021/ja01620a015; *Beilstein* **6** IV 4285.]

D(+)-Neopterin *[2009-64-5]* **$C_9H_{11}N_5O_4$, M 253.2, m >300°(dec), $[\alpha]_{546}^{20}$ +64.5 (c 0.14, 0.1M HCl), $[\alpha]_D^{25}$ +50.1 (c 0.3, 0.1N HCl), pK_1 2.23 (basic), pK_2 7.89 (acidic).** Purification is as for biopterin. Also purify it on a Dowex-1 x 8 (formate form) column and elute with 0.03M ammonium formate buffer pH 8.0 then pH 7.2. The fluorescent neopterin fraction is evaporated under reduced pressure, leaving neopterin and ammonium formate (the latter sublimes out at high vacuum) behind. Stir the residue for 24 hours with EtOH, collect the solid and recrystallise it from H_2O. [Viscontini et al. *Helv Chim Acta* **53** 1202 *1970*, DOI: 10.1002/hlca.19700530537; cf. Wachter et al. Eds *Neopterin* W de Gruyter, Berlin *1992*, ISBN 9783110117905, *Beilstein* **26** IV 4038.]

β-Nicotinamide adenine dinucleotide (diphosphopyridine nucleotide, NAD, DPN) *[53-84-9]* **$C_{21}H_{27}N_7O_{14}P_2$, M 663.4, m 160°, $[\alpha]_D^{23}$ -34.8 (c 1, H_2O), pK_1 2.2 (PO_4H), pK_2 4.0 (adenine NH_2), pK_3 6.1 (PO_4^-).** NAD is purified by paper chromatography or better on a Dowex-1 ion-exchange resin. The column is prepared by washing with 3M HCl until free of material absorbing at 260nm, then with water, 2M sodium formate until free of chloride ions and, finally, with water. NAD, as a 0.2% solution in water, is adjusted with NaOH to pH 8, and adsorbed onto the column, washed with water, and eluted with 0.1M formic acid. Fractions with strong absorption at 360nm are combined, acidified to pH 2.0 with 2M HCl, and cold acetone (*ca* 5L/g of NAD) is added slowly and with constant agitation. It is left overnight in the cold, then the precipitate is collected in a centrifuge, washed with pure acetone and dried under vacuum over $CaCl_2$ and paraffin wax shavings [Kornberg *Methods Enzymol* **3** 876 *1957*, DOI: 10.1016/S0076-6879(57)03468-0]. It has been purified by anion-exchange chromatography [Dalziel & Dickinson *Biochemical Preparations* **11** 84 *1966*.] The purity is checked by reduction to NADH (with EtOH and yeast alcohol dehydrogenase) which has ε_{340mn} 6220 $M^{-1}cm^{-1}$. [Todd et al. *J Chem Soc* 3727 *1957*, DOI: 10.1039/JR9570003727; 3733 *1957*, DOI: 10.1039/JR9570003733.] [For pKa see Lamborg et al. *J Biol Chem* **231** 685 *1958*, PMID: 13539003.] The ***free acid*** crystallises from aqueous Me_2CO with $3H_2O$ and has **m 140-142°**. It is stable in cold neutral aqueous solutions in a desiccator ($CaCl_2$) at 25°, but decomposes at strong acid and alkaline pH. Its purity is checked by reduction with yeast alcohol dehydrogenase and EtOH to NADH and noting the OD at 340nm. Pure NADH (see below) has ε_{340} 6.2 x 10^4 $M^{-1}cm^{-1}$, i.e. 0.1μmole of NADH in 3ml and in a 1cm path length cell has an OD at 340nm of 0.207. [*Beilstein* **26** IV 3644, **26** III/IV 3639.] NAD is a ubiquitous cofactor for oxido-reductase and other enzymes.

β-Nicotinamide adenine dinucleotide reduced di-Na salt trihydrate (reduced diphosphopyridine nucleotide sodium salt, NADH) *[606-68-8]* **$C_{21}H_{27}N_7O_{14}P_2$. 2Na. xH_2O, M 709.4 (anhydrous), pKa as for NAD.** This coenzyme is available in high purity, and it is advisable to buy a fresh preparation rather than to purify an old sample as purification will usually lead to a more impure sample contaminated with the oxidised form (NAD). It has UV with λ_{max} at 340nm (ε 6,200 $M^{-1}cm^{-1}$), at which wavelength the oxidised form NAD

has **no** absorption. At 340nm a 0.161mM solution in a 1cm (pathlength) cell has an absorbance of 1.0 unit. The purity is best checked by the ratio A_{280nm}/A_{340nm} ~2.1, a value which increases as oxidation proceeds. The dry powder is stable indefinitely at -20°. Solutions in aqueous buffers at pH ~7 are stable for extended periods at -20° and for at least 8 hours at 0°, but are oxidised more rapidly at 4° in a cold room (e.g. almost completely oxidised overnight at 4°). [For UV see Drabkin *J Biol Chem* **157** 563 *1945*, http://www.jbc.org/content/157/2/563; Fluorescence: Boyer & Theorell *Acta Chem Scand* **10** 447 *1956*, DOI: 10.3891/acta.chem.scand.10-0447; Redox: Rodkey *J Biol Chem* **234** 188 *1959*, PMID: 13610918; Schlenk in *The Enzymes* **2** 250, 268 *1951*, Kaplan in *The Enzymes* **3** 105, 112 *1960*.] Deuterated NADH, i.e. NADD, has been purified through the anion exchange resin AG-1 x 8 (100-200 mesh, formate form) then a Bio-Gel P-2 column. [Viola et al. *Anal Biochem* **96** 334 *1979*, DOI: 10.1016/0003-2697(79)90590-6.]

β-Nicotinamide adenine dinucleotide phosphate (NADP, TPN) *[53-59-8]* **$C_{21}H_{29}N_7O_{17}P_3$, M 744.4, pK_1 1.1 (PO_4H_2), pK_2 4.0 (adenine NH_2), pK_3 6.1 (PO_4^-).** Purify it by anion-exchange chromatography in much the same way as for NAD [Dalziel & Dickinson *Biochem J* **95** 311 *1965*, DOI: 10.1042/bj0950311; *Biochemical Preparations* **11** 87 *1966*]. Finally it is purified by dissolving in H_2O and precipitating with 4 volumes of Me_2CO and dried *in vacuo* over P_2O_5. It is unchanged by storing *in vacuo* at 2°. [Hughes et al. *J Chem Soc* 3733 *1957*, DOI: 10.1039/JR9570003733; Shuster & Kaplan *J Biol Chem* **215** 183 *1955*, PMID: 14392153.] Deuterated NADPH, i.e. NADPD, has been purified through the anion exchange resin AG-1 x 8 (100-200 mesh, formate form) and through a Bio-Gel P-2 column. It has λ_{min} 259nm (ε 18.000) at pH 7.0. [Viola et al. *Anal Biochem* **96** 334 *1979*, DOI: 10.1016/0003-2697(79)90590-6; *Beilstein* **26** IV 3669, 3672.]

β-Nicotinamide adenine dinucleotide phosphate reduced tetrasodium salt (reduced diphosphopyridine nucleotide phosphate sodium salt, NADPH) *[2646-71-1]* **$C_{21}H_{26}N_7O_{17}P_3$. 4Na. xH_2O, M 833.4, pKa as for NADP.** Purification is mostly similar to that of NADH above. [*Beilstein* **26** III/IV 3671.]

β-Nicotinamide mononucleotide (NMN) *[1094-61-7]* **$C_{11}H_{15}N_2O_8P$, M 334.2, m 90.3°, $[\alpha]_D^{23}$ -38.3 (c 1, H_2O), pK_{Est} ~ 6.1 (PO_4^-).** Purify NMN by passage through a column of Dowex-1 (Cl^- form) and washing with H_2O until no absorbance is observed at 260 nm. The tubes containing NMN are pooled, adjusted to pH 5.5-6 and evaporated *in vacuo* to a small volume. This is adjusted to pH 3 with dilute HNO_3 in an ice-bath and treated with 20 volumes of Me_2CO at 0-5°. The heavy white precipitate is collected by centrifugation at 0°. It is best stored wet and frozen or it can be dried to give a gummy residue. It has λ_{max} at 266nm (ε 4,600) and λ_{min} at 249nm (ε 3600) at pH 7.0 (i.e. no absorption at 340nm). It can be estimated by reaction with CN^- or hydrosulfite which form the 4-adducts (equivalent to NADH) which have UV with λ_{max} at 340nm (ε 6,200). Thus after reaction, an OD_{340} of 'one' is obtained from a 0.1612mM solution in a 1cm path cuvette. [Plaut & Plaut *Biochemical Preparations* **5** 56 *1957*, Kaplan & Stolzenbach *Methods Enzymol* **3** 899 *1957*, DOI: 10.1016/S0076-6879(57)03473-4; Kaplan et al. *J Am Chem Soc* **77** 815 *1955*, DOI: 10.1021/ja01608a098; *Beilstein* **22/2** V 168.]

(-)-Nicotine [(*2S*)-1-methyl-2[3-pyridyl]-pyrrolidine] *[54-11-5]* **$C_{10}H_{14}N_2$, M 162.2, m -79°, b 123-125°/17mm, 243-248°/760mm (partial dec), d_4^{20} 1.097, n_D^{20} 1.5280, $[\alpha]_D^{20}$ -169 (c 1, Me_2CO), pK_1^{15} 6.16 (pyridine N^+), pK_2^{15} 10.96 (pyrrolidine N^+).** (-)-Nicotine is a very pale yellow ***hygroscopic*** oil with a characteristic odour (tobacco extract) which turns brown in air on exposure to light. It is purifed by fractional distillation under reduced pressure in an inert atmosphere. A freshly distilled sample should be stored in dark sealed containers under N_2. It is a strong base; a 0.05 M aqueous solution has a pH of 10.2. It is very soluble in organic solvents. It is soluble in H_2O and readily forms salts. [For UV see Parvis *J Chem Soc* **97** 1035 *1910*, DOI: 10.1039/CT9109701035; Dobbie & Fox *J Chem Soc* **103** 1193 *1913*, DOI: 10.1039/CT9130301193.] The ***hydrochlorides*** (mono- and di-) form ***deliquescent*** crystals soluble in H_2O and EtOH but insoluble in Et_2O. It has also been purified *via* the $ZnCl_2$ double salt. [Ratz *Monatsh Chem* **26** 1241 *1905*, DOI10.1007/BF01526536; Biosynthesis: Nakane & Hutchinson *J Org Chem* **43** 3922 *1978*, DOI: 10.1021/jo00414a027.] The ***picrate*** has **m 218°** (from EtOH). [*Beilstein* **23/6** V 64.] Nicotine is the addictive principle in tobacco smoke with a biological half life of 1-2 hours. **POISONOUS.** ***(±)-Nicotine*** *[22083-74-5]* **$C_{10}H_{14}N_2$, M 162.2,** has **b 113-115°/10mm, 242.3°/atm, d_4^{20} 1.082 (pKa see above).** It is purified by fractional distillation. Its solubility in EtOH is ~5%. The ***picrate*** forms yellow needles from hot H_2O and has **m 219°**. The ***methiodide*** has **m 219°** (from MeOH). Novobiocin (7-[*O*^{3}-carbamoyl-5-*O*^{4}-dimethyl-β-L-*lyso*-6-desoxyhexahydropyranosyloxy]-4-hydroxy-3[4-hydroxy-3-{3-methylbut-2-enyl}-benzylamino]-8-methylcoumarin) *[303-81-1]* **$C_{31}H_{36}N_2O_{11}$, M 612.6, two forms m 152-156° and m 172-174°, 174-178°, λ_{max} at 330nm (acidic EtOH), 305nm (alkaline EtOH), $[\alpha]_D^{25}$ -63 (c 1, EtOH), pK_1 4.03 (4.2), pK_2 9.16.** Crystallise novobiocin from EtOH and store it in the dark. It has also been recrystallised from Me_2CO/H_2O. [Hoeksema et al. *J Am Chem Soc* **77** 6710 *1955*, DOI: 10.1021/ja01629a129; Kaczka et al. *J Am Chem Soc* **77** 6404 *1955*, DOI: 10.1021/ja01628a121.] The ***sodium salt*** *[1476-53-5]* **M 634.6, m 210-215°, 215-220°(dec), 222-229°, $[\alpha]_D^{25}$ -38 (c 1, H_2O)** has been recrystallised from MeOH, then dried at 60°/0.5mm. [Sensi et al, *Anal Chem* **29** 1611 *1957*, DOI: 10.1021/ac60131a011; Kaczka et al. *J Am Chem Soc* **78** 4125 *1956*, DOI: 10.1021/ja01597a072; *Beilstein* **18/8** IV 8125.]

Nucleotide thiophosphate analogues. The preparation and purification of [^{3}H]ATPγS, [^{3}H]GTPγS, S^{6}ITPγS (6-thioinosine), Cl^{6}ITPγS (6-chloroinosine) and [^{3}H]ATPγS were described, and general purification was achieved by chromatography of the nucleotide thiophosphates in the minimum volume of H_2O placed onto a DEAE-Sephadex A25 column and eluted with a linear gradient of triethylammonium bicarbonate (0.1 to 0.6M for G and I nucleotides and 0.2 to 0.5M for A nucleotides). [Goody et al. *Biochim Biophys Acta* **276** 155 *1972*, DOI: 10.1016/0005-2744(72)90016-2.]

Nystatin dihydrate (Mycostatin, Fungicidin) *[1400-61-9]* **$C_{47}H_{79}NO_{19}$, M 962.1, m dec>160° (without melting by 250°), $[\alpha]_D^{25}$ -7 (0.1N HCl in MeOH), -10 (AcOH), +12 (Me_2NCHO), +21 (pyridine).** Nystatin is a light yellow powder with the following solubilities at ~28°: MeOH (1.1%), ethylene glycol (0.9%), H_2O (0.4%), CCl_4 (0.12%), EtOH (0.12%), $CHCl_3$ (0.05%) and $*C_6H_6$ (0.03%). It has been precipitated from MeOH solution by addition of H_2O. Aqueous suspensions of this cyclic macrolide aminoglycoside antifungal antibiotic are stable at 100°/10 minutes at pH 7.0 but decompose rapidly at pH <2 and >9, and in the presence of light and O_2. [Birch et al. *Tetrahedron Lett* 1491 *1964*, DOI: 10.1016/S0040-4039(01)89518-6; 1485 *1964*, DOI: 10.1016/S0040-4039(01)89517-4; Weiss et al. *Antibiot Chemother* **7** 374 *1957*; Gøtzsche & Johansen *Cochrane Database Syst Rev* **9**: CD002033, *2014*, DOI: 10.1002/14651858.CD002033.pub2. PMID: 25188770.] It may contain a mixture of components A_1, A_2 and A_3. [*Beilstein* **18** III/IV 7480.]

Omeprazole

{5-methoxy-2-[(4-methoxy-3,5-dimethyl-2-pyridylmethylsulfinyl)]-1*H*-benzimidazole, Perizac, Losec Omeprazen, Pepticum) *[73590-58-6]* **$C_{17}H_{19}N_3O_3S$, M 345.4, m 156°, pK_1^{25} 3.98 (protonation of pyridine ring), pK_2^{25} 8.70 (deprotonation of the imidazole NH).** Clarke & Slemon have patented a novel synthesis which provides pure product free from coloured and other impurities and in which solids can be isolated [US Pat 5470983 A *1995* (lapsed)]. It involves linking a 4-methoxy-3,5-dimethylpyridin-2-yl moiety with a 5-methoxybenzimidazol-2-yl moiety *via* a bridge [—*$CH(CONH_2)$-S-] to form the thioether 4-OMe-3,5-MePy-2-$CH(CONH_2)$-S-2-(5-OMe)benzimidazole. This allowed the specific oxidation [e.g. with $V(AcAc)_2/H_2O_2$, at 0-5°, then 20-22°/1hr] of the sulfide group into a chiral sulfoxide (sulfinyl) group thus generating diastereoisomers (vicinal chiral centres at py-2-***C** and the **S(O)**-benzimidazole). Mild treatment of 1g in H_2O (1ml) with 5.0g of sodium metabisulfite/75ml H_2O + 25ml MeOH (pH of mixture being at 7.2), followed by dropwise addition of glacial acetic acid (35 drops) to bring the pH to 4.8 resulted in vigorous evolution of CO_2 due to hydrolysis of the amide group and decarboxylation. The clear solution became turbid due to separation of ***omeprazole*** as an oil which, on addition of MeOH (2.0ml) and seeding with the drug, the oil solidified (30 minute). It was collected washed with H_2O and a little Me_2CO and dried to give 0.45g of substantially pure off-white ***omeprazole*** which can be recrystallised from MeCN. Allenmark et al. [*Anal Biochem* **136** 293 *1984*, DOI: 10.1016/0003-2697(84)90219-7] have succeeded in separating the enantiomers by HPLC on an affinity bovine serum albumin column (conditions: 0.08M phosphate pH 5.80, flow rate of 2.0ml/min, 10µl of 0.5mM solutions injected, using a 4.6x150mm Resolvosil 10µm analytical BSA-silica column, developed at Linköping University and available from Macherey-Nagel & Co. GmbH, Düren, GFR).
S-Omeprazole (Esomeprazole) *[11914-88-7]* has been isolated as a syrup with $[\alpha]_D^{20}$ -155 (c 0.5, $CHCl_3$) and

elutes first from a chiral *trisphenylcarbamoylcellulose*-on 3-aminopropyl silica column. Erlandsson et al. [*J Chromatogr* **532** 305 *1990*, DOI: 10.1016/S0378-4347(00)83781-0] showed that the chiral drug is fairly optically stable since, in the minimum volume of 2-propanol diluted with 0.05M sodium phosphate buffer at pH 7.0, it ***racemises*** with half lives of 130 hours at 37º and 55 hours at 75º. They further studied the effect on acid formation in isolated gastric glands and found that the racemate, the (-)- and the (+)- enantiomer were about ***equally effective***. The ***magnesium salt of the* S-*enantiomer* (Esmeprazole magnesium, Nexium)** *[161973-10-0]* **($C_{17}H_{19}N_3O_3S)_2Mg$, M 713.1**, is a white powder with **$[\alpha]_D^{20}$** -128.2 (c 1, MeOH) and similar ***antiulcerative*** activity.

Omeprazole is a ***pro-drug*** which has basic (pKa 3.98) and acidic (pKa 8.70) properties, and its charges are balanced, i.e. would have a pI of *ca* 6.3. It enters the gastric acid secreting parietal cells where it would be entirely in the protonated form which cannot get out of the cells. In these cells it undergoes an acid catalysed intramolecular rearrangement to a product which now has a free thiol group that forms an ***irreversible*** (almost) ***disulfide bond*** with the ***ATPase proton pump***, and thus shuts down its activity (and acidity) [review: Lindberg et al. *Med Res Rev* **10** 1-54 *1990*, DOI: 10.1002/med.2610100102.] In time the pump is then reactivated by cytosolic glutathione to its normal state [Nagaya et al. *J Pharmacol Exp Ther* **252** 1289 *1990*, PMID: 2156997]. [For synthesis related compounds see Vidaillac et al. *Antimicrob Agents Chemother* **51** 831 *2007*, PMCID: 1803156; for reactions see Brändström et al. *Acta Chem Scand* **43** 536 *1989*, DOI: 10.3891/ acta.chem.scand.43-0536; Brändström et al. *Acta Chem Scand* **43** 549 *1989*, DOI: 10.3891/acta.chem.scand.43-0549; Brändström et al. *Acta Chem Scand* **43** 569 *1989*, DOI: 10.3891/acta.chem.scand.43-0569; Brändström et al. *Acta Chem Scand* **43** 595 *1989*, DOI: 10.3891/acta.chem.scand.43-0595.] The ***enantiomers*** have also been separated using *Cellulase*(CBH I)*silica* as chiral stationary phase [Marle et al. *J Chromatogr* **586** 233 *1991*, DOI: 10.1016/0021-9673(91)85127-2; and Stenhoff et al. *J Chromatogr* **734** 191 *1999*, DOI: 10.1016/S0378-4347(99)00324-2],

Omeprazole is a H^+,K^+-ATPase inhibitor (IC_{50} = 5.8μM) that exhibits ***antisecretory*** and ***antiulcer*** activity. It inhibits gastric acid secretion (IC_{50} = 0.16μM for histamine-induced acid production), as well as being antibacterial towards ***Helicobacter pylori*** *in vitro*. It also blocks the swelling-dependent Cl^- channels (ICIswell) in NIH3T3 fibroblasts. [Satoh et al. *J Pharmacol Exp Ther* **248** 806 *1989*, PMID: 2537418; Schmarda et al. *Br J Pharmacol* **129** 598 *2000*, DOI: 10.1038/sj.bjp.0703070.]

Ondansteron (*RS*-9-methyl-(2-methyl-1*H*-imidazol-1-yl)-2,3-dihydro-1*H*-carbazol-4(9*H*)-one) *[RS- 99614-02-5]* **M 293.4, m 231-232º, 232-234º, pK^{25} 7.40.** The synthesis of Ondansteron was described by Coates et al. [US Patent 4695578 *1987*, to Glaxo Group Ltd] with several variations. In one of these *RS*-3-[(dimethylamino)methyl]-2,3-dihydro-9-methyl-4(1*H*)-oxocarbazole (3.8g, see Evans *Aust J Chem* **26** 2555 *1972*, DOI: 10.1071/CH9732555) in MeI (100ml) was stirred while refluxing for 57 hours, the suspension was evaporated *in vacuo* to give the *RS*-3-methanamium iodide (5.72g, m 192-195º). This iodide was stirred with excess of 2-methylimidazole *[693-98-1]* in dry DMF at 100º under N_2 for 17 hours, to give *RS*-2,3-dihydro-3-[(2-methylimidazol-1-yl)methyl]-4*H*-carbazol-4-one which was converted to the 9–sodio derivative with NaH in DMF and methylated at N-9 with Me_2SO_4 to provide ***ondansteron*** which was purified by recrystallisation from MeOH. The ***citrate salt*** was prepared by adding ondansteron (0.89g) to a hot citric acid (0.89g) solution in EtOH (20ml) and allowed to crystallise then recrystallising by dissolving in Me_2CO/H_2O (2:1, 2ml) and diluting with Me_2CO (20ml) to give pure ***RS-citrate salt*** (0.6g) **m 162º**. The ***RS-maleate salt*** formed white crystals **m 123.3º** after recrystallisation from hot EtOH. The ***RS-monophosphate* (1:1) *salt***, **m 225º**, crystallised from hot H_2O.

RS-Ondansteron hydrochloride dihydrate* (Zofran, Zofren)** *[99614-01-4]* **$C_{18}H_{19}N_3O$. HCl. $2H_2O$, M 365.9** was obtained by adding concentrated HCl (6.25ml) to a hot solution of ondansteron (18.3g) in *iso*-PrOH (98ml) and H_2O (90ml) which was filtered, the filtrate was diluted with *iso*-PrOH (90ml), stirred at ~25º for 17 hours, cooled to 2º and the salt (21.6g) was filtered off. A sample of the salt (6g) was recrystallised from a mixture of H_2O (6ml) and *iso*-PrOH (10ml) to provide ***analytically pure white crystalline RS-hydrochloride dihydrate **m 178.5-179.7º**. Its solubility in H_2O was 50mM, and its solubility in DMSO was 100mM.

Optical resolution of *Ondansteron*, which has an asymmetric carbon atom at C-3 of the dihydrocarbazolone ring, was achieved by mixing the free base (0.5g) in hot MeOH (30ml) with a hot solution of (-)-di-*p*-toluoyl-L-tartaric acid (0.7g) in MeOH (10ml) and cooled, whereby the (+)base-(-)acid diasereoisomeric salt (0.8g) separated. This salt was dissolved in hot DMF (20ml) diluted with hot H_2O (10ml) and allowed to crystallise for 3 days. The crystals were isolated, and dried *in vacuo* to give *ca* 95% enantiomerically ***pure*** (by ^{1}H NMR) ***(-)-di-p-toluoyl-L-tartaric salt*** (0.26g) **m 190-192º**. This salt (0.2g) was mixed with 8% $NaHCO_3$ (25ml) and

extracted with $CHCl_3$ (2 x 25ml). Evaporation of the $CHCl_3$ extract gave pure **3-*R*-*Ondansteron*** that had **$[\alpha]_D^{24}$ +16 (c 0.34, MeOH)** which was shown by ^{1}HNMR to have an enantiomer ratio of >95:5 (R:S). Similarly by using (+)-di-*p*-toluoyl-D-tartaric acid, the diastereomeric salt (-)base-(+)-acid was obtained. This salt gave the ***free base***, ***3-S-Ondansteron***, which had **$[\alpha]_D^{24}$ -14 (c 0.19, MeOH)** and shown by ^{1}H NMR to have an enantiomer ratio of 93:7 (*S:R*).
Ondansteron is a prescription drug, and is an ***anti-emetic*** for controlling post-operative nausea and vomiting, and is sometimes used in pregnancy. It is associated with a ***long QT interval of the heart beat*** which can lead to a fatal heart rhythm. [Review: Simpson & Hicks *J Pharm Pharmacol* **48** 774 *1996*, DOI: 10.1111/j.2042-7158.1996.tb03973.x.] ***RS-Ondansteron*** is an effective reversible ***competitive antagonist of 5-HT$_3$ receptors*** in rat vagus nerve and smooth muscle of guinea pig ileum; the ***R-enantiomer is marginally more potent than the S-enantiomer*** [Butler et al. *Brit J Pharmacol* **94** 397 *1988*, PMCID: PMC1854010]. [Cooke & Mehra in *Am J of Hospital Pharm* **51** 762 *1994*, PMID: 8010314; and Zoldan et al. *Neurology* **45** 1305 *1995*, PMID: 7617188.]

Oxcarbazepine (Trilaptal, 10-oxo-10,11-dihydro-5*H*-dibenz[*b*,*f*]azepine-5-carboxamide) *[28721-07-5]* **$C_{15}H_{12}N_2O_2$, M252.3, m 215-216°.** The synthesis of this drug has been described by Schindler [DE 2011087 *1970* and US Patent 3642775 *1972* to Ciba-Geigy]. Briefly it proceeds as follows: 10-methoxy-5*H*-dibenz[*b*,*f*]azepine [m 125-129°; *4698-11-7*] + $COCl_2$/toluene → 10-methoxy-5*H*-dibenz[*b*,*f*]azepine-5-carbonyl chloride [77% yield, m 138° from EtOH; *28721-08-6*] + EtOH/NH_3gas/4hrs → 10-methoxy-5*H*-dibenz[*b*,*f*]azepine-5-carbonxamide [93% yield, m 186-188° from EtOH; *28721-09-7*] + 2N HCl/2hrs reflux, cool filter off crystals and recrystallise → ***Oxcarbazepine*** [80% yield, **m 215-216°** from EtOH]. [see ***Carbamazepine*** [*298-46-4*] above and 5*H*-dibenz[*b*,*f*]azepine in 'Heterocylic Compounds', Chapter 3.]
Oxcarbazepine is an ***anticonvulsant*** drug used for the evaluation and treatment of ***epilepsy***, ***psychosomatic disturbances*** and of ***trigeminal neuralgia***. [Dam et al. *Epilepsy Res* **3**(1) 70 *1989*, DOI: 10.1016/0920-1211(89)90070-3; Mazza et al. *Expert Opinion on Pharmacotherapy* **8**(5) 649 *2007*, PMID: 17376019.]

Oxacillin sodium salt (5-methyl-3-phenyl-4-isoxazolylpenicillin sodium salt) *[1173-88-2, 7240-38-2 (H_2O)]* **$C_{19}H_{18}N_2O_3S$. Na. H_2O, M 423.4, m 188°(dec), $[\alpha]_D^{20}$ +29 (c 1, H_2O), pK_{Est} ~ 2.7.** This antibiotic, which is stable to penicillinase, is purified by recrystallisation from isoPrOH and dried *in vacuo*. Its solubility in H_2O at 25° is 5%. [Doyle et al. *Nature* **192** 1183 *1961*, DOI: 10.1038/1921183a0; Review: Chain et al. *Antibiotics* (Oxford University Press) **2** *1949*.]

Oxolinic acid (5-ethyl-5,8-dihydro-8-oxo-1,3-dioxolo[4,5-*g*]quinoline-3-carboxylic acid) *[14698-29-4]* **M 261.2, m 313-314°(dec), 314-316°(dec), pK_{Est} ~ 2.3.** Purify the acid by recrystallisation from aqueous Me_2CO, 95% EtOH or dimethylformamide. It has UV with λ_{max} at 220, (255.5sh), 259.5, 268, (298sh, 311sh), 321 and 326nm [ε 14.8, (36.8sh), 38.4, 38.4, (6.4sh, 9.2sh), 10.8 and 11.2 x 10^3]. [Kaminsky & Meltzer *J Med Chem* **11** 160 *1968*, DOI: 10.1021/jm00307a041; *Beilstein* **17** III/IV 13, **17/1** V 11.] It is an antibacterial causing DNA cleavage *in vivo* in *E coli* [Snyder & Drlica *J Mol Bol* **131** 287 *1979*, DOI: 10.1016/0022-2836(79)90077-9].

Oxycodone [Endone, Roxicodon, (5R,9R,13S,14S)-4,5-epoxy-14-hydroxy-3-methoxy-17-methylmorphinan-6-one] *[76-42-6]* **$C_{18}H_{21}NO_4$, M 315.4, m 218-220°, pK_{Est} ~9.6.** Oxycodone is a ***semi-synthetic opioid*** prepared from thebaine, but also occurs naturally with other opium alkaloids. Purify it by recrystallisation from EtOH (colourless rods). It is almost insoluble in H_2O and Et_2O but quite soluble in EtOH and $CHCl_3$. This base forms stable salts with acids e.g. tartaric, terephthalic acid as well as HCl, H_2SO_4 and H_3PO_4. ***The hydrochloride (Oxycon)*** *[124-90-3]* crystallises in long rods from H_2O (solubility is 10w/v%/25°) with **m 270-273°(dec)** and **$[\alpha]_D^{20}$ -125 (c 2.5, H_2O)**. It is prepared by hydrolysis of thebaine with dilute H_2SO_4 to convert the dienol-ether into the enone (***codeinone***). The later can also be converted ***4-OH-codeinone***, and reduction of this with hydrosulfite provides ***oxycodone***. Oxycodone exhibits ***keto-enol tautomerism*** and apparently one form can crystallise out from EtOH and the more soluble isomer provides birefringent scales with **m 219-220°**. The two forms give the same salts [Freund & Speyer *J Prakt Chem* **94** 135 *1916*, DOI: 10.1002/prac.19160940112]. It is sold as an ***analgesic***, alone or formulated with non-steroidal anti-inflammatory drugs. [Riley et al. *Curr Med Res Opin* **24** 175 *2008*, PMID: 18039433; Sunshine et al. *J Clin Pharmacol* **36** 595 *1996*, PMID: 8844441.]

Palmitoyl coenzyme A *[1763-10-6]* **$C_{37}H_{66}N_7O_{17}P_3S$, M 1004.9.** Possible impurities are palmitic acid,

S-palmitoyl thioglycolic acid and S-palmitoyl glutathione. These are removed by placing *ca* 200mg in a centrifuge tube and extracting with Me_2CO (20ml), followed by two successive extractions with Et_2O (15ml) to remove S-palmitoyl thioglycolic acid and palmitic acid. The residue is dissolved in H_2O (4 x 4 ml), adjusted to pH 5 and centrifuged to remove insoluble S-palmitoyl glutathione and other insoluble impurities. To the clear supernatant is added 5% $HClO_4$ (6ml) whereby S-palmitoyl CoA precipitates. The precipitate is washed with 0.8% $HClO_4$ (10ml) and finally with Me_2CO (3x 5ml) and dried *in vacuo*. It is stable for at least one year in dry form at 0° in a desiccator (dark). Solutions are stable for several months at -15°. Its solubility in H_2O is 4%. The adenine content is used as the basis of purity with λ_{max} at 260 and 232nm (ε 6.4 x 10^6 and 9.4 x 10^6 cm^2/mol, respectively). Higher absorption at 232nm would indicate other thio ester impurities, e.g. S-palmitoyl glutathione, which absorb highly at this wavelength. Also the phosphate content should be determined, and acid phosphate can be titrated potentiometrically. [Seubert *Biochemical Preparations* **7** 80 *1960*, Srere et al. *Biochim Biophys Acta* **33** 313 *1959*, DOI: 10.1016/0006-3002(59)90118-0; Kornberg & Pricer *J Biol Chem* **204** 329 *1953*, PMID: 13084605; 345 *1953*, PMID: 13084606; *Beilstein* **26** III/IV 3665.] This thiol ester uses serine to biosynthesise sphingosine [Brady et al. *J Biol Chem* **244** 491 *1969*, PMID: 4388074].

3-Palmitoyl-*sn*-glycerol (*R*-glycerol-1-palmitate, L-β-palmitin) *[32899-41-5]* **$C_{19}H_{38}O_4$, M 330.5, $d^{27.3}$ 0.9014, m 66.5° (α-form), 74° (β'-form) and 77° (β-form).** The stable ***β-form*** is obtained by recrystallisation from EtOH or Skellysolve B, but recrystallisation from Et_2O provides the ***β'-form***. The ***α-form*** is obtained on cooling the melt. Store it at -20°. [Malkin & el Shurbagy *J Chem Soc* 1628 *1936*, DOI: 10.1039/JR9360001628; Chapman *J Chem Soc* 55 *1956*, DOI: 10.1039/JR9560000055; Lutton & Jackson *J Am Chem Soc* **70** 2445 *1948*, DOI: 10.1021/ja01187a043; *Beilstein* **2** III 966.]

D-Panthenol (Provitamin B, *R*-2,4-dihydroxy-3,3-dimethylbutyric acid 3-hydroxy-propylamide) *[R- 81-13-0, RS- 16485-10-2]* **$C_9H_{19}NO_4$, M 205.3, 66-69°, b 118-120°/0.02mm, d_{20}^{20} 1.2g/L, n_D^{20} 1.4935, $[\alpha]_D^{20}$ +30 (c 5, H_2O), pK^{25} 13.03.** Purify D-panthenol by distillation *in vacuo*. It is a slightly ***hygroscopic*** viscous oil and is soluble in H_2O and organic solvents. It is hydrolysed by alkali and strong acid. [Rubin *J Am Pharm Assoc (Sci Ed)* **37** 502 *1948*, DOI: 10.1002/jps.3030371208; Bonati & Pitré *Farmaco Ed Scient* **14** 43 *1959*, *Beilstein* **4** IV 1652.] Only the *R*(or D) enantiomer, ***Dexpanthenol***, accelerates epidermal wound healing, but both enantiomers have moisturising properties for which they are used commercially. [Ebner et al. *Am J Clin Dermatol* **3** 427 *2002*, DOI: 10.2165/00128071-200203060-00005, PMID:12113650.]

R*-(+)-Pantothenic acid sodium salt (*N*-[2,4-dihydroxy-3,3-dimethylbutyryl] β-alanine Na salt)** *[867-81-2]* **$C_9H_{16}NO_5$. Na, M 241.2, $[\alpha]_D^{25}$ +27.1 (c 2, H_2O), pK^{25} 4.4 (for free acid).** Recrystallise the salt from absolute EtOH. It is very hygroscopic (keep in sealed ampoules). The ***free acid *[79-83-4]* $C_9H_{17}NO_5$, M 219.2, is a viscous hygroscopic oil (**m 179-179° ?**) with $[\alpha]_D^{25}$ +37.5 (c 5, H_2O), which is easily destroyed by acids and bases. Store it at -20°. See next entry. [*Beilstein* **4** IV 2569.]

R*-(+)-Pantothenic acid Ca salt** *[(*D(+) *0.2Ca 137-08-6*, *63409-48-3]* **$(C_9H_{16}NO_5)_2$. Ca, M 476.5, m 195-196°, 200-201°, $[\alpha]_D^{20}$ +28.2 (c 5, H_2O).** The salt crystallises as needles from MeOH, EtOH or isoPrOH (with 0.5mol of isoPrOH). Its solubility in H_2O is 50ml/ml at 25°, and is moderately ***hygroscopic. The ***S-benzylisothiuronium salt*** has **m 151-152°** (**149°** when crystallised from Me_2CO). [Kagan et al. *J Am Chem Soc* **79** 3545 *1957*, DOI: 10.1021/ja01570a064; Wilson et al. *J Am Chem Soc* **76** 5177 *1954*, DOI: 10.1021/ja01649a071; Stiller & Wiley *J Am Chem Soc* **63** 1237 *1941*, DOI: 10.1021/ja01850a023; *Beilstein* **4** IV 2569.] It is a member of the ***vitamin B complex*** and essential for coenzyme A biosynthesis in mammalian cells.

Papaverine hydrochloride (6,7-dimethoxy-1-veratrylisoquinoline hydrochloride) *[61-25-6]* **M 375.9, m 215-220°, 222.5-223.5°(dec), 231°, pK^{25} 6.41.** Recrystallise it from H_2O. It sublimes at 140°/0.1mm. Its solubility in H_2O is 5%. [For potentiometric titration of alkaloid salts see Saunders & Srivastava *J Pharm Pharmacol* **3** 78 *1951*, DOI: 10.1111/j.2042-7158.1951.tb13047.x; and for pKa determination see Biggs *Trans Faraday Soc* **50** 800 *1954*, DOI: 10.1039/TF9545000800.] The ***free base*** *[58-74-2]* has **m 148-150°**. The ***picrate*** has **m 186-189°(dec**, **186-186.5° dec)** [For regeneration of alkaloids from picrates see Bobbitt *J Org Chem* **22** 1729 *1957*, DOI: 10.1021/jo01363a633]. [*Beilstein* **21** II 202, **21** III/IV 2788, **21/6** V 182.] The alkaloid is a cerebral vasodilator [Jayne et al. *J Clin Invest* **31** 111 *1952*, DOI: 10.1172/JCI102568].

Paromomycin sulfate {amminosidin, *O*-2,6-diamino-2,6-dideoxy-β-L-idopyranosyl-(1→3)-*O*-β-D-ribo-furanosyl(1→5)-*O*-[2-amino-2-deoxy-α-D-glucopyranosyl-(1→4)]-2-deoxystreptamine sulfate} *[1263-89-4]* **$C_{33}H_{45}N_5O_{14}$. xH_2SO_4, M 615.6 (free base), 713.7, amorphous, $[\alpha]_D^{25}$ +50 (c 1.5, H_2O pH6), pKest ~ 9.** Purify this ***antibiotic*** by dissolving it in H_2O (0.5g/10ml) and adding excess EtOH, filter or collect and wash with EtOH, then Et_2O by centrifugation, and dry it *in vacuo*. An aqueous solution is stable at 37° for a week but longer at 0-5°. The ***free base*** *[7542-37-2]* is a white amorphous powder which stored under N_2 as it is strongly basic. It is soluble in MeOH (less so in EtOH) and has **$[\alpha]_D^{25}$ +65 (c 1.5, MeOH)**. It is an ***antimicrobial*** and is ***antiamoebic***. It inhibits initiation and peptide elongation during protein synthesis. [Haskell et al. *J Am Chem Soc* **81** 3480 *1959,* DOI: 10.1021/ja01522a084; 3482 *1959*, DOI: 10.1021/ja01522a087; Hichens & Rinehart *J Am Chem Soc* **85** 1547 *1963*, DOI: 10.1021/ja00893a043; *Beilstein* **18** III/IV 7534.] It has *antiprotozoal* activity.

D-(-)-Penicillamine (*R*-3-mercapto-D-valine, 3,3-dimethyl-D-cysteine, from natural penicillin) *[52-67-5]* **$C_5H_{11}NO_2S$, M 149.2, m 202-206°, 214-217°, $[\alpha]_D^{21}$ -63 (c 1, N NaOH or pyridine), pK_1^{25} 2.44, pK_2^{25} 7.97 (7.88), pK_3^{25} 10.43 (10.46).** The melting point of D-(-)-penicillamine depends on the rate of heating (**m** 202-206° is obtained by starting at 195° and heating at 2°/minute). It is soluble in H_2O and alcohols but insoluble in Et_2O, $CHCl_3$, CCl_4 and hydrocarbon solvents. Purify it by dissolving it in MeOH and adding Et_2O slowly. Dry it *in vacuo* and store under N_2. [Weigert et al. *Angew Chem Int Ed*) **14** 330 *1975*, DOI: 10.1002/anie.197503301; Cornforth in *The Chemistry of Penicillin* (Clarke, Johnson and Robinson eds) Princeton Univ Press, 455 *1949*; Review: Chain et al. *Antibiotics* (Oxford University Press) **2** *1949*; for polymorphism see Vidler *J Pharm Pharmacol* **28** 663 *1976*, PMID: 11326]. The ***D-S-benzyl derivative*** has **m 197-198°** (from H_2O), $[\alpha]_D^{17}$ -20 (c 1, N NaOH), -70° (N HCl). [*Beilstein* **4** IV 3228.] It is a ***penicillin metabolite*** with ***no*** antibiotic activity. For pharmacokinetics dynamics see Joyce [*Pharmacol Therap* **42** 405 *1989*, DOI: 10.1016/0163-7258(89)90033-8]. ***L-(-)-Penicillamine*** *[1113-41-3]* **$C_5H_{11}NO_2S$, M 149.2,** has **m 190-194°, 202-206°, 214-217°, $[\alpha]_D^{21}$ +63 (c 1, N NaOH or pyridine), for pKa see D-isomer**, with same chemistry as the D-enantiomer [*Beilstein* **4** IV 3228.], but is ***toxic***, as it inhibits the action of pyridoxine.

D-Penicillamine disulfide hydrate* (*S*,*S*'-di-[D-penicillamine] hydrate)** *[20902-45-8]* **$C_{10}H_{20}N_2O_4S_2$, M 296.4 + aqueous, m 203-204°(dec), 204-205°(dec), $[\alpha]_D^{23}$ +27 (c 1.5, N HCl), -82 (c 0.8, N NaOH), $pK_{Est(1)}$~ 2.4 (CO_2), $pK_{Est(2)}$ ~10.7 (NH_2).** Purify by recrystallisation from EtOH or aqueous EtOH. [Crooks in *The Chemistry of Penicillin* above, 469 *1949*; for use as ***thiol reagent for proteins see Garel et al. *Eur J Biochem* **123** 513 *1982*, DOI: 10.1111/j.1432-1033.1982.tb06561.x; Süs *Justus Liebigs Ann Chem* **561** 31 *1948*, DOI: 10.1002/jlac.19495610105; *Beilstein* **4** IV 3231.] For its use in ***rheumatic disease*** see Howard-Lock et al. [*Arthritis and Rheumatism* **15** 261 *1986*, DOI: 10.1016/0049-0172(86)90022-3].

Penicillic acid* [5-hydroxy-5-isopropenyl-4-methoxy-2(5*H*)furanone (*lactone)*, 3-methoxy-5-methyl-4-oxo-2,5-hexadienoic acid]** *[90-65-3]* **$C_8H_{10}O_4$, M 158.2, m 58-64°, 64-65° (monohydrate, acid), 83-84°, 87° (anhydrous, lactone), pK^{25} 5.9.** The lactone (furanone, ***anhydrous) hydrolyses to the acid (3-methoxy-4-oxo-hexa-2,5-dienoic acid, ***hydrate***). It crystallises from H_2O as the ***monohydrate*** (acid), or petroleum ether as the ***anhydrous lactone***. The ***free acid*** and ***lactone*** are in equilibrium. Its UV has λ_{max} at 221nm (ε 12,500) in 0.02M KOH, and 228nm (ε 11,500) in 0.02M HCl [Raphael *J Chem Soc* 1508 *1948*, DOI: 10.1039/JR9480001508]. [*Beilstein* **3** II 519, **3** III 1467.] It is a possible ***antineoplastic***.

(±)-Pentobarbital (5-ethyl-5-1'-methylbutyl barbituric acid, Nembutal is the Na salt) *[76-74-4]* **$C_{11}H_{18}N_3O_2$, M 226.4, m ~127°(dec), $pK_{Est(1)}$~ 8.0, $pK_{Est(2)}$~12.7.** A solution of the sodium salt in 10% HCl is prepared, and the acid is extracted with ether. Evaporation of the extract gives a solid which is then purified by repeated crystallisation from $CHCl_3$. It sublimes at 95-105°/10-12mm. [Bucket & Sandorfy *J Phys Chem* **88** 3274 *1984*, DOI: 10.1021/j150659a027.] The *(+)-* and *(-)-enantiomers* crystallise from 50% aqueous EtOH with **m 120-121°** and have $[\alpha]_D^{25}$ +4.73 and –4.93 (EtOH) [Kleiderer & Shonle *J Am Chem Soc* **56** 1772 *1934*, DOI: 10.1021/ja01323a036]. [*Beilstein* **24** I 419, **24** II 287, **24** III/IV 1951.] It is a sedative and a hypnotic.

3-sn-Phosphatidylethanolamine (L-α-cephalin, from Soya bean) *[39382-08-6]* **$C_{37}H_{74}NO_8P$, M 692.0, M_r ~600-800, amorphous, $pK_{Est(1)}$~ 5.8 (PO_4^-), $pK_{Est(2)}$~ 10.5 (NH_2)**. Purify the cephalin by dissolving it in EtOH, adding $Pb(OAc)_2.3H_3O$ (30g in 100ml H_2O) until presence of Pb^{2+}. Filter off the solid, pass CO_2 until precipitation of $PbCO_3$ ceases. Filter the solid off and evaporate (while bubbling CO_2) *in vacuo*. H_2O (equal volume) is added to the residual oil and extracted with hexane. The extract is washed with H_2O until the aqueous phase is free from Pb [test with dithizone (2 mg in 100 ml CCl_4; Feigel *Spot Tests* Vol I, Elsevier p. 10

1954, ISBN-13: 978-0444409294,ISBN-10: 0444409297)]. The hexane is dried (Na_2SO_4), filtered and evaporated to give a yellow waxy solid which is *in vacuo*. It is insoluble in H_2O and Me_2CO, freely soluble in $CHCl_3$ (5%) and Et_2O, but slightly soluble in EtOH. [Schofield & Dutton *Biochemical Preparations* **5** 5 *1957*.]

O*-Phosphocolamine (2-aminoethyl dihydrogen phosphate)** *[1071-23-4]* **$C_2H_8NO_4P$, M 141.1, m 237-240°, 242.3°, 241.3-243°, 234.5-244.5°, 244-245°(capillary), pK_1^{20} <1.5 (PO_4H_2), pK_2^{20} 5.77 (PO_4H^-), pK_3^{20} 10.26 (NH^+).** Purification by recrystallisation from aqueous EtOH gives a ***hydrate (**m 140-141°**). Its solubility in H_2O is 17% and 0.003% in MeOH or EtOH at 22°. [Fölsch & Österberg *J Biol Chem* **234** 2298 *1959*, PMID: 13823772; Baer & Stancer *Can J Chem* **34** 436 *1956*, DOI: 10.1139/v56-062; Christensen *J Biol Chem* **135** 399 *1940*, http://www.jbc.org/content/135/2/399.] A potent ***inhibitor of ornithine decarboxylase*** [Gilad & Gilad *Biochem Biophys Res Commun* **122** 277 *1984*, DOI: 10.1016/0006-291X(84)90471-6]. [*Beilstein* **4** IV 1415.]

Phosphoenolpyruvic acid monopotassium salt (KPEP) *[4265-07-0]* **$C_3H_4O_6P$. K, M 206.1, pK_1^{25} 3.4 (CO_2), pK_2^{25} 6.35 (PO_4H^-) (for free acid).** KPEP is purified *via* the cyclohexylamine salt (see below). The salt (534mg) in H_2O (10ml) is added to Dowex 50Wx4 H^+ form (200-400 mesh, 2ml, H_2O washed) and stirred gently for 30min then filtered. The resin is washed with H_2O (6ml), and combined solutions are adjusted to pH 7.4 with 3N KOH (~1.4ml) and volume adjusted to 18.4ml with H_2O, to give 0.1M KPEP that is lyophilised to a ***pure powder*** useful for enzyme work. Also recrystallise from MeOH/Et_2O. [Clark & Kirby *Biochemical Preparations* **11** 103 *1966*, Wold & Ballou *J Biol Chem* **227** 301 *1957*, PMID: 13449074; Cherbuliez & Rabinowitz *Helv Chim Acta* **39** 1461 *1956*, DOI: 10.1002/hlca.19560390536; *Beilstein* **3** IV 977.] ***The triNa salt*** *[5541-93-5]* **M 360.0,** is purified by dissolving 1g of salt in MeOH (40ml) and excess dry Et_2O is added. The white crystals are collected and dried (P_2O_5/20°). [Cramer & Voges *Chem Ber* **92** 952 *1959*, DOI: 10.1002/cber.19590920429.]

Phosphoenolpyruvic acid tris(cyclohexylamine) salt (PRP-3CHA) *[35556-70-8]* **$C_3H_5O_6P$. $3C_6H_{13}N$, M 465.6,** has **m 155-180°(dec)**, is recrystallised from aqueous Me_2CO and dried *in vacuo*. Store at -20°. It is stable at 4° for >2 years. Its IR has ν_{max} 1721cm^{-1} (C=O). [Wold & Ballou *J Biol Chem* **227** 301 *1957*, PMID: 13449074; see Clark & Kirby *Biochemical Preparations* **11** 103 *1966* for the ***monocyclohexylamine salt***.]

D(-)-3-Phosphoglyceric acid disodium salt (D-glycerate 3-phosphate di-Na salt) *[80731-10-8]* **$C_3H_5O_7P$. 2Na, M 230.0, $[\alpha]_D^{20}$ -13.9 (c 5, H_2O), -745° (in aqueous NH_4^+ molybdate), $pK_{Est(1)}$~1.0 (PO_4H_2), $pK_{Est(2)}$~6.66 (PO_4H^-) (for free acid).** It is best purified by conversion to the ***Ba salt*** by precipitation with $BaCl_2$, which is recrystallised three times before conversion to the sodium salt. The ***Ba salt*** (9.5g) is shaken with 200ml of a 1:1 slurry of Dowex 50 (Na^+ form) for 2 hours. The mixture is filtered, and the resin is washed with H_2O (2 x 25ml). The combined filtrates (150ml) are adjusted to pH 7.0 and concentrated *in vacuo* to 30-40ml and filtered if not clear. Absolute EtOH is added to make 100ml, followed by *n*-hexane when a white solid and/or a second phase separates, which provides the complete solid ***Na salt*** on standing at ~25°. The salt is removed by centrifugation, washed with Me_2CO, dried in air then in an oven at 55° to give a stable powder (4.5g), with no weight loss when kept over P_2O_5 at 78°/8 hours. The high optical rotation in the presence of $(NH_4)_6Mo_7O_{24}$ is not very sensitive to the concentration of molybdate or pH. Store it at -20°. It is ***50% hydrolysed*** in M HCl at 100°/35.7hrs, and at 125°/3hrs. [Towne et al. *J Biol Chem* **226** 777 1957, PMID: 13438863; Cowgill *Biochim Biophys Acta* **16** 613 *1955*, DOI: 10.1016/0006-3002(55)90299-7; Embdan et al. *Hoppe Seyler's Z Physiol Chem* **230** 20 *1934*, *Beilstein* **3** IV 1051.]

Phospholipids. For the removal of ionic contaminants from raw zwitterionic phospholipids, the lipids are purified twice by passage though mixed-bed ionic exchange resins (Amberlite AB-2) in methanolic solutions. (About 1g of lipid in 10ml of MeOH). In both runs the first 1ml of the eluate is discarded. The main fraction of the solution is evaporated at 40°C under dry N_2 and recrystallised (3x) from *n*-pentane. The resulting white powder is dried (4 hours at 50° *in vacuo*) and stored at 3°. Purify also by mixed-bed ion exchange resins suspended in the aqueous phase. [Kaatze et al. *J Phys Chem* **89** 2565 *1985*, DOI: 10.1021/j100258a028.]

***O*-Phospho-L-serine** *[407-41-0]* **$C_3H_5O_6P$, M 185.1, m 175-176°, 190°, 228°, $[\alpha]_D^{20}$ +4.3 (c 3.2, H_2O), +16.2 (c 3.2, 2N HCl), pK_1^{25} <1 (PO_4H_2), pK_2^{25} 2.08 (CO_2H), pK_3^{25} 5.65 (PO_4H^-), pK_4^{25} 9.74 (NH_3^+).** Recrystallise the phospho-serine by dissolving 10g in H_2O (150ml) at 25°, stirring for up to 20 minutes. Undissolved material

is filtered off (Büchner), and 95% EtOH (85ml) is added dropwise during 4 minutes, set aside at 25° for 3 hours, then at 3° overnight. The crystals are washed with 95% EtOH (100ml), then dry Et_2O (50ml), and dried in a vacuum (yield 6.5g). A further quantity (1.5g) can be obtained by keeping the mother liquors and washings at -10° for 1 week. The ***DL-isomer*** has **m 167-170°(dec)** after recrystallisation from H_2O/EtOH or MeOH. Store it at -20°. [Neuhaus & Korkes *Biochemical Preparations* **6** 75 *1958*, Neuhaus & Byrne *J Biol Chem* **234** 113 *1959*, PMID: 13610904; IR: Fölsch & Mellander *Acta Chem Scand* **11** 1232 *1957*, DOI: 10.3891/acta.chem.scand.11-1232; *Beilstein* **4** IV 3120.]

***O*-Phospho-L-threonine (L-threonine-*O*-phosphate)** *[1114-81-4]* **$C_4H_{10}NO_6P$, M 199.1, m 194°(dec), $[\alpha]_D^{24}$ -7.4 (c 2.8, H_2O) (pKa as above).** Dissolve the phosphate in the minimum volume of H_2O, add charcoal, stir for a few minutes, filter and apply onto a column of Dowex 50W (H^+ form), then elute with 2N HCl. Evaporate the eluates under reduced pressure whereby the desired fraction produces crystals of the phosphate which can be recrystallised from H_2O/MeOH mixtures, and the crystals are then dried *in vacuo* over P_2O_5 at 80°. Store it at -20°. [de Verdier *Acta Chem Scand* **7** 196 *1953*, DOI: 10.3891/acta.chem.scand.07-0196; *Beilstein* **4** IV 3175.]

Phytol (*d*-2E-3,7*R*,11*R*,15-tetramethylhexadec-2-en-1-ol) *[150-86-7, 7541-49-93]* **$C_{20}H_{40}O$, M 296.5, b 145°/0.03mm, 150-151°/0.06mm, 203-204°/10mm, d_4^{25} 0.8497, n_D^{25} 1.437, $[\alpha]_D^{22}$ +0.06 (neat).** This ***acyclic triterpene*** is commercially available as a mixture of isomers. Phytol is purified by distillation under high vacuum. It is almost insoluble in H_2O but soluble in most organic solvents. It has UV with λ_{max} at 212nm (log ε 3.04) in EtOH, and the IR has ν_{max} at 3300 and 1670cm^{-1}. [Demole & Lederer *Bull Soc Chim Fr* 1128 *1958*, Burrell *J Chem Soc (C)* 2144 *1966*, DOI: 10.1039/J39660002144; Bader *Helv Chim Acta* **34** 1632 *1951*, DOI: 10.1002/hlca.19510340546; *Beilstein* **1** IV 2208.]

Pirfenidone (5-methyl-1-phenylpyridin-2-one) *[53179-13-8]* **$C_{12}H_{11}NO$, M 185.2, m 103-105°, 107-111°.** It can be prepared by a general procedure where 2-cyano-*N*-(phenyl)acetamide (prepared by heating ethyl cyanoacetate with aniline under reflux for 2 hours, and crystallising from *C_6H_6-petroleum ether) is condensed with methylmalonaldehyde bis(dimethyl acetal) in boiling EtOH (3 hours) containing a catalytic amount of piperidine to give 3-cyano-5-methyl-1-phenylpyridin-2-one which is subsequently hydrolysed and de-carboxylated to ***Pirfenidone*** [see Ismail & Noaman *Med Chem Res* **14** 382 *2006*, DOI: 10.1007/s00044-006-0146-2]. Purify it by recrystallisation from large volumes of H_2O (solubility 0.1w/v% at 20° and >1w/v% at 60°), dry it in air and sublime it *in vacuo*. Its solubility in DMSO > 2w/v% at 20°.
Pirfenidone is a ***pulmonary antifibrotic drug*** effective in models of pulmonary and lung fibrosis, is anti-inflammatory and is an analgesic.
[For novel Pirfenidone analogues see Ammar et al. *Archiv der Pharmazie* **339** 429 *2006*, DOI: 10.1002/ardp.200600017; for pharmacokinetics see Sun et al. *J Chromatogr* B **35** 981 *2015*, DOI: 10.1016/j.jchromb.2014.12.027; Kehrer & Margolin *Toxicol Lett* **90** 125 *1997*, DOI: 10.1016/S0378-4274(96)03845-3; Richeldi et al. *Nature Reviews Drug Discovery* **10**, 489 *2011*, DOI: 10.1038/nrd3495; Kaneko et al. *Clin Exp Immuol* **113** 72 *1998*, DOI: 10.1046/j.1365-2249.1998.00618.x; PMCID: PMC1905007.]

Podophylotoxin [Wartec, Podofilox, (10*R*,11*R*,15*R*,16*R*)-16-hydroxy-10-(3,4,5-trimethoxyphenyl)-4,6,13-trioxatetracyclo-[7.7.0.0^{3,7}.0^{11,15}]hexadeca-1,3(7),8-trien-12-one] *[518-28-5]* **$C_{22}H_{22}O_8$, M 414.4, m 181-181°, 183-184°, 188-189°, $[\alpha]_D^{20}$ -132 (c 1, $CHCl_3$).** This ***toxin*** recrystallises from *C_6H_6 (with 0.5C_6H_6), EtOH/*C_6H_6, aqueous EtOH (with 1-1.5H_2O, **m 114-115°**) and CH_2Cl_2/pentane. When dried at 100°/10mm it has **m** 183-184°. Its biological half life is 1 to 4.5 hours. [UV: Stoll et al. *Helv Chim Acta* **37** 1747 *1954*, DOI: 10.1002/hlca.19540370620; IR: Schrecker et al. *J Org Chem* **21** 288 *1956*, DOI: 10.1021/jo01109a008.] It is an ***inhibitor of microtubule assembly*** [Prasad et al. *Biochemistry* **25** 739 *1986*, DOI: 10.1021/bi00351a035]. [*Beilstein* **19/10** V 666.] In the form of a cream, it is used for the topical treatment of ***genital and other warts***.

Polyethylene glycol *[25322-68-3]* **$C_{2n}H_{4n+2}O_{n+1}$, M_r various, from PEG ~200 to ~35,000, m 182-287°.** PEG is available commercially as a powder or as a solution in various degrees of polymerisation depending on the average molecular weight, e.g. PEG 400 and PEG 800 have average molecular weights of 400 and 800, respectively. They may be contaminated with aldehydes and peroxides. Solutions ***deteriorate*** in the presence of air due to the formation of these contaminants. Methods available for purification are as follows:
Procedure A: A 40% aqueous solution of PEG 400 (2L, average molecular weight 400) is de-aerated under vacuum and made 10mM in sodium thiosulfate. After standing for 1 hour at 25°, the solution is passed through a column (2.5x20cm) of mixed-bed R-208 resin which has a 5cm layer of Dowex 50-H^+ at the bottom of the column. The column is previously flushed with 30% aqueous MeOH, then thoroughly with H_2O. A flow rate of 1ml/minute is maintained by adjusting the fluid head. The first 200ml are discarded, and the effluent is then collected at an increased flow rate. The concentration of PEG solution is checked by density measurement, and it is stored (preferably anaerobically) at 15°.
Procedure B: A solution of PEG 800 (500g in 805ml H_2O) is made 1mM in H_2SO_4 and stirred overnight at 25° with 10g of treated Dowex 50-H^+ (8% crosslinked, 20-50 mesh). The resin, after settling, is filtered off on a sintered glass funnel. The filtrate is treated at 25° with 1.5g of $NaBH_4$ (added over a period of 1 minute) in a beaker with tight but removable lid through which a propeller-type mechanical stirrer is inserted and continuously flushed with N_2. After 15 minutes, 15g of fresh Dowex 50-H^+ are added, and the rate of stirring is adjusted to maintain the resin suspended. The addition of an equal quantity of Dowex 50-H^+ is repeated and the reaction times are 30 and 40 minutes. The pH of a 1 to 10 dilution of the reaction mixture should remain above pH 8 throughout. If it does not, more $NaBH_4$ is added or the addition of Dowex 50-H^+ is curtailed. (Some samples of PEG can be sufficiently acidic, at least after the hydrolysis treatment, to produce a pH that is too low for efficient reduction when the above ratio of $NaBH_4$ to Dowex 50-H^+ is used.) About 30 minutes after the last addition of $NaBH_4$, small amounts of Dowex 50-H^+ (~0.2g) are added at 15 minute intervals until the pH of a 1 to 10 dilution of the solution is less than 8. After stirring for an additional 15 minutes the resin is allowed to settle, and the solution is transferred to a vacuum flask for brief de-gassing under a vacuum. The de-gassed solution is passed through a column of mixed-bed resin as in procedure A. The final PEG concentration would be about 40% w/v. Assays for aldehydes by the purpural method and of peroxides are in the reference below.
Treatment of Dowex 50-H+ (8% crosslinked, 20-50 mesh): The Dowex (500g) is suspended in excess 2N NaOH, and 3ml of liquid Br_2 is stirred into the solution. After the Br_2 has dissolved, the treatment is repeated twice, and then the resin is washed with 1N NaOH on a sintered glass funnel until the filtrate is colourless. The resin is then converted to the acid form (with dilute HCl, H_2SO_4 or AcOH as required) and washed thoroughly with H2O and sucked dry on the funnel. The treated resin can be converted to the Na salt and stored. [Ray & Puvathingal *Anal Biochem 146* 307 1985, DOI: 10.1016/0003-2697(85)90544-5.]

Porphobilinogen (PBG, 5-amino-4-carboxymethyl-1*H*-pyrrole-3-propionic acid) *[487-90-1]* **$C_{10}H_{14}N_2O_4$, M 226.2, m 172-175°(dec), 175-180°(dec, darkening at 120-130°), pK_1 3.70 (4-CH_2CO_2H), pK_2 4.95 (3-$CH_2CH_2CO_2H$), pK_3 10.1 (NH^+).** Porphobilinogen recrystallises as the ***monohydrate*** (pink crystals) from dilute NH_4OAc solutions of pH 4, and is dried *in vacuo*. The ***hydrochloride monohydrate*** has **m 165-170°(dec)** (from dilute HCl). Porphyrin A {from ox heart, coproporphyrin, 3-[18-(2-carboxyethyl)-7-ethenyl-17-formyl-12-[(4E,8E)-1-hydroxy-5,9,13-trimethyltetradeca-4,8,12-trienyl]-3,8,13-trimethyl-22,24-dihydroporphyrin-2-yl]propanoic acid) *[5162-02-1]* **$C_{49}H_{58}N_4O_4$, M 799.0, m dec on heating.** It is purified on a cellulose powder column followed by extraction with 17% HCl and fractionated with HCl. [Morell et al. *Biochem J* **78** 793 *1961*, DOI: 10.1042/bj0780793.] It recrystallises from $CHCl_3$/petroleum ether or Et_2O/*C_6H_6 [detailed UV-VIS and NMR data: Caughey et al. *J Biol Chem* **250** 7602 *1975*, PMID: 170266; Lemberg *Adv Enzymol* **23** 265 *1961*, DOI: 10.1002/9780470122686.ch6].

Prazosin hydrochloride (2[4-{(2-furoyl)piperazin-1-yl}4-amino-6,7-dimethoxyquinazoline hydrochloride, Minipress, Vasoflex) *[19237-84-4, 19216-56-9 free base]* **$C_{19}H_{21}N_5O_4$. HCl, M 419.9, 383.4 (free base), m 278-280°, 280-282° (free base), pK^{25} 6.5.** The salt is recrystallised by dissolving it in hot MeOH, adding a small

volume of MeOH/HCl (dry MeOH saturated with dry HCl gas) followed by dry Et_2O until crystallisation is complete. Dry it *in vacuo* over solid KOH till free of HCl. Also recrystallise from hot H_2O, and remove any H_2O azeotropically with CH_2Cl_2, then dried *in vacuo*. The solubility at ~25° in H_2O is ~0.5mg/ml; in MeOH it is 6mg/ml, but is poorly aqueous mineral acids. [NMR and IR: Honkanen et al. *J Heterocycl Chem* **17** 797 *1980*, DOI: 10.1002/jhet.5570170436; cf. Armarego & Reece *Aust J Chem* **34** 1561 *1981*, DOI: 10.1071/CH9811561.] Several syntheses of ***Prazosin*** and related compounds have been devised, but most of them run along similar lines. They start with 4,5-dimethoxyanthranilic acid that is converted ***6,7-dimethoxyquinazolin-2,4-dione*** (**m 323-325°**, platelets from aqueous AcOH), and provides ***2,4-dichloro-6,7-dimethoxyquinazoline*** (**m 158°**, colourless needles from light petroleum b 80-100°) on treatment with $POCl_3$/Me_2NPh/4.5hrs [Curd et al. *J Chem Soc* 1759 *1948*, DOI: 10.1039/JR9480001759]. Dry NH_3 is bubbled through a solution of this dichloroquinazoline in dry THF at 0°/30min and set aside to give ***4-amino-2-chloro-6,7-dimethoxyquinazoline*** (**m 302° dec**, from MeOH). When the latter is mixed with a slight excess of 1-(2-furoyl)piperazine [Althuis & Hess *J Med Chem* **20** 146 *1977*, DOI: 10.1021/jm00211a031] in *iso*-pentanol and refluxed for 2.5 hours (clear after 1.5hrs) and cooled, ***Prazosin hydrochloride*** is formed (>73% yield, **m 280-282°**, on crystallisation by dissolving in MeOH adding a slight excess of ~8N MeOH/HCl then by Et_2O until crystal separation is complete). [See Hess US3511836 A *12 May 1970* to Pfizer & Co; also Baker & Davies EP0520722 A1 *30 Dec 1992*, to Zeneca Ltd.]
Many studies have been made to identify and quantify *Prazosin* and its ***metabolites*** in human blood and urine from users of this ***antihypertensive*** drug. Althius and Hess [reference above] prepared the following: ***2,4-diamino-6,7-dimethoxyquiazoline*** **m 244-246°** (from H_2O) R_F 0.41; ***2-(1-piperazinyl)-4-amino-6,7-dimethoxyquinazoline HCl*** **m 285-287°** (from 1.0 N HCl) R_F 0.24; ***6-demethyl-prazosin trifluoroacetate hydrate*** m 220° (from CF_3CO_2H-Et_2O) R_F 0.47; ***7-demethyl-prazosin trifluoroacetate hydrate*** **m 230°** (from CF_3CO_2H-Et_2O) R_F 0.43; and using TLC silica gel plates, eluting with EtOAc-MeOH-Et_2NH (70:20:5) where ***Prazosin*** has R_F 0.70. Armarego and Reece [reference above] prepared ***8-chloroprazosin hydrochloride*** (**m 207-208° dec**) and as a ***non-interfering internal standard in the HPLC*** for quantitative estimation of ***Prazosin*** and its metabolites in human plasma. Armarego et al. have also prepared a water soluble ***Prazosinamine hydrochloride*** [*1-(4'-amino-6',7'-dimethoxyqinazolin-2'yl)-4-(6"-aminohexanoyl)piperazine hydrochloride*, **m >210°** (with effervescence on slow heating, from MeOH/~7N MeOH-HCl followed by Et_2O; also TLC, IR and ^1H NMR data provided] which ***reversibly inhibits the calcium-mobilizing action*** of α_1-adrenergic agonists in perfused rat liver [*Biochem Pharmacol* **36** 1583 *1987*, DOI: 10.1016/0006-2952(87)90040-2].
Prazosin is an ***antihypertensive drug*** and is an α_1- and α_{2B}-adrenergic antagonist [Brosman et al. *Proc Natl Acad Sci USA* **82** 5915 *1985*, PMID: 2994053]. It is also a potent ***antagonist*** at the ***melatonin MT_3 receptor*** (K_i = 10.2nM) [Pickering & Niles *Eur J Pharmacol* **175** 71 *1990*, DOI: 10.1016/0014-2999(90)90154-X], and ***inhibits MK-801***(a psychotomimetic, non-competitive NMDA receptor antagonist)***—induced hyperlocomotion and dopamine release*** in the *nucleus accumbens* [Mathé et al. *Eur J Pharmacol* **309** 1 *1996*; DOI: 10.1016/0014-2999(96)00315-9].

Procaine hydrochloride (Novocain, 2-diethylaminoethyl-4-aminobenzoate HCl) *[51-05-8]* **$C_{13}H_{20}N_2O_2$. HCl, M 272.8, 236.3(free base), m 153-156°, 154-156°, 156°, $pK_{Est(1)}$~ 2.52 (NH_2^+) pK_2^{20} 9.0 (Et_2N^+).** Novocain is recrystallised from aqueous EtOH. It is soluble at 25° in H_2O (86.3%), EtOH (2.6%) and Me_2CO (1%), it is slightly soluble in $CHCl_3$, but is almost insoluble in Et_2O. The anhydrous ***free base*** *[59-46-1]* is recrystallised from ligroin or Et_2O and has **m 61°**. Its biological half life is 40-84 seconds. [Einhorn *Justus Liebigs Ann Chem* **371** 125 *1909*, DOI: 10.1002/jlac.19093710202; IR: Szymanski & Panzica *J Am Pharm Assoc* **47** 443 *1958*, DOI: 10.1002/jps.3030470618; *Beilstein* **14** IV 1138.]

Propericiazine [Pericyazine, 10-{3-(4-hydroxy-1-piperidinyl)-propyl}-10*H*-phenothiazine-2-carbonitrile] *[2622-26-6]* **$C_{21}H_{23}N_3OS$, M 365.4, m 116-117°.** It crystallises from a saturated solution in cyclohexane. It is an antipsychotic drug, and is a sensitive reagent for Pd, Ru, Rh and Au. [Gowda et al. *Anal Chem* **55** 1816 *1983*, DOI: 10.1021/ac00261a041; Gowda et al. *Anal Chim Acta* **154** 347 *1983*, DOI:10.1016/0003-2670(83)80039-7.]

R*(+)-Propranalol hydrochloride (*R*-1-isopropylamino-3-(1-naphthyloxy)-2-propanol HCl)** *[13071-11-9]* **$C_{16}H_{21}NO_2$. HCl, M 295.8, 259.3(free base), m 192°, 193-195°, $[\alpha]_D^{20}$ +25 (c 1, EtOH), pK^{20} 9.5 (for free base).** The hydrochloride is recrystallised from *n*-PrOH or Me_2CO. It is soluble in H_2O and EtOH but is insoluble in Et_2O, *C_6H_6 or EtOAc. The ***racemate salt *[318-98-9, 3506-09-0 100mM in H_2O]* has **m 163-164°**,

and is ***less active*** than an equal mixture of *R- and S-* isomers. The ***free base*** recrystallises from cyclohexane with **m 96°**. [Howe & Shanks *Nature* **210** 1336 *1966*, DOI: 10.1038/2101336a0.] The ***S(-)-isomer*** (below) is physiologically the ***more active*** isomer. [For *RS-* and *R- isomer*: Xe et al. *Br J Pharmacol* **123** 599 *1998*, DOI: 10.1038/sj.bjp.0701630; Litwin et al. *Br J Pharmacol* **127** 1671 *1999*, DOI: 10.1038/ sj.bjp.0702701.]

S(-)-Propranalol hydrochloride **(*S*-1-isopropylamino-3-(1-naphthyloxy)-2-propanol HCl)** *[4199-10-4]* **$C_{16}H_{21}NO_2$. HCl, M 295.8,** has **m 192°, 193-195°, $[\alpha]_D^{20}$ -25.5 (c 1, EtOH) pK^{20} 9.5.** See preceding entry for physical properties and purification. The (-)-salt is the more active isomer which ***blocks isoprenaline tachycardia*** and is a β-adrenergic blocker and ***antiarrhythmic***. It is also a local ***anaesthetic***. [Leclerc et al. *Trends Pharmacol Sci* **2** 18 *1981*, DOI: 10.1016/0165-6147(81)90248-0; Howe & Shanks *Nature* **210** 1336 *1966*, DOI: 10.1038/2101336a0.] The *S*(-)-isomer is the physiologically more active (by 2 orders of magnitude), but the ***R*-isomer** is not devoid of activity as it exhibits significant prolongation of the PR interval of the electrocardiogram. The enantiomers have been separated using *Cellulase*(CBH I)*silica* as chiral stationary phase [Marle et al. *J Chromatogr* **586** 233 *1991*, DOI: 10.1016/0021-9673(91)85127-2; Bond et al. [*Nature* **213** 721 *1967*, DOI: 10.1038/213721a0; PMID: 6031788; Barrett et al. [*Br J Pharmacol* **34** 43 *1968*, PMID: 19108278].

6-Propyl-2-thiouracil (propacil, propycil) *[51-52-5]* **M 170.2, m 218-220°, pK_1^{21} -6.54 (aqueous H_2SO_4), pK_2^{21} 8.25 (4% aq EtOH).** Purify by rcrystallisation from H_2O (solubility: 900 parts at 20°, and 100 parts at 100°). UV, MeOH has λmax 277nm. [Anderson et al. *J Am Chem Soc* **67** 2197 *1945*, DOI: 10.1021/ja01228a042; Vanderhaegue *Bull Soc Chim Belg* **59** 689 *1950*, DOI: 10.1002/bscb.19500590911; *Beilstein* **24** III/IV 1333.] It is an antihyperthyroid drug and promotes fattening.

Protoporphyrin IX (3,18-divinyl-2,7,13,17-tetramethylporphin-8,12-dipropionic acid, ooporphyrin) *[553-12-8]* **$C_{34}H_{34}N_4O_4$, M 562.7, pK_{Est} ~ 4.8.** Purify it by dissolving (4g) in 98-100% HCOOH (85ml), diluting with dry Et_2O (700ml) and keeping at 0° overnight. The precipitate is collected and washed with Et_2O, then H_2O, and dried in a vacuum at 50° over P_2O_5. It crystallises from aqueous pyridine or Et_2O in monoclinic, brownish-yellow prisms. The UV (25% HCl) has λ_{max} at 557.2, 582.2 and 602.4nm. It is freely soluble in ethanolic HCl, AcOH, $CHCl_3$, and Et_2O containing AcOH. It forms sparingly soluble diNa and diK salts. [Ramsey *Biochemical Preparations* **3** 39 *1953*; Drabkin *Haematin Enzymes* pp 142-172 *1961*, DOI:10.1016/B978-1-4831-9646-6.50016-8; Granick *J Biol Chem* **175** 333 *1948*, PMID: 18873307; see Falk 'Porphyrins and Metalloporphyrins' Vol 2 *1964* Elsevier, NY, Lib Cong No: 62-19821; *Beilstein* **26** IV 3042.]

Protoporphyrin IX dimethylester *[5522-66-7]* **$C_{36}H_{38}N_4O_4$, M 590.7,** has **m 225-228°**, **228-230°.** The crude dimethyl ester (1g) in $CHCl_3$ (200 ml) is mixed with petroleum ether (b 70-90°, 600ml), and any porphyrin (m > 260°) which is insoluble in this mixture is filtered off. The filtrate is passed through a column of $CaCO_3$ [from $CaCO_3$ (130g) which is kept overnight in a mixture of $CHCl_3$/petroleum ether (b 70-90°, 1:3), and the slurry is poured into a glass tube (2.5 x 26cm) to form the column]. After all the filtrate is applied, the column is eluted with a solution of $CHCl_3$/petroleum ether (b 70-90°, 1:3). All the coloured eluates are collected, evaporated at room temperature in a vacuum to give a residue (0.8g), m 208-211°. The residue (0.8g) in $CHCl_3$ (66ml) is heated briefly to its boiling point, then boiling MeOH (198ml) is added immediately to it. The mixture is allowed to cool to room temperature, refrigerated for 2 days and the solid is filtered off. The solid is washed on the filter funnel with $CHCl_3$/MeOH (1:9, 50ml) and dried at 50°/vacuum (yield 0.62-0.66g). It can also be recrystallised by dissolving in as little hot dry $*C_6H_6$ as possible and left overnight at 20°, or with $CHCl_3$/MeOH (1:9). Its UV has λ_{max} at 631, 576, 541, 506 and 407nm in $CHCl_3$ and 601, 556 and 406nm in 25% HCl. [see Ramsey above.]

Pterin-6-carboxylic acid (2-amino-4-oxo-3,4-dihydropteridine-6-carboxylic acid) *[948-60-7]* **$C_7H_5N_5O_3$, M 207.2, m >360°, pK_1^{20} 1.43, pK_2^{20} 2.88, pK_3^{20} 7.72**. The acid gives yellow crystals by repeated dissolution in aqueous NaOH and adding aqueous HCl. It has UV with λ_{max} at 235, 260 and 265nm (ε 11,000, 10,500 and 9,000) in 0.1N HCl, and 263 and 365nm (ε 20,500 and 9,000) in 0.1N NaOH. [For UV see Pfleiderer et al. *Justus Liebigs Ann Chem* **741** 64 *1970*, DOI: 10.1002/jlac.19707410108; Stokstad et al. *J Am Chem Soc* **70** 5 *1948*, DOI: 10.1021/ja01181a003; and for fluorescence see Kavanagh & Goodwin *Arch Biochem* **20** 315 *1949*, PMID: 18108925; *Beilstein* **26** III/IV 4053.]

butanone/Mebutanone/MeOH or EtOH and forms a ***MeOH photo-adduct***. It is a strong ***inhibitor of adenosine deaminase*** [EC 3.5.4.4]. [Nair & Wiechert *Bioorg Chem* **9** 423 *1980*, DOI: 10.1016/0045-2068(80)90002-4; Löfgren et al. *Acta Chem Scand* **7** 225 *1953*, DOI: 10.3891/acta.chem.scand.07-0225; UV: Brown & Weliky *J Biol Chem* **204** 1019 *1953*, PMID: 13117878; *Beilstein* **26** III/IV 1740.]

Puromycin dihydrochloride (*O*-methyl-l-tyrosine[N^6,N^6-dimethylaminoadenosin-3'-yl-amide]) *[58-58-2]* **$C_{22}H_{28}N_7O_5$, 2HCl, M 616.5, m 174°, 178-180°, $[\alpha]_D^{25}$ -11 (free base in EtOH), pK_1 6.8, pK_2 7.2.** Puromycin dihydrochloride is purified by recrystallisation from H_2O (solubility 50mg/ml). It has some solublity in EtOH (~1mg/ml), DMSO (~13mg/ml) and DMF (~14mg/ml). The ***free base*** *[58-60-6]* M 544.4, has **m 175.5-177° (172-173°)** (from H_2O). The ***sulfate*** has **m 180-187° dec** (from H_2O), and the ***picrate monohydrate*** has **m 146-149°** (from H_2O). [Baker et al. *J Am Chem Soc* **77** 1 *1955*, DOI: 10.1021/ja01606a001; Fryth et al. *J Am Chem Soc* **80** 2736 *1958*, DOI: 10.1021/ja01544a039.] An ***aminopeptidase inhibitor*** that terminates protein synthesis [Reboud et al. *Biochemistry* **20** 5281 *1981*, DOI: 10.1021/bi00521a029; *Beilstein* **26** III/IV 3704.]

Pyridoxal hydrochloride *[65-22-5]* **$C_8H_9NO_3$, HCl, M 203.6, m 173°(dec), 176-180°(dec), pK_1^{20} 4.23 (3-OH), pK_2^{20} 8.7 (Pyridinium$^+$), pK_3^{20} 13.04 (CH_2OH?).** Dissolve it in water and adjust the pH to 6 with NaOH. Set aside overnight to crystallise. The crystals are washed with cold water, dried in a vacuum desiccator over P_2O_5, and stored in a brown bottle at room temperature. The ***free base*** *[66-72-8]* $C_8H_9NO_3$, M 167.2, **m 165° dec**, is then converted to the hydrochloride with one equivalent of HCl. [Fleck & Alberty *J Phys Chem* **66** 1678 *1962*, DOI: 10.1021/j100815a028; *Beilstein* **21/13** V 44.]

Pyridoxal-5'-phosphate monohydrate (PLP, codecarboxylase) *[54-47-7, 41468-25-1]* **$C_8H_{10}NO_6P.H_2O$, M 265.2, m 140-143°(dec), pK_1^{25} <2.5 (PO_4), pK_2^{25} 4.14 (3-OH), pK_3^{25} 6.20 (PO_4), pK_4^{25} 8.69 (pyridinium$^+$).** PLP has been purified by dissolving 2g in H_2O (10-15ml, in a dialysis bag a third full) and dialysing with gentle stirring against 1L of H_2O (+ two drops of toluene) for 15 hours in a cold room. The dialysate is evaporated to 80-100ml, then lyophilised. Lemon yellow microscopic needles of the ***monohydrate*** remain when all the ice crystals have been removed. Check putity by paper chromatography (in EtOH or *n*-PrOH/NH_3), and visualise spot(s) under UV light after spraying with *p*-phenylene diamine, NH_3 and molybdate. Solutions in a freezer are 2-3% hydrolysed in 3 weeks. Only 4-6% hydrolysis occurs in N NaOH or HCl at 25°, and 2% at 37° in 1 day—but is complete at 100° in 4 hours. Store as a dry solid at -20°. In aqueous acid the solution is colourless but is yellow in alkaline solutions. It has UV with λ_{max} at 305nm (ε 1100) and 380nm (ε 6550) in 0.1 N NaOH; 330nm (ε 2450) and 388nm (ε 4,900) in 0.05M phosphate buffer pH 7.0, and 295nm (ε 6700) in 0.1N HCl. [Peterson et al. *Biochemical Preparations* **3** 34, 119 *1953*.] The ***oxime*** decomposes at **229-230°** and is insoluble in H_2O, EtOH and Et_2O. The ***O-methyloxime*** decomposes at **212-213°**. [Heyl et al. *J Am Chem Soc* **73** 3430 *1951*, DOI: 10.1021/ja01151a126.] Also purify by chromatography through a column of Amberlite IRC-50 (H^+) [Peterson & Sober *J Am Chem Soc* **76** 169 *1954*, DOI: 10.1021/ja01630a045]. [*Beilstein* **21/13** V 46.]

Pyridoxamine hydrochloride *[5103-96-8, 524-36-7 (free base)]* **$C_8H_{12}N_2O_2$. 2HCl, M 241.2, m 224-226°(dec), 226-227°(dec), pK_1^{25} 3.54 (3-OH), pK_2^{25} 8.21 (ring N$^+$), pK_3^{25} 10.63 (NH_2).** The amine salt is recrystallised from hot MeOH. The ***free base*** *[85-87-0]* $C_8H_{12}N_2O_2$, M 168.2, crystallises from EtOH with **m 193-193.5°** [Harris et al. *J Biol Chem* **154** 315 *1944*, http://www.jbc.org/content/154/1/315; *J Am Chem Soc* **66** 2088 *1944*, DOI: 10.1021/ja01240a025]. [*Beilstein* **22** IV 6064, **22/12** V 324.]

(±)-Quinacrine [Atebrine, Mepacrine, 3-chloro-9(4-diethylamino-1-methyl)butylamino-7-methoxy)-acridine] dihydrochloride] *[69-05-6]* **$C_{23}H_{30}ClN_3O$. 2HCl, M 472.9, m 248-250°(dec), pK_1^{30} -6.49 (aq H_2SO_4), pK_2^{30} 7.73 (ring NH$^+$), pK_3^{30} 10.18 (Et_2N).** It crystallises from H_2O (soly 2.8w/v% at ~25°) as yellow crystals. Poorly soluble in MeOH and EtOH. The ***free base*** has **m 86-88°** (from Me_2CO or petroleum ether) or **m 85-87.5°**(aqueous EtOH). The ***bismethiodide*** has **m 224°** (from MeOH/EtOAc/Et_3N), and ***picrate*** has **m 207-208° dec** (from Me_2CO/EtOH). It is an antimalarial, antiprotozoal and intercalates DNA. [Wolfe *Antibiot* **3** (Springer-Verlag) 203 *1975*, *Beilstein* **22** III/IV 6247, **22/12** V 235.]

Quizalofop ethyl {[ethyl 2-[4-(6-chloro-2-quinoxalinyloxy)phenoxy]propionate} *[(±) 76578-14-8; R-100646-51-3, 100646-52-4, 100760-08-5, 100760-10-9]* **$C_{19}H_{17}ClN_2O_4$, M 372.8, m 91.7-92.1°, 92-93°, b 220**

/0.2mm. This ***(±)-herbicide*** forms white crystals from Me_2CO/EtOH and sublimes *in vacuo*. Large quantities can be distilled at high vacuum. Its solubilities at 20° in g/10ml are 0.09 (EtOH), 1.1 (Me_2CO), 1.2 (xylene), 2.9 ($*C_6H_6$), and is nearly insoluble in H_2O (0.3mg/l). The ***(±)-acid*** has *[95977-28-9]*. The ***R-ester enantiomer*** has **m 76-77°** (pale brown crystals from EtOH), **$[\alpha]_D^{20}$ +35.9 (EtOH)**. It is the ***more active fatty acid synthase inhibitor*** (designated DPX-Y6202) and is used to control grassy weeds in broadleaf crops. The ***R-acid*** has *[94051-08-8]*. [Shiu et al. [*Rev Environ Contam Toxicol* **116** 15 *1990*, PMID: 2205893]. **POISONOUS**

Racetams are pyrrolidin-2-ones with ***nootropic properties***, and of importance for the treatment of Alzheimer. The effects of *racetams* potentiation already present neurotransmission, and appear to modulated ion flux. They have low toxicity and lack serious side effects. For a review on Piracetam and related nootropics' see Gouilaev & Senning [*Brain Research Rev* **19** 180 *1994*, DOI: 10.1016/0165-0173(94)90011-6 and Waegemans et al. *Dementia and geriatric cognitive disorders* **13**(4) 217 *2002*, DOI:10.1159/000057700, PMID: 12006732]. Some of the compounds studied are listed below.

PIRACETAMIDE (2-oxo-1-pyrrolidine acetamide) *[7491-74-9]* **$C_6H_{10}N_2O_2$, M 142.2, m 151.5-152.5°.** This typical nootropic (Alzheimer) drug modulates Na flux in AMPA receptors and is purified by recrystallisation from isoPrOH. **ANIRACETAM (1-[4-methoxybenzyl]-2-pyrrolidinone)** *[72432-10-1]* **$C_{12}H_{13}NO_3$, M 219.1, m 121-122°.** Purify aniracetam by recrystallisation from EtOH. [Hoffmann-La Roche & Co AG *Jpn Kokai Tokkyo Koho* JP 54,117,468 *1979*; *Chem Abstr* **92** 41755t.] **OXIRACETAM (4-hydroxy-2-oxo-1-pyrrolidine acetamide)** *[62613-82-5 unspecified, 68567-97-5 racemate]* **$C_6H_{10}N_2O_3$, M 158.2, m 160-162°, 165-168°.** This nootropic (Alzheimer, anti-amnesic, memory enhancing) drug is purified by recrystallisation from MeOH or aqueous Me_2CO and dried *in vacuo*. [NMR, IR: Pifferi & Pinza *Farmaco Ed Sci* **32** 602 *1977*, Banfi et al. *Farmaco Ed Sci* **39** 16 *1984*.] ***R*-(+)-OXIRACETAM (4-hydroxy-2-oxo-1-pyrrolidine acetamide)** *[68252-28-8]* **$C_6H_{10}N_2O_3$, M 158.2, m 135-136°, $[\alpha]_D^{20}$ +36.2 (c 1, H_2O),** and ***S*-(-)-oxiracetam** *[88929-35-5]* **m 135-136°, $[\alpha]_D^{20}$ +36.5 (c 1, H_2O),** have been recrystallised from aqueous Me_2CO. There are differences in activity between the enantiomers in which it appears that the ***S-enantiomers*** exhibit ***significantly higher activities***. [Leonard et al. *J Am Chem Soc* **69** 690 *1947*, DOI: 10.1021/ja01195a067.]

Ramipril {Prilace, Ramace, Altace, (2*S*,3a*S*,6a*S*)-1-[(2*S*)-2-[[(1*S*)-1-ethoxycarbonyl-3-phenylpropyl]amino]-1-oxopropyl]-octahydrocyclopenta[b]pyrrole-2-carboxylic acid, (1*S*,5*S*,7*S*)-8-[(2*S*)-2-[[(1*S*)-1-ethoxycarb-onyl-3-phenyl-propyl]amino]propanoyl]-8-azabicyclo[3.3.0]octane-7-carboxylic acid} *[87333-19-5, mixt diastereomers 87269-97-4]* **$C_{23}H_{32}N_2O_5$, M 416.5, m 109°, d ^{20} 1.20g/cm^3, $[\alpha]_D^{24}$ +33.2 (c 0.1N HCl in EtOH), pK_a, 3.17.** Prepared in various ways by Gold et al. [US 4587258 *1986*], e.g. condensing benzyl *cis,endo*-octahydrocyclopenta[b]pyrrole-2-carboxylate hydrochloride with N[1(*S*)-carboethoxy-3-phenylpropyl]-(*S*)-alanine using a carbodiimde method then de-benzylating (with 10% Pd/C) and recrystallising of the resulting ***1-[N-(1(S)-carboethoxy-3-phenylpropyl)-(S)-alanyl]-cis,endo-octahydrocyclopenta[b]pyrrole-2(S)-carboxylic acid*** (**m** 110-112° dec) from Et_2O. It provides a ***hydrochloride*** when a 1.3M HCl in Et_2O is added to it. See also the patent of Stepankova et al. [WO2005121084, *2005*]. This drug is an **ACE** (angiotensin converting enzyme, see 'Proteins, Enzymes…' in this Chapter) **inhibitor**, causing vasodilation by blocking the conversion of angiotensin I to angiotensin II which lowers blood. [See Ruggenenti et al. *Lancet* **352** 1252 *1998*, PMID: 9788454; and Bosch et al. *Br Med J* **324** 699 *2002*, PMCID: PMC99052.]

Captopril {Acepress, Capoten, 1-[(2*S*)-3-mercapto-2-methyl-1-oxopropyl]-L-proline} *[62571-86-2]* **C_9H_{15}-**

NO_3S, M 217.3, m 103-104°(polymorphic unstable form m 86°, melts at 87-88° solidifies and then melts again at 104-105°), $[\alpha]_D^{22}$ -131.0 (c 1.7, EtOH), pK_1^{25} 3.7 (COOH), pK_2^{25} 9.8 (SH). It is the first ***antihypertensive ACE*** (Angiotensin-Converting Enzyme) ***inhibitor*** from the work of Nobel Laurate John Vane and developed by Squibb & Sons Pharmaceuticals. The synthesis involved reaction of L-proline with (2*S*)-acetylthiopropanoyl chloride in basic conditions (NaOH) followed by deactylation (NH_3) [Shimazaki et al. *Chem Pharm Bull Jpn* **30** 3139 *1982*, DOI :10.1248/cpb.30.3139], and later improved by Nam et al. [*J Pharm Sci* **73** 1843 *1984*, DOI:10.1002/jps.2600731251. PMID: 6396401]. Purify it by recrystallisation from EtOAc/hexane. It is purified also by dissolving in the minimum volume of EtOAc and fractionating through a column of Wakogel C200 with a linear gradient (0 to 100) of MeOH and EtOAc, and the fractions which gave a positive test with sodium nitroprusside (test for SH) are combined, evaporated and the residue recrystallised from EtOAc/hexane (1:1) to give the white crystalline drug [Nam et al. *J Pharm Sci* **73** 1843 *1984*, DOI:10.1002/jps.2600731251. PMID: 6396401]. *Alternatively*, dissolve it in H_2O, purify through AG-50Wx2 (BioRad)/eluting with H_2O. The free acid is converted to the ***dicyclohexylamine salt*** in MeCN by addition of the amine until the pH is 8-9. The salt free acid is obtained by shaking with EtOAc/10% aqueous $KHSO_4$ or passage through AG50Wx2. The EtOAc solution is dried ($MgSO_4$), evaporated and the residue is recrystallised from EtOAc/hexane [Cushman et al. *Biochemistry* **16** 5484 *1977*, DOI: 10.1021/bi00644a014]. Of the N-proline derivatives that Cushman et al. studied for competitive *ACE* inhibition ***Captopril*** was the ***most potent*** with a Ki of 0.0017μM (in 0.1M phosphate, 0.3M NaCl, pH 8.3 with Hip-His-Leu (5mM) as substrate at 37°).

Resazurin sodium salt (Alamar blue, 7-hydroxy-3*H*-phenoxazin-3-one-10-oxide Na salt) *[62758-13-8]* **$C_{12}H_6NO_4$. Na, M 251.2, decomposes on heating.** It is a bluish powder that can be dissolved in hot MeOH and precipitated out on adding Et_2O. *Alternatively*, dissolve it in conc H_2SO_4 and dilute the solution (**care**, use ice cooling). Filter off the orange solid, wash well with hot H_2O and dry *in vacuo*. The ***Na salt*** can be obtained by careful titration with NaOH or Na_2CO_3. It is soluble in H_2O and MeOH, less in higher alcohols, and has λ_{max} (MeOH) at 604nm with ε_{max} 60,000$cm^{-1}M^{-1}$. It is an ***indicator***: pH 3.8 (orange) —6.5 (blue). It is a versatile ***biological stain***. [For preparation and properties see Sabnis in *Handbook of Biological Dyes and Stains* Wiley, Hoboken pp 406-407 *2010*, onlinelibrary.**wiley**.com/doi/10.1002/9780470586242.fmatter/pdf; for oxidation-reduction of Resazurin and Resorufin (below) see Twigg *Nature* **155** 401 *1945*, DOI: 10.1038/155401a0.]

Rescinnamine (Anaprel, Apoterin, a β-carboline alkaloid) *[24815-24-5]* **$C_{25}H_{42}N_2O_9$, M 634.7, m 238-239°(vacuum), 240°, $[\alpha]_D^{20}$ -97 (c 1, $CHCl_3$), $pK_{Est(1)}$~<0 (carbazole N), $pK_{Est(2)}$~7.0 (quinolizidine N), pK^{25} 6.4 (75% aqueous $HCONMe_2$).** Crystallise it from *benzene, MeOH or aqueous Me_2CO. The *hydrochloride* has **m 232° dec** (from MeOH) and $[\alpha]_D^{20}$ -74 (MeOH). It is an antihypertensive. [Klohs et al. *J Am Chem Soc* **77** 2241 *1955*, DOI: 10.1021/ja01613a065; *Beilstein* **25** III/IV 1323.]

Resorufin (7-hydroxy-3*H*-phenoxazin-3-one Na salt) *[34994-50-8]* **$C_{12}H_6NO_3$. Na, M 235.2, decomposes on heating >300°, pK^{25} 5.8 (H_2O), 6.10 (50% aqueous MeOH).** The ***free acid*** *[635-78-9]* $C_{12}H_7NO_3$, M 213.2. is purified by dissolving the salt in ice cold concentrated H_2SO_4 which on dilution precipitates resorufin (pink) and is filtered off, washed with hot H_2O and dried. [Eichler *J Prakt Chem* **139** 113 *1934*, DOI: 10.1002/prac.19341390305.] Detailed UV and IR studies were reported by Musso & Matthies *Chem Ber* **90** 1814 *1957*, DOI: 10.1002/cber.19570900919]. For pKa see Musso & Rathjen [*Chem Ber* **92** 751 *1959*, DOI: 10.1002/cber.19590920331; *Beilstein* **27** 1V 2263.] See also entry *[635-78-9]* in 'Organo-metallic Compounds' in Chapter 4. The ***O^7-monoacetate*** *[1152-14-3]* **$C_{14}H_9NO_4$, M 255.2, m 223°** is a ***fluorogenic substrate*** used for hydrolytic enzymes; its fluorescence has λ_{em} 593nm (λ_{ex} 500nm, in 0.1M phosphate pH 8.0 with lipase) [Kitson & Kitson *Biochem J* **322** 701 *1997*, DOI: 10.1042/bj3220701]. [*Beilstein* **27** IV 2263.]
The ***O^7-methylresorufin* (7-methoxy-3*H*-phenoxazin-3-one)** *[5735-89-3]* **$C_{13}H_9NO_3$, M 227.2, m >220°** has fluorescence at Eem 585nm (Eext 571 nm in deacylase solution) and is used to ***differentiate isoenzymes of cytochrome P-450***. It is insoluble in H_2O and dilute alkali, but is soluble in EtOH and $CHCl_3$ to give an orange yellow colour. [Kehrmann *Justus Liebigs Ann Chem* **372** 287 *1910*, DOI: 10.1002/jlac.19103720303; *Beilstein* **27** II 108.] Several **O^7-substituted** derivatives are commercially available. They are ***biological stains and dyes***.

Rifampicin (Rifampin, Rifadin) *[13292-46-1]* **$C_{43}H_{58}N_4O_{12}$, M 823.0, m 183-185°, pK_1 1.7, pK_2 7.9.** This ***macrolide antibiotic*** crystallises form Me_2CO in red-orange plates. It has UV with λ_{max} at 237, 255, 334, and 475nm (ε 33,200, 32,100, 27,000 and 15,400) at pH 7.38. It is stable in Me_2SO and H_2O, and is freely soluble in

most organic solvents, but slightly soluble in H_2O at pH <6. [Binda et al. *Arzneim.-Forsch* **21** 1907 *1971*.] It ***inhibits cellular RNA synthesis*** without affecting DNA [Calvori et al. *Nature* **207** 417 *1965*, DOI: 10.1038/207418a0].

Rifamycin B *[13929-35-6]* **$C_{39}H_{49}NO_{14}$, M 755.8, m 300° (darkening at 160-164°), $[\alpha]_D^{20}$ -11° (MeOH), pK_1 2.60, pK_2 7.76.** Rifamycin B forms yellow needles from *C_6H_6. Its solubilities are: H_2O (0,027%), MeOH (2.62%) and EtOH (0.44%), also soluble in DMSO and EtOAc. It has UV with λ_{max} at 223, 304 and 245nm ($A^{1\%}_{1cm}$ 555, 275 and 220). [Oppolzer & Prelog *Helv Chim Acta* **56** 2287 *1973*, DOI: 10.1002/hlca.19730560717; Oppolzer et al. *Experientia* **20** 336 *1964*, PMID: 5855864; for X-ray structure see Brufani et al. *Experientia* **20** 339 *1964*, PMID: 5855865.] It is a macrolide antibacterial agent.

Rifamycin SV *[6998-60-3]* **$C_{37}H_{46}NO_{12}$. Na, M 697.8, m 300°(darkening >140°), $[\alpha]_D^{20}$ -4° (MeOH), pK_{Est} ~7.8.** Rifamycin SV gives yellow-orange crystals from Et_2O/petroleum ether or aqueous EtOH, is very soluble in MeOH, EtOH, Me_2CO and EtOAc, and is less soluble in Et_2O and HCO_3^-, but slightly soluble in H_2O and petroleum ether. Its UV has λ_{max} at 223, 314 and 445nm ($A^{1\%}_{1cm}$ 586, 322 and 204) in phosphate buffer pH 7. [For NMR see Bergamini & Fowst *Arzneim.-Forsch* **15** 951 *1965*.] It is a macrolide antibacterial agent.

(-)-Scopolamine hydrobromide $3H_2O$ **(6β,7β-epoxy-3α-tropanyl *S*(-)-tropate HBr, hyoscine HBr)** *[114-49-8, 6533-68-2, 51-34-3 free base]* **$C_{17}H_{21}NO_4$. HBr. $3H_2O$, M 438.3, m 193-194°, 195°, 195-199°, $[\alpha]_D^{25}$ -25(c 5, H_2O), pK^{20} 8.15.** The ***hydrobromide*** is crystallised from Me_2CO, H_2O or EtOH/Et_2O, and dried *in vacuo*. It is soluble in H_2O (60%) and EtOH (5%) but insoluble in Et_2O and slightly in $CHCl_3$. The ***hydrochloride*** has **m 300°** (from Me_2CO). The ***free base*** is a viscous liquid which forms a crystalline ***hydrate*** with **m 59°** and $[\alpha]_D^{20}$ -28 (c 2.7, H_2O). It hydrolyses in dilute acid or base. [Meinwald *J Chem Soc* 712 *1953*, DOI: 10.1039/JR9530000712; Fodor *Tetrahedron* **1** 86 *1957*, DOI: 10.1016/0040-4020(57)85013-3; *Beilstein* **6** III 4185.] A drug for treatment of motion sickness (Kwells) and post-operative nausea and vomiting.

Serotonin hydrochloride (5-HT, 3-[2-aminoethyl]-5-hydroxyindole HCl) *[153-98-0]* **$C_{10}H_{12}N_2O$. HCl, M 212.7, m 149-154°, 167-168°, 178-180°, pK_1^{25} 4.9, pK_2^{25} 9.8 (10.0, NH_2), pK_3^{25} 11.1 (5-OH), pK_4^{25} 18.25 (acidic indole NH).** 5-HT is purified by recrystallisation from EtOH/Et_2O or Et_2O to give the *hygroscopic* salt. Store it in the dark as it is light sensitive. The ***free base*** has **m 84-86°** (from Et_2O). The ***5-benzyloxy*** derivative has **m 84-86°** (from Et_2O). [Ek & Witkop *J Am Chem Soc* **76** 5579 *1954*, DOI: 10.1021/ja01651a001; Hamlin & Fischer *J Am Chem Soc* **73** 5007 *1951*, DOI: 10.1021/ja01154a551.] The ***picrate*** *$1H_2O$* has **m 196-197.5°** (dec with sintering at 160-165°) after crystallisation from Et_2O. Serotonin is a natural neurotransmitter [Roth & Chuang *Life Sci* **41** 1051 *1987*, DOI: 10.1016/0024-3205(87)90621-7]. [*Beilstein* **22/12** V 16.]

Spectinomycin dihydrochloride pentahydrate (Actinospectacin) *[22189-32-8, 21736-83-4]* **$C_{14}H_{24}N_2O_7$. 2HCl. $5H_2O$, M 495.3, m 205-207°(dec), $[\alpha]_D^{20}$ +14.8° (c 0.4, H_2O), pK_1 6.95, pK_2 8.70.** The salt is purified by recrystallisation from aqueous Me_2CO and is soluble in H_2O, MeOH and dilute acid and base, but only slightly soluble in Me_2CO, EtOH, $CHCl_3$ and *C_6H_6. The ***free base*** is an amorphous solid, **m 184-194°** with $[\alpha]_D^{20}$ -20 (H_2O). [Wiley et al. *J Am Chem Soc* **93** 2652 *1963*, X-ray: Cochran et al. *JCS Chem Commun* 494 *1972*, DOI: 10.1039/C39720000494.] It is an ***aminoglycoside antibiotic*** which interacts with 16S ribosomal RNA [Moazed & Noller *Nature* **327** 389 *1987*, DOI: 10.1038/nature01493, PMID: 2953976] and is used for the ***treatment of gonorrhea*** [Rinehart *J Infect Dis* **119** 345 *1969*, DOI: 10.1093/infdis/119.4-5.345].

D-Sphingosine (2*S*,3*S*-D-*erythro*-2-aminooctadec-4*t*-ene-1,3-diol from bovine brain) *[123-78-4]* **$C_{18}H_{37}NO_2$, M 299.5, m 79-82°, 82° 82.5° (softens at ~70°), $[\alpha]_D^{22}$ -3.4 (c 2, $CHCl_3$), pK_{Est} ~ 8.8.** D-Sphingosine is purified by re-crystallisation from EtOAc, Et_2O or petroleum ether (60-80°). It is insoluble in H_2O but is soluble in Me_2CO, EtOH and MeOH and $CHCl_3$ (20mg/ml). It has IR bands at 1590 and 875 cm^{-1}, and is characterised as the ***tribenzoate*** **m 122-123°** (from 95% EtOH). Store it at -20°. [Tipton *Biochemical Preparations* **9** 127 *1962*; for 'Biochemistry of the sphingolipides. III. Structure of sphingosine' see Carter et al. *J Biol Chem* **170** 285 *1947*, http://www.jbc.org/content/170/1/285; and Carter et al. *J Biol Chem* **169** 77 *1947*, PMID: 20240540.] Important lipid for membranes, and in cellular signaling and other processes. For 'Killing tumours by ceramide-induced apoptosis: a critique of available drugs' see Radin [*Biochem J* **371** (Pt 2) 243

2003, DOI: 10.1042/BJ20021878, PMID: 12558497].

Statins. These are a group of lipid lowering drugs that act by strongly inhibiting 3-hydroxy-3-methylglutamylCoA reductase (HMG-CoA reductase Ki is ~in the nM range) which is the first enzyme of the *de novo* biosynthesis of cholesterol (e.g. in mammalian liver) and have the effect of increasing LDL (low density lipoproteins) uptake by hepatocytes, decrease HDL-C (high density lipoprotein cholesterol) and lower triglyceride levels. The pyrrol-type statins related to Lipitor have been mentioned above, and here are included four 1,2,6,7,8,8a-hexahydronaphthalene-type statins (denoted ***S***) with a ***S-1***-(*R*-3,*R*-4-dihydroxyheptanoic acid, or its lactone group), an ***S-2***-methyl group, a 6-unsubstituted or a ***S-6***-(methyl or hydroxyl) group, ***S-8***-hydroxy group (esterified), and an ***R-8a*** hydrogen at the bridgehead. The lactones are *pro-drugs* which are hydrolysed to the corresponding hydroxyl-heptanoic acids *in vivo*. These acids can be converted into their lactones by azeotropic removal of H_2O in boiling toluene.

Pravastatin Na salt {Pravachol, (β*R*,δ*R*-1*S*,2*S*,6*S*,8*S*,8a*R*)-1,2,6,7,8,8a-hexahydro-β,δ,6-trihydroxy-2-methyl-1-oxo-2-methyl-8-[*S*-2-methyl-1-oxobutoxy]-1-naphthaleneheptanoic acid monoNa salt) *[81131-70-6, free acid 81093-37-0]* **$C_{23}H_{35}O_7Na$, M 446.5, m 171.2-173° (for free acid), m 138-142° (for δ-lactone), $[\alpha]_D^{22}$ +194 (c 0.5, MeOH for δ-lactone), pK_1^{25} 4.21 (CO_2H), pK_2^{25} -2.7 (basic).** Crystallise from H_2O (solubility 0.45g/L) by addition of Me_2CO, or MeOH/Me_2CO then wash with Et_2O and dry *in vacuo* to give a pale white powder or fine crystals. It is soluble in MeOH but insoluble in Me_2CO, MeCN and $CHCl_3$. The UV (MeOH) has λ_{max} at 230, 237 and 245nm, as for the δ-lactone. Its Ki (*in vivo*) for HMG-CoA reductase is ~1nM, and displays cardioprotective properties. [Hamelin & Turgeon *Trends Pharmacol Sci* **19** 26 *1998*, PMID: 9509899.]

Lovastatin {Mevacore, Mevinolin, (2*S*)-(1*S*,3*R*,7*S*,8*S*,8a*R*)-1,2,3,7,8,8a-hexahydro-3,7-dimethyl-8-[2-[2*R*,4*R*)tetrahydro-4-hydroxy-6-oxo-2*H*-pyran-2-yl]ethyl]-1-naphthalenyl-methyl butanoate} *[75330-75-5]* **$C_{24}H_{36}O_5$, M404.5, m 174.5° (under N_2), $[\alpha]_D^{25}$ +323 (c 0.5, MeCN), pK_1^{25} 14.9 (v weak acid), pK_2^{25} -2.8 (v weakly basic).** This fungal metabolite was isolated from *Aspergillus Terreus*. Recrystallise it from a combination of solvents which do not allow hydrolysis of the lactone ring. It crystallises from EtOH in thick colourless needles, and crystallises also from MeCN then EtOAc and dried at 40°/16hrs. Its solubility at ~25° (g/100ml) is: $CHCl_3$ (35), DMF (9.0), Me_2CO (4.7), DMSO (4.0), MeCN (2.8), MeOH (2.8), *iso*PrOH (2.0), EtOH (1.6), *iso*BuOH (1.4). *n*-PrOH (1.1), *n*-BuOH (0.7), *n*-octanol (0.2), H_2O (almost insol, 0.4 x 10^{-5}). The UV (MeOH) has λ_{max} at 231 (ε 21,490), 238 (ε 25,090) and 247 (ε 16,890 $M^{-1}cm^{-1}$) nm, and ^1H NMR and MS are consistent with its structure and similar to those reported below for Mevastatin. [Alberts et al. *Proc Natl Acad Sci* USA **77** 3957 *1980*; PMID: 6933445; Hirama & Iwashita *Tetrahedron Lett* **24** 1811 *1983*, DOI: 10.1016/S0040-4039(00)81777-3]. Its Ki (*in vivo* and *in vitro*) for HMG-CoA reductase is ~0.6nM, decreases CDK2, 4, 6, and cyclin E levels, and induces G_1 arrest and apoptosis in tumour cell lines *in vitro* [Alberts *Am J Cardiol* **62** 10J *1988*, PMID: 3055919; Park et al. *Anticancer Res* **19** 3133 *1999*, PMID: 10652602.]

Mevastatin {Compactin (2*S*)-2-methyl-(1*S*,7*S*,8*S*,8a*R*)-1,2,3,7,8,8a-hexahydro-7-methyl-8-[2-[(2*R*,4*R*)tetrahydro-4-hydroxy-6-oxo-2*H*-pyran-2-yl]ethyl]-1-naphthalenyl-methyl butanoate} *[73573-88-3]* **$C_{23}H_{34}O_5$, M 390.5, m 152°, $[\alpha]_D^{22}$ +283 (c 0.84, Me_2CO), pK_1^{25} 4.21 (CO_2H), pK_2^{25} -2.7 (basic) of hydrolysed lactone.** It has been isolated from *Penicillium brevicompactum* and purified by recrystallisation from aqueous EtOH. Its UV (EtOH) has λ_{max} at 230 (logε 4.28), 237 (logε 4.30) and 246 (logε 4.11) nm; the IR (KBr) has ν_{max} at 3520, 1750 (lactone CO) and 1710 (ester CO) cm^{-1}; the IR ($CHCl_3$) has ν_{max} at 3510 and 1724 (lactone and ester CO) cm^{-1}; the ^1H NMR ($CDCl_3$) has δ at 5.59 (1H, d, *J* =10Hz, H-4), 5.71 (1H, dd, *J* =10 and 5Hz, H-3'), 5.44 br (1H, s, H-5'), 5.33br (1H, s, H-8'), 4.62 (1H, m, H-3), 4.35 (1H, m, H-5), 3.28br (1H, s, OH), 2.64 (2H, d, *J* = 4Hz, H-6), 2.37 (2H, m, H-2' and H-2"), 2.2—1.3 (14H, m, CH_2 and CH), 1.13 (3H, d, *J* =7Hz, 2"-Me), 0.90 (3H, d, *J* =7Hz, 2'-Me) and 0.88 (3H, t, *J* =7.5Hz, CH_3-CH_2); MS has M^+ 390.2403, $C_{23}H_{34}O_5$ requires *M* 390.2406, and *m/e* **390(4%)**, 372(3), 288(4), 273(4), 270(12), 210(14), 186(12), 185(42), 184(57), 183(24), 169(11), 159(34), 158(56), 155(30), **145(100)**, 144(40), 143(81), 129(28), 91(15) and 57(31). The ***benzoate*** has **m 88-89°** after recrystallisation from aqueous EtOH and MS has M^+ 494.2667, $C_{30}H_{38}O_6$ requires *M* 494.2668. A fragment was cut from a large crystal and subjected to X-ray crystallographic studies which showed that the structure and relative configurations of the chiral centres were as expected for this lactone. [Brown et al. *JCS Perkin Trans 1* 1165 *1976*, DOI: 10.1039/P19760001165.] [For the total chiral synthesis of Compactin see Hirama & Uei *J Am Chem Soc* **104** 4251 *1982*, DOI: 10.1021/ja00379a037.]

Simvastatin {Zocor, Sivastin (1*S*,3*R*,7*S*,8*S*,8a*R*)-1,2,3,7,8,8a-hexahydro-3,7-dimethyl-8-[2-[(2*R*,4*R*)-tetrahydro-4-hydroxy-6-oxo-2*H*-pyran-2-yl]ethyl]-1-naphthalenyl-2,2-dimethylbutanoate} *[79902-63-9]*

$C_{28}H_{38}O_5$, M 418.6, m 135-138°, $[\alpha]_D^{22}$ +292 (c 0.5, MeCN), pK_1^{25} 4.21 (CO_2H), pK_2^{25} -2.7 (basic) of hydrolysed lactone. By altering the acid which esterifies the OH group at *S*-1 from 2-methylbutanoic acid (in Mevinolin, Lovastatin above) to 2,2-dimethylbutanoic acid (in Simvastatin, Zocor) Hoffman et al. [*J Med Chem* **29** 849 *1986*, DOI: 10.1021/jm00155a040] have succeeded in increasing the intrinsic inhibition of HMG-CoA reductase by ~2.5 times. Prepared by adding 2,2-dimethylbutyryl chloride (4.6mmol, b 130-134°/atm) over 2 minutes to a stirred solution of the ***S-1***-OH compound (0.5g, 1.15mmol) and DMAP (50mg) in dry pyridine (5ml) at 0°/N_2, and stirring at 0°/1hr then at ~25°/18hrs. Et_2O (100ml) is added to the mixture which is washed with 2% aqueous HCl (3 x 25ml), saturated $NaHCO_3$ solution (25ml), and brine (2 x 25ml), the organic layer is dried ($MgSO_4$), filtered and evaporated to dryness. The residual oil is chromatographed through a silica gel (230-400 mesh) column, eluted with $CHCl_3$/Me_2CO (32:1 v/v, 200ml), discarded this fraction, then continue with the same eluant (200ml) to give the ***desired ester***. This is then recrystallised from *n*-C_4H_9Cl/hexane. It is soluble (in g/100ml at ~25°) in *n*-hexane (0.015), propylene glycol (3), polyethylene glycol-400 (7), EtOH (16), MeOH (20), DMSO (54), $CHCl_3$ (61), 0.1M HCl (0.006) and 0.1N NaOH (7, most propably the lactone has hydrolysed to give the Na salt of the hydroxyl acid formed). [For the preparation by fermentation of *Penicillium citrunum* and further reactions, see patents to Merck and Co *1980*, by Hoffman et al. US 444.4784, and Willard et al. EP 33538.] Apart from inhibiting HMG-Co reductase and decreasing levels of LDL [White *J Clin Pharmacol* **39** 111 *1999*, DOI: 10.1177/00912709922007642], it has many other biological effects such as stimulating bone formation (*in vitro* and *in vivo*) [Garrett et al. *Curr Pharmaceut Des* **7** 715 *2001*, DOI: 10.2174/1381612013397762], inhibition of smooth muscle cell proliferation and migration [Reinso et al. Methods Find Exp Clin Pharmacol **24** 593 *2002*, PMID: 12616706], and anticancer and anti-inflammatory activity [Kaushal et al. *Endothelium* **10** 49 *2003*, PMID: 12699077].

Sterigmatocystin (3a,12c-dihydro-8-hydroxy-6-methoxy-3*H*-furo[3',2':4,5]furo[2,3-c]xanthen-7-one) *[10048-13-2]* **$C_{18}H_{12}O_6$, M 324.3, m 246°, 247-248°, $[\alpha]_D^{20}$ -398 (c 0.1, $CHCl_3$), pK_{Est} ~ 8.0.** It crystallises from amyl acetate, Me_2CO or EtOH and sublimes *in vacuo*. It has UV with λ_{max} at 208, 235, 249 and 329nm (log ε 4.28, 4.39, 4.44 and 4.12). [For UV see Bullock et al. *J Chem Soc* 4179, *1962*, DOI: 10.1039/JR9620004179; for UV and IR see Holker & Mulheirn *JCS Chem Commun* 1576 *1968*, DOI: 10.1039/C19680001576; Birkinshaw & Hammady *Biochem J* **65** 162 *1957*, DOI: 10.1042/bj0650162.] This ***mycotoxin*** induces ***bone marrow changes*** in mice [Curry et al. *Mutation Res* **137** 111 *1984*]. [*Beilstein* **19/10** V 575.]

Stigmatellin A (2-[4,6-dimethoxy-3,5,11-trimethyltridecatri-7*t*,9*t*,11*t*-enyl]-8-hydroxy-5,7-dimethoxy-3-methyl-4*H*-1-benzopyran-4-one) *[91682-96-1, 94234-27-2]* **$C_{30}H_{42}O_7$, M 514.6, m 128-130°, $[\alpha]_D^{20}$ +38.5 (c 2.3, MeOH), pK_{Est} ~7 (phenolic OH).** Stigmatellin A is stable in aqueous solution at neutral pH but decomposes at pH <5. It is purified by recrystallisation from toluene/hexane. It has UV with λ_{max} nm (ε) at 248sh (4,100), 258 (59,500), 267 (65,500), 279 (1,400) and 335 (5,200) in MeOH; 249sh (45,600), 258 (60,000), 268 (72,700), 277 (54,100), 320 (2,500) and 370 (3,000) in MeOH + 1 drop of N KOH; 243sh (29,300), 264 (63,200), 274 (64,100), 283sh (45,800), 329 (4,800) and 420 (21,000) in MeOH + 6N HCl; and IR ($CHCl_3$) with ν_{max} at 3550m, 1645chs, 1635ss, 1620ss, 1590s, 1510m and 905m cm^{-1}. It gives colour reactions at 110° with vanillin/H_2SO_4 (grey), Ce(IV)/$(NH_4)_2SO_4$ (yellow) and phosphomolybdate (blue-grey). [Höfle et al. *Justus Liebigs Ann Chem* 1883 *1984*, DOI: 10.1002/jlac.198419841202.] It ***inhibits electron transport*** by interfering with the quinol oxidation (Q_o) site of cytochrome Bc1 [von Jagow & Link *Methods Enzymol* **126** 253 *1986*, DOI: 10.1016/S0076-6879(86)26026-7; Robertson et al. *Biochemistry* **32** 1310 *1933*, DOI: 10.1021/bi00056a016], and has antibiotic properties [Kunze et al. *J Antibiot* **37** 454 *1984*]. The **7*t*,9*t*,11*c*-isomer** is ***Stigmatellin B*.**

Streptomycin sulfate *[3810-74-0]* **$C_{21}H_{39}N_7O_{12}$. 1.5H_2SO_4, M 7268.7, 1457.4 (for 2 base. 3 H_2SO_4), $[\alpha]_D^{20}$ -84.3 (c 3, H_2O), $pK_{Est(1)}$~ 9.5 (MeNH), $pK_{Est(2,3)}$~ 13.4 (guanidino).** The sulfate is recrystallised from H_2O/EtOH, washed with a little EtOH, Et_2O and dried in a vacuum. Streptonigrin (nigrin, 5-amino-6-[7-amino-5,8-dihydro-6-methoxy-5,8-dioxo-2-quinolinyl]-4-[2-hydroxy-3,4-dimethoxyphenyl]-3-methyl-2-pyridinecarboxylic acid) *[3930-19-6]* **$C_{25}H_{22}N_4O_8$, M 506.5, m 262-263°, 275°(dec), pK^{25} 6.3 (1:1 aqueous dioxane).** Streptonigrin is purified by TLC on pH 7-buffered silica gel plates and eluted with 5% MeOH/$CHCl_3$. The extracted band crystallises from Me_2CO or dioxane (black plates or needles) and is soluble in pyridine, Me_2NCHO, aq $NaHCO_3$ (some dec), and poorly soluble in MeOH, EtOH, EtOAc and H_2O. It has UV with λ_{max} at 248, 375-380nm (ε 38,400 and 17,400). [Weinreb et al. *J Am Chem Soc* **104** 536 *1982*, DOI: 10.1021/ja00366a028; Rao et al. *J Am Chem Soc* **85** 2532 *1963*, DOI: 10.1021/ ja00899a051.] It is an ***anti-neoplastic antibiotic*** [Wilson et al. *Antibiot Chemother* **11** 147 *1961*].

Succinyl coenzyme A trisodium salt *[108347-97-3]* **$C_{25}H_{40}N_7O_{19}P_3S$, M 933.5, 867.7 (free acid).** If impure dissolve it in H_2O (0.05g/ml) adjusted to pH 1 with 2M H_2SO_4 and extract many times with Et_2O. Remove excess Et_2O by bubbling N_2 through it and store frozen at pH 1. When required, adjust the pH to 7 with dilute NaOH and use within 2 weeks (freeze samples). It is estimated by the hydroxamic acid method [Hersh & Jencks *J Biol Chem* **242** 3468 *1967*, http://www.jbc.org/content/242/15/3468; Hersh & Jencks *J Biol Chem* **242** 3481 *1967*, http://www. jbc.org/content/242/15/3481]. More stable in acidic than neutral aqueous solutions, but neutral solutions are stable at –15°. [Jordan & Laghai-Newton *Methods Enzymol* **123** 435 *1986*, DOI: 10.1016/S0076-6879(86)23054-2; *Beilstein* **26** III/IV 3666.] An intermediate in the citric acid cycle.

Terramycin (oxytetracycline) *[79-57-2; 6153-64-6 ($2H_2O$)]* **$C_{22}H_{24}N_2O_9$, M 460.4 (anhydrous), 496.5 ($2H_2O$), sinters at 182°, melts at 184-185°(dec), $[\alpha]_D^{20}$ -196.6 (equilibrium in 0.1M HCl), -2.1°(equilibrium in 0.1M NaOH).** It crystallises (as ***dihydrate***) from H_2O (0.25mg/ml at 25°) or aqueous EtOH and is soluble in MeOH and Me_2CO but insoluble in Et_2O and petroleum ether. It is amphoteric; aqueous solutions have pH 2.0-5.0. It has UV with λ_{max} at 247, 275 and 353nm in 0.1 M phosphate (pH 4.5). [Finlay et al. *Science* **111** 85 *1950*, DOI: 10.1126/science.111.2874.85.] The ***hydrochloride***, *[2058-46-0]* M 496.9 [*Beilstein* **14** IV 2630], crystallises from MeOH in needles and from H_2O at 50° it forms plates. Terramycin has also been purified *via* the ***hydrochloride*** by dissolving it in H_2O, adjusting to pH 6, and the solid is filtered off after 1 hour. The crystals of the ***dihydrate*** are dried to constant weight in vacuum/$CaCl_2$/25°. Drying at 60° *in vacuo* gives the ***anhydrous base*** **m 184.5-185.5°** (sintering at 180°). The ***dihydrate*** has **m 181-182°**, and its optical rotation in MeOH decreases from $[\alpha]_D^{25}$ +26 (c 0.5%) to $[\alpha]_D^{25}$ +11.3 after standing for 16 hours. Its biological half life is 6-8 hours. It forms a ***sodium salt*** and a ***$CaCl_2$ complex***. [Regna et al. *J Am Chem Soc* **73** 4211 *1951*, DOI: 10.1021/ja01153a050; *Beilstein* **14** IV 2633.] A broad spectrum tetracycline antibiotic.
Tetracycline *[60-54-8]* **$C_{22}H_{24}N_2O_8$, M 444.4, m 172-174°(dec), $[\alpha]_{546}^{20}$ -291 (c 1, MeOH), pK_1^{25} 3.30, pK_2^{25} 7.68, pK_3^{25} 9.69.** Recrystallise the antibiotic from toluene or aqueous MeOH as the ***trihydrate***. Its biological half life is 8-11hrs (normally), but 57-108hrs (in kidney impairment). Store it at -20°. [Stephens et al. *J Am Chem Soc* **76** 3568 *1954*, DOI: 10.1021/ja01642a064; *Beilstein* **14** IV 2625.] ***Tetracycline hydrochloride*** *[64-75-5]* **$C_{22}H_{24}N_2O_8$. HCl, M 480.9,** has **m 214°(dec), 215-220°, $[\alpha]_D^{25}$ -258 (c 0.5, 0.1N HCl), $[\alpha]_D^{20}$ -245 (c 1, MeOH), $[\alpha]_D^{25}$ -257.9 (c 0.5, aqueous HCl), pK_1 1.4 (enolic OH), pK_2 3.30, pK_3 7.68 (phenolic OH), pK_4 9.27 (Me_2N).** The hydrochloride is recrystallised from MeOH/*n*-BuOH or *n*-BuOH/HCl. It is insoluble in Et_2O and petroleum ether. It has UV with λ_{max} at 270 and 366nm in MeOH. [Gottstein et al. *J Am Chem Soc* **81** 1198 *1959*, DOI: 10.1021/ja01514a046; Conover et al. *J Am Chem Soc* **84** 3222 *1962*, DOI: 10.1021/ja00875a063; Stephens et al. *J Am Chem Soc* **78** 4155 *1956*, DOI: 10.1021/ ja01597a081; *Beilstein* **14** IV 2627.]

Terreic acid (2-hydroxyl-3methyl-1,4-benzoquinone-5,6-epoxide) *[121-40-4]* **$C_7H_6O_4$, M 154.1, m 127-127.5°, $[\alpha]_D^{22}$ +74 (pH 4, phosphate buffer), pK^{25} 4.5.** Recrystallise the acid from $*C_6H_6$, $*C_6H_6$/petroleum ether or hexane, and sublime at 80-100°/1mm. It is an inhibitor of Burton's tyrosine kinase. [Kawakami et al. *PNAS* **26** 2227 *1999*, PMID: 10051623; *Beilstein* **17** IV 6698.]

6*R*-Tetrahydro-*erythro*-biopterin dihydrochloride (BH_4.2HCl, 6*R*-2-amino-4-hydroxy-6-[{1*R*,2*S*}-1,2-dihydroxypropyl]-5,6,7,8-tetrahydropteridine 2HCl) *[69056-38-8]* **$C_9H_{15}N_5O_3$. 2HCl, M 314.2, m 245-246°(dec), $[\alpha]_D^{25}$ -6.8 (c 0.67, 0.1N HCl), pK_1 1.37 (pyrimidine$^+$), pK_2 5.6 (5-NH^+), pK_3 10.6 (acidic, 3NH).** Recrystallisation of BH_4.2HCl from HCl enriches BH_4 in the natural 6*R* isomer. Dissolve the salt (~6g) in concentrated HCl (15ml) under gentle warming, then add EtOH (30ml) dropwise, chill and collect the colourless needles (67%, up to 99% if the mother liquors are concentrated), and dry it *in vacuo* immediately over P_2O_5 and

KOH. It is stable indefinitely at -20° in a dry atmosphere. Better store it in sealed ampoules under dry N_2. It can be recrystallised from 6N aqueous HCl. It has UV with λ_{max} (in 2N HCl) at 264nm (ε 16,770; pH 3.5 phosphate buffer) 265nm (ε 13,900); (in pH 7.6) at 297nm (ε 9,500) and 260nm sh (ε 4,690). It has been separated from the 6*S*-isomer by HPLC on a Partisil-10SCX column using 30mM ammonium phosphate buffer (pH 3.0) containing 3mM $NaHSO_3$ (2ml/minute flow rate; 275nm detector) with retention times of 5.87 minutes (6*R*) and 8.45 minutes (6*S*). It is stable in acidic solutions and can be stored for extended periods at -20° in 0.04M HCl. Above pH 7 the neutral species are obtained, and these are readily oxidised by the oxygen in the solvent to the ***quinonoid species***, and then further oxidation and degradation occurs at room temperature. These changes are slower at 0°. The ***sulfate salt*** can be obtained by recrystallisation from 2M H_2SO_4 and is less soluble in water than the hydrochloride salt. The ***6R-2',5',1',2'-tetraacetylbiopterin derivative*** has **m 292°(dec)** after recrystallisation from MeOH (100 parts) and $[\alpha]_{589}^{20}$ -144 (c 0.5, $CHCl_3$), $[\alpha]_{589}^{20}$ +12.8 (c 0.39, Me_2SO). [For NMR and UV see Matsuura et al. *Heterocycles* **23** 3115 *1985*, DOI: 10.3987/R-1985-12-3115; Furrer et al. *Helv Chim Acta* **62** 2577 *1979*, DOI: 10.1002/hlca.19790620811; Armarego et al. *Aust J Chem* **37** 355 *1984*, DOI: 10.1071/CH9840355; *Beilstein* **26** III/IV 4032.] It is a natural cofactor for several oxygenases.

Tetrahydrofolic acid dihydrochloride $2H_2O$ (THFA, 6*S*- or 6*RS*- 5,6,7,8-tetrahydrofolic acid 2HCl $2H_2O$, 5,6,7,8-tetrahydropteroyl-L-glutamic acid 2HCl $2H_2O$) *[135-16-0]* **$C_{19}H_{23}N_7O_6$. 2HCl. $2H_2O$, M 544.4, m >200°(dec), $[\alpha]_D^{27}$ +16.9 (H_2O pH 7.0 + 2-mercaptoethanol), pK_1 1.7 (pyrimidine N^+), pK_2 2.4 ($10N^+$), pK_3 3.5 (α-CO_2H), pK_4 4.9 (γ-CO_2H), pK_5 5.6 (5-NH^+), pK_6 10.4 (acidic, 3NH).** Very high quality material is now available commercially, and should be a white powder. Dry it over P_2O_5 *in vacuo* and store in weighed aliquots in sealed ampoules. It is stable at room temperature in this way for many months and much longer at -10°. When moist, it is extremely sensitive to air whereby it oxidises to the yellow *7,8-dihydro* derivative. In solution it turns yellow in colour as it oxidises, and then particularly in the presence of acids it turns dark reddish brown in colour. Aqueous solutions should be frozen immediately when not in use. It is advisable to add 2-mercaptoethanol (if it does not interfere with further procedures) which depletes the solution of O_2. The ***sulfate salt*** is more stable but is much less soluble. The best way to prepare standard solutions of this acid is to dissolve it in the desired buffer and estimate the concentration by UV absorption in pH 7 buffer at 297nm (ε 22,000 $M^{-1}cm^{-1}$). If a sample is suspect, it is not advisable to purify it because it is likely to deteriorate further as 'dry box' conditions are necessary. Either a new sample is purchased or one is freshly prepared from folic acid. [Hafeti et al. *Biochemical Preparations* **7** 89 *1960*, UV: Mathews & Huennekens *J Biol Chem* **235** 3304 *1960*, PMID: 13768089; Osborn & Huennekens *J Biol Chem* **233** 969 *1958*, PMID: 13587525; O'Dell et al. *J Am Chem Soc* **69** 250 *1947*, DOI: 10.1021/ja01194a023; Blakley *Biochem J* **65** 331 *1957*, DOI: 10.1042/bj0650331; *Beilstein* **26** III/IV 3879.] A natural cofactor and vitamin.

5,6,7,8-Tetrahydropterin sulfate (2-amino-5,6,7,8-tetrahydropteridin-4-one H_2SO_4) *[20350-44-1]* **$C_6H_9N_5O$. H_2SO_4, M 265.2, m >200°(dec), pK_1^{25} 1.3 (pyrimidine$^+$), pK_2^{25} 5.6 (5-NH^+), pK_3^{25} 10.6 (acidic, 3NH).** If its colour is strongly violet, then it needs to be reduced again. It is best to check the UV in N HCl where the peak at ~265nm drops sharply to zero at ~340nm. UV absorption at 340nm indicates oxidation to quinonoid or 7,8-dihydropterin. If absorption is weak, then dissolve it in the minimum volume of dry trifluoroacetic acid (fume hood), add charcoal, filter, add two drops of N H_2SO_4 then dry Et_2O at 0°, allow the white tetrahydro salt to settle, collect it, and wash it with dry Et_2O, by centrifugation. Dry the residue *in vacuo* over P_2O_5 and KOH. Store in aliquots in the dark at <0°. For the UV spectra of the monocation, dication, neutral species and anion see references. [Blakley *Biochem J* **72** 707 *1959*, DOI: 10.1042/bj0720707; Pfleiderer in *Pterins and Folate* (Benkovic and Blakley Eds) J Wiley **Vol 2** p 97 *1985*, Blakley *The Biochemistry of Folic Acid and Related Pteridines*, North-Holland Publ Co., Amsterdam, pp 157-163 *1969*, ISSN 0071-965X.]

Theophylline (1,3-dimethyl-2,6-dioxopurine, Theocin) *[58-55-9]* **$C_7H_8N_4O_2$, M 180.2, m 272-274°, pK_1^{40} -0.24, pK_2^{40} 8.79, pK_3 11.5 (acidic).** It crystallises from H_2O as the *monohydrate* which dehydrates >100°. It complexes with heavy metals, is a diuretic, vasodilator and cardiac stimulant. [Lister *Purines Part II. Fused Pyrimidines* Brown Ed. p 253 *1971*, J.Wiley & Sons NY, ISBN 047138205-1; *Beilstein* **26** III/IV 2331.]

Thiamine monophosphate chloride $2H_2O$ (Aneurine monophosphate chloride) *[532-40-1, 273724-21-3]* **$C_{12}H_{18}ClN_4O_4PS$. $2H_2O$, M 416.8, m 193°(dec), 200°(dec), 200-203°(dec), pK_1 2.40, pK_2 4.80, pK_3 6.27, pK_4 9.65, pK_5 10.20.** Purify the salt by recrystallisation from aqueous HCl, EtOH slightly acidified with HCl,

EtOH/Me_2CO, H_2O, or H_2O/EtOH/Et_2O. Dissolve it in a small volume of H_2O and mix it with EtOH/Me_2CO (1:1) to give the HCl.H_2O as crystals. Filter it off, wash it with Et_2O and dry it in a vacuum. The ***chloride hydrochloride***, **m 215-217°(dec)** is obtained when it is crystallised from aqueous HCl. [Wenz et al. *Justus Liebigs Ann Chem* **618** 210 *1958*, DOI: 10.1002/jlac.19586180124; Viscontini et al. *Helv Chim Acta* **34** 1388 *1951*, DOI: 10.1002/hlca.19510340521; Leichssenring & Schmidt *Chem Ber* **95** 767 *1962*, DOI: 10.1002/cber.19620950330; Matsukawa et al. *Methods Enzymol* **18A** 141, 147 *1970*, DOI: 10.1016/0076-6879(71)18293-6; *Beilstein* **27** III/IV 1766.] It is a vitamin.

Thiamphenicol (Thyocymetin, 1*R*,2*R*-2-[2,2-dichloroacetylamino]-1-[4-methanesulfonyl-phenyl]-propan-1,3-diol) *[15318-45-3 (*D*-threo), 90-91-5]* **$C_{12}H_{15}Cl_2NO_5S$, M 356.2, m 163-166°, 165.2-165.6°, 165-166°, $[\alpha]_D^{25}$ +15.6 (c 2, EtOH), pK^{25} 7.2.** Recrystallise thiamphenicol from H_2O or $CHCl_3$. The UV has λ_{max} at 224, 266 and 274nm (ε 13,700, 800 and 700) in 95% EtOH. The ***1S,2S-isomer*** *[14786-51-7]* has **m 164.3-166.3°** (from H_2O/EtOAc/petroleum ether) and $[\alpha]_D^{25}$ -12.6 (c 1, EtOH); and the ***racemate*** *1RS,2RS*-**Racefenical** *[847-25-6]* has **m 181-183° (dec)** from $CHCl_3$/EtOAc/petroleum ether. [Cutler et al. *J Am Chem Soc* **74** 5475 *1952*, DOI: 10.1021/ja01141a074; For UV see Nachod & Cutler *J Am Chem Soc* **74** 6291 1952, DOI: 10.1021/ja01144a517; Suter et al. *J Am Chem Soc* **75** 4330 *1953*, DOI: 10.1021/ja01113a057; Cutler et al. *J Am Pharm Assoc* **43** 697 *1954*, DOI: 10.1002/jps.3030431121; *Beilstein* **13** IV 2957.] It is an antibiotic and has biological half life of 0.5 hours. For the 'Role of thiamphenicol in the treatment of community-acquired lung infections' see Raymond et al. [*Med Trop (Mars)* **64** 33 *2004*, PMID: 15224555].

ε-[2-(4-Thiazolidinone)]hexanoic acid (Mycobacidin, Acidomycin, 6[4-oxothiazolidin-2-yl]hexanoic acid) *[539-35-5]* **$C_9H_{15}NO_3S$, M 215.3, m 140°, pK^{25} 5.1**. The ***dl-form is dimorphic***; it crystallises from $CHCl_3$ with **m 116-117°**, and from H_2O with **m 123°**. The ***l(-)-enantiomer*** (from Actinomyces) crystallises from H_2O, MeOH (**m 139-140°**), aqueous EtOH (**m 140-141°**) or EtOAc, and has $[\alpha]_D^{20}$ -54 (c 1, MeOH). The ***l(-)-methyl ester*** $C_{10}H_{17}NO_3S$, M 231.3, has **m 53-54°** (needles from Et_2O/hexane), $[\alpha]_D^{20}$ -50.9 (MeOH). The ***d(+)-enantiomer*** (from optical resolution of the brucine salt) has **m 138-139°** (from H_2O) and $[\alpha]_D^{25}$ +57 (c 1, MeOH). The optically active acids ***racemise*** in hot alkali. [McLamore et al. *J Am Chem Soc* **75** 105 *1953*, DOI: 10.1021/ja01097a030; isolation: Tejera et al. *Antibiot Chemother* **2** 333 *1952*; *Beilstein* **27** III/IV 4281.]

6-Thioguanosine (2-amino-6-mercapto-9-β-D-ribofuranosylpurine) *[85-31-4, 345909-25-3]* **$C_{10}H_{13}N_5O_4S$, M 299.3, m 224-227°(dec), 230-231°(dec), $[\alpha]_D^{20}$ -64 (c 1.3, 0.1N NaOH), pK^{25} 8.33.** Thioguanosine is crystallised (as ***hemihydrate***) from hot H_2O (charcoal) and cooled slowly to give tapered prisms. It also crystallises by dissolving in dilute NH_3 and acidifying with acetic acid, and then recrystallising from H_2O. Its UV (pH 4-6) has λ_{max} at 257nm (ε 8,820) and 342nm (ε 24,800), and at pH 10.4-12.0 it has λ_{max} at 252nm (ε 14,700) and 319.5nm (ε 21,000). [Fox et al. *J Am Chem Soc* **80** 1669 *1958*, DOI: 10.1021/ja01540a041; *Beilstein* **26** III/IV 3927.]

dl*-α-Tocopherol** (see **vitamin E)** *[10191-41-0]* **$C_{29}H_{50}O_2$, M 430.7, $A_{1cm}^{1\%}$ 74.2 at 292 nm in MeOH.** Dissolve *dl*-α-tocopherol in anhydrous MeOH (15ml/g) cool to -6° for 1 hour, then chill in a Dry-ice/acetone bath; crystallisation is induced by scratching with a glass rod. The ***dl*-α-*acetate [*52225-20-4*, *7695-91-2*] (*see DL-vitamin E actetate below*) is a viscous yellow liquid with **m -7°**, **b 184°/0.01mm**, **224°/0.3mm**, d_4^{20} 0.953, n_D^{20} 1.496. It is used as a standard for Vitamin E activity where the unit of activity is attained with 1mg of pure *dl*-α-acetate. [Friedrich 'Vitamins' Water de Guyter Publ, Berlin 1988, *Beilstein* **17/4** V 168.]

γ-Tocopherol (3,4-dihydro-2,7,8-trimethyl-2-(4,8,12-trimethyltridecyl)-2*H*-benzopyran-6-ol) *[54-28-4]* **$C_{28}H_{48}O_2$, M 416.7, m -30°, b 200-210°/0.1mm, d_4^{20} 0.951, n_D^{20} 1.505, $[\alpha]_D^{20}$ -2.4 (EtOH).** γ-Tocopherol is purified by distillation at high vacuum and stored in dark ampoules under N_2. Its UV has λ_{max} at 298nm ($A_{1cm}^{1\%}$ 92.8). It is insoluble in H_2O but soluble in organic solvents. The ***allophanate*** (used for separating it from its isomers) has **m 136-138°**, $[\alpha]_D^{18}$ +3.4 ($CHCl_3$). [Baxter et al. *J Am Chem Soc* **65** 918 *1943*, DOI: 10.1021/ja01245a041; Emerson et al. *Science* **83** 421 *1936*, DOI: 10.1126/science.83.2157.421; Evans et al. *J Biol Chem* **113** 319 *1936*, http://www.jbc.org/content/113/1/319; *Beilstein* **17/4** V 158.] It is a food additive.

Tomatidine (5α,20β,22α,25β,27-azaspirostan-3β-ol) *[77-59-8]* **$C_{27}H_{45}NO_2$, M 415.7, m 202-206°, $[\alpha]_D^{20}$ +5.9 (c 1, MeOH), $[\alpha]_D^{20}$ +8 ($CHCl_3$).** Tomatidine forms plates from EtOAc. It is also purified by dissolving

80mg in *C_6H_6 and applying to an Al_2O_3 column (3.0g) and eluting with *C_6H_6, evaporating and recrystallising the residue three times from EtOAc. The ***hydrochloride*** *[6192-62-7]* $C_{27}H_{45}NO_2$. HCl, M 452.1, has **m 265-270°** (**281-284° dec**) from EtOH and $[\alpha]_D^{25}$ -5 (MeOH). Store it at -20°. Tomatine (22*S*,25*S*-3β,β-lycotetraosyloxy-5α-spirosolan) *[17406-45-0]* **$C_{50}H_{83}NO_{21}$, M 1034.2, m 263-268°(dec), 290-291°(evacuated capillary), 283.5-287°(dec), 272-277°(dec), 300-305°(dec), $[\alpha]_D^{20}$ -18 to -34 (c 0.55, pyridine).** Tomatine is recrystallised from MeOH, EtOH, aqueous EtOH or dioxane/NH_3. It is almost insoluble in petroleum ether, Et_2O or H_2O. [Reichstein *Angew Chem* **74** 887 *1962*, DOI: 10.1002/ange.19620742202; *Beilstein* **27** III/IV 1954.] It is an antimicrobial.

Tubercidin (7-deazaadenosine) *[69-33-0]* **$C_{11}H_{14}N_4O_4$, M 266.3, m 247-248°**, **$[\alpha]_D^{17}$ -67 (50% aqueous AcOH), pK^{10} 5.2-5.3.** 7-Deazaadenosine forms needles from hot H_2O. It is soluble in H_2O (0.33%), MeOH (0.5%) and EtOH (0.05%). It has UV with λ_{max} at 270nm (ε 12,100) in 0.001N NaOH. The ***picrate*** has **m** 229-231°(dec). [Tolman et al. *J Am Chem Soc* **91** 2102 *1969*, DOI: 10.1021/ja01036a040; Mizuno et al. *J Org Chem* **28** 3329 *1963*, DOI: 10.1021/jo01047a012; *Beilstein* **26** IV 1117.] Antifungal that blocks purine biosynthesis.

Tunicamycin *[11089-65-9]* **$C_{39}H_{64}N_4O_{16}$, M ~780, m 234-235°(dec), $[\alpha]_D^{20}$ +52 (c 0.5, pyridine), pK_{Est} ~ 9.4.** The components of this homologous nucleoside antibiotic from *Streptomyces sp*. are purified by recrystallising 3 times from hot glass-distilled MeOH, and the white crystals are dissolved in 25% aqueous MeOH and separated on a Partisil ODS-10μ column (9.4 x 25 cm) [Magnum-9 Whatman] using a 260nm detector. The column is eluted with a MeOH/H_2O mixture adjusted to 1:4 (v/v) then to 2:4 (v/v). The individual components are recovered and lyophilised. Ten components have been isolated, and all were active (to varying extents) depending on the lengths of the aliphatic side-chains. The mixture has UV with λ_{max} at 205 and 260nm ($A_{1cm}^{1\%}$ 230 and 110). It is stable in H_2O at neutral pH but unstable in acidic solution. It inhibits protein glycosylation. [Mahoney & Duksin *J Biol Chem* **254** 6572 *1979*, PMID: 447736; Elbein *Trends Biochem Sci* **6** 219 *1981*, DOI: 10.1016/0968-0004(81)90080-3; for ***teichoic acid synthesis inhibition*** see Hashizume et al. *J Antibiot* **68** 373 *2015*, DOI:10.1038/ja.2014.169.]

Uracil, uridine and uridine nucleotides. These are resolved by ion-exchange chromatography with AG1 (Cl^- form). [Lindsay et al. *Anal Biochem* **24** 506 *1968*, DOI: 10.1016/0003-2697(68)90158-9.]

Uridine 5'-(1-thio) monophosphate *[15548-52-4, 18875-72-4 (Absolute Stereochemistry specified)]* **and Uridine 5'-(α-thio) diphosphate** *[RS(α-P) 27988-67-6; R(α-P) 72120-52-6]* **, $pK_{Est(1)}$~ 6.4, $pK_{Est(2)}$~ 9.5** The Et_3N salts are purified by dissolving ~4g in 500ml of H_2O (adding a drop or two of Et_3N if they do not dissolve) and chromatograph by applying to a column (3 x 30cm) of DEAE-Sephadex A-25 and eluting with 1.4L of a linear gradient of $Et_3NH.HCO_3$ from 0.05 to 0.55M, pH 7.8 and 4°. The product elutes between 0.2-0.3M $Et_3N.HCO_3$. The pooled fractions are evaporated, and the residue is twice taken up in EtOH and evaporated to dryness to remove the last traces of $Et_3NH.HCO_3$. ^{31}P NMR: P_α is a doublet at -40.81 and -40.33, and P_β at 7.02ppm, $J_{\alpha,\beta}$ 32.96Hz. [Sheu et al. *Biochemistry* **18** 5548 *1979*, DOI: 10.1021/bi00592a004.]

Uridylic acid (di-Na salt) *[27821-45-0, 3387-36-8, 58-97-9 free acid]* **$C_9H_{11}N_2O_9P$. 2Na M 368.2, m 198.5°, 202°(dec), pK_1^{25} 1.0, pK_2^{25} 6.63, pK_3^{25} 9.71.** Crystallise it from MeOH. It may contain some Ba salt(s); hence stir it with Amberlite IR-120 cation exchanger (25ml, wet resin, 15-50 mesh in H^+ form) in H_2O (50ml) until the nucleotide dissolves. Filter, wash resin with H_2O until the eluate is neutral. Combine the filtrate and washings, and adjust the pH to 8.0 with 2.0 M aqueous NaOH. Concentrate it *in vacuo* to ~ 20ml, and add Me_2CO dropwise until crystallisation begins. Cool to 0°, and the shiny plates of di ***Na uridine-5'-phosphate dihydrate*** are filtered off and dried over P_2O_5 at 25°/0.1mm for 24 hours (>76% recovery). Its solubility in H_2O at 20° is

40g/100ml. The UV has λ_{max} at 262nm (ε 10,000 $M^{-1}cm^{-1}$) in 0.1 M HCl. [Brown et al. *J Chem Soc* 408 *1950*, DOI: 10.1039/JR9500000403; Smith *Biochemical Preparations* **8** 130 *1960*.] [*Beilstein* **24** IV 1214.]

(+)-Usnic acid (2,6-diacetyl-7,9-dihydroxy-8,9b-dimethyldibenzofuran-1,3(2*H*,9b*H*)-dione) *[7562-61-0, 125-46-2]* **$C_{18}H_{16}O_7$, M 344.3, m 201-204°, 203-206°, $[\alpha]_{546}^{20}$ +630 (c 0.7, $CHCl_3$), $[\alpha]_D^{20}$ -488 (c 0.7, $CHCl_3$), pK_1 4.4, pK_2 8.8, pK_3 10.7.** This very weak acid is the natural form which is recrystallised from Me_2CO, MeOH or $*C_6H_6$. At 25° it is soluble in H_2O (<0.01%), Me_2CO (0.77%), EtOAc (0.88%), $MeOCH_2CH_2OH$ (0.22%), and furfural (7.32%). [Curd & Robertson *J Chem Soc* 894 *1937*, DOI: 10.1039/JR9370000894; Barton & Bruun *J Chem Soc* 603 *1953*, DOI: 10.1039/JR9530000603; resolution: Dean et al. *J Chem Soc* 1250 *1953*, DOI: 10.1039/JR9530001250; for synthesis see Barton et al. *J Chem Soc* 530 *1956*, DOI: 10.1039/JR9560000530; *Beilstein* **18/5** V 586.] It is a phytotoxic lichen metabolite. Optical and racemic isomers occur in lichens, andused in medicine, perfumery and cosmetics. The sodium salt (Lipokinetix) is claimed to induce weight loss and increase metabolic rate. For 'A review on usnic acid, an interesting natural compound' see Cocchietto et al. [*Naturwissenschaften* **89**(4) 137 *2002*, DOI: 10.1007/s00114-002-0305-3, ISSN 0028-1042].

(-)-Usnic acid (2,6-diacetyl-7,9-dihydroxy-8,9b-dimethyldibenzofuran-1,3(2*H*,9b*H*)-dione) *[6159-66-6, 7562-61-0]* **$C_{18}H_{16}O_7$, M 344.3, m 201-204°, 204°, $[\alpha]_D^{20}$ -495 (c 0.9, $CHCl_3$).** Its properties are similar to those of the acid in the preceding entry. [*Beilstein* **18** II 241, **18** III/IV 3522.] *Racemic* **(±)-usnic acid** *[125-46-2]* has **m 200°, 201-203°, 204°**.

Valinomycin (Potassium ionophore I) *[2001-95-8]* **$C_{54}H_{90}N_6O_{18}$, M 1111.3, m 172°, 186-187°, 190°, $[\alpha]_D^{20}$ +31.0 (c 1.6, $*C_6H_6$).** Recrystallise the cyclic dodecadepsipeptide valinomycin from dibutyl ether or Et_2O. It is ***dimorphic***: modification A crystallises from *n*-octane, and modification B crystallises from EtOH/H_2O. It is soluble in petroleum ether, $CHCl_3$, AcOH, BuOAc, Me_2CO and Me_2SO (~10mg/ml) but is insoluble in H_2O. [Smith et al. *J Am Chem Soc* **97** 7242 *1975*, DOI: 10.1021/ja00858a008; for UV, IR and NMR see Brockmann & Schmidt-Kastner *Chem Ber* **88** 57 *1955*, DOI: 10.1002/cber.19550880111; *Beilstein* **27** I 9728. **17** IV 9728.] For 'Interaction of valinomycin and monovalent cations, e.g. Li^+, Na^+, K^+, Cs^+, Rb^+, with the (Ca^{2+}, Mg^{2+})-ATPase of skeletal muscle sarcoplasmic reticulum' see Davidson & Berman *J Biol Chem* **260** 7325 *1985*, PMID: 3158656; and for 'The effects of the ionophore valinomycin on biomimetic solid supported lipid DPPTE/EPC membranes' see Rose & Jenkins [*Bioelectrochem* **70** 387 *2007*, DOI: 10.1016/j.bioelechem.2006.05.009].

(±)-Verapamil hydrochloride (5-[*N*-{3,4-dimethoxyphenylethyl}methylamino]-2-[3,4-dimethoxyphenyl]-2-isopropylvaleronitrile HCl) *[152-11-4, 23313-68-0]* **$C_{27}H_{38}N_2O_4$. HCl, M 491.1, m 138.5-140.5°, 142°(dec), pK_{Est} ~ 10.6.** The salt is purified by dissolving it in EtOH, filtering (if insoluble particles are present), and adding Et_2O, filtering the salt, washing it with Et_2O and drying it *in vacuo*. It has the following solubilities: hexane (0.001%), CH_2Cl_2 (~10%), MeOH (~10%), EtOH (20%) and H_2O (8.3%). It has UV with λ_{max} at 232 and 278nm. The ***free base*** *[52-53-9]* $C_{27}H_{38}N_2O_4$, M 454.6, is a viscous yellow oil **b 243-246°/0.01mm** (n_D^{25} 1.5448) and is almost insoluble in H_2O but soluble in organic solvents. Its biological half life is 2.8-7.4 hours. It is a Ca channel antagonist and is a coronary vasodilator; and is used for treating hypertension in cases of atrial fibrillation or other types of arrhythmia. Also used for controlling high blood pressure and angina. [Ramuz *Helv Chim Acta* **58** 2050 *1975*, DOI: 10.1002/hlca.19750580720; Harvey et al. *Biochem J* **257** 95 *1989*, DOI: 10.1042/bj2570095.]

Veratridine (3-veratroylveracevine) *[71-62-5]* **$C_{36}H_{51}NO_{11}$, M 673.8, m 160-180°, ~180° (after drying at 130°, pK 9.54 (quinolizidine N), $[\alpha]_D^{20}$ +8.0 (c ~5, EtOH).** It is an alkaloid neurotoxin which prevents inactivation of Na^+ channels. Its solubility in EtOH is ~5%; and it separates as a pale yellow powder from an ethanolic solution on addition of Et_2O. It forms nitrate, sulfate and perchlorate salts. [McKinney et al. *Anal Biochem* **153** 33 *1986*, DOI: 10.1016/0003-2697(86)90056-4; *Beilstein* **21** V/13 709.] It binds to activated Na^+ leading to nerve excitability.

Vinblastine sulfate (VLB, vincaleucoblastine sulfate) *[143-67-9]* **$C_{46}H_{58}N_4O_9$. H_2SO_4, M 909.5, m 284-285°(dec), 267°(dec), $[\alpha]_D^{26}$ -28 (MeOH), pK_1 5.5, pK_2 7.4.** Crystallise the sulfate from MeOH or EtOH and

dry it *in vacuo* over conc H_2SO_4. The ***free base*** crystallises from EtOH or MeOH **m** 211-216° (with 2MeOH and $1H_2O$) and forms a stable ***etherate*** from Et_2O with **m 201-211°**, and $[\alpha]_D^{25}$ +42 ($CHCl_3$); and its UV has λ_{max} at 214 and 259nm (log ε 4.73 and 4.21). The ***dihydrochloride*** has **m 244-246° dec** (MeOH). Store it at -20°. It is a ***monoamine oxidase B inhibitor*** and ***induces microtubule aggregation***, and is an ***antineoplastic*** drug for Hodgkin's lymphoma. [Neuss et al. *J Am Chem Soc* **81** 4754 *1959*, DOI: 10.1021/ja01526a086; Son et al. *J Med Chem* **33** 1845 *1990*, DOI: 10.1021/jm00169a002; Warfield & Bouck *Science* **186** 1219 *1974*, DOI: 10.1126/science. 186.4170.1219; *Beilstein* **26** III/IV 3167.]

Vincristine sulfate (22-oxovincaleucoblastine sulfate) *[2068-78-2]* **$C_{46}H_{56}N_4O_{10}\cdot H_2SO_4$, M 925.1, m 218-220°, $[\alpha]_D^{25}$ +26.2 (CH_2Cl_2), pK_1 5.0, pK_2 7.4 (in 33% Me_2NCHO/H_2O).** The salt is recrystallised from MeOH. It has UV with λ_{max} at 220, 255 and 296nm (log ε 4.65, 4.21 and 4.18). Store it at -20°. It is a ***monoamine oxidase inhibitor*** and is used in cancer research [Son et al. *J Med Chem* **33** 1845 *1990*, DOI: 10.1021/jm00169a002; Horio et al. *Proc Natl Acad Sci USA* **85** 3580 *1988*, PMID: 3368466]. Viomycin sulfate (Viocin, Tuberactinomycin B) *[37883-00-4]* **$C_{23}H_{46}N_6O_{13}\cdot 2.5H_2SO_4$, M 614.7, 685.7, m 266°(dec), $[\alpha]_D^{17}$ -29.5 (c 1, H_2O), pK_1 7.2 (8.2), pK_2 10.3.** The aminoglycoside antibiotic viocin crystallises from H_2O/EtOH and is dried in a vacuum. The dry material is ***hygroscopic*** and should be stored dry. The UV has λ_{max} at 268 and 285nm (log ε 4.4 and 4.2) in H_2O. [Kitigawa et al. *Chem Pharm Bull Jpn* **20** 2176 *1972*, DOI: org/10.1248/cpb.20.2176.] The ***hydrochloride*** forms ***hygroscopic*** plates with **m 270° dec**, and $[\alpha]_D^{18}$ -16.6 (c 1, H_2O), with λ_{max} at 268nm (log ε 4.5) in H_2O; 268nm (log ε 4.4) in 0.1N HCl and at 285nm (log ε 4.3) in 0.1N NaOH. [*Beilstein* **26** III/IV 4245.] Antibiotic used in topical medications like ointments, creams and eyedrops.

Vitamin A acetate (retinyl acetate) *[127-47-9]* **$C_{22}H_{32}O_2$, M 328.5, m 57°, 57-58°.** The acetate is separated from retinol by column chromatography, then crystallised from MeOH. [Kofler and Rubin *Vitamins and Hormones (NY)* **18** 315 *1960*, DOI: 10.1016/S0083-6729(08)60867-5; for purification methods]. Store it in the dark, under N_2 or argon, at 0°. [*Beilstein* **6** IV 4135.]

Vitamin A acid [Retinoic acid, 3,7-dimethyl-9-(2,6,6-trimethyl-1-cyclohexenyl)-2,4,6,8-nonatetraen-1-oic acid, (2E,4E,6E,8E)-3,7-dimethyl-9-(2,6,6-trimethylcyclohexen-1-yl)nona-2,4,6,8-tetraenoic acid] *[302-79-4]* **$C_{20}H_{28}O_2$, M 300.4, m 180-181°, 180-182°, pK_{Est} ~ 4.2.** Purify the acid by chromatography on silicic acid columns, and eluting it with a small amount of EtOH in hexane. Also dissolve it in Et_2O, wash it with H_2O, dry (Na_2SO_4), evaporate and the solid residue is recrystallised from MeOH (0.53g /3.5ml MeOH to give 0.14g) or EtOH. It also recrystallises from *i*-PrOH, or as the ***methyl ester*** from MeOH. Its UV(MeOH) has λ_{max} at 351nm (ε 45,000). ***9-Cis-acid*** forms yellow needles from EtOH, with **m 189-190°**, and its UV(MeOH) has λ_{max} at 343nm (ε 36,500); the ***13-cis-acid*** forms red-orange plates from *i*-PrOH with **m 174-175°**, and its UV has λ_{max} at 345nm (ε 39,800). Store it in the dark, in an inert atmosphere, at 0° [Robeson et al. *J Am Chem Soc* **77** 4111 *1955*, DOI: 10.1021/ja01620a043]. [*Beilstein* **9** IV 2387.]

Vitamin A alcohol (retinol) *[68-26-8]* **$C_{20}H_{30}O$, M 286.5, m 62-64°, $A_{1cm}^{1\%}$ (max) (*all-trans*) 1, 832 (325 nm), (*13-cis*) 1686 (328nm), (*11-cis*) 1230 319 nm), (*9-cis*) 1480 (323 nm), (*9,13-di-cis*) 1379 (324 nm), (*11,13-di-cis*) 908 (311 nm) in EtOH.** Purify retinol by chromatography on columns of water-deactivated alumina and elute with 3-5% acetone in hexane. Separate the isomers by TLC plates on silica gel G, developed with petroleum ether (low boiling)/methyl heptanone (11:2). Store it in the dark, under N_2, at 0°, or in Et_2O, Me_2CO or EtOAc. [See Ganguly et al. *Arch Biochem Biophys* **38 2**75 *1952*, DOI: 10.1016/0003-9861(52)90032-5; *Beilstein* **6** IV 4133.]

Vitamin A aldehyde [all-*trans*-retinal; 3,7-dimethyl-9-(2,6,6-trimethyl-1-cyclohexenyl)-2,4,6,8-nonatetraen-1-al] *[116-31-4]* **$C_{20}H_{28}O$, M 284.4, m 61-64°.** The aldehyde is separated from retinol by column chromatography on water-deactivated alumina. Elute with 1-2% acetone in hexane, or on TLC plates of silica gel G and using the same eluting solvent. It crystallises from petroleum ether or *n*-hexane as yellow-orange crystals, and the UV in hexane has λ_{max} at 373nm ($A_{1cm}^{1\%}$ 1,548) and 368nm (ε 48,000). It is an **irritant** and is light sensitive. Store it in sealed ampoules under N_2. The ***semicarbazone*** forms yellow crystals from

$CHCl_3/Et_2O$ or EtOH, **m 199-201° dec**. The **9-*cis-isomer*** *[514-85-2]* and the **13-*cis-isomer*** *[472-86-6]* [λ_{max} at 375nm (ε 1,250) in EtOH] are also available commercially. [*Beilstein* **7** III 1742.]

Vitamin A palmitate (retinyl palmitate) *[79-81-2]* **$C_{36}H_{60}O_2$, M 524.9, m 28-29°, $\varepsilon\ ^{1\%}_{1cm}$(all – trans) 1000 (325 nm) in EtOH.** The palmitate is separated from retinol by column chromatography on water-deactivated alumina with hexane containing a very small percentage of acetone. It is also chromatographed on TLC silica gel G, and developed with pet. ether/isopropyl ether/acetic acid/water (180:20:2:5) or petroleum ether/acetonitrile/acetic acid/water (190:10:1:15). Then recrystallize it from propylene at below -47°. [*Beilstein* **6** IV 4135.]

Vitamin B_1 Hydrochloride [Aneurine hydrochloride, Thiamine hydrochloride, 3{(4-amino-2-methyl-5-pyrimidinyl)methyl}-4-methylthiazolium chloride monohydrochloride] *[67-03-8, 59-43-8 chloride]* **$C_{12}H_{17}ClN_4OS$. HCl, M 337.3, m 248°(dec), 249-250°, monohydrate m 135°(dec), pK_1^{25} 4.8, pK_2^{25} 9.2.** The hydrochloride crystallises from 95% EtOH (solubility is *ca* 1%). The ***monohydrate*** is dehydrated at 100° *in vacuo* over H_2SO_4, but is ***hygroscopic*** and picking up one H_2O readily. It can be sterilised at 100° if the pH is below 5.5. The ***nitrate*** has **m 196-200° (dec)** and is more stable than the hydrochloride. The ***picrolonate*** crystallises from H_2O and is ***dimorphic***, **m 164-165°** and **228-229°(dec)**. [Todd & Bergel *J Chem Soc* 364, 367 *1937*, DOI: 10.1039/JR9370000364; Williams et al. *J Am Chem Soc* **58** 1063 *1936*, DOI: 10.1021/ja01297a515; 1504 *1936*, DOI: 10.1021/ja01299a505; **59** 526 *1937*, DOI: 10.1021/ja01282a028; *Beilstein* **27** IV 1766.]

Vitamin B_2 [Riboflavin, Lactoflavin, 6,7-dimethyl-9-(D-1'-ribityl)isoalloxazine] *[83-88-5]* **$C_{17}H_{20}N_4O_6$, M 376.4, m 278-282°(dec with darkening at 240°), 281-282°, $[\alpha]_D^{25}$ -9.8 (H_2O), $[\alpha]_D^{25}$ -112 to -125 (c 2.5, 0.02N NaOH), $[\alpha]_D^{20}$ -59 (c 0.23, AcOH), pK_1 1.7, pK_2 9.69 (10.2, acidic NH).** It crystallises from H_2O as a yellow-orange powder in three different forms with differing amounts of H_2O. It melts if placed in an oil bath at 250°, but decomposes at 280° if heated at a rate of 5°/minute. It is also purified by crystallisation from 2M acetic acid, then extracted with $CHCl_3$ to remove lumichrome impurity. [Smith & Metzler *J Am Chem Soc* **85** 3285 *1963*, DOI: 10.1021/ja00903a051.] Its solubility in H_2O is 1g in 3-15L depending on the crystal structure. Its solubility in EtOH at 25° is 4.5mg in 100ml. Store it in the dark because it is decomposed to lumichrome by UV light. [Pearson *The Vitamins* **vol V** pp1-96 *1967*, **vol VII** pp 1-96 *1972*, Academic Press, *Beilstein* **26** IV 2542.]

Vitamin B_3 (Nicotinamide, Niacin, vitamin PP) *[98-92-0]* **$C_6H_6N_2O$, M 122.1, m 128-131°, b ~150-160°/high vac, pK_1^{25} 0.5, pK_2^{25} 3.33.** Crystallise niacin from *benzene. Its solubility in g/ml is H_2O (1), EtOH (0.7) and glycerol (0.1). [*Methods in Enzymology* **66** 23 *1980*, UV: Armarego *Physical Methods in Heterocyclic Chemistry* (Ed Katritzky, Academic Press) **Vol III** 83 *1971*, *Beilstein* **22** III/IV 389, **22/2** V 80.]

Vitamin B_6 hydrochloride (adermine, pyridoxine HCl, 3-hydroxy-4,5-bis[hydroxymethyl]-2-methylpyridine HCl) *[58-56-0]* **$C_8H_{11}NO_3$. HCl, M 205.6, m 208-208.5°, 208-209°(dec), 209-210°(dec), 205-212° (sublimes), 214-215°, pK_1^{25} 5.0 (3-OH), pK_2^{25} 8.96 (pyridinium$^+$).** Purify the vitamin by recrystallisation from EtOH/Me_2CO, *n*-BuOH or MeOH/Et_2O. Its solubility in H_2O is 22%, and in EtOH it is 1.1%. It is insoluble in Et_2O and $CHCl_3$. Acidic aqueous solutions are stable at 120°/30minute. The ***free base*** *[65-23-6]* **$C_8H_{11}NO_3$, M 168.2,** has **m 159-160°** after recrystallisation from Me_2CO and sublimation at 140-145°/0.0001mm. It has UV with λ_{max} at 290nm (ε 84,000), 253 and 325nm (ε 3,700 and 7,100) in 0.1N aqueous HCl. [Khun & Wendt *Chem Ber* **71** 780 *1938,* DOI: 10.1002/cber.19380710415; **72** 311 *1939,* DOI: 10.1002/cber.19390720214; Harris et al. *J Am Chem Soc* **61** 1242 *1939*, DOI: 10.1021/ja01874a068; **62** 3198 *1940*, DOI: 10.1021/ja01868a086; *Beilstein* **21/5** V 492.] See also **Pyridoxal-5'-phosphate H_2O** above.

Vitamin B_7 [Levocarnitine, carnitine, α-hydroxy-β-*N*,*N*,*N*-trimethylaminopropionic acid) *[R(+) 541-14-0, S*(L-*) 541-15-1, RS 461-06-3]* **$C_7H_{15}NO_3$, M 161.2, m *R* or *S isomer* 197-198°(dec), 210-212°(dec), *RS isomer* 195-197°, $[\alpha]_{546}^{20}$ (+) and (-) 36 (c 10, H_2O), pK^{25} 3.6.** The *S*(L) isomer is **levocarnitine**, the vitamin. The *R* or *S* isomers crystallise from EtOH/Me_2CO (***hygroscopic***). The ***R* or *S hydrochlorides*** crystallise from hot EtOH or EtOH/Et_2O and have **m 142°(dec)**. The ***racemate*** crystallises from hot EtOH (***hygroscopic***), and its ***hydrochloride*** crystallises in needles from hot EtOH and has **m 196°(dec)**. [For racemate see Mazzetti & Lemmon *J Org Chem* **22** 228 *1957*, DOI: 10.1021/jo01353a606; *Beilstein* **4** H 513, **4** I 548, **4** II 937-8, **4** III 1632-5, **4** IV 3185.] It is a nutrient involved in lipid metabolism [see Steiber et al. 'carnitine perspectives' *Mol Aspects Med* **25**(5–6) 455 *2004*, DOI: 10.1016/ j.mam.2004.06.006, PMID: 15363636].

Vitamin B_{12} (cyanocobalamine, α-[5,6-dimethylbenzimidazolyl]cobamidcyanide) *[68-19-9]* **$C_{63}H_{88}CoN_{14}O_{14}P$. M 1355.4, m darkens at 210-220° and does not melt below 300°, $[\alpha]_{656}^{23}$ -59 (H_2O).** Vitamin B_{12} crystallises from de-ionised H_2O, with a solubility in H_2O of 1g/80g, and is dried under vacuum over $Mg(ClO_4)_2$. The dry red crystals are ***hygroscopic*** and can absorb ~12% of H_2O. A solution at pH 4.5-5 can be autoclaved for 20 minutes at 120° without decomposition. Aqueous solutions are stabilised by addition of $(NH_4)_2SO_4$. [Golding *Comprehensive Organic Chem* Vol **5** (Ed. Haslam; Pergamon Press, NY, *1979*) pp 549-584.]

Alternatively, an aqueous solution of the coenzyme can be concentrated, if necessary in a vacuum at 25° or less, until the concentration is 0.005 to 0.01M (as estimated by the OD at 522nm of an aliquot diluted with 0.01M K-phosphate buffer pH 7.0). If crystals begin to form on the walls of the container, they should be re-dissolved with a little H_2O. The concentrated solution is placed in a glass stoppered flask and diluted with 5 volumes of Me_2CO. After 2-3 hours at 3° it is centrifuged (10,000xg/10minutes) in Me_2CO-insoluble plastic tubes to remove some amorphous precipitate. The clear supernatant is inoculated with a small crystal of the vitamin and allowed to crystallise overnight at 3°. Crystals are formed on the walls and the bottom of the container. A further 2 volumes of Me_2CO are added and set aside at 3° to further crystallise. Crystallisation is followed by observing the OD_{522} of the supernatant. When the OD falls to 0.27, then *ca* 94% of the crystals have separated. The supernatant is decanted (saved for obtaining a second crop), and the crystals are washed with a little cold 90% aqueous Me_2CO (2x), 100% Me_2CO (2x), Et_2O (2x) at which time the crystals separate from the glass walls. Allow them to settle and remove residual Et_2O with a stream of dry N_2. The process can be repeated if necessary. The crystals can be dried in air or in a vacuum for 2 hours over silica gel at 100° with an 8-9% weight loss. [Barker et al. *Biochemical Preparations* **10** 33 *1963*.] This material gives a single spot on paper chromatography [see Weissbach et al. *J Biol Chem* **235** 1462 *1960*, PMID: 13843764.] The vitamin is soluble in H_2O (16.4mM at 24°, 6.4mM at 1°), in EtOH and PhOH but insoluble in Me_2CO, Et_2O, CH_2Cl_2 and dioxane. Its UV has λ_{max} at 260, 375 and 522nm (ε 34.7 x 10^6, 10.9 x 10^6 and 8.0 x 10^6 /mole) in H_2O. The dry crystals are stable for months in the dark, but aqueous solutions decompose on exposure to VIS or UV light or alkaline CN^-, but are stable in the dark at pH 6-7. The vitamin is inactivated by strong acids or alkalies. It is an essential cofactor for various enzymes, and deficiency leads to ***pernicious anaemia***, hence its use as a food supplement. Its biological half life is ~6 days (400 days in the liver) and it is excreted *via* the kidneys. [Barker et al. *J Biol Chem* **235** 480 *1960*, PMID: 13796809; see also *Vitamin B_{12}* (Zagalak & Friedrich Eds) Walter de Gruyter, Berlin *1979*, ISBN 10: 3110076683, ISBN 13: 9783110076684; for the publication series 'Corrin Synthesis—Parts I to IV' which include the A. Eschenmoser and R.B. Woodward synthesis of *Vitamin B_{12}* see Eschenmoser et al. *Helv Chim Acta* **98** 1475 *2015*, DOI: 10.1002/hlca.201400399, and subsequent papers; *Beilstein* **26** IV 3117.]

Vitamin C See ascorbic acid entry in 'Carbohydrates' in this Chapter.

Vitamin D_2 (ergocalciferol) *[50-14-6]* **$C_{28}H_{44}O$, M 396.7, m 114-116°, 114-118°, $[\alpha]_{546}^{20}$ +122 (c 4, EtOH)** It is converted into its 3,5-dinitrobenzoyl ester and crystallised repeatedly from acetone. The ester is then saponified and the free vitamin is isolated. [Laughland & Phillips *Anal Chem* **28** 817 *1956*, DOI: 10.1021/ac60113a012; *Beilstein* **6** IV 4404.] A secosteroid which enhances intestinal absorption of Ca, Fe, Mg, Zn and phosphate in humans.

Vitamin D_3 (cholecalciferol, Calcitol, activated 7-dehydrocholesterol, (+)-vitamin D_3) *[67-97-0]* **$C_{27}H_{44}O$, M 384.6, m 83-85°, 83-86°, $[\alpha]_{546}^{20}$ +126 (c 2, EtOH).** It is converted into its 3,5-dinitrobenzoyl ester and crystallised repeatedly from acetone. The ester is then saponified and the free vitamin is isolated. Store it in sealed ampoules under argon below 8°. It acts through a receptor which modulates differentiation and proliferation of normal and neoplastic cells. [Laughland & Phillips *Anal Chem* **28** 817 *1956*, DOI: 10.1021/ac60113a012; DeLuca & Schnoes *Ann Rev Biochem* **52** 411 *1983*, DOI: 10.1146/annurev.bi.52.070183.002211; *Beilstein* **6** III 2811, **6** IV 4149.]

Vitamin E (2*R*,4'*R*,8'*R*-α-tocopherol, natural active isomer) *[59-02-9]* **$C_{29}H_{50}O_2$, M 430.7, m 2.5-3.5°, b 200-220°/0.1mm, 200°/0.005mm, d_4^{25} 0.950, n_D^{25} 1.5045, $[\alpha]_D^{25}$ +3.58 (c 1, *C_6H_6).** Vitamin E is a viscous yellow oil which is distilled at high vacuum. It has λ_{max} at 294nm ($E_{1cm}^{1\%}$ 71). It is oxygen and light sensitive and is best stored as its stable ***D-α-acetate*** *[58-95-7]* which is purified by evaporative distillation at **b 180-200°**

(bath temperature)/0.7mm, and has $[\alpha]_D^{25}$ +3.3 (c 5.1, EtOH). It forms needles at -30° and has **m** 26.5-27.5°, and $[\alpha]_D^{25}$ +0.25 (c 10, $CHCl_3$). [For NMR see Cohen et al. *Helv Chim Acta* **64** 1158 *1981*, DOI: 10.1002/hlca.19810640422; Burton & Ingold *Acc Chem Res* **19** 194 *1986*, DOI: 10.1021/ar00127a001; Karrer et al. *Helv Chim Acta* **21** 520 *1938* DOI: 10.1002/hlca.19380210173; Robeson *J Am Chem Soc,* **64** 1487 *1942*, DOI: 10.1021/ja01258a507; **65** 1660 *1943*, DOI: 10.1021/ja01248a510.] Of the ***eight isomers*** the D-α-isomer is the most active. [See W. Friedrich 'Vitamins' Walter de Guyter Publ, Berlin 1988.] [*Beilstein* **17/4** V 168.] ***(±)-α-Tocopherol*** *[10191-41-0],* which is a mixture of ***four racemates***, is a thick oil with **b 200-220°/0.1mm**, **d** $_4^{25}$ **0.950, n** $_D^{25}$ **1.5045,** and λ_{max} at 294nm ($E_{1cm}^{1\%}$ 71) see above. Store in the dark below 10°. Tocopherols generally are freely soluble in most organic solvents, insoluble in H_2O; and in the absence of oxygen are stable to heat alkali and acids (<100°), but are sensitive to light and traces of metal salts (e.g. Fe, Ag) in air.

DL-Vitamin E acetate (DL-α-tocopheryl acetate) *[7695-91-2]* **$C_{31}H_{52}O_3$, M 472.8, m -27.5°, b 194-196°/0.01mm, 222-224°/0.3mm, d** $_4^{20}$ **0.958g/ml, n** $_D^{20}$ **1.4958.** It is a viscous liquid which is purified by distillation under high vacuum under N_2 or argon, and stored in sealed ampoules in the dark. It is considerably more stable to light and air than the parent unacetylated vitamin. It is insoluble in H_2O but freely soluble in organic solvents. All ***eight stereoisomers*** have been synthesised. The commercially pure ***d-α–tocopheryl acetate (2R,4'R,8'R)*** has **b 180-200°/0.7mm** and $[\alpha]_D^{20}$ +3.9 (c 5, EtOH); see above. [Cohen et al. *Helv Chim Acta* **64** 1158 *1981*, DOI: 10.1002/hlca.19810640422; *Beilstein* **17/4** V 169.]

Vitamin K_1 (2-methyl-3-phytyl-1,4-naphthoquinone) *[84-80-0]* **$C_{31}H_{46}O_2$, M 450.7, m -20°, b 141-140/0.001mm, b 140-145°/10^{-3} mm, d** $_{25}^{25}$ **0.967, n** $_D^{25}$ **1.527, $[\alpha]_D^{20}$ -0.4 (c 57.5, *C_6H_6).** Vitamin K_1 is a yellow viscous oil, which can be distilled at high vacuum practically unchanged. It is insoluble in H_2O, but soluble in common organic solvents. Store it in the dark under N_2 as it is oxygen sensitive. It has $A_{1cm}^{1\%}$ 328 at 248nm. [Fieser et al. *J Am Chem Soc* **61** 2559 *1939*, DOI: 10.1021/ja01878a514; DOI: 10.1021/ja01878a515; Hirschmann et al. *J Am Chem Soc* **76** 4592 *1954*, DOI: 10.1021/ja01647a026; Isler & Doebel *Helv Chim Acta* **37** 225 *1954*, DOI: 10.1002/hlca.19540370128; *Beilstein* **7** IV 2496.]

Vitamin K_3 (2-methyl-1,4-naphthoquinone, Menadione, Menaphthone) *[58-27-5]* **$C_{11}H_8O_2$, M 172.2, m 105-106°, 105-107°.** Recrystallise it from 95% EtOH, or MeOH after filtration. It forms bright yellow crystals which are decomposed by light. Its solubility in EtOH is 1.7% and in *C_6H_6 it is 10%. It **IRRITATES** mucous membranes and skin. [Fieser *J Biol Chem* **133** 391 *1940*, http://www.jbc.org/content/133/2/391; *Beilstein* **7** IV 2430.]

Vitamin K_5 (4-Amino-2-methyl-1-naphthol hydrochloride) *[130-24-5]* **$C_{11}H_{12}NO$. HCl, M 209.6, m 283°(dec), $pK_{Est(1)}$ ~5.6 (NH_2), $pK_{Est(2)}$ ~10.4 (OH).** Crystallise it from dilute HCl. [Sah *Recl Trav Chim Pays-Bas* **59** 454 *1940*, DOI: 10.1002/recl.19400590505; Sah *Recl Trav Chim Pays-Bas* **60** 373 *1941*, DOI: 10.1002/recl.19410600509; Veldstra & Wiardi *Recl Trav Chim Pays-Bas* **61** 547 *1942*, Veldstra & Wiardi *Recl Trav Chim Pays-Bas* **62** 75 *1943*, DOI: 10.1002/recl.19430620203; *Beilstein* **13** III 1921.]

Vitamin P [(+)-Quinacr, quercetin-3-rubinoside, 2-(3,4-dihydroxyphenyl)-5,7-dihydroxy-3-[α-L-rhamno-pyranosyl-(1→6)-β-D-glucopyranosyloxy]-4*H*-chromen-4-one, (+)-Rutin] *[153-18-4]* **$C_{27}H_{30}O_{16}$, M 610.5, 664.5 (trihydrate), m 188-189°, 195-196°, 242° (anhydrous?) $[\alpha]_{546}^{20}$ +13 (c 5, EtOH), $[\alpha]_D^{24}$ -37.6 (c 1.24, pyridine), (polyphenolic flavone pKs 7—10).** The vitamin crystallises from MeOH or water/EtOH, dry it in air, then dry it further for several hours at 110° or in high vacuum at 120°. It forms yellow crystals from EtOH/Me_2CO/H_2O (2:1:1). Its solubility in H_2O is 13mg/100ml (25°). It has also been purified by passing (0.5g) through a Kieselgel column (30 x 5cm) with EtOAc/MeOH/H_2O (100:20:15), and after 750ml have passed through, the yellow fraction of 250ml gives the glycoside (0.3g) on evaporation. [Hörhammer et al. *Chem Ber* **101** 1183 *1968*, DOI: 10.1002/cber.19681010407; Marini-Bettòlo *Gazz Chim Ital* **80** 631 *1950*, *Beilstein* **18/5** V 519.] Rutin has antioxidant and antibacterial properties.

Vitamin U (S-Methyl-L-methionine chloride) *[S- 1115-84-0, S-ion- 6708-35-6 and 4727-40-6, RS- 44901-24-8]* **$C_6H_{15}NO_2S$. Cl, M 199.5, 164.3 (ion), m 135° (dec), 139° (dec), $[\alpha]_D^{23}$ +33 (0.2M HCl), pK_1 1.9, pK_2 7.9.** Likely impurities are methionine, methionine sulfoxide and methionine sulfone. Crystallise Vitamin U from water by adding a large excess of EtOH. It is ***hygroscopic***. It should be stored in a cool, dry place and protected

from light. It has also been purified on a column of Dowex 50 H^+ form, washed with H_2O and eluted with 6N ammonia, lyophilised, the residue is dissolved in dilute HCl, lyophilised again and then it is obtained as colourless prisms by vapour diffusion of Et_2O in a 1:1 (v/v) mixture of MeOH/EtOH in which the ***hydrochloride*** is dissolved [Del Re *Acta Cryst B* **33** 3289 *1977*, DOI: 10.1107/S0567740877010887]. The ***iodide salt***, **m ~150°(dec)**, is obtained by dissolving it in 50% aqueous EtOH and adding ~3.5 volumes of absolute EtOH. The ***bromide salt*** has **m 140°(dec)** [Toennies & Kolb *J Am Chem Soc* **67** 849 *1945*, DOI: 10.1021/ja01221a046]. It is a ***biological methylating agent***. For 'Anti-peptic ulcer dietary factor (vitamin 'U') in the treatment of peptic ulcer' see Cheney [*J Am Diet Assoc* **26**(9) 668 *1950*, PMID: 15436263].

dl-Warfarin (Coumafene, 4-hydroxy-3-(3-oxo-1-phenylbutyl)-2*H*-1-benzopyran-2-one) *[81-81-2]* $C_{19}H_{16}O_4$, M 308.3, m 162-164°, pK^{20} 4.85 (the 4-mercapto derivative has pK^{20} 6.60).

dl-Warfarin crystallises from EtOH or MeOH. Its UV has λ_{max} at 308nm (ε 13,610) in H_2O. The ***acetate*** has **m 117-118°**, the ***O-triflate*** has **m 90-91°**, and the ***2,4-dinitrophenylhydrazone*** has **m 215-216°**. [West et al. *J Am Chem Soc* **83** 2676 *1961*, DOI: 10.1021/ja01473a020; HPLC: Banfield & Rowland *J Pharm Sci* **72** 921 *1983*, DOI: 10.1002/jps.2600720820; *Beilstein* **17** III/IV 6794.]

R*-(+)-Warfarin** has **m 170-171°, $[\alpha]_D^{23}$ +149 (c 1.2, in 0.5N NaOH), +25.5 (c 2, AcOH), +15.5 (c 2, MeCN) and -19 (c 1.1, propan-2-ol),** and ***S*-(-)-Warfarin (*more active enantiomer*)** has **m 172-173°, $C_{19}H_{16}O_4$, M 308.3, $[\alpha]_D^{23}$ -148 (c 1.2, in 0.5N NaOH), -25.5 (c 2, AcOH), -15.5 (c 2, MeCN) and +19 (c 1.1, propan-2-ol).** *dl*-Warfarin is ***optically resolved *via* recrystallisation of the ***quinidine salt***, and the ***free acids*** are recrystallised (70g) from 600ml of 80% aqueous Me_2CO. Large prismatic crystals of the pure enantiomers are obtained by slow crystallisation from Me_2CO or AcOH. The solubilities of the pure enantiomers at 25° are 11.2% in Me_2CO and 2.6% in AcOH, whereas the racemate has solubilities of 6.5% in Me_2CO and 2% in AcOH. The IR spectra are the same with ν_{max} ($CHCl_3$) at 2.78 (w), 5.88, 6.16 and 6.38μ. [West et al. *J Am Chem Soc* **83** 2676 *1961*, DOI: 10.1021/ja01473a020; Cbz-proline diastereoisomeric esters were used for HPLC analysis: Banfield & Rowland *J Pharm Sci* **72** 921 *1983,* DOI: 10.1002/jps.2600720820.] Although both enantiomers produce anticoagulant results, the ***S-enamtiomer*** is 2-5 times ***more potent*** than the *R-enantiomer*, but they are cleared differently because the metabolite of the former is the 7-OH derivative, whereas the 10-OH metabolite is cleared from *R-warfarin*. For 'Foundation guide to warfarin therapy' see Hirsch et al. *J Am Coll Cardiol* **41**(9) 1633 *2003*, DOI: 10.1016/S0735-1097(03)00416-9, PMID: 12742309; and for metabolites see Naveed et al. *J Chromatogr B* **1008**(1) 164–173 *2016*, DOI: 10.1016/j.jchromb.2015.11.036. They are effective ***anticoagulants*** and ***rodenticides***.

Xanthopterin monohydrate (2-amino-4,6-dihydroxypteridine, 2-aminopteridin-4,6(1*H*,5*H*)-dione) *[5979-01-1 (H_2O), 119-48-8 (anhydrous)]* $C_6H_5N_5O_2.H_2O$, M 197.2, m <300°, pK_1 1.6 (basic), pK_2 6.59 (acidic), pK_3 9.31 (acidic)(anhydrous species), and pK_1 1.6 (basic), pK_2 8.65 (acidic), pK_3 9.99 (acidic)(7,8-hydrated species).

Purification is as for isoxanthopterin (see *[529-69-1]* 'Heterocyclic Compounds', Chapter 3). It is crystallised by acidifying a hot ammoniacal solution with formic acid, and collecting the crystals by centrifugation followed by washing with EtOH, ether and drying at 100° *in vacuo*. Its R_F values on paper chromatography are 0.15 (*n*-PrOH, 1% aqueous NH_3, 2:1), 0.36 (*n*-BuOH/AcOH/H_2O, 4:1:1) and 0.47 (3% aqueous NH_3). [Inoue & Perrin *J Chem Soc* 2600 *1962*, DOI: 10.1039/JR9620002600; Inoue *Tetrahedron* **20** 243 *1964*, DOI: 10.1016/S0040-4020(01)93212-0; see also Blakley *Biochemistry of Folic Acid and Related Pteridines* North Holland Publ Co, Amsterdam 1969, ISSN 0071-965X; *Beilstein* **26** II 313, **26** III/IV 4000.] It is a urinary metabolite as a marker of malignant disease [for 'Altered urinary excretion of pteridines in neoplastic disease. Determination of biopterin, neopterin, xanthopterin, and pterin' see Rokos et al. *J Clin Chim Acta* **105** 275 *1980*, DOI: 10.1016/0009-8981(80)90470-2].

Xanthotoxin (Methoxalen, 9-methoxypsoralen, Ammoidin, 9-methoxyfuro[3,2-g][1]benzopyran-7-one) *[298-81-7]* $C_{12}H_8O_4$, M 216.2, m 146-148°, 148°, 148-149°, 148-150°. Purify xanthotoxin by recrystallisation from *C_6H_6/petroleum ether (b 60-80°) to give silky needles, or from EtOH/Et_2O to give rhombic prisms or from hot H_2O to give needles. It is soluble in aqueous alkali due to ring opening of the cyclic lactone but recyclises upon acidification. It has UV with λ_{max} (EtOH) at 219, 249 and 300nm (log ε 4.32, 4.35 and 4.06) and ^1H NMR in $CDCl_3$ with δ at 7.76 (d, 1H, *J* = 10Hz), 7.71 (d, 1H, *J* = 2.5Hz), 7.38 (s, 1H), 6.84 (d, 1H, *J* = 2.5Hz), 6.39 (d, 1H, *J* = 10Hz) and 4.28 (s, 3H). [Nore & Honkanen *J Heterocycl Chem* **17** 985 *1980*, DOI:

10.1002/jhet.5570170527.] It is a ***DNA intercalator***, is used in the treatment of dermal diseases, and is a ***human carcinogen*** [Tessman et al. *Biochemistry* **24** 1669 1985, DOI: 10.1021/bi00328a015.] [*Beilstein* **19** I 711, **19/6** V 15.] The drug has been used for the treatment of eczema, psoriasis, vitiligo and cutaneous lymphomas.

Zeatin **(*trans*-N^6-[4-hydroxy-3-methylbut-2-en-1-yl]adenine)** *[1637-39-4]* **$C_{10}H_{13}N_5O$, M 219.3, m 207-208°, 209-209.5°, 208-210°, pK_1 4.4 (basic), pK_2 9.8 (acidic).** Purify zeatin by recrystallisation from EtOH or H_2O. Its UV has λ_{max} at 207 and 275nm (ε 1,400 and 14,650) in 0.1N aqueous HCl; 212 and 270nm (ε 17,050 and 16,150) in aqueous buffer pH 7.2; and 220 and 276nm (ε 15,900 and 14,650) in 0.1N aqueous NaOH. The ***picrate*** has **m 192-194°** (from H_2O) from which zeatin can be recovered by treatment with Dowex-1 x 8 (200-400 mesh, OH^- form). Zeatin was isolated from sweet corn kernels (1mg from 70g of corn). It was synthesised from 6-mercaptopurine [see *154-42-7*] and *trans*-4-hydroxy-3-methyl-2-buten-1-ylamine at 134° overnight followed by isolation as the ***picrate*** **m 180-190°**, and liberating the ***free base*** *Zeatin* by passing an aqueous solution through an analytical Dowex 1x8 (200-400 mesh) column in the OH^- form. The *trans*-buten-1-ylamine was prepared from reaction of methyl γ-bromotiglate [Ratney & English *J Org Chem* **25** 2213 *1960*, DOI: 10.1021/jo01082a600; Inhoffen et al. *Justus Liebigs Ann Chem* **580** 7 *1953*, DOI: 10.1002/jlac.19535800103] and NaN_3 in MeCN followed by reduction of the resulting methyl γ-azidotiglate (b 52-54°/0.2mm, ν 2100cm^{-1} for $-N_3$) with $LiAlH_4$. With acetic anhydride in dry pyridine (shaking for 30 minutes to give a clear solution then overnight at ~25°), and the isolated ***mono-O-acetylzeatin*** has **m 168-169°** (needles) after recrystallisation from H_2O. It has strong IR bands at ν 1740 and 1240cm^{-1}. [For isolation and characterisation see: Letham et al. *Aust J Chem* **22** 205 *1969*, DOI: 10.1071/CH9690205; Letham et al. *Proc Chem Soc* p.230 (in **notes** starting on p.201) *1964*, DOI: 10.1039/PS9640000201; for synthesis see Shaw & Wilson *Proc Chem Soc* p.231 (in **notes** starting on p.201) *1964*, DOI: 10.1039/PS9640000201, and Shaw et al. *J Chem Soc* (C) 921 *1966*, DOI: 10.1039/J39660000921.]
It is a cell division factor (***plant growth regulator***) [Letham & Palni *Ann Rev Plant Physiol* **34** 163 *1983*, DOI: 10.1146/annurev.pp.34.060183.001115] and ***inhibits mitochondrial function*** [Miller *Plant Physiol* **69** 1274 *1982*, DOI: 10.1104/pp.69.6.1274]. **Trans-*Zeatin hydrochloride*** *[6025-81-6]* **$C_{10}H_{13}N_5O$. HCl,** M 255.7, is commercially available as is the ***trans-9-riboside derivative***, *[6025-53-2]* **$C_{15}H_{21}N_5O_5$, M 351.4**, and is a cytokine which separates from aqueous AcOH with **m 177-179°**. It solubility in AcOH is ~5%. [McDonald & Morris *Methods Enzymol* **110** 347 *1985*, DOI: 10.1016/S0076-6879(85)10093-5]. For 'Gerontomodulatory and youth-preserving effects of zeatin on fibroblasts of human skin' see Rattan & Sodagam [*Rejuvenation Res* **8**(1) 46 *2005*, DOI: 10.1089/rej.2005.8.46, PMID: 15798374].

Zoxazolamine (Flexin, 5-chloro-2-benzoxazolamine) *[61-80-3]* **$C_7H_5ClN_2O$, M 168.6, m 184-185°, 185-185.5°, 189-190°.** Purify flexin by recrystallisation from $*C_6H_6$ or 50% aqueous EtOH. Its solubility at ~25° in DMSO is 34mg/ml, in EtOH it is 34mg/ml and in H_2O it is <1mg/ml. It sublimes at high vacuum. In MeOH it has UV λ_{max} at 244 and 285nm. The synthesis of this oxazoline is briefly described by Nagano et al. [Nagano et al. *J Am Chem Soc* **75** 2770 *1953*, DOI: 10.1021/ja01107a511; English Patent 240,969 *1925*], but the synthesis of the 4,6-d_2 derivative used in pharmacological studies described by Tanabe et al. [*J Med Chem* 13 30 *1970*, DOI: 10.1021/jm00295a008] is reported here because more details about the reaction are provided by the latter authors. Thus, a mixture of 2-amino-4-chlorophenol-3,5-d_2 (2.351g) and CNBr (3.4g) in H_2O (225ml) are heated in a steam bath for 15 minutes (**CARE as CNBr is highly toxic**). The mixture is cooled to ~25° and neutralised with 15M NH_4OH to pH 8 with cooling, and the solid product is filtered off. After drying *in vacuo*, it is sublimed at 160°/0.020mm to provide ***5-chloro-2-benzoxazolamine-4,6-d_2*** (1.926g) **m 182-183°** with the correct deuterium content.
The known (quantified) ***muscle relaxant*** (paralytic) potency of ***Zoxazolamine*** (the so-called '***Zoxazolamine Effect***') is employed as a benchmark standard when new compounds are tested as muscle relaxant inhibitors [see Decken & Gossage *J Inorg Biochem* **99**(2) 664 *2005*, PMID: 15621301]. For 'A quantitative assessment of motor function in cerebral palsy and evaluation of zoxazolamine (flexin) as a new muscular relaxant drug' see Hadra & Millichap [*Neurology* **6**(12) 843*1956*, PMID: 13378587]. Zoxazolamine, as a centrally-acting muscle relaxant, reportedly acts by decreasing CNS interneuronal activity, by decreasing dopaminergic turnover and by inducing a pacemaker-like discharge pattern in dopaminergic neurons without being anxiolytic [McMillen et al. *J Neural Transm Gen Sect* **89** 11 *1992*, PMID: 1329854]. In addition to its muscle relaxant activity, Zoxazolamine is also a useful tool for assessing hepatic cytochrome P-450 activity [Sternson & Gammans *J Med Chem*, 19 174 *1976*, DOI: 10.1021/jm00223a034].

CHAPTER 7

NANOMATERIALS AND NANOTECHNOLOGY

INTRODUCTION

Nanomaterials are substances that are, or have been, reduced in size to the range from 1nm to ~100nm (i.e. 1 to ~100 nanometers, or 1 to ~100 x 10^{-9} meters). ***Nanotechnology*** is the science and applications of nano-materials, and is growing at an ever increasing pace. At this particle size the properties of materials can be altered dramatically. Properties such as solubility, reactivity, spectroscopy, electrical and magnetic, transport through membranes etc. are generally different from those of the same materials with large particle size. The applications of materials of nano size have escalated in the last fifteen or so years and are currently gaining momentum. The technology has broad applications in performance materials, health, consumer products, water, information technology and energy. The discovery of ***fullerenes*** (1996 Nobel Prize for Chemistry to H.W. Kroto, R.E. Smalley and R.F. Curl) and of ***Graphene*** (2010 Nobel Prize for Physics to A. Geim and K Novoselov) are very important factors in the development of nanotechnology. Not very many nanomaterials have so far been included in chemical catalogues of commercially available substances, e.g. as compared with catalysts (although some catalysts are now available as nanoparticles), hence the relatively smaller size of this chapter. Fullerenes and related materials such as carbon nanotubes have found applications in medicine for the transport of drugs and biological materials to targeted sites and some readily available derivatives are described in this chapter, together with other commercially available nanoparticulate substances, e.g. catalysts, magnetic and electrically conducting thin films, and quantum dots. General safety aspects of handling nanomaterials have been briefly addressed. Nanoscience and nanotechnology is developing explosively as the awareness and usefulness of materials at the nano scale is becoming evident. In the past few years this has resulted in the appearance of an enormous number of journals and periodicals in which scientific, technological and medical discoveries are readily published. Many of these publications are listed at the end of this chapter and can be accessed *via* their International Standard Series Numbers (ISSNs). A large number of books have also been published on these subjects and can be accessed *via* their International Standard Book Numbers (ISBNs).

IDENTIFICATION AND MEASUREMENT OF NANOMATERIALS

The 1 to ~ 100nm (10 to ~1000Å) particles are smaller than the wavelength of UV light, and thus the use of appropriate small particles e.g. electrons, or radiation e.g. X-rays is necessary to identify and measure these particles. Instrumentation for these purposes has been developed and the resolutions are continuously being improved. These instruments can measure very accurately, and depending on the physical principles of the machines, they measure different parameters of the nanoparticles, e.g. diameter (if spherical), length (if rod like), width (if bulky) etc, and not necessarily all parameters at the same time with one instrument. The commonly used instruments include the ***Transmission Electron Microscope*** (TEM) in which the electron beam runs past the particles placed on a transparent surface, and then through the surface giving a 2D image and magnifying one million times. In the ***Scanning Electron Microscope*** (SEM) and ***Scanning Tunneling Microscope*** (STM, or *Spectroscopy* STS) the electron beam scans the surface of the particles to provide a 3D picture, e.g. of hairs on a fly. ***Dynamic Light Scattering*** (DLS) uses light scattering through solutions of nanoparticles. Another technique, ***Scattering Probe Microscopy*** (SPM), allows scanning with a probe over a surface and includes ***Atomic Force Microscopy*** (AFM, or ***non-contact atomic force microscopy*** NC-AFM) where a ceramic or semiconductor tip scans the surface (much like a phonograph needle scans a record), and measures the atomic forces beneath it. The NC-AFM tip is attached to a very small tuning fork that oscillates at amplitudes of 0.2 to 0.5Å, smaller than the diameter of an atom. When the tip is brought very close to a molecule on a surface, this frequency alters slightly thus ***detuning*** due to the atomic forces between the tip and the molecule to give a complete picture of the molecule on the surface. By placing a CO (carbon monoxide)

Purification of Laboratory Chemicals.
http://dx.doi.org/10.1016/B978-0-12-805457-4.50007-0,

molecule at the tip, and keeping it there throughout the imaging process, very high resolution can be obtained. Gross and coworkers [Gross et al. *Science* **325** 1110 *2009*, DOI: 10.1126/science.1176210] obtained the complete image of pentacene on a copper surface in this way, and succeeded in imaging the amount of charge on a single atom [Gross et al. *Science* **324** 1428 *2009*, DOI: 10.1126/science.1172273]. The sensitivity of ***Magnetic Resonance Imaging*** (MRI) has been considerably increased (with a resolution of ~4nm), by Rugar and coworkers [Degen et al. *Proc Natl Acad Sci* **106** 1313 *2009*, DOI: 10.1073/pnas.0812068106; cf H. Birch *MRI on the Nanoscale,* RSC *Chemistry World* **6**(2) 28 *2009*, J. M. Crow *Picture perfect pentacene,* RSC *Chemistry World* **6**(1) 46*2011*] who have developed the ***Magnetic Resonance Force Microscopy*** (MRFM) technique. Here the sample is placed at the end of a tiny silicon cantilever to which is applied, *via* a magnetic tip, a radio frequency magnetic field. The spin of the nuclei alternate (*up* and *down*) when the frequency reaches their 'wobbling' frequencies making the cantilever vibrate. Photon density 3D images of the specimen (e.g. tobacco mosaic virus, *ca* 18 nanometers across) can be obtained by using a laser to detect the cantilever vibrations. The technique does not affect the sample and gives superior images to those from STM and AFM. [A.I. Kirkland and J. I. Hutchinson (eds) *Nanocharacterisation* RSC Publishing UK, *2007*, ISBN 9781847557926, 1847557929; A. Turley *Sizing it up,* RSC *Chemistry World* **8**(3) 50 *2011*; M. Thompson RSC *The Characterisation of Nanoparticles; Analytical Methods Committee Technical Briefs 48,* December *2010*; ISSN 1757-5958, http://bit.ly/AMCparticle). Other techniques include ***Near-Infrared Spectroscopy*** (NIR) and solution phase NIR [Itkis et al. *Nano Lett* **3** 309 *2003*, DOI: 10.1021/nl025926e], general ***Electron Microscopy*** (EM), ***Field Emission Microscopy*** (FEM), ***FT-Raman Scattering Spectroscopy***, *Nuclear (proton)* ***Magnetic Resonance Spectroscopy*** (NMR for derivatised carbon nanotubes, CNTs), ***Thermo Gravimetric Analysis*** (TGA), ***Energy Dispersive X-ray Spectroscopy*** (EDX), as well as other optical techniques (see Bibliography at the end of this chapter).

Preparation of the specimen is very important since the atoms or/and molecules have to be spread over the surface in as close to one atom or molecule thick. Where thicknesses (*t*) of 7 to ~13nm need to be measured ***Grazing Incident X-Ray Reflectometry*** (GICRR/XRR) provides an initial measure of particle lengths (*l*) of 1 to 35nm. ***Spectroscopic Elipsometry*** (SE, t = ~ 10.5 to 12.3nm, l = 1 to 10.5nm), ***Scanning Ion Mass Spectrometry*** (SIMS, t ~ 10.4 to 10.8nm, l = ~12 to 13 nm), ***Transmission Electron Microscopy*** (TEM, t ~ 7.5 to 12.5nm, l = 12.5 to 18.5 nm), *X-Ray* ***Fluorescence Spectroscopy*** (XFS, t ~ 7.5 to 9.3nm, l = 16.0 to 19.5 nm), ***X-Ray Photoelectron Spectroscopy*** (XPS, t ~ 9.2 to 11.7, l = 18.5 to 25.5 nm) and higher resolution ***Grazing Incident X-Ray Reflectometry*** (GIXRR/XRR, t ~ 9.2 to 11.7, l = 24.0 to 36.0 nm) provide the approximate t and l values stated in the brackets. It must be noted that these values are approximate as they do vary depending on the nature of the materials that are measured.

Average particle size: The accepted method for determining the primary particle size of nanomaterials is by TEM analysis. However, this is expensive and time-consuming. Studies have shown that an average primary particle size for spherical or cubic shaped dry nanoparticles of roughly uniform shape and size can be calculated from the equation:

Average particle size (nanometers) = (6/BET surface area* x density**) x 1000

Where surface area* is in sq. m/g, and density** is in g/cc. ***Micrometrics Analytical Services*** (MAS) will measure **BET surface area** by a gas absorption procedure and the real density by gas pycnometry. This gives a good estimate of average primary particle size. For further information see www.micromeritics.com, Micromeritics Analytical Services Downloads.

FULLERENES AND RELATED SUBSTANCES

Fullerenes and related substances are made by heating carbon (e.g. soot, graphite) to form nano-sized carbon 'balls'. These nanoparticles look like 'footballs' in being constructed of five (pentagon) and/or six (hexagon) carbon rings. Their carbon ring sizes make for stable 'ball-like' molecules of 60 or more carbon atoms and have some solubility in organic solvents. These carbon **allotropes** have a variety of exotic properties including electrochemical [Echegoyen & Echegoyen *Acc Chem Res* **31** 593 *1998*, DOI: 10.1021/ar970138v], ferromagnetism [Allemand et al. *Science* **253** 301 *1991*, DOI: 10.1126/science.253.5017.301], superconductivity [Hebard et al. *Nature* **350** 600 *1991*, DOI: 10.1038/350600a0], photophysical [Guldi *Chem Commun* 321 *2000*, DOI: 10.1039/A907807J], anti-HIV bioactivity [Friedman et al. *J Am Chem Soc* **115** 6506 *1993*, DOI: 10.1021/ja00068a005], and their 'aromatic' nature allows them to react accordingly and be functionalised (see below) for further chemical reactions [Kordatos et al. *J Org Chem* **66** 4915 *2001*, DOI:

10.1021/jo015608k]. New and useful applications are continually being found in nano science, medicine, pharmaceuticals, and nanotechnology [see references below].

FULLERENES

Fullerene C_{60} (Buckminsterfullerene C_{60}, Footballene, Buckyball 60) *[99685-96-8]* **M 720.66 and Fullerene C_{70}** *[115383-22-7]* **M 840.77.** ***Purification procedures:*** **(a)** These were purified from the soluble toluene extract (400mg) of the soot (Fullerite), formed from resistive heating of graphite, by adsorption on neutral alumina (100g, Brockmann I, 60 x 8cm). Elution with toluene/hexane (5:95 v/v) gives *ca* 250mg of quite pure C_{60}. It has characteristic spectral properties (see below). Further elution with toluene/hexane (20:80 v/v, i.e. increased polarity of solvent) provides 50mg of 'pure' C_{70} [Allemand et al. *J Am Chem Soc* **113** 1050 *1991*, DOI: 10.1021/ja00003a053].

Chromatography on alumina can be improved by using conditions that favour adsorption rather than crystallisation. Thus the residue from toluene extraction (1g) in CS_2 (*ca* 300ml) is adsorbed on alumina (375g, standard grade, neutral *ca* 150 mesh, Brockmann I) and loaded as a slurry in toluene/hexanes (5:95 v/v) to a 50 x 8cm column of alumina (1.5Kg) in the same solvent. To avoid crystallisation of the fullerenes, 10% of toluene in hexane is added quickly followed by 5% of toluene in hexane after the fullerenes had left the loading fraction (2-3 hours). With a flow rate of 15ml/minute the purple C_{60} fraction is eluted during a 3-4 hour period. Evaporation of the eluates gives 550-630mg of product which, after recrystallisation from CS_2/cyclohexane yields 520-600mg of C_{60} which contains adsorbed solvent. On drying at 275°/10^{-3}mm for 48 hours a 2% weight loss is observed although the C_{60} still contains traces of solvent. Further elution of the column with 20% of toluene in hexane provides 130mg of C_{70} containing 10-14% of C_{60} (by ^{13}C NMR). This was re-chromatographed as above using a half scale column and adsorbing the 130mg in CS_2 (20ml) on alumina (24g) which gave 105mg of recrystallised C_{70} (containing 2% of C_{60}). The purity of C_{60} can be improved further by washing the crystalline product with Et_2O and Me_2CO followed by recrystallisation from $*C_6H_6$ and vacuum drying at high temperatures.

(b) Carbon soot from resistive heating of a carbon rod in a partial helium atmosphere (0.3bar) under specified conditions is extracted with boiling $*C_6H_6$ or toluene, filtered and the red-brown solution is evaporated to give crystalline material in 14% yield which is mainly a mixture of fullerenes C_{60} and C_{70}. Chromatographic filtration of the 'crude' mixture with $*C_6H_6$ allows no separation of components, but some separation was observed on silica gel TLC with *n*-hexane or *n*-pentane, but not cyclohexane as eluants. Analytical HPLC with hexanes (5μm Econosphere silica) gave satisfactory separation of C_{60} and C_{70} (retention times of 6.64 and 6.93 minutes respectively) at a flow rate of 0.5ml/minute and using a detector at 256nm. HPLC indicated the presence of minor (<1.5% of total mass) unidentified C_n species with retention times of 5.86 and 8.31 minutes. Column chromatography on flash silica gel with hexane gives a few fractions of C_{60} with ≥95% purity, but later fractions contain mixtures of C_{60} and C_{70}. These can be obtained in 99.85 and >99% purity, respectively, by column chromatography on neutral alumina. [Ajie et al. *J Phys Chem* **94** 8630 *1990*, DOI: 10.1021/j100387a004.]

(c) Separation of C_{60} and C_{70} can be achieved by HPLC on a dinitroanilinopropyl (DNAP) silica (5μm pore size, 300Å pore diameter) column with a gradient from *n*-hexane to 50% CH_2Cl_2 using a diode array detector at wavelengths 330nm (for C_{60}) and 384nm (for C_{70}). [Cox et al. *J Am Chem Soc* **113**, 2940, 1991, DOI: 10.1021/ja00008a023.] By using Soxhlet extaction of 'soot' and recrystallisation from toluene, and using the greater affinity of 95.% pure C_{60}

Soxhlet extraction of the 'soot' with toluene is a good preliminary procedure, and as C_{70} has greater affinity for the solvent and recrystallisation from toluene gave 99.5% of pure C_{60}. [See *Purification of Laboratory Chemicals* 7th edition and Coustel et al. *JCS Chem Commun* 1402 *1992*, DOI: 10.1039/C39920001402.]

(d) Purification of C_{60} from a C_{60}/C_{70} mixture was also achieved by dissolving it in an aqueous solution of γ (but not β) cyclodextrin (0.02M) with refluxing and recovery of C_{60} of >99 purity [See *Purification of Laboratory Chemicals* 7th edition, and Andersson et al. *JCS Chem Commun* 604 *1992*, DOI: 10.1039/C39920000604.]

(e) Similarly C_{60} and C_{70} from fresh carbon-arc soot can also be readily purified by using inclusion complexes with *p-tert*-butylcalix[6] *p-tert*-butylcalix[8]arenes. [See *Purification of Laboratory Chemicals* 7th edition, *2013*, and Atwood et al. *Nature* **368** 229 *1994*, DOI: 10.1038/368229a0.]

(f) Rapid and economical purification of C_{60} fullerene *[22685-96-8, 99685-96-8]* **M 720.6, m >280°, flash point 94°** from crude soot enriched in fullerenes with ~5% of soluble fullerenes available from suppliers such as

Texas Fullerene Corporation (8926 Kirby Drive, Houston, USA) and *Polygon Enterprises* (P.O.Box 5536, Waco) was used [See See *Purification of Laboratory Chemicals* 7th edition, *2013*].

(g) A higher purity C_{60} can be obtained by using a glass filter funnel with a *D4* frit (diameter 6.5cm) on a suction flask filled with a slurry of silica gel (~84g, 230-400 mesh) and *Darco G60* charcoal (42g) in toluene to a plug height of 9cm; and covered with sea sand (1cm) [See *Purification of Laboratory Chemicals* 7th edition *2013*, and for HPLC and NMR see Isaacs et al. *Helv Chim Acta* **76** 1231 1993, DOI: 10.1002/hlca.19930760310].

(h) Tour and coworkers [Scrivens et al. *J Am Chem Soc* **114** 7917 *1992*, DOI: 10.1021/ja00046a051] described another ***gram-quantity purification procedure for C_{60} fullerene*** where a slurry of alkaline decolorising carbon Norit-A (36g) and silica gel (72g, flash chromatography grade 60 of 230-240 mesh ASTM, 0.040-0.063mm particle size) in toluene (200ml) was used. [See *Purification of Laboratory Chemicals* 7th edition, *2013*.] Repeated chromatography on neutral alumina yields minor quantities of solid samples of C_{76}, C_{84}, C_{90} and C_{94} believed to be higher fullerenes have been separated by repeated flash chromatography on alumina with gradient elution using hexane/toluene mixtures. A stable oxide $C_{70}O$ has been identified [Diederich et al. *Science* **252** 548 *1991*, DOI: 10.1126/science.252.5005.548, see also *Purification of Laboratory Chemicals* 7th edition, *2013*].

Physical properties of Fullerene C_{60}: *[135105-52-1]* **C_{60} fullerene, M 720.64, does not melt below 360°, and starts to sublime at 300° *in vacuo***, and is now available commercially in a high state of purity. It is a mustard-coloured solid that appears brown or black with increasing film thickness. It is soluble in common organic solvents, particularly aromatic hydrocarbons which give a beautiful magenta colour. Toluene solutions are purple in colour. It is soluble in $*C_6H_6$ (5mg/ml), but dissolves slowly. C_{60} crystallises in needles or plates. [Taylor *JCS Chem Commun* 1423 *1990*, DOI: 10.1039/C39900001423.]

UV-Vis in hexanes: λ_{max}nm(log ε) 211(5.17), 227sh(4.91), 256(5.24), 328(4.71), 357sh(4.08), 368sh(3.91), 376sh(3.75), 390(3.52), 395sh(3.30), 403(3.48), 407(3.78), 492sh(2.72), 540(2.85), 568(2.78), 590(2.86), 598(2.87) and 620(2.60). IR (KBr): ν_{max} 1429m, 1182m, 724m, 576m and 527s cm^{-1}. ^{13}C NMR: one signal with δ at 142.68. C_{60} fullerene is a nano-channel organic semiconductor [Newman et al. *Chem Mater* **16** 4436 *2004*, DOI: 10.1021/cm049391x].

Purification of [5,6] C_{70} fullerene for derivatisation *[115383-22-7]* **C_{70} fullerene, M 840.8, m >280°**. By using a toluene extract (845mg) of Norit A (Aldrich) and a single-column purification using activated charcoal and derivatised polystyrene as stationary phases with toluene/1,2-dichlorobenzene then pure 1,2-dichlorobenzene as eluants, the six fractions obtained (confirmed by HPLC) were: (i) 205mg of pure C_{60}, (ii) 231mg of 38:62 C_{60}/C_{70}, (iii) 101mg of 88% pure C_{70}, (iv) 66mg of 92% pure C_{70}, (v) 131mg of 96% pure C_{70} and (vi) 57mg of 94% pure C_{70}. Fractions with >90% purity were satisfactory for the preparation of fullerene C_{70} derivatives. [Herrmann et al. *Helv Chim Acta* **78** 1673 1995, DOI: 10.1002/hlca.19950780705; for column used see Tour above and below.] Fullerene C_{70} forms a ***nano adduct*** with 4,5-dimethoxy-1,2-quinonedimethane [Smith et al. *J Am Chem Soc* **117** 9359 *1995*, DOI: 10.1021/ja00141a031; Tour *J Org Chem* Perspective **72** 7477 *2007*, DOI: 10.1021/jo070543s].

Tour and coworkers [Scrivens et al. *J Am Chem Soc* **116** 6939 *1994*, DOI: 10.1021/ja00094a060] described a ***gram-quantity purification procedure for C_{70} fullerene*** and separation of C_{60}/C_{70} by HPLC [Scrivens & Tour *J Org Chem* **57** 6932 *1992*, DOI: 10.1021/jo00051a047] [For details of purification and ^{13}C NMR in $*C_6H_6$ see *Purification of Laboratory Chemicals* 7th edition, *2013*].

Physical properties of Fullerene C_{70}: **C_{70} (5,6)-fullerene** *[115383-22-7]* **M 840.78, does not melt below 360°, and starts to sublime at 300° *in vacuo***, and is now available commercially in a high state of purity. It is a reddish-brown solid but greenish black in thicker films. Solutions are port-wine red in colour. Mixtures of C_{60} and C_{70} are red due to C_{70} being more intensely coloured. It is less soluble than C_{60} in $*C_6H_6$ and also dissolves slowly. C_{70} gives orange-coloured solutions in toluene. Drying at 200-250° is not sufficient to remove all the solvent. Samples need to be sublimed to be free from solvent. [Taylor *JCS Chem Commun* 1423 *1990*, DOI: 10.1039/C39900001423.] UV-Vis in hexanes: λ_{max} nm(log ε) 214(5.05), 235(5.06), 249sh(4.95), 268sh(4.78), 313(4.23), 330(4.38), 359(4.29), 377(4.45), 468(4.16), 542(3.78), 590sh(3.47), 599sh(3.38), 609(3.32), 623sh(3.09), 635sh(3.13) and 646sh(2.80). IR (KBr): ν_{max} 1430 m, 1428m, 1420m, 1413m, 1133mw, 1087w, 795s, 674ms, 642ms, 5778s, 566m, 535ms and 458m cm^{-1}. ^{13}C NMR [run in the presence of Cr (pentan-2,4-dione)$_3$ which induces a *ca* 0.12ppm shift in the spectrum]: Five signals with δ at 150.07, 147.52, 146.82, 144.77 and 130.28, which are unaffected by proton decoupling.C_{70} fullerene is a nano-channel organic semiconductor [Newman et al. *Chem Mater* **16** 4436 *2004*, DOI: 10.1021/cm049391x].

FUNCTIONALISED FULLERENES.
A large number of functionalised fullerenes have been reported. They are synthesised by chemical reactions at the double bonds of the 'ball' to form anchors for further condensation with small or large molecules such as proteins, lipids, DNA etc. They find applications in a variety of industries including drugs and pharmaceutical industries and in medicine. They are of nano size, can circulate in the animal's body and can be used to deliver substances to targeted tissues. A few of these are commercially available in chemical catalogues and a few are described here to show how fullerenes can be made to react with reagents.

1,4-Bis(pentafluorobenzyl)[C_{60}]fullerene {7,8-dihydro-7,8-bis[(2,3,4,5,6-pentafluorophenyl)methyl]-[5,6]-fullerene-C_{60}-I_h} *[1260376-31-5]* **$C_{60}(C_6F_5CH_2)_2$, M 914.6.** This bifunctional [C_{60}]fullerene was prepared in an argon atmosphere by adding potassium metal (124mg, 3.19mmol) in one portion to a freeze-thawed degassed mixture of fullerene (1.0g, 1.93mmol) and 1-methylnaphthalene (5.93g, 4.1.7 mmol, 30 equivalents, see [90-12-0]) in THF (150ml). This produced a dark red solution after stirring at ~25° for 3 hours under argon. Pentafluorobenzyl bromide (3.63g, 13.9mmol, tenfold excess) is then added, stirring is continued for 8 hours, the reaction is stopped by addition of aqueous NH_4Cl (0.5ml), the mixture is concentrated *in vacuo* down to ~10ml and the crude desired product is precipitated by addition of MeOH. It is purified by chromatography through silica gel and eluting first with CS_2/hexane (1:1) then CS_2 to provide the ***bis-perfluorobenzyl fullerene*** (830mg, 55%) which is fully characterised by its spectroscopic properties. It is stable in air and in solution (e.g. $CHCl_3$). For further purification preparative HPLC or GPC may be necessary. It is identified by investigations of dynamic light scattering (DLS), X-ray diffraction (XRD), differential scanning calorimetry (DSC), thermogravimetric analysis (TG-DTA), and of its electrochemical (OVP) properties. The data showed that the perfluoroaromatic rings interact in a face-to-face π-π manner with the [C_{60}]fullerene surfaces and exhibit unique aggregation-deaggregation behaviour. These properties allow this fullerene to be used for ***high-performance organic photovoltaic devices***. [see Y. Matsuo and coworkers in Li et al. *Chem Commun* **46** 8582 *2010*, DOI: 10.1039/C0CC03028G; Matsuo et al. *Synfacts* **2** 148 *2011*, DOI: 10.1055/s-0030-1259252, Darwish *Annu Rep Prog Chem, Sect A: Inorg Chem* **107** 473 *2011*, DOI: 10.1039/C1IC90014E.] ***Note*** that the name within the chain brackets above is the name given by the *Chemical Abstract Service*.

tert*-Butyl (1,2-methanofullerene C_{60})-61-carboxylate [*6,6-closed* 1,2-dihydro-1,2-methanofullerene C_{60})-61-carboxylic acid *tert*-butyl ester]** *[150493-29-1]* **C_{60}[=CHCO$_2$C(CH$_3$)$_3$], M 834.8.** The crude *tert*-butyl ester was prepared as for the ethyl ester below and obtained in 25% yield as a 1:1:3 mixture of ***6,6-closed, ***trans-5,6-open*** and ***cis-5,6-open esters***. As for the diethyl ester below, the mixture (20mg) was equilibrated in boiling toluene to give pure ***6,6-closed-tert-butyl ester*** (15mg 75%) which held toluene very strongly. It has UV/VIS with λ_{max} nm(ε) in toluene at 334 (40250), 406 (*sh* 3850), 429 (1800), 503 (1150), 593 (*br* 750); the ^{1}H NMR (500 MHz, in *C_6D_6) has δ at 4.38 (*s* 1 H), 1.51 (*s*, 9 H); and for IR-DRIFT, ^{13}C NMR and FAB-MS see references. [Isaacs et al. *Helv Chim Acta* **76** 1231 *1993* DOI: 10.1002/hlca.19930760310; Isaacs & Diederich *Helv Chim Acta* **76** 2454 *1993*, DOI: 10.1002/hlca.19930760704.]

Diethyl (1,2-methanofullerene C_{60})-61,61-carboxylic acid [*6,6-closed*-1,2-dihydro-1,2-methanofullerene C_{60})-61,61-carboxylic acid diethyl ester] *[155679-98-4]* **C_{60}{=C=[CO$_2$C(CH$_3$)$_3$]$_2$}, M 878.8, m >270°.** If the ^{1}H NMR spectrum indicated the presence of isomeric esters then dissolve it in chlorobenzene (0.2g in 100ml) and heat it under reflux for 24 hours to convert the isomers to the more stable ***[6,6-closed]-ester***. Column chromatography on silica and elution first with toluene/hexane (1:1) then toluene followed by recrystallisation from $CHCl_3$/MeOH and drying (60°/0.1 Torr, 6 hours) provided the desired diester as a dark solid [R_F: SiO_2/toluene is 0.50]. Store it at 2-8°. The ^{1}H NMR (200MHz; $CDCl_3$) has δ_H at 4.75 (q, *J* = 7Hz) and 1.53 (t, 6H, *J* = 7Hz); and for IR and ^{13}C NMR see references. The ***di-tert-butyl ester*** was similarly purified (see above). [Bingel *Chem Ber* **126** 1957 *1993*, DOI: 10.1002/cber.19931260829; Diederich et al. *JCS Perkin Trans II* 391 *1994*, DOI: 10.1039/P29940000391.]

Diethyl (1,2-methanofullerene C_{70})-71,71-carboxylate [*6,6-closed*-1,2-dihydro-1,2-methanofullerene C_{70})-71,71-carboxylic acid diethyl ester] *[153218-95-2]* **C_{70}[=C=(CO$_2$CH$_2$CH$_3$)$_2$], M 998.9.** It was prepared by reaction of diethyl bromomalonate with fullerene C_{70} in the presence of DBU in toluene (4 hours, ~25°), filtered and purified by chromatography through Kieselgel (0.063—0.2mm) by eluting with a gradient of toluene/*iso*-hexane (1/1 to 4/1). This gave the ***diester*** in 60% yield [R_F: SiO_2/toluene is 0.50], with a 40% recovery of the fullerene. Store it at 2-8°. The ^{1}H NMR (360MHz; $CDCl_3$) has δ_H at 4.75 (q, *J* = 7.1Hz) and 1.46 (t, 6H, *J* = 7.1Hz); and for ^{13}C NMR see refreferences. [Bingel *Chem Ber* **126** 1957 *1993*, DOI: 10.1002/cber.19931260829.]

1,2-Dihydro-[1,2]fullereneC_{60}[3,4]pyrrolidin-1-ylethoxyethoxyethylammonium bis-trifluoroacetate {2-[2-[2-(2'*H*-[5,6]fullereno-C60-*I*$_h$-[1,9-*c*]pyrrol-1'(5'*H*)-yl)ethoxy]ethoxy]ethanamine bis-2,2,2-trifluoroacetate} [C_{60} =CH)$_2$NH$^+$-CH$_2$CH$_2$OCH$_2$CH$_2$OCH$_2$CH$_2$NH$_3^+$. 2CF$_3$COO$^-$, $C_{70}H_{20}O_6N_2F_6$] *[356066-52-9 for mono(trifluoroacetate)]* **M 1123.0.** *N*-Boc-aminoethoxyethoxyethylaminoacetic acid (423mg, 1.38mmol, see below in SWCNT[=CH)$_2$N-CH$_2$CH$_2$O-CH$_2$CH$_2$O-CH$_2$CH$_2$NH$_3^+$. HCl]$_n$), paraldehyde (456mg, 3.45mmol) and fullerene C_{60} (500mg, 0.69mmol) in toluene (300ml) are refluxed for 1 hour. After cooling to ~25° the mixture is applied onto a column of silica gel (NM Kieselgel 60, 70-320 mesh) and eluted with 9:1 toluene/EtOAc to give the ***analytically pure*** (elemental C, H, N) **C_{60}=*N-Boc-pyrrolidinyl derivative*** (212mg, 0.29mmol, 31%). The UV-VIS (cyclohexane) has λ_{max} at 254, 309, 429, 466sh, 546sh, 703 nm; the ^{1}H NMR (200 MHz, $CDCl_3$, TMS) has δ at 5.08 (bs, 1H), 4.50 (s, 4H), 4.05 (t, *J* = 5.5Hz, 2H), 3.77 (m, 4H), 3.60 (t, *J* = 5.3Hz, 2H), 3.36 (m, 4H), 1.44 (s, 9H); and for IR-DRIFT, ^{13}C NMR and ES-MS see references.

The *N*-Boc group is removed by treating the pure C_{60}=*N-Boc-pyrrolidinyl* derivative (150mg, 0.14mmol) in CH_2Cl_2 (3ml) with CF_3COOH (3ml), and stirring for 3 hours. The solvent is removed *in vacuo*, the residue is washed with toluene and dried *in vacuo* to give the ***analytically pure*** (elemental C, H, N) functionalised title ***fullerene* C_{60}=*N-pyrrolidinyl bis-trifluoroacetate salt*** (168mg, 0.15mmol, ~99%). The UV-VIS (cyclohexane) has λ_{max} at 331, 430, 484sh, 684 254, 309, 429, 466sh, 546sh, 703 nm; the ^{1}H NMR (200 MHz, DMSO-d_6, TMS) has δ at 7.81 (brs, 3H), 4.58 (s, 4H), 3.93 (t, *J* = 5.5Hz, 2H), 3.71-3.43 (m, 6H), 3.32 (m, 2H), 2.95 (m, 2H); and for IR, ^{13}C NMR and ES-MS see references. Related compounds with a two carbon atoms and a thirteen carbon atoms chain between the pyrrolidine nitrogen atom and the terminal amino nitrogen atom have also been prepared. The ω-primary amino groups at the end of the chains were derivatised (e.g. with 12-acetylsulfanildodecanoic acid in the presence of EDCI and HOBt for ***self-assembled monolayers (SAMs) purposes***, or various ***fluorescent*** indole-2-carboxylic acids) by standard procedures. Useful applications for nano materials science and nano medicinal chemistry (e.g. ***by linking to DNAs or other biological materials***) have been made possible with such fullerene precursors by M. Prato and coworkers. [Kordatos et al. *J Org Chem* **66** 4915 *2001*, DOI: 10.1021/jo015608k.]

Ethyl (1,2-methanofullerene C_{60})-61-carboxylate [*6,6-closed* 1,2-dihydro-1,2-methanofullerene C_{60})-61-carboxylic acid ethyl ester] *[50493-27-9]* **C_{60}(=$CHCO_2CH_2CH_3$), M 806.8.** Fullerene C_{60} reacts with an equimolar amount of ethyl diazoacetate in boiling toluene for 7 hours to provide a 30% yield of a 1:1:3 mixture of ***6,6-closed***: ***trans-5,6-open*** : **cis-5,6-open** *tert*-butyl (1,2-methanofullerene C_{60})-61-carboxylate. This mixture was isolated by applying the residual solid from the reaction onto a silica gel column which was first eluted with hexane to remove fullerene C_{60} then with toluene-hexane (1:1) to provide the mixture at R_F *ca* 0.43. The mixture was isomerised almost entirely to the ***more stable 6,6-close ester*** by refluxing it (35mg) in toluene (105ml) for 24 hours when the initial purple solution turned pink in colour. Chromatography on silica gel as before provided a pink-red product eluting at the same R_F *ca* 0.43 which was then evaporated to dryness. The black microcrystalline residue was washed with Et_2O and dried at 25º/0.1 Torr (31mg, 89%). It holds residual toluene tenaciously. It has UV/VIS with λ_{max} nm(ε) in toluene at 331 (40250), 395 (*sh* 5250), 404 (*sh* 3300), 417 (1900), 429 (2250), 495 (*br* 1250); the ^{1}H NMR (400 MHz, in $*C_6D_6$) has δ at 4.31 (*s* 1 H), 4.10 (*q*, *J* = 7.1Hz, 2 H), 1.06 (*t*, *J* = 7.1Hz, 3 H); the elemental analysis is consistent with $C_{62}H_6O_2$, and for IR, ^{13}C NMR and FAB-MS see references. [Isaacs et al. *Helv Chim Acta* **76** 1231 *1993*, DOI: 10.1002/hlca.19930760310; Isaacs & Diederich *Helv Chim Acta* **76** 2454 *1993*, DOI: 10.1002/hlca.19930760705.]

Fullerene C_{60}–γ-lactone esters. G-W. Wang and coworkers [Li et al. *Org Lett* **12** 4896 *2010*, DOI: 10.1021/ol102056k] have improved the condensation yields of diethyl malonate esters with [C_{60}] fullerene to form the disubstituted fused **γ-**lactone esters by using $Fe(ClO_4)_3$ instead of $Mn(OAc)_3$ for assistance (catalysis). Although the yields are still low, they are however, considerably higher when mediated by the iron perchlorate, and the products are cleaner. The solvent is *o*-dichlorobenzene and the ratios of reagents are 1:2:2:20 for [C_{60}]fullerene: EtOCOCH**R**COOEt: $Fe(ClO_4)_3$:Ac_2O. The following results were obtained: **R** ester (reaction temperature, reaction time, **yield** of γ-lactone ester, consumed fullerene): **Me** (80º, 20 minutes, **34%**, 55%); **Et** (80º, 20 minutes, **37%**, 71%); **PhCH$_2$** (80º, 30 minutes, **27%**, 61%); **Ph*** (0º, 180 minutes, **12%**, 67%); **Br** (80º, 30 minutes, **22%**, 56%); and **EtOCO** (110º, 20 minutes, **16%**, 53%); ***** reactant ratio was 1:2:2:50. The structures of the lactones are consistent with their HRMS, ^{1}H NMRs, ^{13}C NMRs, FT-IRs and UVs. It should be possible to convert these lactones into hydrofullerenes, fullerene hemiacetals, fullerene hemiketals and fullerenols. [Li et al. *Synfacts* **1** 38 *2011*, DOI: 10.1055/s-0030-1259158.]

Fullerene C_{60}/Poly(bisphenol A)carbonate. C_{60} is a known '***radical sponge***' [Morton et al *J Am Chem Soc* **114** 5454 *1992*, DOI: 10.1021/ja00039a083; McEwen et al. *J Am Chem Soc* **114** 4412 *1992*, DOI: 10.1021/ja00037a064]. It reacts readily with free radicals and undergoes photolysis to generate C_{60} radical ions. Thus irradiating a mixture of C_{60} and poly(bisphenol A)carbonate polymer (PC, [25037-45-0]) at room temperature with a conventional UV lamp, or warming the mixture at 60º with AIBN (a radical initiator, see [78-61-1]) results in fullerenated-PC. By controlling the ratio of reagents (i.e. 5.4mg C_{60}/500mg PC in 1,1,2,2-tetrachloroethane), a ***C_{60}/PC*** can be obtained with a C_{60} content as high as 6.3% (i.e. >2 C_{60} per PC chain) in ~99% yield. Multi-additions of PC did not lead to heavy cross-linking. The fullerenated polymer is a brown powder which is soluble in common organic solvents such as THF and $CHCl_3$. When the polymer is dissolved in THF (a solvent that does not dissolve C_{60}) and the solution is precipitated into hexane through a filter, no particles are left on the filter, and the hexane supernatant is colourless. This shows that all the C_{60} is incorporated into the polymer. The precipitate is then collected and dried under high vacuum to constant weight. The C_{60} content is 1.16 wt%, has M_n ~27,000; the UV (0.3mg/ml in THF) has λ_{max} at 238.9, 259.4, 262.0, 287.2, 329.5sh nm, and for IR see references. This fullerenation provides a versatile synthetic tool for making processable fullerene polymers. [Tang et al. *Macromolecules* **30** 2848 *1997*, DOI: 10.1021/ma961731f.]

(1,2-Methanofullerene C_{60})-61-carboxylic acid [*6,6-closed*-1,2-dihydro-1,2-methanofullerene C_{60})-61-carboxylic acid] *[155116-19-1]* **C_{60}(=$CHCO_2H$), M 778.7.** Attempted hydrolysis of the ethyl ester (see *[155679-98-4]* above) was unsuccessful, however, treatment of the *6,6-**closed**-ethoxycarbonylmethyl ester* with BBr_3 in $*C_6H_6$ under N_2 and stirring for 9 hours gave an 82% yield of the acid. Similarly the *tert*-butyl ester (see *[150493-29-1]* above), but in refluxing toluene for 8 hours, gave a 77% yield of the acid. After hydrolysis, the acid was purified by dissolving it in $CHCl_3$/Me_2SO, re-precipitating with hexane and drying overnight at 25º/0.1 Torr, or at 60º/0.1 Torr for 12 hours. The brown or black solid ***6,6-closed-acid*** was mostly insoluble in common solvents and slightly soluble in bromobenzene and 1,2-dichlorobenzene. This 6,6-closed acid (i.e. cyclopropane acid) has IR (KBr) with strong bands ν_{max} at 525, 699, 810, 847, 1013, 1426, 1785, 1794 cm^{-1} and twenty other medium to weak bands. The ^{1}H NMR (300 MHz, in $CHCl_3$/Me_2SO, 1:1) has one signal for

the cyclopropane H at 5.13 ppm; the ^{13}C NMR consists of 32 signals between δ 136 and 167, and signals at δ 40.34 and 71.66. Elemental analysis is consistent with the formula $C_{62}H_2O_2.0.5Me_2SO$.
With alcohols in the presence of dicyclohexylcarbodiimide, 1-*H*-benzotriazol-1-ol and a base [e.g. 4-$(Me_2N)C_6H_4N$ or Et_3N] in bromobenzene, the corresponding esters were obtained. Similarly peptides with ***methyl glycinate*** and ***methyl*-L-*phenylalaninate*** were obtained by using the corresponding amino acid esters. [Isaacs & Diederich *Helv Chim Acta* **76** 2454 *1993*, DOI: 10.1002/hlca.19930760705; Diederich et al. *Chem Soc Rev* **23** 243 *1994*, DOI: 10.1039/CS9942300243.]

6,9,12,15,18-Pentamethyl-1,6,9,12,15,18-hexahydro(C_{60}-I_h)fullerene *[244229-54-7]* **C_{60}[H, $(CH_3)_5$], M 796.7.** Preparation of these substituted fullerenes should be carried out in Schlenk-type equipment under an inert atmosphere (N_2 or argon), in dry solvents and reagents (at least in the early stages of the reactions), and any oxygen or air in solvents should be flushed out by bubbling dry inert gas through them. Microcrystalline [C_{60}] fullerene (2.0g, 2.78mmol, *[99685-96-8]*) in 1,2-dichlorobenzene (90ml), cooled in an ice-water bath, stirred under reduced pressure (1mm) to remove dissolved O_2, and warmed to ~25°, is added during 15 minutes to a stirred mixture of CuBr.SMe_2 (6.84g, 33.3mmol, use an efficient fume cupboard) in THF (47ml) at ~25° to which is previously added MeMgBr in THF (3 M, 11.1ml, 33.3mmol) followed by DMI (3.62ml, 33.3mmol, see [80-73-9], 1,3-dimethyl-2-imidazolone) and rapidly warmed to ~35° within 5 minutes. The colour of the white suspension soon turned to dark brown. After stirring at 35° for 40 minutes under a flow of N_2 (***note*** that some liberation of ethane may occur), a degassed saturated aqueous NH_4Cl solution (3.0ml) is added *via* a syringe, the colour of the solution changes from dark brown to red-brown and the mixture is stirred under a vacuum (*ca* 1mm) at ~25° to remove THF and Me_2S and reduce it to half its volume. This is diluted with degassed toluene (200ml) and subjected to silica gel flash chromatography (45 x 200mm size, using 90g of silica gel 230-450 mesh) with toluene as eluant (total volume 100ml). It should be done as rapidly as possible, as care should be taken to avoid oxygen and formation of $C_{60}Me_5O_nH$ (n = 2-3). The vermillion eluate is evaporated at ~40°/10mm then at 80° (to remove 1,2-dichlorobenzene) until solid begins to appear on the sides of the flask. N_2 is allowed to enter the evacuated flask and degassed MeOH is added along the inside wall of the flask, whereby the mixture becomes cloudy, and MeOH (~400ml total) is added until precipitation is complete. The solid is filtered off, washed with MeOH (5 x 10ml) and hexane (3 x 10ml) and dried *in vacuo* (1mm) to give red microcrystals of pentamethylfullerene (2.08g, 94%) of ~91% purity. Purity and/or purification is carried out using a Buckyprep or ODS column (4.6 x 150mm, flow rate 1ml/minute) and eluting with toluene/*i*-PrOH (7:3) or (3:7) respectively. The solid should be stored in an inert atmosphere, as on storage in air it deteriorates slowly over several months, and in solution in the presence of air its purity decreases by 80% in 24 hours. It has ^1H NMR (500 MHz, CS_2/$(CD_3)_2CO$ 5%) has δ at 2.34 (s, 6H), 2.35 (s, 6H), 2.46 (s. 3H), 4.50 (s, 1H, C_{60}-*H*); and for IR and ^{13}C NMR see referenses. [Matsuo, Mueamatsu, Tahara, Koide and Nakamura *Org Synth* **83** 80 *2006*, DOI: 10.15227/orgsyn.083.0080; Matsuo et al. *Functional Organic Materials* 58-80 *2007*, ISBN: 978-3-527-31302-0.]
The procedure described above is unique as all five substituents are symmetrically placed on the bridgehead carbons of five six-membered rings surrounded by a fused five membered cyclopentadiene ring (X-ray evidence). Similar reactions also produce very high yields of fullerenes with *five* ***C_6H_5***, *five* ***4-$CF_3C_6H_5$***, *five* ***4-$MeOC_6H_4$***, *five* ***4-ClC_6H_5***, *five* ***4-PhC_6H_5***, *five* ***(E)-1-propenyl***, *five* ***(Z)-1-propenyl*** and *five* ***(E)-2-phenylethenyl*** groups all symmetrically placed as in the pentamethyl derivative above. [see Matsuo, Mueamatsu, Tahara, Koide and Nakamura *Org Synth* **83** 80 *2006*, DOI: 10.15227/orgsyn.083.0080; and references therein.] The hydrogen atom of the central cyclopentadiene ring can be displaced by potassium with t-BuOK to form the ***K($C_{60}Me_5$) complex*** in which the potassium atom can then be displaced to form iridium complexes such as ***Ir(η^5-$C_{60}Me_5$)$(CO)_2$*** [Matsuo, Iwashita and Nakamura *Organometallics* **24** 89 *2005*, DOI: 10.1021/om049333l], and with rhodium to form ***Rh(η^5-$C_{60}Me_5$)$(CO)_2$*** [Sawamura, Kuninobu and Nakamura *J Am Chem Soc* **122** 12407 *2000*, DOI: 10.1021/ja005564h], structures which are supported by X-ray structure analyses. The same cyclopentadiene can complex with Fe and cyclopentadiene (Cp) to form a hybrid of '***buckyferrocene***' ***Fe($C_{60}Me_5$)Cp*** [Sawamura et al. *J Am Chem Soc* **124** 9354 *2002*, DOI: 10.1021/ja026069j; Nakamura *Pure Appl Chem* **75** 427 *2003*].

***N*-Tosyl[1,2]-aziridino[C_{60}]fullerene {2*a*[(4-methylphenyl)sulfonyl]-2*a*-aza-1,2(2*a*)-homo[5,6]fullerene-C60-I_h** *[226909-63-3]* **C_{60}[=N-(*p*-$C_6H_4CH_3$)], M 889.0.** This useful fullerene precursor is readily prepared. In a dry Schlenk flask with flushing argon is added CuCl (1.2mg, 12μmol), *o*-dichlorobenzene (40ml) and 2,6-toluidine (2.0 μL, 24 μmol), then stirring at ~25° for 30 minutes, followed by adding C_{60} fullerene (432mg,

600μmol) and ***TsN=IPh*** (224mg, 600μmol, see synthesis below*). The mixture is stirred ~25º for 12 hours and purified by flash chromatography through silica gel (toluene/hexane 1.2 ~ 1.1) to provide the pure aziridinofullerene (228mg, 43%) as a dark brown solid [and recovered 185mg, 43%, of unreacted C_{60} fullerene]. It has ^{1}H NMR (400 MHz, $CDCl_3/CS_2$ = 1:1, TMS) with δ at 2.56 (s, 3H), 7.50 (d, *J* = 8.3Hz, 2H), 8.19 (d, *J* = 8.3Hz, 2H); for the ^{13}C NMR and the HRMS (ESI-TOF; negative) see references. ***Note*** that other Cu catalysts and other pyridine bases resulted in lower yields of this reaction. Itami and coworkers [Nambo et al. *J Am Chem Soc* **133** 2402 *2011*, DOI: 10.1021/ja111213k] developed the use of this aziridinofullerene as a versatile platform for preparing a variety of functionalised fullerenes. Thus it reacts with aryl and heteroaryl compounds (5% TfOH, 1,2-$Cl_2C_6H_4$, 100º, 12 hours) to replace the 1,2-aziridine by two aryl or heteroaryl groups to form 1,4-disubstituted fullerenes in over 80% yields; it reacts with bifunctional nucleophiles of the type R-Z(**H**)=Y(X-**H**)-R' (10% TfOH, 1,2-$Cl_2C_6H_4$, 100º, 12 hours) to form 1,2-disubstituted fullerenes (1,2-disubstituted fullerenes fused with a 5-membered ring where the **H**'s are replaced by bonds with C1 and C2 of the fullerene), such as ***2,3-furano***, ***2,3-pyrrolo***, ***2,3-thiazolo-***, ***1,2-cyclic[1,3,2]-dioxaborolan- fullerenes*** in over 60% yields; it reacts with ***2,2'-bithiophenes*** in various ways, and undergoes formal ***[2+2] cycloaddition reactions*** with ***1,2-[bis(p-methoxyphenyl]acetylyene*** (10% TfOH, 1,2-$Cl_2C_6H_4$, 100º, 12 hours) to form a ***3,4-adduct*** (***cyclobutene***) which retains the ***1,2-aziridino*** moiety in 81% yields. Some of the structures were supported by X-ray crystal structure analysis.

[*N*-(*p*-Toluenesulfonyl)imino]phenyliodinane (TsN=IPh)** *[55962-05-5]* **$C_{70}(C_{13}H_{12}INO_2S$, M 373.2, m 102-104º (dec).** Toluene-*p*-sulfonamide (3.42g, 20mmol) and diacetoxyiodobenzene (6.4g, 20mmol, see *[2340-34-4]*) are added to a solution of KOH (2.8g, 50mmol) dissolved in MeOH (80ml, or better use CH_2Cl_2) at 0º, and then stirred at 25º for 3 hours. The mixture is poured into distilled water at 0º, kept at 4º overnight, the solid is filtered off, drained and recrystallised from hot MeOH (20ml) to give TsN=IPh (2.6g, 35%). ***Note the reagent reacts slowly with DMSO-d_6 and MeOH, so allow minimum contact time with these solvents (work rapidly). It has ^{1}H NMR (200 MHz, DMSO-d_6, TMS) with δ at 7.80-7.73 (m, 2H), 7.56-7.48 (m, 3H), 7.40-7.31 (m, 2H), 7.15-7.10 (m, 2H), 2.34 (s, 3H). [Heuss et al. *Inorg Chim Acta* **342** 301 *2003*, DOI: 10.1016/S0020-1693(02)01145-3; Besenyi et al. *Tetrahedron Lett* **34** 6105 *1993*, DOI: 10.1016/S0040-4039(00)61740-9; Evans & Barnes *e*-EROS *Encyclopedia of Reagents for Organic Synthesis* Published Online 15 APR *2001*, DOI: 10.1002/047084289X.rt139].

2,5,10-Triphenyl-2,5,6,10-tetrahydro(C_{70}-I_h)fullerene *[244237-40-9]* **$C_{70}(C_6H_4)_3H$, M 1073.0.** When a procedure similar to the preparation of $C_{60}Me_5H$ above is applied to fullerene-C_{70} only ***three substituents are inserted***. A suspension of CuBr.SMe_2 (374mg, 1.82mmol, 30 equivalents) in THF (23.0ml) is treated with PhMgBr (0.98M, 1.86ml, 1.82mmol, 30 equivalents) and stirred at 28º for 20 minutes. To the resulting yellow suspension is added a degassed solution of C_{70} (49.6mg, 59μmol) in 1,2-dichlorobenzene (25ml) and stirring is continued for 24 hours. The reaction is treated with 5% aqueous HCl, the organic layer is washed with H_2O, brine, dried ($MgSO_4$), evaporated to a small volume and diluted with MeOH to give a dark brown precipitate which is washed thoroughly with MeOH, Et_2O, H_2O again and dried *in vacuo* to give ***$C_{70}Ph_3H$*** (61.2mg, 95%, 96% purity, *cf* $C_{60}Me_5H$ above). The ^{1}H NMR (400 MHz, $CDCl_3$) has δ at 7.8-7.78 (m, 2H), 7.74-7.70 (m, 2H), 7.61-7.57 (m, 3H), 7.39-7.23 (m, 8H), 4.43 (s, 1H); and for the ^{13}C NMR and the APCI-MS see references. Similarly prepared are ***$C_{70}Me_3H$***, ***$C_{70}(4\text{-}PhC_6H_4)_3H$***, ***$C_{70}(4\text{-}ClC_6H_4)_3H$***, and ***$C_{70}(1\text{-}naphthyl)_3H$***. [Sawamura et al. *J Mater Chem* **12** 2109 *2002*, DOI: 10.1039/B202130G; *cf* Matsuo, Mueamatsu, Tahara, Koide and Nakamura *Org Synth* **83** 80 *2006,* DOI: 10.15227/orgsyn.083.0080; and references therein.] ***$C_{70}(4\text{-}CF_3C_6H_4)_3H$*** is also prepared similarly and is believed to proceed by formation of $[(4\text{-}CF_3C_6H_4)_2Cu^-]$ from the reaction between the arylMgBr and CuBr.SMe_2 which attacks successively three six-membered rings around a cyclopentadiene ring to give the ***intermediate $C_{70}(4\text{-}CF_3C_6H_4)_3Cu^-Ar$*** which decomposes on addition of acid or NH_4Cl to provide the desired ***$C_{70}(4\text{-}CF_3C_6H_4)_3H$***. When the latter, in THF-d_8, is treated with 1 equivalent of *t*-BuOK or TlOEt at 25º, the colour changes from reddish-brown to dark red to provide ***$K[\eta^5\text{-}C_{70}(4\text{-}CF_3C_6H_4)_3]$*** {whose ^{1}H NMR (400 MHz, THF-d_8) has δ at 8.07-8.05 (m, Ar-H, 6H), 7.57-7.54 (m, ArH, 6H); and for the ^{13}C NMR see references. For ***$Tl[\eta^5\text{-}C_{70}(4\text{-}CF_3C_6H_4)_3]$*** {whose ^{1}H NMR (400 MHz, THF-d_8) has δ at 8.09-8.07 (m, Ar-H, 6H), 7.59-7.53 (m, ArH, 6H)} also see Sawamura et al. [*J Am Chem Soc* **120** 8285 *1998*, DOI: 10.1021/ja981256w].

1,4,11,15,30-Pentakis(4-hydroxyphenyldimethylsilylmethyl)-2*H*-1,2,4,11,15,30-hexahydro-(60)fullerene {[4-$HOC_6H_4Si(Me)_2CH_2]_5$-2*H*-1,2,4,11,15,30-hexahydro-(C_{60}-I_h)fullerene, 1,7,8,11,24,27-hexahydro-1,7,-11,24,27-pentakis(dimethyl 4-hydroxyphenylsilyl)methyl-[5,6]fullerene-C60-I_h} *[658080-04-7]* **[4-$HOC_6H_4Si(Me)_2CH_2$-]$_5$- (6H)- C_{60}, M 1549.1.** This functionalised fullerene can be used as an example of a molecule to which ***long chains can be coupled*** for specialised purposes. Typically, using Schlenk equipment under N_2 or argon in strict absence of H_2O, the protected Grignard compound Me_2(4-tetrahydropyranylOC_6H_4)$SiCH_2MgCl$ (0.656M in THF, 13.0ml, 9.84mmol) is added to a purple suspension of a white powder of CuBr.SMe_2 (3.00g, 14.6mmol) and microcrystalline [C_{60}]fullerene (400mg, 0.555mmol) in 1,2-dichlorobenzene (80ml), and stirred at 25º for 1 hour. The mixture is treated with saturated aqueous NH_4Cl (0.5ml), concentrated *in vacuo* to *ca* 60ml and diluted with toluene. The brown mixture is applied onto a silica column and washed with toluene (~100ml, i.e. until the effluent becomes yellow), followed by EtOAc/toluene (3:97) and the effluent is collected until its colour is pale yellow. This is evaporated *in vacuo* to a small volume and MeOH is added rapidly to precipitate a brown powder which is collected under N_2, dissolved in MeOH/toluene (1:1, 46ml) and TsOH.H_2O (92mg, 0.48mmol) is added to it. After stirring for 1 hour at 25º, the mixture is neutralised with $NaHCO_3$, the solvent is evaporated, the residue is dissolved in MeOH/toluene (1:9, ~30ml), filtered from some insoluble material and evaporated *in vacuo*. The crude residue is purified by preparative HPLC (Nomura Chemical RPFullerene, with toluene/MeOH 1:9 as eluant) to give on evaporation the ***desired fullerene*** as an orange powder (99.5mg, 0.064mmol, 12% yield). Its ^{1}H NMR (400 MHz, acetone-d_6, TMS) has δ at 7.32-7.28 (m, 8H), 7.23 (d, *J* = 8.0Hz, 2H), 6.69-6.64 (m, 10H), 4.55 (s, 1H), 2.38 (s. 2H), 2.31 (d, *J* = 14.4Hz, 2H), 2.23 (d, *J* = 14.4Hz, 2H), 2.11 (d, *J* = 14.8Hz, 2H), 2.05 (d, *J* = 14.8Hz, 2H), 0.36 (s, 6H), 0.35 (s, 6H), 0.34 (s, 6H), 0.33 (s, 6H), 0.27 (s, 6H); and for ^{13}C NMR and HRMS (APCI+) see references. This fullerene now has ***five phenolic groups for condensation*** with lipid molecules. When a mixture of it (9.40mg, 6.07μmol) and 4-(dodecan-1-yloxy)benzoyl chloride (13.0mg, 9.81μmol) in THF (3.0ml) is treated with Et_3N (5.8 μL, 42mmol) and 4-dimethylaminopyridine (3.5mg, 29μmol), stirred at 25º for 3 hours, evaporated *in vacuo*, and the residue in toluene is filtered through a silica gel pad, and then purified by GPC (JAIGEL 3H, eluting with toluene), precipitated with MeOH/toluene as above and dried *in vacuo* (at 25º for 12 hours), it provided ***1,4,11,15,30-pentakis{4-[4-(dodecan-1-yloxy)benzoyloxy]phenyldimethylsilylmethyl}-2H-1,2,4,11,15,30-hexahydro-(60)fullerene*** (12.9mg, 71% yield). Similarly the ***[4-tetradecan-1-yloxy]*** (75% yield), ***[4-hexadecan-1-yloxy]*** (72% yield), ***[4-octadecan-1-yloxy]*** (61% yield) and ***[3.4-di(octadecan-1-yloxy]*** (37% yield) ***derivatives*** were obtained in high purity and characterised by ^{1}H NMR, ^{13}C NMR and ACPI MS analysis. These form beautifully coloured liquid crystals and X-ray diffraction studies showed interesting stacking of these fullerene molecules. CARBON NANOTUBES (CNTs) AND RELATED MATERIALS

The development of carbon nanotubes (CNTs) since their discovery by Sumio Iijima [*Nature* **354** 56 *1991*, DOI: 10.1038/354056a0] has been explosive, not only because of their mechanical, thermal and electronic properties but because they can be modified physically and chemically in a variety of ways to suit a plethora of applications. Structurally, they are made of rolled up sheets of carbon atoms forming fused hexagonal carbon rings just like a monolayer of graphite. The sides of the sheet are fused to form complete tubes. When one or both ends of a tube come together, like the bottom of a test tube, the round portion is more like ***half a 'fullerene ball'***. The way that the carbon atoms in the half fullerene ball '***finger tip***' structure are stable is by forming both hexagonal and pentagonal rings (see Marchand et al. *Nano Lett* **9** 2961 *2009*, DOI: 10.1021/nl901380u; FEM imaging below).

Many carbon nanotubes are now available commercially in chemical catalogues, and a selected number are entered here. Their chemical and biochemical applications include diagnostics, novel devices for rapid DNA sequencing, human personalised medicine, bio-labelling for cancer research, novel biomaterials for human implants, and for tissue engineering implants. The non-chemical applications have also been extended to attachments to surfaces with patterned and unpatterned textures to form conductors, and exciting applications as for nano-filters, in LEDs, nanostructured optical fibres, lasers, and solar cells. Carbon nanotubes are very strong materials and could be ~200 stronger than steel. When mixed with building materials, such as cement or aluminium composites, they not only increase their strength but make them much lighter. Carbon sheets such as graphene are conducting surfaces and have found extensive use in touch screens, i-Pods, mobile phones, bicycle frames, fishing rods, air-craft materials to name a few. [Haddon *Carbon Nanotubes (editorial), Acc Chem Res* **35** 997 *2002*, DOI: 10.1021/ar020259h; see also P. Calvert *A recipe for strength, Nature* **399** 210 *1999*, DOI: 10.1038/20326].

PREPARATION OF CNTs (NTs)

MWCNTs (multi walled CNTs) were first prepared by the ***arc discharged evaporation method*** (as for fullerene synthesis) where the needles (nanotubes) grew at the negative end of the carbon electrode in an argon filled vessel (at 100Torr). TEM micrographs showed tubes of 5 concentric graphic sheets (6.7nm diameter), 2 concentric graphic sheets (5.5nm diameter, DWCNT, double walled CNTs), and 7 concentric sheets (2.2nm diameter MWCNT). Electron diffraction patterns show that the tubes were formed from rolled up graphite sheets of carbon hexagons into helical structures. [Iijima *Nature* **354** 56 *1991*, DOI: 10.1038/354056a.] In chemical arc deposition, acetylene (at partial pressure ~10^{-2}mbar, 0.0075mm Hg at 0º) is often used as the hydrocarbon gas. J-M Bonard and coworkers prepared CNTs by growing them on 0.3mm diameter wires of Kanthal (Fe-Al-Cr alloy) in the centre of the anode at the rather low temperatures of 700-900º, hence the name ***Cold Atmosphere Chemical Vapour Deposition*** *CVD* (CACVD, compare below). The technique produces homogeneous films of well-graphitised NTs allowing control of their length and density. [Croci et al. *Chem Vap Deposition* **8** 89 *2002*, DOI: 10.1002/1521-3862(20020503)8; Bonard et al. *Appl Phys Lett* **81** 2836 *2002*, http://dx.doi.org/10.1063/1.1511539]. MWCNTs are generally formed to a smaller or larger extent in the procedures used, together with small quantities of ***buckyballs*** and ***amorphous carbon*** which can be invariably sublimed out, annealed out, or separated by chromatography. Annealing at high temperatures (~2500-2700º) removes volatile carbon, metals (generally bound to the open end of the tubes) and improves the structural order of the tubes.

SWCNTs (single walled CNTs): Among the techniques that have been developed for making SWNTs are ***EA (electric arc) methods*** which use a carbon source and catalytic amounts (~ 1 to 6 atom%) of transition metals, commonly Ni/Co, Ni/Y, Rh/Pt or Fe that are allowed to supersaturate the carbon [Kokai et al. *J Phys Chem B* **103** 4346 *1999*, DOI: 10.1021/jp990065s; Sen et al. *Chem Phys Lett* **349** 383 *2001*, DOI: 10.1016/S0009-2614(01)01208-8]. The methods have been studied in detail in order to optimise the sizes and yields of CNTs. The technique developed by R.C Haddon and co-workers [Itkis et al. *J Phys Chem B* **108** 12770 *2004*, DOI: 10.1021/jp0487307], and the purity estimated by solution phase NIR [Itkis et al. *Nano Lett* **3** 309 *2003*, DOI: 10.1021/nl025926e] adopts the EA method where an electric arc discharge is applied between a graphite cathode and composite anode containing catalytic amounts of metal(s), e.g. 4:1 atom% of Ni/Y, under He buffer gas at ~680Torr, and arc current 90A with a 10mm arc gap. These conditions produce high yields of AP-SWCNT (high purity, As-Prepared nanotubes). The purity can be assessed by Near-Infrared (NIR) spectroscopy.

Large scale production of SWCNTs by the EA technique is achieved by using an arc generated between a graphite rod (16mm diameter, 40mm long) cathode and an anode of graphite (6mm diameter, 100mm long) in which a hole 3.5mm diameter, 40mm deep, is drilled and filled with a mixture of a metallic catalyst (Ni 4.2 atom%/Y1 atom% and graphite) in a He atmosphere (660mbar) formed by a current of 100A/30V and keeping a constant distance (~3mm) between the electrodes. Within ~2 minutes, the total carbon mass was in ~2g quantities consisting of ~70% SWCNTs in highly crystalline bundles. The nature of the product(s) was assessed by SEM, high resolution TEM, Raman spectroscopy and X-ray diffraction. [Journet et al. *Nature* (letter) **388** 756 *1997*.]

Another technique developed by R.E. Smalley and coworkers is the ***laser ablation*** of carbon targets (***Carbon Vapour Deposition***, ***CVD***), e.g. laser-vaporised carbon-Ni/Co mixture (e.g. 1:1 1.2 atom% in C) at high temperatures (e.g. 1200°C) and vacuum (e.g. 500Torr) and an argon stream. [Thess et al. *Science* **273** 483 *1996*, DOI: 10.1126/science.273.5274.483, Sen et al. *Chem Phys Lett* **332** 467 *2000*, DOI: 10.1016/S0009-2614(00)01320-8; for the *Role of temporal delay in dual-laser ablated plumes* see Witanachchi & Mukherjee *J Vac Sci Technol A* **13** 1171 *1995*, http://dx.doi.org/10.1116/1.579856]. This CVD produces high yields (~ 70%) of SWCNTs as assessed by X-ray diffraction and electron microscopy (EM) methods at a rate of ~80mg/day. The production of SWCNTs can be increased to ~1g/day by using a 2" tube and dual laser pulses. However, by modifying the apparatus, using up and down scanning of the laser pulses onto a rotating carbon-Ni/Co target in a 4" diameter tube, a lower temperature (1100°C) can be used to generate 20g of 40-50vol% SWCNT material in 48 hours of continuous (largely unattended) operation [Rinzler et al. *Appl Phys A* **67** 29 *1998,* DOI: 10.1007/s 003390050734]. The high purity was checked by EM, XRD, Raman spectroscopy and TGA. ***Note*** that higher temperature operations produce tubes of larger diameters, albeit well within the nanometer scale.

In a more recent, essentially CVD procedure, S.T. Purcell and co-workers [Marchand et al. *Nano Lett* **9** 2961 *2009*, DOI: 10.1021/nl901380u; which provide an animated supplement, and summarised by H. Birch '*Nanotube growth on camera*', RSC *Chemistry World* **6**(9) 26 *2009*] have demonstrated by *Field Emission Microscopy* (FEM) how the growth of SWCNTs takes place. They used a W-tip connected to the electrodes (at 1200°C) in a chamber at ultra high vacuum (5 x 10^{-10} Torr base pressure). The W-tip (tip radius ~ 60nm) is first covered with a graphite diffusion barrier by heating in acetylene (at $P_{C_2H_2}$ ~1 x 10^{-4} Torr), and Ni nanoparticles are induced to grow directly onto the tip [by dewetting, from a circular Ni wire in the chamber using CVD in acetylene (~1-2 x 10^{-7} Torr during growth) at 800°C] while FEM imaging is performed. The images are collected on camera, and a frame-by-frame analysis of the video showed that the SWCNT grows at one end of the carbon tube at a time. The tube rotates in discrete steps, ~24 per rotation (half of the number of carbon atoms on the circumference of a common SWCNT) with the CNT turning ~180 times during its 11 minutes growth (as in the '***screw-dislocation-like***' model). Growth starts at the Ni atom (of the catalyst), the carbon attaches itself to the metal then it forms carbon rings (as hexagons, because these are the more stable configuration), and the molecule rotates as the tube is being formed. In the end, the tube is sealed by forming a semi-fullerene ball '***finger tip***' structure, and produces a '***test-tube like'*** nano carbon structure with the metal atom at its mouth. The metal can then be removed by heating the SWCNT strongly (annealing).

The ***HiPco*** **process** for preparing SWCNTs developed by R.E. Smalley and co-workers [Nikolaev et al. *Chem Phys Lett* **313** 91 *1999*, DOI: 10.1016/S0009-2614(99)01029-5] involves formation of the catalysts by *in situ* ***thermal decomposition of Fe(CO)$_5$*** in a heated flow of CO in the gas phase at 1-10atm and 800-1200°C. By adjusting the processing parameters (best at 1-10atm and 800-1200°C), SWCNTs were produced in high yields (79 mole%, i.e. 44 wt%) with narrowest tubes (as small as 0.7nm in diameter, same as in C_{60} fullerene) at the rate of 1.24mg/hour. The structures were confirmed by TEM, SEM, EDX and TGA. An important advantage of this procedure is that it is a ***continuous-flow process*** that can be used for bulk production of narrow SWCNTs. See below for purification of HiPco tubes.

PURIFICATION OF CNTs (NTs)

***MWCNTs*:** Raw tubes, as prepared by the EA method, contain about one third of other nanomaterial. This material is best removed by oxidation. Pure tubes can thus be prepared, although the procedure is wasteful. The purest tubes are obtained when 99% is oxidised; but when 95% is oxidised only 10-20% of product contains pure nanotubes. A ground raw sample is placed in an oven and the temperature is raised to 750° in air or oxygen for ~30 minutes until ~1% is left. This consists mostly of pure tubes with length/diameter ratios that exceed 100, and traces of open cylinders with the ratio of 20. [Ebbesen et al. *Nature* **367** 519 *1994*, DOI: 10.1038/367519a0; see also Chen et al. *Adv Mater* **8** 1012 *1996*, DOI: 10.1002/adma.19960081216.]

MWCNTs, prepared by the CVD procedure using ferrocene and xylene (0.75% Fe/C) as catalyst and precursor with argon/H_2 at ~700º [Andrews et al. *Chem Phys Lett* **303** 467 *1999*, DOI: 10.1016/S0009-2614(99)00282-1; (a step closer to commercialisation), Rao et al. *Appl Phys Lett* **76** 3813 *2000*, http://dx.doi.org/10.1063/1.126790], or acetylene as precursor and 2.5wt% Co-2.5wt% Fe/NaY zeolite as catalyst with argon/H_2 at ~700º [Bulusheva et al. *J Phys Chem B* **105** 4853 *2001*, DOI: 10.1021/jp010056v], were purified by heating the raw tubes (200mg) in 2.6M aqueous HNO_3 (40ml) for 48 hours. The cooled solution was centrifuged (use PTFE tubes, ~20,000g/30 minutes), the sediment was washed/re-centrifuged with de-ionised H_2O until the supernatant was barely acidic and the MWCNT sediment was dried *in vacuo*. This material was ***satisfactory for functionalising*** [Lin et al. *J Phys Chem B* **106** 1294 *2002*, DOI: 10.1021/jp013501v]. *Alternatively*, to a dispersed suspension of MWCNTs (100mg), formed by sonication (1 minute), is added an acidic solution of $KMnO_4$ (4g in 120ml of 1N H_2SO_4) dropwise and refluxed for 12 hours, cooled, and centrifuged. The sediment is treated with concentrated HCl (20ml) and refluxed for 24 hours to dissolve the MnO_2, cooled, centrifuged and the sediment is refluxed with 68% (azeotropic) HNO_3 (40ml) for 24 hours, cooled, and centrifuged again. The solids are washed repeatedly (using several centrifugation/washing cycles) with de-ionised H_2O until almost neutral then dried in a vacuum oven. This ***procedure exposes the CO_2H groups*** on the CNTs and can be ***used for conversion to COCl groups***, and ***further reactions*** to make soluble MWCNTs. [Fu et al. *Nano Lett* **1** 439 *2001*, DOI: 10.1021/nl010040g.]

SWCNTs*: (i)** Mechanically ground cloth-like raw SWCNTs from the electric arc process (EA) can be purified in reproducibly high yields (optimally 25-30wt% and containg <1wt% of transition metal) in two steps. The ***first involves thermal annealing in air by rotating the powders at 470ºC for 50 minutes in a quartz tube at 30rpm which burns the carbonaceous particles out, and the ***second*** is acid treatment which etches out the metals. The powder is immersed in aqueous 6M HCl for 24 hours, filtered (or centrifuged) several times until the colour of the acid is unaltered, and then washed with de-ionised H_2O. The SWCNTs are then '***unbundled***' by boiling in 30% aqueous HNO_3 for 4-6 hours, and the suspension is filtered with a polytetrafluoroethyene (PTFE) membrane in deionised H_2O, rinsed and dried to give a greyish black, thin mat of SWCNTs. The purity at each stage can be observed by SEM, TEM, FT-Raman spectroscopy and TGA which usually show ~96% purity after HCl treatment. The HNO_3 treatment, however, appears to break down the CNTs into small pieces and sometimes forms MWCNTs. [Moon et al. *J Phys Chem B* **105** 5677 *2001*, DOI: 10.1021/jp0102365.]

(ii) A gas-phase purification procedure developed by Margrave and co-workers [Zimmerman et al. *Chem Mater* **12** 1361 *2000*, DOI: 10.1021/cm990693m] involved purging the CNT sample [prepared by the pulsed laser method (Rinzler et al. *Appl Phys A* **67** 29 *1998*, DOI: 10.1007/s003390050734), from Graphite (1-2mm), or from EA] in a quartz tube with a mixture of Cl_2 (7.2ml/min), H_2 (2.7ml/min) and argon (3.0ml/min) for 1 hour at ~25º, which is then lowered into a furnace at 500º while the evolving gases (CO, $COCl_2$, CCl_4 and CO_2) are monitored by IR. Purging is continued until the CO partial pressure is <0.5Torr. The temperature of the sample is lowered to ~25º, sonicated in DMF/0.6M HCl (1:1) to remove metals, then pure DMF, filtering, and washing with MeOH to form an **SWCNT '*paper*'**. (*Alternatively*, the metals, if present, can be removed by sublimation in HCl gas at higher temperature.) The SWCNT 'paper' is dried at 160º and the purity assessed by SEM, TGA and UV-VIS. Any fullerenes present may be removed by refluxing in toluene or by sonication. The yield is ~15wt% to give CNTs that are generally ***more reactive due to their larger curvature***.

(iii) Raw HiPco SWCNTs can be purified in a multi-step process. Low density raw HiPco (~100mg, d ~0.01g/cc) is compressed onto dry filter paper (vacuum), placed in a ceramic boat and inserted into a quartz tube furnace while a gas mixture of 20% O_2 (or air) in argon (wetted by bubbling through H_2O) is allowed to flow over the sample in the furnace at 100cc/sec. The nanotubes are heated at 225º for 18 hours, sonicated for ~15 minutes (or stirring overnight) in concentrated HCl (yellow colour due to Fe^{3+} ions). The suspension is filtered onto a Teflon membrane (47mm, 1.0μm pore size), washed several times with de-ionised H_2O, MeOH, and dried in a vacuum oven at 100º for 2 hours (weight loss 33.7%; 0.67% residual metal). This oxidation with wet O_2 (or air) in argon, and extraction cycle is repeated at 325º for 1.5 hours (further weight loss 8.3%, 0.05% residual metal), and again at 425º for 1 hour (further weight loss 22.9%, 0.09% residual metal). After drying *in vacuo*, the HiPco tubes are annealed at 800º in argon for 1 hour (further weight loss 4.2%, 0.03% residual metal). Assessment of purity is by SEM, TEM, TGA, Raman and UV-VIS-NIR spectroscopy. The onset of oxidation of the smaller diameter HiPco SWCNTs is *ca* 100º lower than for the purification of large diameter tubes obtained in the laser-oven process, and is consistent with the greater steric strain present in small diameter SWCNTs. [Chiang et al. *J Phys Chem B* **105** 8297 *2001*, DOI: 10.1021/jp0114891.]

(iv) A ***general purification procedure*** for raw SWCNTs obtained by the EA process (reaching 2-3g, containing ~70% SWCNTs) [Ebbesen & Ajayan *Nature* **358** 220 *1992*, DOI: 10.1038/358220a0; Journet et al. (letter) *Nature* **388** 756 *1997*], or the laser ablation method (reaching ~20g, containing up to 50% SWCNTs) was developed by A. Hirsch and coworkers [Holzinger et al. *Appl Physics A* **70** 599 *2000*,]. The process involves three steps. **(a)** Raw material (100mg) was refluxed with 65% HNO_3 (150ml) for 3 hours, and centrifuged. The sediment was washed with H_2O and centrifuged repeatedly until the supernatant (first colourless then darkens, still containing some SWCNTs and was kept for further use) has pH ~1. The sediment was suspended in distilled H_2O, subjected to two and three 0.5 seconds of ultrasonic pulses when the liquid became weakly acidic (pH 3-4), almost free from metal catalyst, and contained ~1mg/ml H_2O of only SWCNTs and nanoparticles. For storage, the pH is adjusted to 8-9 with K_2CO_3 which increased the repulsive interactions between the carboxylate groups of the SWCNTs. **(b)** The suspension is sonicated for 1 minute which reduces the nanoparticles to smaller pieces. The tubes and bundles were also smashed and the difference in size between the SWCNTs and degraded particles increased (as observed by AFM). **(c)** This most important step involved elution of the suspension through a column of potassium polyacrylate which was swollen (the cross-linked polymer particle size swells from <1μm to ~300μm) creating pores large enough to entrap nanoparticles as well as SWCNTs and bundles of comparable size. [Optimum: 15ml of swollen polymer per 1ml of a 1g/L aqueous SWCNTs, and choosing a diameter to gave a column height of 6-7cm held by a glass filter pore size 2]. A vacuum was applied at the bottom of the column which squeezes the swollen polymer particles. The SWCNTs were so large that they cannot now be entrapped and eluted freely to give large quantities (> 40% of the total mass) in the first fraction. The remaining material contained a large portion of SWCNT fraction of lesser quality which can be recycled. Most of the degraded material and smaller nanoparticles remain in the cavities. The purification can be followed by AFM and the purity can be assessed by Raman spectroscopy. In the Raman spectrum, ***pristine*** SWCNTs have a doublet at 1546 and 1575 cm^{-1} (of about equal intensity — **G**-lines) and a less intense band (**D**-line, *ca* 1/4.75th of the **G**-lines) at ~1342 cm^{-1}. The relative intensity of the G-lines increase as the purity increases. The broadness of the D-band may originate from disordered or carboxylated carbon formed by oxidation.

PREPARATION AND PURIFICATION OF FULLERENE PIPES (TUBES)

These are ***short SWCNTs*** of 100 to 300nm lengths and ~1.2 to 1.4nm in diameter which are most useful for preparing functionalised SWCNTs. They are distinct from the above ***fullerenes*** which are 'bucky balls' and are made up of tubes consisting of a network of hexagonal carbon rings like in CNTs. As prepared, the CNTs are long almost endless single walled highly convoluted, entangled, bundled tubes. R.E. Smalley and coworkers [Rinzler et al. *Appl Phys A* **67** 29 *1998*, DOI: 10.1007/s003390050734; Liu et al. *Science* **280** 1253 *1998*, DOI: 10.1126/science.280.5367.1253] have purified, and cut such material from large batches into small lengths of open-ended tubes, which form stable colloidal suspensions in the presence of detergents. These can be made to react like ordinary organic molecules to form any variety of derivatives. In a typical preparation, the raw tubes (10g) in 2.6M HNO_3 were refluxed for 45 hours, cooled, and the black solution was centrifuged in PTFE (Teflon) tubes (20,000g, 20 minutes, Sorvall R5C centrifuge). The supernatant was decanted off, the sediment was resuspended in de-ionised H_2O by vigorous shaking and the centrifuging/washing cycle repeated 3 to 4 times until the supernatant was almost neutral, although black in colour. The acid treatment not only assists in separating the bundles, but also oxidises the material, thus producing carboxylic acid groups at the ends as well as at the sides of the tubes. This makes ***'holes'*** in the sides of the tubes and causes them to be ***'cut'*** [cf K. Kinoshita *Carbon Electrochemical and Physicochemical Properties* Wiley, New York *1988*, ISBN 978047184802-8]. The sediment as examined by SEM and TEM contains carboxylated carbon tubes and other species such as fullerenes, polycyclic aromatic sheets and cross-linked sheets edged with CO_2H groups that, by virtue of de-protonation allow mutual repulsion between the particles. The sediment (using 10g) was dispersed in aqueous NaOH (1.8L, pH 10) containing 0.5vol% of the non-ionic surfactant Triton X 100 by sonication for ~1 hour, and purified by ***cross-flow-filtration*** (**CFF**, cellulose ester M22M 600 01N, mini-Kros® Spectrum cartridge: 0.6mm diameter, 200nm pores and 0.56m^2 of surface area) against a buffer of aqueous NaOH (40L, pH 10) containing 0.2vol% of Triton X 100. At a head pressure of 5-6psi and flow rate of ~70ml/min the process was complete in ~10 hours. Salt was removed by washing with de-ionised H_2O (10L). Clogging occasionally occurred and was overcome by momentarily reversing the flow before continuing. Clamping off the buffer line and opening a vent allowed concentration of the SWCNTs down to ~200ml of solution. When a portion of this solution was filtered through a PTFE membrane (Millipore LS 5μ pore) using a vacuum, it deposited a thick pad of SWCNTs on the membrane. After washing with MeOH, the pad can be easily peeled

off to give a freestanding mat which was called ***'Bucky Paper'*** and was estimated as typically 10 to 20% yield depending on the initial raw material. TEM images of the ***SWCNT 'Bucky paper'*** showed that the pipes still contained impurities which were removed by two further oxidising acid treatment which ***'cut'*** (by reacting at the sides of the tubes) and ***'polished'*** the tubes.

In a typical ***cutting***, the purified SWCNT ***'Bucky Paper'*** (10mg) was suspended in a 3:1 mixture of concentrated H_2SO_4/HNO_3 (40ml), sonicated (55kHz) at 35º to 40º for 24 hours. The suspension was diluted with H_2O (200ml), larger tubes were collected onto a 100nm pore filter membrane (Millipore, VCTP type), and washed with 10mM NaOH solution. ***Polishing*** was performed by suspension in a 4:1 mixture of concentrated H_2SO_4/30% H_2O_2, stirring at 70º for 30 minutes, filtering and washing again on a 100nm filter, and re-suspending at 0.1mg/ml of 0.5wt% Triton X100 in H_2O to avoid flocculation. On a larger scale ***CFF purification*** was carried out after each oxidation step. Finally, to obtain ***best purified 'Bucky Paper'***, annealing *in vacuo* at 1200º was necessary. ***Note*** that in 3:1 H_2SO_4/HNO_3 at 70º the average cutting was at a rate of ~130nm/hour, and in 4:1 H_2SO_4/30% H_2O_2 the shortening rate was at ~200nm/hour.

Characterisation of these fullerene tubes was done by ***electro-deposition*** [developed by Smalley and coworkers, see above references] which drives the suspended tubes onto the surface of highly oriented pyrolytic graphite surface and are scanned by AFM. The molecular nature of the tubes was demonstrated by converting their CO_2H groups to COCl, followed by reaction with $H_2N(CH_2)_{11}SH$ and exposure to 10nm gold particles. Gold (which reacts with SH) was only found on the carboxylated fullerene tubes.

SOLUBILISATION OF CNTs

CNTs, whether MWCNTs or SWCNTs, readily form bundles, and attempts to separate the bundles by means such as sonication or use of detergents have been uniformly unattractive. The carbon material is 'non-wettable' and quite insoluble in polar and non-polar liquids. Considerable effort has been expended to find means of separating the bundles and much success has been achieved by functionalising the carbon matrices, which destabilise the interaction between the fibres, but also introduce bound groups which afford solubility in organic solvents as well as aqueous solutions. These provide opportunity for purification because the partly purified CNTs are not homogeneous. The non-homogeneity is not only in the length and/or diameter, but also in their nature since during the formation of the tubes, the row of hexagonal rings do not only align to form straight tubes (with parallel hexagonal rows), but can also form spiral tubes in which the row can be out of line by one and/or more than one hexagon while forming the tube. [For the *Dislocation theory of chirality-controlled nanotube growth* see B.I. Yakobsen and coworkers *Proc Natl Acad Sci USA* **106**(8) 2506 *2009*, and for a review see H. Birch RSC *Chemistry World* **6**(3) 25 *2009*.] This provides the opportunity for a variety of ***chiral CNTs***. In his respect M Zheng and coworkers [Zheng & Semke *J Am Chem Soc* **129** 6084 *2007*, DOI: 10.1021/ja071577k; Tu et al. *Nature* **460** 250 *2009*, DOI: 10.1038/nature08116; see also P. Broadwith RSC *Chemistry World* **6**(8) 28 *2009*] have selected short strands of DNA [8 to 12 mers, with repeating nucleotides e.g. $(GTC)_2$, $(GTC)_2GT$, $(GTT)_3G$, $(TAT)_4$ etc] which entwine around the SWCNTs (e.g. produced from HiPco, see above) of *ca* 1nm diameter with different selectivities depending on the '*n,m* chirality' of the nanotubes [e.g. (8,6), (9,4), (7,6), (6,5) etc respectively] to form barrels around the tubes. The mixture is dispersed in appropriate aqueous solutions (e.g. 0.1M NaCl, 0.1M NaCl/10% glycerol) by sonication (~60 minutes), incubated for a period of time, centrifuged (16,000g/90 minutes) and the supernatant is fractionated by Size Exclusion Chromatography (SEC) through an IEX resin (CNT-NS 1500, Biochrom, Terre Haute, IN, USA), and the various DNA-wrapped-SWCNTs are eluted with 2x(0.3M NaCl, 0.03M sodium citrate)/0.5mM EDTA/pH 7.0 and a 0 to 1M sodium benzoate gradient. The fractions are monitored at 300nm and 425nm. The DNA interaction is electrostatic and is easily removed by thermal treatment.

Strong acids solubilise SWCNT and MWCNT bundles by protonating them causing the strands to separate, but chlorosulfonic acid is by far (~1,000 times) the best acid as shown by M. Pasquali and the late R.E. Smalley [Davis et al. *Nature Nanotechnology* **4** 830 2009, DOI: 10.1038/nnano.2009.302; summarised by P. Broadwith RSC *Chemistry World* **6**(12) 32 *2009*]. SWCNTs spontaneously dissolve in $ClSO_3H$ at a concentration of as low as 0.5wt%. The Phase Diagram in strong H_2SO_4 exhibited true thermodynamic behaviour forming isotropic (I), liquid crystal (LC), crystal solvate (CS) and solid (S) phases at different concentrations of SWCNTs, $ClSO_3H$ and H_2SO_4. When an 8.5vol% of SWCNTs was coagulated in 96% aqueous H_2SO_4 by extrusion through an orifice while co-flowing with $CHCl_3$ or CH_2Cl_2, the resulting nanotube bundles (10-100nm) combined into larger bundles to form macroscopic fibres which were easily ***spun into tens of meters*** of continuous fibres in a matter of minutes. ***These fibres can yield a strength in excess of 320 MPa***. By

sandwiching the dope between glass plates, long ribbons of material were produced, and possibly any shapes (e.g. coils) can be made. The technological applications are enormous.
For examples of some currently commercial CNTs and functionalised CNTs see the following paragraphs.

CARBON NANOTUBES (CNTs)
Carbon annealed nanodiscs/nanocones *[7440-44-0, EC Number 231-153-3]* **C, M 12.0, m 3652-3697°(sublimes), d ^{20} 1.8-2.1g/cm^3.** These are available as a black powder containing a mixture of 20% cones, 70% discs and 10% of carbon black impurities by weight. The carbon cones have a nearly perfect geometry. The five theoretically possible cones with apical angles of 19.2°, 38.9°, 60°, 84.6° and 112.9° are all present in the mixture with cone lengths of 0.3-0.8μ, maximum base diameter of 1-2μ and wall thickness of 20-50 nanometers. The diameter and thickness of the discs are 0.88-3.5μ and 20-50 nanometers respectively. A product of almost 100% carbon is obtained by annealing at 2500-2700° which increases the structural order and reduces the concentration of impurities particularly of metals (from catalyst). They are similar to multi-walled carbon nanotubes (MWCNTs).

Carbon multi-walled nanotubes (MWCNTs or **MWNTs)** *[1333-86-4, EC Number 215-609-9]* **C, M 12.0, m 3652-3697°(sublimes), bulk density 0.346g/cm^3.** These are produced as a black powder by chemical vapour deposition (CVD) and contain >90% of nanotubes which are almost free from metal impurities. The tubes are ~7μ in length and ~140 nanometers in diameter. Multi-walled smaller nanotubes of ~1.5μ in length and ~20-25 nanometers in diameters are similarly prepared. When the multi-walled carbon nanotubes are ***'arc-produced'*** they are even smaller in size with ~2μ in length and ~2-50 nanometers in diameter *[double-walled 308068-56-6]*. This ***'arc process'*** produces a mixture of 55-65wt% of straight multi-walled nanotubes and 35-45wt% of graphite nanoparticles. They contain almost 100% carbon. By growing the tubes at 3000-4000° using this process they contain less defects than by other procedures, and are purified in this way. They are stable in air up to 700°.
MWCNT arrays for ***nanoelectronics*** with nickel-carbide particle tips with same diameters as above are also available. Vertically aligned ***MWCNTs on a silicon wafer substrate*** with low resistivity (1-30 ohm-cm), as well as on a ***copper wafer substrate*** (1cm x 1cm x 0.05cm high conductivity low-oxygen copper) have been prepared. The latter are produced by ***plasma-enhanced chemical vapour deposition (PECVD)***. MWCNTs have also been made in 3-19, 7-13 and 5-15 graphene layers wall thichnesses. See below for breaking up the bundles and graphene.

Carbon double-walled nanotubes (DWCNTs or **DWNTs)** *[308068-56-6]* MDL number MFCD06411993. These have been prepared by the *Carbon Vapour Deposition* (CVD) method with >90% carbon content and 50-80% DWCNT. They can be prepared with approximately the following dimensions 5nm OD, 1.3-2.0nm ID and 50μm length; and with 0.12-0.14g/ml bulk density and >600m^2/g surface area. The rest (10-40%) consists of amorphous carbon and residual metal catalysts that are deliberately placed in the original carbon in order to synthesise the carbon tubes. [Double-walled Carbon Nanotubes by Pfeiffer et al. *Topics in Appl Phys* **111** 495 *2008*, DOI: 10.1007/978-3-540-72865-8_16.]

Carbon single-walled nanotubes (SWCNTs or **SWNTs)** *[308068-56-6]* **M 3652-3607**, **d^{25} 1.7-1.9g/ml.** The SWCNTs are of particular use for derivatisation and the applications stated above. They can be prepared in various bundle dimensions, *viz*: d = 1.2-1.5nm, l = 2-5μm (40-60% SWCNT, arc method); d = 1.1-0.5nm, l = 100μm (>50% SWCNT, Carbon Vapour Deposition, CVD, method); d = 2-10nm, l = 1-5μm (50-70% SWCNT, arc method); individual short tubes d = 1-2nm, l = 0.5-2μm (90% SWCNT, electric arc, EA, method), and individual long tubes d = 1.3-1.5nm, l = 1-5μm (40-60% SWCNT, arc method, EA) and the HiPco process (see above). [See 'Single-walled Carbon Nanotubes' by Nanot et al. in *Springer Handbook of Nanomaterials (Part A)* Springer Verlag, pp 105-146 *2013*, DOI: 10.1007/978-3-642-20595-8_4, ISBN: 978-3-642-20594-1 print, 978-3-642-20595-8 on line.]

FUNCTIONALISED CNTs.
MWCNTs and SWCNTs have been functionalised successfully, and the products have found numerous applications. They are conducive to further chemical reactions as they are readily soluble, thus amenable to solution chemistry [see R.C. Haddon and coworkers in *Chemistry of Single-Walled Carbon Nanotubes,* Niyogi et al. *Acc Chem Res* **35** 1105 *2002*, DOI: 10.1021/ar010155r; and Sun and coworkers in *Functionalized Carbon*

Nanotubes: Properties and Chemistry, Sun et al. *Acc Chem Res* **35** 1096 *2002*, DOI: 10.1021/ar010160v]. When purified by the acid and oxidising conditions the tubes invariably are oxidised to form CO_2H or quinone groups, particularly at the ends of the tubes. Depending on the conditions, ***'cutting'*** may occur leaving open-ended tubes (see fullerene tubes above). Annealing at high temperatures *in vacuo* causes some decarboxylation and closing up of the ends that form half ***fullerene tips*** (like the end of a glass test tube, see above). Because of the larger curvature at the tips than on the sides of the tubes, the tips are more readily functionalised (due to the easier conversion of sp^2 to sp^3 carbon atoms); but then again they would lose the added function more readily on annealing. The tips are also more easily cleaved by oxidants ($KMnO_4$, OsO_4 and RuO_4) at 100° under acidic conditions [Hwang *JCS Chem Commun* 173 *1995*, DOI: 10.1039/C39950000173]. Functionalised SWCNTs dissolve in organic solvents (e.g. THF, CH_2Cl_2) and can be examined by optical spectroscopy. Tubes with CO_2H groups on the sides are commonly formed, are readily converted to COCl groups, and can react with a variety of reagents possessing the appropriate functional group. Also by virtue of the double bonds in the hexagonal rings, the tubes condense with nitrenes (to form aziridino compounds with UV light), react with carbenes (to form cyclopropane derivatives), are reduced (by Birch reduction), form metal derivatives which can be reacted further, react with aryl diazonium compounds (arylation), undergo 1,3-dipolar cycloaddition reactions (e.g. to form pyrrolidine derivatives), undergo nucleophilic reactions, radical reactions, and halogenation. J.L. Musgrave and coworkers [Khabashesku et al. *Acc Chem Res* **35** 1087 *2002*, DOI: 10.1021/ar020146y] have prepared ***'fluoronanotubes'*** by direct fluorination of SWCNTs, and the fluoronanotubes dispersed in THF reacted with alkyl-Li reagents, Grignard reagents, alkoxides, hydrazine and ω-diamines to form a variety of useful functionalised tubes. Sun and coworkers [Fu et al. *Nano Lett* **1** 439 *2001*, DOI: 10.1021/nl010040g] functionalised SWCNTs with ***lipophilic and hydrophilic dendra*** and showed that they can be defunctionalised in homogeneous solutions by base- and acid- catalysed hydrolysis demonstrating the existence of ester linkages. Absorption in the UV/VIS spectra of these ***functionalised tubes obey Beer's law*** demonstrating no aggregation effects, and SEM analysis was not successful due to the extent of substitution, whereas the de-functionalised SWCNTs and MWCNTs gave successful SEM imaging. SWCNTs attached to a silicon substrate can be used as very small highly sensitive ***chemical sensors or memristors*** for gases. They also adsorb chemicals such as alcohols, aromatics, amines and phosphonates, some of which do not readily desorb and slow the process down unless they are removed by other means such as high temperatures which tend to be time consuming and degrade the sensor. Masel and coworkers [Salehi-Khojin et al. *Science* **329** 1327 *2010*, DOI: 10.1126/science.1194210, reviewed by H. Birch, '***Electric shock resets nanotube sensor***', RSC *Chemistry World* **7** (10) *2010*] showed that current induced voltage above the Poole-Frenkel conduction threshold (>12V) desorbed most molecules effectively after 3 hours and the sensors returned rapidly to baseline. The carbon of SWCNTs can be functionalised when coated with SDS in H_2O by reaction with *p*-substituted phenyldiazonium tetraflurorborate to form ***functionalised SWCNTs.*** These have 1 to 9 carbon atoms along their backbones which will be attached to the organic moiety, and they remain unbundled throughout their entire lengths. Typically the SDS coated CNTs (10ml, 2.08μM, 0.02mmol) and the aryldiazonium salt (0.32nmol, 16 equiv/mol of carbon; with *p*-Cl, *p*-Br, *p*-*t*-Bu, *p*-CO_2Me, *p*-NO_2, *p*- C=C-Ph) are stirred in a flask for 10min. Completion of reaction can be ascertained from the UV spectrum of an aliquot, then the mixture is diluted with Me_2CO, filtered through a PTFE (0.2μm) membrane. The filtrate is washed with H_2O (100ml) the Me_2CO (100ml x 3) to remove the SDS and unreacted diazonium salt completely. The functionalised solid nanotubes are collected and dried overnight at 65° *in vacuo* and characterised. AFM (atomic force microscopy) analysis of the original nanotubes and the functionalised tubes showed that the latter are either incapable of bundling or easily exfoliated in organic solvents. Some solutions of them can remain without precipitation or flocculation for months. [Dyke & Tour *Nano Lett* **3** 1215 *2003*, DOI: 10.1021/nl034537x.] Although functionalisation affects the electronic properties of the nanotubes, their use for rheological modification of blended materials can be extensive. For the application of this procedure to carbon or graphite coated nanometals see for example carbon coated cobalt nanoparticles below.

Rapid determination of the carbonaceous content of bulk SWCNT soot uses a solution-phase near-IR procedure. Thus the AP-SWCNT (10g, AP = as prepared) is homogenised mechanically to a fine powder, then a small portion (50mg) is dispersed in DMF (100ml) by ultrasonication and mechanical stirring (5min) to a slurry. A few drops of the slurry are further dissolved in DMF (10ml) to give a faintly coloured non-scattering dispersion after further ultrasonication (2min). Keep the sonication to a minimum to avoid damaging the sample. The concentration of the dispersion should be adjusted to obtain an optical density of 0.15—0.2 at 12,000 cm^{-1}. This concentration gives the minimum signal/noise ratio for recording spectra and the range

corresponds to a concentration of *ca* 0.01mg/ml. It should be noted that at higher concentrations dispersions were less stable. A reference sample (from highest purity material) is used to evaluate the purity and ustilising the region of the second interband transition (S_{22}) for semiconducting SWCNTs. [Itkis et al. *Nano Lett* **3** 309 *2003*, DOI: 10.1021/nl025926e].

SWCNT—$(CO_2H)_n$, 89-90% SWCNT (carbonaceous purity), bundle dimension: diam 4-5nm x length 0.5-1.5μm. The SWCNTs were produced by EA discharge [Journet et al. *Nature* (letter) **388** 756 *1997*, Itkis et al. *J Phys Chem B* **108** 12770 *2004*, DOI: 10.1021/jp0487307] or the HiPco procedure (see above). SWCNT-CO_2H is prepared as follows: HiPco SWCNTs (0.2g) are sonicated in a 3:1 mixture of concentrated H_2SO_4/concentrated HNO_3 (80ml) for 4 hours, diluted with de-ionised H_2O and filtered through a 0.2μm pore acid-resistant membrane. The solid is dried at ~25°, then sonicated in a solution of 4:1 concentrated H_2SO_4/30% H_2O_2 for 15 minutes, diluted with excess de-ionised H_2O, filtered again and dried *in vacuo* at 25° to give 79w/w% of ***'shortened'*** product (85% have length < 600nm, i.e. ~0.6μm). [Zhao et al. *Adv Funct Mater* **14** 71 *2004I,* DOI: 10.1002/adfm.200304440.] Solution phase NIR spectroscopy against a standard [see Itkis et al. *Nano Lett* **3** 309 *2003*, DOI: 10.1021/nl025926e], gave a carbonaceous purity of 80-90% and 3-6 atom% carboxylic acid. Its solubility is 1mg/ml in DMF, and 0.1mg/ml in H_2O. Metal content is 5-10%. This is suitable for further reactions. [see *652490 ALDRICH*.]

SWCNT—$(COCl)_n$. The preceding shortened SWCNT-acid (100mg) [see also Liu et al. *Science* **280** 1253 *1998*, DOI: 10.1126/science.280.5367.1253] is stirred in $SOCl_2$ (20ml) containing DMF (1ml) at 70° for 2 hours, centrifuged, the brown coloured supernatant is decanted, the sediment is washed with anhydrous THF, centrifuged again; the pale yellow supernatant is decanted and the sedimented SWCNT-$(COCl)_n$ is dried at ~25° *in vacuo*. This product is reactive and should be used immediately. [Chen et al. *Science* **282** 95 *1998*, DOI: 10.1126/science.282.5386.95]. *Alternatively,* the preceding acid (12mg) in dry DMF (20ml) is sonicated for 30 minutes to give a homogeneous suspension, to which is added redistilled oxalyl chloride (0.4ml) dropwise at 0° under N_2. The mixture is stirred at 0° for 2 hours, then stirred at 70° overnight to remove excess oxalyl chloride, and dried *in vacuo*. This reactive product must be used immediately. [See Itkis et al. *Nano Lett* above.]

SWCNT—$(CONH_2)_n$, 89-90% SWCNT (carbonaceous purity), bundle dimension: diam 4-6nm x length 0.7-1.0μm, average diameter of individual SWCNT being 1.4nm ±0.1nm [MFCD09753863**].** The preceding cooled SWCNT-$(COCl)_n$ in dry DMF (~0°) is treated with liquid NH_3 (~0.5ml) and stirred while the temperature rose to ~25°, and kept there with stirring for 24 hours. Dry N_2 is bubbled through the mixture to remove excess of NH_3, excess of dry THF is added and the mixture is centrifuged, the supernatant is decanted off, the sediment is washed with dry THF, centrifuged again and the SWCNT-NH_2 residue is dried *in vacuo* at ~25°. The extent of labelling is the same as in the original acid, i.e. 3-6 atom % (amide groups) and metals ~6-8%. Their solubilities are 0.5 to 1.0mg/ml, in each of the alcohols, acetone and DMF; and can be functionalised with any reagent that will react with amide groups.

SWCNT-$(ODA)_n$ {SWCNT-[$CONHCH_2(CH_2)_{16}CH_3$)]$_n$, octadecylamide functionalised}, 89-90% SWCNT (carbonaceous purity), bundle dimension: diam 2-10nm x length 0.5-2.0μm, average diameter of individual SWCNT being 1.4nm ±0.1nm, [MFCD07370655**].** It is prepared from the above SWCNT-$(COCl)_n$ (obtained from 100mg of the acid) by mixing with octadecylamine (ODA, 2g, m 55-57°) and heating at 90-100° for 96 hours under dry N_2, and cooled. Excess of ODA is removed by washing with EtOH four times (5-10 minutes sonication at 40 KHz) by centrifugation/decantation, the sediment is dissolved in CH_2Cl_2, filtered, the black coloured filtrate is evaporated to dryness in a rotavap and the residue is dried *in vacuo* at ~25° to give >60% yield based on shortened SWCNTs. ***Note*** that the reaction of SWCNTS-$(COCl)_n$ and excess of ODA in toluene at ~25° for several days gives only traces of product and the success of the former procedure was attributed to expansion and defoliation of the SWCNTs bundles to give the more reactive individual nanotubes [Chen et al. *Science* **282** 95 *1998*, DOI: 10.1126/science.282.5386.95]. The extent of labeling in the commercial sample is 30-40wt% (ODA) and contains 4% of metals. The amide is soluble in $CHCl_3$, CH_2Cl_2, $*C_6H_6$, toluene, and the solubility in CS_2 or THF is >1mg/ml. The solubility of the ODA derivative made it amenable to purification, and R.C. Haddon and coworkers purified it by gel permeation chromatography (SEC) using Styragel HMW7 [Niyogi et al. *J Am Chem Soc* **123** 733 *2001*, DOI: 10.1021/ja0024439] and PLgel MIXED-A [Zhao et al. *J Am Chem Soc* **123** 11673 *2001*, DOI: 10.1021/ja010488j], both being polystyrene divinylbenzene resins. The latter proved to be a superior gel (300 x 7.5mm column), and when using THF as eluent three bands

were separated at a flow rate of 0.5ml/minute. The first band contained 74% of SWCNTs-ODA (as detected by AFM, UV and NIR) [MW range 2000 to 4 x 10^7, particle size 15-20μm, retention time 8 minutes], the second band with retention time of 9 minutes contains mostly nanoparticles with traces of SWCNTs, and the third band with retention time of 19 minutes contained amorphous carbon. IR, Raman and UV spectra confirmed the ODA component, and ^{1}H NMR (200MHz, $CDCl_3$) demonstrated bands characteristic of CH_2 groups and the terminal CH_3 group. The nature (e.g. such as broadness) of the bands was indicative that both ionic (charge transfer) and covalent interactions had occurred.

SWCNT-{CONH-*p*-[C_6H_3(*m*-SO_3H)-*p*-NHC_6H_3(*m*-SO_3H)-]$_m$}$_n$ [SWCNT-*n*-poly-*p*-aminobenzene-*m*-sulfonic acid, SWCNT-(CO-PABS)$_n$], 75-85% SWCNT (carbonaceous purity), average size of individual SWCNT is L 1.1nm x 0.5-1.0μm, average PABS Mw ~400-600g/mol, [MFCD05865412**].** The PABS polymer was prepared by mixing *m*-aminobenzenesulfonic acid (ABS, 0.865g) and aniline (15-20mol% of ABS, as inhibitor of polymerisation) and 1M HCl with ammonium persulfate as oxidant, stirred at 0º for 6 hours, concentrated at ~25º (*in vacuo*), filtered and the solid was washed with Me_2CO. This was dissolved in H_2O, and the aqueous solution was slowly added to a large excess of Me_2CO. The black solid was filtered off and dried at ~25º (*in vacuo*) to give PABS (340mg, 40%, Av M_W ~400-600 g/mol), which was identified by its UV spectrum that has λ_{max} at 290 and 510nm in aqueous 1N NaOH [Roy et al. *Synth Met* **100** 233 *1999*, DOI: 10.1016/S0379-6779(98)01505-7]. **SWCNT-(CO-PABS)$_n$** was obtained from SWCNT-$(COCl)_n$ [prepared as above by the oxalyl method from HiPco SWCNTs (12mg, Carbon Nanotechnologies Inc.)] in dry DMF (~20ml) by mixing with PABS (120mg) in DMF (~50ml) and stirring at 100º for 5 days. After cooling to 25º the solid was filtered through a 0.2mm pore-size membrane and washed thoroughly with DMF and EtOH, and dried *in vacuo*. The black **SWCNT-(CO-PABS)$_n$** (57mg) on the membrane was collected and dried *in vacuo* overnight. Its solubilities are 0.05mg/ml in EtOH, 0.1mg/ml in DMF and 5.0mg/ml in H_2O. The commercial product has 65% (PABS) and 4% metals. The water soluble graft polymer had a much higher conductivity (5.6 x 10^{-3} Scm^{-1}) than PABS (5.4 x 10^{-7} Scm^{-1}), and IR spectrum wasconsistent with an amide bond being formed; the ^{1}H NMR (300MHz, D_2O) exhibited a very weak broad spectrum compared with the sharp signals of PABS itself, characteristic of the effect of ring currents in the nanotubes. The UV/VIS/MIR spectrum showed the presence of the interband transitions of the semiconducting SWCNTs and an absorption at 17,750 cm^{-1} due to the PABS moiety. [Zhao et al. *Adv Funct Mater* **14** 71 *2004*, DOI: 10.1002/adfm.200304440.] Solution phase NIR spectroscopy against a standard, provided a carbonaceous purity of 80-90% — a procedure which has an accuracy of ~3% [see Itkis et al. *Nano Lett* **3** 309 *2003*, DOI: 10.1021/nl025926e].

SWCNT-(PEG)$_n$ {SWCNT-[COO(CH_2CH_2-O-)$_m$-H)]$_n$, polyethylene glycol functionalised}, 80-90% SWCNT (carbonaceous purity), bundle dimension: diam 4-5nm x length 0.5-0.6μm, average diameter of individual SWCNT being 1.4nm ±0.1nm, PEG Mw ~600g/mol, [MFCD07370656]. The above SWCNT-$(COCl)_n$ prepared from 30mg of SWCNT-CO_2H is mixed with PEG (250mg, m 20-25º) and heated under N_2 at 75º with vigorous stirring for 48 hours. The mixture is cooled to 25º extracted with $CHCl_3$ several times, filtered, and the dark coloured solution is repeatedly precipitated with EtOH to give SWCNT-$(PEG)_n$ which is collected (filtration or centrifugation) and dried *in vacuo*. Its solubility in H_2O is high (5.0mg/ml) and has ~30wt% (PEG) and ~6% trace metals. The ester function can be identified by IR (ν_{max} ~1700 cm^{-1}), but the ^{1}H NMR signals are weak and broad (see above). The ester-free SWCNTs can be recovered by acid- and base-catalysed hydrolysis [see above Fu et al. *Nano Lett* **1** 439 *2001*, DOI: 10.1021/nl010040g]. Solution phase NIR spectroscopy against a standard, provided a carbonaceous purity of 80-90% — a procedure which has an accuracy of ~3% [see Itkis et al. *Nano Lett* **3** 309 *2003*, DOI: 10.1021/nl025926e].

SWCNT-(*p*-C_6H_4-R; R = F, Cl, Br, I, SO_3H, CO_2H, NO_2, *n*-butyl, *t*-Bu or CO_2Me)$_n$. These were prepared by ***'on water'*** functionalisation of bundled SWCNTs. The term 'on water' refers to the water-based reactions of water-insoluble organic substrates [see K.B. Sharpless and coworkers in Narayan et al. *Angew Chem Int Ed* **44** 3275 *2005*, DOI: 10.1002/anie.200462883; and Klijn & Engberts *Nature* **435** 746 *2005*, DOI: 10.1038/435746a]. This technically involves the reaction of *p*-substituted benzene diazonium compounds with the hexagonal rings on the walls of SWCNTs in aqueous medium and represents a ***'green'*** or ***'environmentally friendly'*** process. The following are optimal conditions for functionalisation. HiPco SWCNTs (10mg) and de-ionised H_2O (30ml) were homogenised in a flask (100ml) by stirring at medium setting for 30 minutes, then heating at 80º with the substituted aniline (4 equivalents/SWCNT) and isoamyl nitrite (2 equivalents/SWCNT) with vigorous stirring (stirrer bar) under a reflux condenser overnight. The mixture is then cooled, filtered

through a 0.45μm Teflon filter, the filter cake is washed with de-ionised H_2O, and Me_2CO until the filtrate is clear. The cake is collected, sonicated in DMF (25ml) to remove any remaining organic compounds, collected by filtration (0.45μm Teflon filter) and rinsed with Me_2CO to give the desired functionalised SWCNTs as evidenced by 20-30% weight increases. TGA, Raman [elevated D (diamondoid, ν_{max} at 1290 cm^{-1})/G (graphic, ν_{max} 1590 cm^{-1}) band ratios] and UV-VIS-NIR spectroscopy, XPS, AFM and TEM confirmed the structures. It is interesting that TEM images (on a carbon grid) showed that the SWCNT bundles have smooth edges, whereas functionalised SWCNT bundles have ***'bumps'*** all along the edges. These functionalised nanotubes should be useful for further functionalisation reactions [Price & Tour *J Am Chem Soc* **128** 12899 *2006*, DOI: 10.1021/ja063609u]. By using the above procedure **SWCNT-(*p*-C_6H_4-CH_2NH_2)** and **MWCNT-(*p*-C_6H_4-CH_2NH_2)** were prepared and successfully coupled, *via* their terminal amino group to the carboxy group of *N*(1)-carboxymethyl-thymine, to form thymine ends. These functionalised CNTs readily form stable *double* hydrogen bonds with other thymine groups of these CNTs. This induces controlled non-covalent self-assembled supramolecular aggregation of the CNTs in solvents that do not break hydrogen bonds such as CH_2Cl_2, and can form good dispersions in polar aprotic solvents such as DMF. All characterisations were performed using spectroscopic, analytical and microscopic techniques. [Quintana & Prato *Chem Commun* 6005 *2009*, DOI: 10.1039/B915126E; reviewed by K. Davies RSC *Chemistry World* **6**(11) 6005 *2009*.] These properties can be of importance in ***nanoelectronics***, or in ***biological applications*** such as making patterned active substrates for neuronal growth [Cellot et al. *Nat Nanotechnol* **4** 126 *2009*, DOI: 10.1038/nnano.2008.374].

I-SWCNT, I = {-$COOCH_2$-[3,5-di(hexadecyloxy)phenyl]}$_n$ and I_{PEG}-SWCNT, I_{PEG} = {-$COOCH_2$-[3,5-di(methyltriglycoloxy)phenyl]}$_n$. These are respectively hydrophobic and hydrophilic SWCNTs which were prepared as described by Y.-P. Sun and coworkers [Fu et al. *Nano Lett* **1** 439 *2001,* DOI: 10.1021/nl010040g] by stirring vigorously SWCNT-$(COCl)_n$ (30mg, see above) and carefully dried **I** (250mg) under N_2 at 75°/48 hours. The cooled mixture is extracted several times with $CHCl_3$, the combined dark-coloured extracts were repeatedly precipitated with EtOH to give **I-SWCNT** with ^{1}H NMR (500MHz, $CDCl_3$) which had δ at 0.88 (t, J = 6.5Hz) and typically weak broad bands at 1.1-1.5, 1.6-1.8, 3.5-3.9, 4.0-4.2 and 6.0-6.5 caused by the effect of the SWCNT. **I_{PEG}-SWCNT** was prepared in a similar manner except that its solubility in H_2O allowed further purification by dialysis for several days against de-ionised H_2O (dialysis tubing with Mr ~100,000 cut off to remove PEG). Dendron **I** was prepared by reaction of methyl 3,5-dihydroxybenzoate and hexabromodecane followed by reduction with LAH, and Dendron **I_{PEG}** was obtained from the same benzoate and triethylene glycol monoethyl ether in the presence of Ph_3P and diethyl azidodicarboxylate in THF, followed LAH reduction. The corresponding hydrophobic **I-MWCNT** and hydrophilic **I_{PEG}-MWCNT dendra** were similarly prepared by reacting SWCNT—$(COCl)_n$ with the benzylic OH group in the **dendra**, and all were characterised by ^{1}H NMR, UV-Vis spectroscopy, TGA and SEM as well by de-functionalisation of homogeneous solutions under acid- and base- catalysed reaction conditions.

MWCNT-$(COOH)_n$ are commercially available [*755125 ALDRICH*], with average diameter, 9.5nm length x 1.5μm and >8% -COOH functionalised. For the preparation of the polyurethane (**PU**) carbon nanotube composite **MWCNT-(COEDA-PU-PTMO)$_n$,** the MWCNT-$(COOH)_n$ was converted into MWCNT-$(COEDA)_n$ in two steps ($SOCl_2$ then $H_2NCH_2—CH_2NH_2$, EDA), and the grafted amide groups reacted readily with toluene-2,4-diisocyanate (TDI) to form MWCMT-(COEDA-TDI)$_n$ which were condensed with PTMO {polyoxytramethylene glycol, HO[-$(CH_2)_4$-O-$(CH_2)_4$-]$_n$-OH, M_n = 1000} to form the hard segment of the polyurethane, **PU**. The microstructure of this composite containing 2 wt% of MWCMT was investigated by FESEM (field emission scanning electron microscopy) and TEM (transmission electron microscopy); and the IR of a wafer in KBr confirmed that condensation had occurred. The thermal and mechanical properties (tensile strength) of the polyurethane/multi-walled carbon nanotube composite were found to be superior in comparison with pure polyurethane composite [Xiong J, et al. *Carbon* **44** 2701 *2006*, DOI: 10.1016/j.carbon.2006.04.005].

MWCNT-(PPEI-EI)$_n$. These functionalised MWCNTs were prepared in two ways. ***Firstly***, the MWCNTs (20mg) were refluxed with $SOCl_2$ (5ml) for 24 hours and evaporated *in vacuo*, then the co-polymer PPEI-EI [200mg, poly(propionylethylenimine-*co*-ethylenimine) [as prepared by Y.-P. Sun and coworkers *Macromolecules* **32** 8747 *1999*, DOI: 10.1021/ma9906736; *Photochem Photobiol* **66** 301 *1997*, DOI: 10.1111/j.1751-1097.1997.tb03152.x; *Chem Commun* 2699 *1996*, DOI: 10.1039/CC9960002699] was added and heated at 160-180° for 12 hours under N_2, cooled, repeatedly extracted with $CHCl_3$ and the dark combined

extracts were precipitated with hexane. The isolated solid was dissolved in de-ionised H_2O and dialysed against fresh H_2O (dialysis tubing with Mr ~100,000 cut off to remove PPEI-EI) for 3 days. Further purification was by re-precipitation from $CHCl_3$ solution into hexane, and drying the dark **MWCNT-(PPEI-EI)$_n$** solid which had ^{1}H NMR (500MHz, $CDCl_3$) with broad weak bands at δ 0.8-1.4, 1.9-2.6, 2.7-2.9, 3.1-4.3. ***Secondly***, (without forming the COCl derivative) by directly heating the MWCNTs (20mg) with PPEI-EI (200mg) at 160-180^o for 12 hours under N_2 and worked up as above provided **MWCNT-(PPEI-EI)$_n$** which had ^{1}H NMR (500MHz, $CDCl_3$) with broad weak bands at δ 0.8-1.4, 1.9-2.6, 2.7-2.9, 3.1-4.3. Raman, UV-VIS spectroscopy, SEM, TEM and TGA showed that both procedures were effective in producing functionalised MWCNTs which were readily soluble in common organic solvents and in H_2O. The latter method may have caused amidation as well as ionic interaction between the amino-polymer and the MWCNT. [Lin et al. *J Phys Chem B* **106** 1294 *2002*, DOI: 10.1021/jp013501v.]

SWCNT[=CH)$_2$N-CH$_2$CH$_2$OCH$_2$CH$_2$OCH$_2$CH$_2$NH$_3^+$. HCl]$_n$ and **MWCNT[=CH)$_2$N-CH$_2$CH$_2$OCH$_2$CH$_2$-OCH$_2$CH$_2$NH$_3^+$. HCl]$_n$.** These salts are very soluble in H_2O and solutions are stable for more than a month at concentrations of 20mg and 12mg per ml respectively. The free amino terminal group is a useful handle for attachment to physiologically active molecules (see below). They are formed in a 1,3-dipolar cycloaddition reaction between the C=C bonds of the CNTs with the N-glycine **N** atom and formaldehyde. The glycine in this case is BocNHCH$_2$CH$_2$O-CH$_2$CH$_2$OCH$_2$CH$_2$**N**HCH$_2$CO$_2$H and is prepared as follows: BocNHCH$_2$CH$_2$O-CH$_2$CH$_2$OCH$_2$CH$_2$NH$_2$ (30mmol) in dioxane (20ml) at 0^o is treated dropwise with a solution of benzyl bromoacetate (2.3g, 10mmol) in dioxane (30ml) during 1 hour, and the mixture is stirred overnight. The solvent is evaporated off *in vacuo*, the residue is dissolved in H_2O (70ml) and extracted with EtOAc (3 x 50ml). The combined organic phases are dried (Na_2SO_4), evaporated *in vacuo*, and the residue is purified by chromatography on Silica gel [NM Kieselgel 60 (70-230 mesh)] and eluted with 1:1 EtOAc/petroleum ether then pure EtOAc to give ***N-Boc-aminoethoxyethoxyethylaminoacetic*** as an oil. To a solution of this oil (5.05mmol) in MeOH (50ml) is added 10% Pd/C (50mg), the mixture is stirred under H_2 for 24 hours, the catalyst is filtered off (through Celite), the solvent is evaporated and the residue is triturated with dry Et_2O to give ***aminoethoxyethoxyethylaminoacetic acid*** as a pure white solid (1.6g, 99%, 5.05mmol), **m 105-106^o** with the expected elemental (C, H and N) analyses. The acid has IR-DRIFT (KBr) with ν_{max} at 3250, 2970, 1706, 1620, 1540, 1365, 1115, 686, 590, 480 cm^{-1}; the ^{1}H NMR (200MHz, $CDCl_3$, TMS) has δ at 1.40 (s, 9H), 3.22 (m, 2H), 3.49 (t, *J* = 5.1 Hz, 2H), 3.64-3.53 (m, 8H), 3.79 (bt, 2H), 5.54 (bt, 1H), 6.23 (bs, 1H), 8.21 (bs, 1H); the ^{13}C NMR (50MHz, $CDCl_3$, TMS) has δ at 170.5, 156.2, 79.1, 70.4, 70.3, 70.1, 66.6, 49.8, 46.8, 40.4, 28.6; and EI-MS found *m/z* 306 (M$^+$). [Kordatos et al. *J Org Chem* **66** 4915 *2001*, DOI: 10.1021/jo015608k.]

For **functionalisation**, a suspension of full length SWCNTs or MWCNTs [diameter 20-30nm, from Carbon Nanotechnologies, Inc USA (www.cnanotech.com), and Nanostructured & Amorphous Materials Inc USA, (www.nanoamor.com) respectively] in DMF is treated with the preceding *N-Boc-aminoethoxyethoxy-ethylaminoacetic* (or and paraformaldehyde, and the mixture is heated at 130^o for 96 hours. Unreacted material is removed by filtration, the filtrate is evaporated, the residue is dissolved in $CHCl_3$, washed with H_2O, dried, evaporated, redissolved in $CHCl_3$, precipitated with Et_2O, collected (on a 0.45mm Teflon filter) and washed several times with Et_2O to give the functionalised CNTs in ~10% yields based on the amount of starting CNTs. They are soluble in solvents such as CH_2Cl_2, $CHCl_3$, toluene and Me_2CO. Removal of the *N*-Boc group is achieved by dissolving the previous functionalised SWCNTs or MWCNTs in CH_2Cl_2, dry HCl gas is bubbled through the solution whereby the ***CNT-chloride hydrochloride salts*** (desired materials) separate out. They are collected (or the solvent is evaporated), dissolved in MeOH and precipitated with dry Et_2O. *Alternatively*, the *N*-Boc group is removed by treatment with TFA (~25^o/3hrs, evaporate, wash residue with toluene and dry *in vacuo*) in which case the ***CNT-trifluoroacetate salts*** are obtained. A variety of such funtionalised CNTs were prepared and some were methylated (at the pyrrolidine that was produced) to form the quaternary bases. The desired products, as identified by TEM showed that the functionalised SWCNTs and MWCNTs have 10-50nm and 20-30nm mean diameters respectively, their ^{1}H NMR spectra are similar with the signals from the oligoethylene glycol chains appearing as broad peaks at ~3.6 ppm, and absence of the Boc methyl groups which would have been at 1.2 ppm from TMS. [Georgakilas et al. *Chem Commun* 3050 *2002*, DOI: 10.1039/B209843A.] These functionalised CNTs were successfully coupled *via* their terminal amino group to the carboxy group of *N*(1)-carboxymethyl-thymine to produce thymine ends. The thymine functionalised CNTs readily form stable double hydrogen bonds with other thymine groups of these CNTs. This induces controlled non-covalent self-assembled supramolecular aggregation on the CNTs in solvents that do not break hydrogen bonds such as CH_2Cl_2, and can form good dispersions in polar aprotic solvents such as DMF. All characteris-

ations were performed using spectroscopic, analytical and microscopic techniques. [Quintana & Prato *Chem Commun* 6005 2009, DOI: 10.1039/B915126E; reviewed by K. Davies RSC *Chemistry World* **6**(11) 6005 *2009*.] These properties can be of importance in ***nanoelectronics*** or in ***biological applications*** such as making patterned active substrates for neuronal growth [Cellot et al. *Nat Nanotechnol* **4** 126 *2009*, DOI: 10.1038/nnano.2008.374.]

SWCNT[=(CHR')(CH_2)N-R"), where R' = H, 4-$MeOC_6H_4$- or 2-pyrenyl-, and R" = -$(CH_2CH_2O)_3CH_3$ or -$(CH_2)_7CH_3]_n$ and MWCNT[=(CHR')(CH_2)N-R"), where R' = H, 4-$MeOC_6H_4$- or 4-pyrenyl-, and R" = -$(CH_2CH_2O)_3CH_3$ or -$(CH_2)_7CH_3]_n$ were prepared by 1,3-dipolar cycloaddition reactions with short oxidised SWCNTs or purified MWSCNTs as in the preceding entry and using paraformaldehyde, 4-methoxybenzaldehyde or 4-formylpyrene to form the substituted pyrrolidines with the double bond(s) of the CNTs. They were characterised by UV-VIS, Raman and ^1H NMR spectroscopy and by TEM. The fluorescence of the pyrene derivatives were of interest, and all provide means for the preparation of nanocomposites. [Georgakilas et al. *J Am Chem Soc* **124** 760 *2002*, DOI: 10.1021/ja016954m; Calvert *Nature* **399** 210 *1999*, DOI: 10.1038/20326.]

GRAPHENE MATERIALS

Graphene is the name given to a flat monolayer of carbon atoms packed in a two-dimensional (2D) honeycombe lattice of six-membered carbon rings. It is the unit block (2D sheet) of graphitic materials which stack into multilayers to form graphite (3D), rolls to form nanotubes (1D) or wraps to form buckyballs (0D)[see above]. 'Graphenes' are defined as single-, double-, and few (3 to <10) carbon layers (2D), with characteristic electrical properties not found in graphite. ***Graphene*** is the accepted name for a single, or at most a double carbon thick layer which is ≈ 5Å thick. Single layer (**SLG**) 2D crystals have been prepared (see below) that have high crystal quality where charge carriers can travel thousands of atomic distances without scattering. Its electrical behaviour includes a pronounced ambipolar electric field effect in which charged carriers could be tuned continuously between electrons and holes at concentrations n as high as 10^{13} cm^{-2}, with mobilities μ greater than15,000 cm^2 V^{-1} s^{-1} under laboratory conditions. Films of 5 layers would be considered as ***'bulk material'***, and films with more than 100 layers are considered as thin films of 3D graphite (see graphite [7782-42-5] below). [Geim & Novosolov *The Rise of Graphene: Nature Materials* **6** 183 *2007*, DOI: 10.1038/nmat1849.]

Graphene films were obtained by mechanical exfoliation (repeated peeling) of highly oriented pyrolytic graphite. The 2D crystallites were collected from a fresh surface of a layered crystal using ***few-layered graphene, FLG***, by rubbing against another surface (any solid is suitable, but an oxidised silicon wafer, i.e. SiO_2 would be also useful later for identification). This allows flakes of graphene to be attached to the surface for characterisation. This approach was very reproducible, has also been used for preparing thicker films (≥ 3nm) that were up to 100μm across, as well as FLGs of up to 10μm in size and visible to the naked eye.

Preliminary identification of single layer films among the resulting flakes was done with an optical microscope. These became visible when they were on top of an oxidised silicon wafer (see above) because even a monomolecular layer adds enough to the optical path of reflected light that the interference colour changes reveal the presence and contours of the film. The process is simple and the 2D crystallites can be identified in about half an hour. Further identification of selected single layers is then done by AFM. It was pointed out that only a small number of single films among the many thicker films were produced by this method, they could not be identified by TEM, but they were transparent to visible light on surfaces other than SiO_2 wafers, and thus required AFM and high resolution AFM imaging for definitive identification, and are difficult to find by scanning surfaces at random. These atomically thin sheets, particularly very large 2D molecules, unprotected from the environment are stable in air under laboratory conditions, have high crystal quality and maintain macroscopic continuity. [Novoselov, Geim and coworkers, '*Electric field effects in atomically thin carbon films*' *Science* **306** 666 *2004*, DOI: 10.1126/science.1102896, '*Two dimensional atomic crystals*' *Proc Natl Acad Sci USA* **102** 10451 *2005*, DOI: 10.1073/pnas.0502848102.]

The sp^2 character of all the C-C bonds of graphene confer remarkable electric conductivity to it due to the delocalisation of electrons, and it is difficult to stop the flowing current at will. Geim and Novoselov and their coworkers [Elias et al. '*Control of Graphene's properties by reversible hydrogenation: Evidence for graphite*' *Science* **323** 610 *2009*, DOI: 10.1126/science.1167130] have succeeded in hydrogenating the double bonds of graphene to make ***graphane*** which now has C-C bonds with sp^3 character. The reduction transforms graphene from the highly conductive zero-overlap semimetal into an ***insulator***. Reduction was achieved with a hydrogen-

helium mixture (10% H_2) at low pressure (0.075mm Hg) and the direct current plasma ignited between two aluminium electrodes with the samples 30cm away from the discharge zone to avoid damage by energetic ions. Graphene and graphane have distinctly different Raman properties. The reaction is reversed by annealing graphane at 450° (higher temperatures damage graphene) in an argon atmosphere for 24 hours. Thus the original metallic state, lattice spacing, Raman and TEM properties, and even the quantum *'Hall effect'* are restored. ***Note*** that when the thin film is on a substrate, reduction takes place on the upper face of the film, and for more effective reduction they used free-standing graphene membranes. If one can imagine a magic pencil which can remove hydrogen from graphane and drawing channels of graphene into it, better control of current flow can be achieved [see review by J. Urquart RSC *Chemistry World* **6** (3) 23 *2009*].

Cutting of single-layer graphene (**SLG**) by anisotropic etching using thermally activated Ni nanoparticles has been developed by Jarillo-Herrero and coworkers [Campos et al. *Nano Lett* **9** 2600 *2009*, DOI: 10.1021/nl900811r; reviewed by L. Brindley, '*Cutting Graphene to ribbons*' RSC *Chemistry World* **9** (8) *2009*]. Unlike previous methods for making graphene nanoribbons and the like, their procedure makes SLG nanoribbons and other SLG structures (e.g. triangles, rectangles) in which all cuts (sub-10nm width) are oriented with the same edge-chirality, i.e. aligned along a single crystallographic directions with no hanging edges. Thus the cuts are straight, and always at an angle of 60° and/or 120°. With graphite and FLGs, etching occurs with chirality changing angles of 30°, 90°, and 150°, as well as 60° and 120°. Their method is described here in some detail as it involves ***purification procedures useful for SLG preparation.*** To ensure reliable cuts in nanoparticle assisted etching, the SiO_2/Si substrates (wafers, see above) have to be cleaned with Me_2CO and *iso*-PrOH, and submitted to UV illumination for 5 minutes to remove organic material and for making the SiO_2/Si surface more hydrophilic to ensure proper wetting during the spin-coating deposition of Ni from solution. Graphene is exfoliated on this clean surface using semiconductor grade tape. The SLG on the clean substrate is identified by optical spectroscopy (see above), AFM (typically SLGs are at a height of 0.8nm) and Raman spectroscopy (graphene's G' 2D peak, see above). The tape residue is removed by heating the SLGs in a quartz tube at 500° for 15 minutes under an argon:H_2 flow (850:150 sccm). After this heat 'cleaning', an aqueous solution of $NiCl_2$ (2.4mg/ml) is centrifuged onto this surface at 1800rpm for 60 seconds, then heated at 90° for 10 minutes on a hot plate to eliminate H_2O. The $NiCl_2$ treated sample in an argon: H_2 flow (850:150 ratio) is firstly annealed at 500° for 20 minutes to convert the salt into Ni nanoparticles, and then the etching is carried out at 1000° for 25 minutes in the same gas flow. The best etching conditions require a slow heating/cooling rate of ~50°/minute. During the etching the Ni nanoparticle (with H_2 adsorbed) furrows through the SLG by catalytically hydrogenating the carbon atoms in its path and converting each atom into a molecule of methane. With SLGs, but not with FLGs or graphite, the cutting paths never cross each other; as soon as the Ni nanoparticle comes within a 10nm distance of a preformed path it changes direction at a 60° or 120° angle. The purification procedure and the Ni concentration stated are very critical if the formation of CNTs are to be avoided. This opens many future directions for studying SLG nanoribbons and other shapes, constrictions and quantum dots with crystallographic edges. H-H. Ahn and B.H. Hong and coworkers [Bae, et al, *Nature Nanotechnology* **5** 574 *2010*, DOI: 10.1038/nnano.2010.132] have pressed rectangular graphene films (76cm diagonal) with a roller against an adhesive polymer support and the copper etched away. The graphene is pressed with rollers onto a polyethylene terephthalate substrate and the polymer adhesive is released on heating. In this way further layers of graphene can be added. When treated with HNO_3, the graphene sheet acts as a transparent electrode for touchscreen devices. It is tougher and has better transparency than indium-tin oxide (ITO) electrodes [see below, and review by S. Hadlington RSC *Chemistry World* **7** (8) 22 *2010*].

Stacked Graphene Platelet Nanochips (stacked graphene nanofilms, SGNF heat treated) and Platelet Nanofibres (SGNF acid washed) are commercially available as black powders with 40-50nm mean width, 0.1-10μ length, 0.3g/cm^3 density, and 120m^2 of surface area. The electrical resistivities are 55μWcm and 120μWcm for the chips and fibres respectively. These SGNFs are used in nanotechnology research. [US Patents 6,995,115 and 7,001,586.]

Graphite *[7782-42-5]* **m 3652-3697°, d^{25} 2.09, 2.23.** It is available commercially in various forms such as ***flakes*** (mesh 75+), ***rods*** (6mm x 150mm, low density and high density, 3mm x 150mm low density), ***powder*** (≤20μm, ≤45μm, and 150≤μm), ***nanofibres*** (I.D. 0.5-10nm x O.D 80-200nm x L. 0.5-20μm, bulk density 0.06-0.08g/ml), ***graphitised nanopowder*** (particle size <200nm with large mesopores, 10% graphite lattice content, surface area 70m^2/g, average pore ~137Å and d 1.818g/cm^3) and ***platelet nanofibres*** (prepared by catalytic CVD then de-mineralised by HCl, with surface area 80m^2/g, particle width ~100nm and particle length of

~2.5μm, TEM). [For purification by acid treatment see entry *[7782-42-5]* in Chapter 4, 'Inorganic Compounds'.] The applications of graphite include the manufacture of 'lead' pencils, lubricants, polishing, pigments, explosives, commutator brushes, carbon anodes, and arc-lamp carbon among many others. **Avoid breathing it** as it can cause coughing, decreased lung function and fibrosis, **use a mouth mask**. [See Holliday et al. in '*Comprehensive Inorganic Chemistry*' **vol 1**, Bailar Jr et al. Eds, Pergamon Press, Oxford, pp1250-1294 *1973*; ISBN 9780080172750.]

SELF ASSEMBLED MONOLAYERS (SAMs).

SAMs have been of considerable interest for some time [see Chechik, Crooks and Stirling, '*Reactions and reactivity of self-assembled nanolayers*' *Adv Mater* **12** 1161 *2000*, DOI: 10.1002/1521-4095(200008)12: 16<1161] and several useful ones have been prepared using a variety of materials and methods. Only a recent report will be described here, and it is of 2D carbon nanolayers prepared by Mo(IV) and Cu catalysed crosslinking of 1,4-bispropyne- (**1**), 1,4-bisacetylene- **(2),** and 1,4-bis(2,3,4-triacetylenephenyl)propyne- **(3)** benzenes with each benzene ring further substitued with a 3-(triethoxysilyl)propylaminocarbonyloxymethyl— [$(EtO)_3SiCH_2CH_2CH_2$-NH-$COOCH_2$—] group which acts as a linker in the polymerisation process. These three organic compounds are connected by vacuum-driven Mo(IV) catalysed alkyne metathesis [cf Zhang & Moore *Adv Synth Catal* **349** 93 *2007*, DOI: 10.1002/adsc.200600476], or oxidative Cu catalysed Hay-type coupling [cf Siemsen et al. *Angew Chem Int Ed* **39** 2632 *2000*, DOI: 10.1002/1521-3773(20000804)39:15<2632] which polymerise them to form self-assembled monolayers on SiO_2-, Si_3N_4-coated substrates (wafers) or quartz/glass slides when immersed in monomer solutions.

Preparation and purification of substrates: The freshly cleaned and dried SiO_2-, Si_3N_4- coated substrates or quartz/glass slides are placed in a reaction tube containing a 15mM solution of **(1)** or **(2)**, or **(3)** in toluene and Me_3N (10mM) under N_2, sealed and heated at 95-100° for 24 hours. The liquid is removed, the substrate is rinsed with toluene (1x), CH_2Cl_2 (2x), and sonicated for 5 minutes in toluene. The rinse is repeated, the substrate is sonicated in MeOH for 5 minutes, the rinse is repeated again and the substrate is blown dried under a stream of N_2 ready for monolayer formation.

Preparation and purification of polymerised coated substrate linked monolayers by Cu Coupling: CuCl (20mg) and degassed Me_2CO (3ml) in a reaction vial are treated with TMEDA (61μl), stirred under N_2 at 20° for 30 minutes and the preceding coated substrates are added. The mixture is purged with O_2 from a balloon and stirred under O_2 for 15 hours. The polymerised coated substrate is collected, rinsed with DMF (1x), with a solution of 0.1M sodium diethyldithiocarbamate in DMF (1x), with toluene (1x), with CH_2Cl_2 (2x), sonicated in toluene for 5 minutes, the rinse is repeated, the substrate is finally sonicated for 5 minutes in MeOH, and the *polymerised linked substrate* blown dry with a stream of N_2.

Preparation and purification of polymerised coated substrate linked monolayers by alkyne metathesis: A mixture of trisamidomolybdenum(IV) propylidyne (5.0mg) and *p*-nitrophenol (3.3mg) dissolved in trichlorobenzene (3.3ml, 1,2,4-) are placed in a vial, the coated substrate is added, the flask is sealed under a vacuum (5 Torr) for 22 hours. The substrate is collected. Rinsed with DMF (1x), 0.1M sodium diethyldithiocarbamate in DMF (1x), toluene (1x), CH_2Cl_2 (2x), then sonicated in toluene for 5 minutes. The rinse is repeated, the substrate is sonicated in MeOH for 5 minutes, the rinse repeated again and finally the *polymerised linked substrate* is blown dry in a stream of N_2.

These monolayers (SAMs) are characterised by UV-Vis, fluorescence and Raman spectroscopy. This is made easy because of the presence of benzene cores within the acetylene and linker chains, these being made of poly(1,4-phenylene-1,3-butadiynylene) polymers. AFM then provides the topology, i.e. shapes (contours), thicknesses and aspect ratios (length and width), of the 2D SAMs. This is done at all stages including those described below.

Lift-off and transfer of the SAMs: The ***'lifting off'*** is carried out by simple oxygen-reactive ion etching through a layer of 'photoresist' (e.g. 5μm x 5μm 'aspect ratio') patterned by photolithography. The 'photoresist' is placed on top of the monolayer which lies on top of the silicon substrates (support, i.e. the films of SiO_2, or Si_3N_4, or glass). Selective etching from the support is done with concentrated HF which dissolves the silicon, leaving photoresist/SAM or photoresist/monolayer membrane hybrid which can be transferred onto other substrates and then freed from the 'photoresist' layer by sonication in Me_2CO. Characterisation of the monolayers during these stages showed that very little, if any, changes in structure has occurred. The atomic force micrographs (AFMs) showed that the SAMs derived from **(1)** are monolayers with thicknesses of ≈ 1.5nm (average roughness of 0.18-0.27nm), and those from **(2)** and **(3)**, unlike from **(1),** formed multilayers of 2.8nm

and 4.7nm respectively (average roughness of 0.5nm and 0.3nm respectively). These SAMs, with aspect ratios being the same as the 'photoresist' can be transferred by contact onto a variety of surfaces such as films, pleated sheets, spheres, tubes, cones and any other shapes (followed by removal of the 'photoresist' by sonication in Me_2CO). With a free-standing shape, a free standing silicon support can be used which is then removed by etching to give a ***free standing SAM***. The monolayers are quite robust and can be stretched over ~440nm holes without tearing. This approach and these procedures that were developed by J.S. Moore, J.A. Rogers and coworkers [Schultz et al. *Proc Natl Acad Sci USA* **105** 7353 *2008*, DOI: 10.1073/pnas.0710081105] have considerable merit for ***synthesising monolayer carbon networks*** of varying shapes which can be accessible for analysis and device applications.

DIAMOND NANOMATERIALS

Nanodiamond (ND) *[7782-40-3]* **M 12.01** is commercially available in powder form with particle spherical size <10nm and ≥ 97% trace metal basis, bulk density 0.2-0.7g/ml with BET surface area of 200-450m^2/g, and in powder form with particle spherical size <10nm and ≥ 95% trace metal, bulk density 0.17g/ml with BET surface area of 278-335m^2/g. The diamond powder is made by ***explosive detonation procedures*** that are performed in stainless steel hermetic tanks (e.g. of 0.17m). Carbon condensed products [the HE (High Explosive) composite explosives] such as cast trotyl/cyclotrimethylene-trinitramine (TNT/RDX) in various proportions from 50/50 and increasing RDX, with various initial inert gas (N_2 or Ar) pressures were used to determine the best conditions to produce diamonds. Thirty minutes after the explosion, the pressure in the tank is slowly released, and the carbon product is washed out with water, allowed to settle (requiring quite a long period), the water is decanted off, and residual water is evaporated at 150°. This yielded solid carbonaceous soots that contain ultradispersed diamond (UDD, 2-15nm), together with amorphous carbon (4-25nm), graphite ribbons (<20nm), and spheres (2-4nm) as investigated by TEM, XRD, SAXS (small angle X-ray scattering) and Auger spectroscopy. Purification was carried out to remove amorphous and graphite-like carbon from the detonation soot by boiling with perchloric acid, and the maximum yield of diamond was identified by X-ray analysis. The best yield was ~7wt% obtained when TNT/RDX was 50/50 and initial pressure in the tank was ~7 atmospheres which optimised the yield of **UDD**. It was also shown that the UDD was thermally transformed into onion-like carbon (**OLC**) particles. [Kuznetsov et al. *Carbon* **32** 873 *1994*, DOI: 10.1016/0008-6223(94)90044-2.] Annealing studies, in the temperature range of 750°—1900° of detonation diamond (e.g. OLC) in an inert atmosphere (e.g. argon) affected the structure as shown by XRD and HRTEM as well as purified the material further. The IR showed that all the oxygenated groups (mainly OH, COOH and C=O) were removed, and that at the lower temperatures of ~700-800° a higher coverage of the diamond surface with π-bonds resulted. At higher temperatures the powder undergoes a ***phase transition*** from cubic diamond to graphite. [Chen et al. *Appl Phys Lett* **74** 3651 *1999*, http://dx.doi.org/10.1063/1.123211; Okotrub et al. *J Phys Chem A* **105** 9781 *2001*, DOI: 10.1021/jp011808o.] Previously, reactions of ND with free radicals lead to diamond alkylation [Nakamura et al. *Chem Commun* 900 *2003*, DOI: 10.1039/B211807F]; and arylation with diazonium salts [Yeap et al. *Langmuir* **25** 185 *2009*, DOI: 10.1021/la8029787; Liang et al. *ACS Nano* **3** 2288 *2009*, DOI: 10.1021/nn900339s] resulted in low yields of ***functionalized nanodiamond***. However, with ND annealing at ~800°, the larger coverage of diamond surface with π-bonds allowed A. Kreuger and coworkers [Jarre et al. *Chem Commun* **47** 544 *2011*, DOI: 10.1039/C0CC02931A] to achieve stable covalent C-C bonding of aromatic groups using Diels-Alder reactions onto surface annealed ND. The key reaction involved the addition of *o*-quinodimethane [acting as diene, generated *in situ* from *o*-bis(bromomethyl)benzene and substituted benzenes] to the π-bonds of ND in the presence of ***18-crown-6*** and KI in refluxing toluene for 72 hours. The substituent on the benzene ring can be ***functionalised*** further, e.g. with an SO_3H group (formed by sulfonation of the benzene ring) which can be converted into an SH group (PPh_3, I_2, $*C_6H_6$ reflux, 24 hours), and which can be made to react with *N*-dye substituted maleimide to form a condensed sulfide. The dye being fluorescent Oregon Green 48 which provided fluorescent diamond particles. The applications of such functionalisations are similar to those of functionalised fullerenes and CNTs including fluorescence labeling, drug delivery, magnetic sensing, electrochemistry, and composite materials among others.

SOLVENT RESISTANT NANO FILTERS (SRNF)

During the past decade and a half considerable effort has be expended in developing filters for separating mixtures down to the molecular level. An alternative name to SRNF is organic solvent nanofiltration (**OSN**). This shows promise as an energy- and waste- efficient process. SRNF has been developed particularly for use with organic solvents but it also applies to aqueous media, with the *proviso* that the membranes may be differ-

ent. The driving force is the pressure applied to the membranes which are classified as **UF** (ultrafiltration) with pressures of 1 to 5 bar, **NF** (nanofiltration) with pressures from 5 to 20 bar and **RO** (reverse osmosis) with pressures >10 bar. In UF substances between 2nm and 0.1μm are rejected, in NF particles or dissolved molecules smaller than 2nm are removed from solution, and in RO only solvents permeate.

SRNFs are essentially of two types, the organic polymer type or the ceramic type. The former are polymers which need to be cross-linked in order to increase their strength. A variety of polymers have been prepared and studied including the composites: PAN (polyacrylonitrile), PVDF [poly(vinylidene fluoride)], PI [polyimide (Matrimide) and (Lenzing P84)], PEI [poly(etherimide)], PA (polyamide), PAH [poly(amide hydrazide)], PSf (polysulfone), PES [poly(ethersulfone)], PEEK (polyether ether ketone), SPEEK (sulfonated PEEK), PPESK [poly(phthalazinone ether sulfone ketone)], SPPESK (sulfonated PPESK), CA (cellulose acetate), and PBI (polybenzimidazole). The polymers are supported by an ultra-thin (submicron) barrier (TFC, thin film composite) on top of a chemically different polymer support. The TFCs are made of a variety of substances including PDMS (polydimethylsiloxane), PEi (polyethyleneimine), PAA (polyacrylic acid), PPz (polyphosphazene) among others. The TFCs cause the membranes to be quite strong, as the membranes need to be used and reused over again.

Ceramic membranes, which are much stronger than polymer membranes, are commonly made of Al, Si, Ti or Zr oxides and mixed oxides. The top layers of the membrane are prepared by sol-gel synthesis which converts a colloidal or polymeric solution of inorganic precursors (e.g. alkoxides or salts) to a gelatinous product. Viscous binders are usually added prior to layering followed by controlled calcination and finally sintering to form the ceramic membrane. The process can be controlled to provide membranes with specific MWCOs (molecular weight cut-offs) and which can sustain defined solvents, temperatures and pressures.

Unfortunately at present not many of either type of membranes are available commercially, but undoubtedly many more will appear on the market in the near future. Commercially available SRNF include the ***SelRO membranes*** (Koch Membrane Systems, USA), ***Starmem membranes*** (Membrane Extraction Technologies, UK), ***SolSep membranes*** (SolSep, The Netherlands), and ***Desal-5 and Desal-5-DK membranes*** (GE/Osmomics, USA) designed for aqueous applications, as well as for SRNF.

SRNFs have found applications in food chemistry, catalysis, chiral separations, petrochemical industry and pharmaceutical manufacturing. The preparation, practical considerations, and theoretical transport mechanisms of SRNFs have been critically reviewed by P. Vandezande, L.E.M. Gevers and I.F.J. Vankelecom [*Chem Soc Rev* **37** 365 *2008*, DOI: 10.1039/B610848M].

NANO METALS AND METAL DERIVATIVES

Generally the methods for producing such nanoparticles include attrition in which the particles are ground, e.g. in a ball mill, to a fine size; pyrolysis where the precursor is vapourised and forced through an orifice at high pressure and temperature as well as using aids such as ultrasonic nozzles for spraying; by radiolytic methods with radiation chemistry; and hydrothermal synthesis.

Cadmium selenide nanoparticles *[1306-24-7]* **CdSe, M 191.4, m 1268º; Cadmium sulfide** *[1306-23-6]* **CdS, M 144.5, m 1750º; and Cadmium telluride** *[1306-25-8]* **CdTe, M 240.0, m 1041º.** For details of crystalline forms see Chapter 4 in 'Inorganic Compounds'. CdSe, CdS and CsTe nanoparticles with particles that are smaller than 10nm exhibit ***quantum confinement***, in which case the electrons are restricted in a very small volume and have specific properties. Such nanoparticles are CdSe, CdS and CdTe ***quantum nanodots*** which can fluoresce strongly with high quantum yields.

Preparation of monodispersed CdSe semiconductor nanocrystallites [capped with trioctylphosphine (TOP see *[4731-53-7]* in 'Miscellaneous As, B, P, Si, S Se and Te Compounds' Chapter 3*)* ***and trioctylphosphine oxide (TOPO,*** see in 'Miscellaneous As, B, P, Si, S, Se and Te Compounds' Chapter 3*)]*: The method of Bawendi and coworkers [Murray, Norris and Bawendi *J Am Chem Soc* **115** 8706 *1993*, DOI: 10.1021/ja00072a025] is described here. In a vessel containing TOPO (50g) which is dried and degassed by heating at ~200º/1mm for 20min and flushing with argon is then kept at 300º under 1mm pressure of Ar. To this reaction vessel is added a mixture of Me_2Cd (1ml, 13.35mmol, see *[506-82-1]* below) and TOP (25ml) prepared separately in a dry-box, and a mixture of 1.0M TOPSe (10ml, 10mmol) stock solution in TOP (15ml) together all at once through a syringe with vigorous stirring. A deep-yellow orange solution develops and light absorption at 440-460nm results while the temperature drops (to ~180º), and is then restored gradually to 230-260º. Aliquots (~10ml) are withdrawn at 5-10min intervals and their light absorptions are monitored for crystal growth. Best quality cryst-

allites are formed over a period of a few hours of steady growth by regulating the growth temperature depending on size distribution as estimated from the absorption spectra; the temperature being raised if growth appeared to stop. As the desired absorption characteristics are obtained, the portions (aliquots) of the growth solution that are withdrawn through a cannula are stored in appropriate vials. Thus a series of nanocrystallites (II to IV) with ~15Å to 115Å diameters is obtained. These are ***purified*** by cooling the 10ml aliquots to ~60°, slightly above the m.p. of TOP and adding anhydrous MeOH (20ml) whereby the crystallites flocculate and are separated from the supernatant by centrifugation. The flocculant is then dispersed in anhydrous 1-butanol (25ml) followed by centrifugation which results in an optically clear solution of microcrystallites with a grey precipitate of reaction byproducts (shown to be Cd and Se by X-ray analyses) which are discarded. Addition of anhydrous MeOH (25ml) to the supernatant causes the crystallites to flocculate again and removes excess TOP and TOPO. Final rinsing with dry MeOH (50mL) and subsequent drying *in vacuo* produces ~300mg of free flowing TOP/TOPOcapped CdSe nanocrystallites. This powder is readily dispersed in a variety of alkanes, long-chain alcohols, aromatics, chlorinated solvents and bases such as amine, pyridines as well as furans and phosphines. ***Size-selective precipitation*** can be achieved by dispersion in 1-butanol till optically clear, adding dry MeOH dropwise until opalescence persists on stirring or sonication, then separation of flocculant by centrifugation provides a precipitate of the *largest* crystallites in the sample. This process is repeated until no further sharpening of optical absorption is observed. This size selection can also be carried out in a variety of solvent/non-solvent pair such as pyridine/hexane or $CHCl_3$/MeOH. Similarly, ***CdS semiconductor nanocrystallites*** and ***CdTe semiconductor nanocrystallites*** can be obtained. Surface exchange, e.g. replacing the TOP/TOPO caps by pyridine, can be achieved by heating the TOP/TOPOcapped nanocrystallites (~50mg) to ~60° with pyridine (~5-10ml) which gradually disperses the crystallites in the solvent, and is then treated with excess of hexane and the pyridine capped crystallites are isolated by centrifugation. This hexane precipitation is repeated a number of times to produce crystallites that will disperse readily in pyridine, MeOH and aromatic solvents, but no longer in hexane. These nearly monodispersed II—IV semiconductor nanocrystallites ranging from ~12Å to 115Å were characterised by TEM (Transmission Electron Microscopy) and X-ray diffraction spectra which provide a self-consistent description of the nanocrystallite structures. The physical properties have been described and discussed in detail by Bawendi and coworkers [Murray et al. *Science* **270** 1335 *1995*, DOI: 10.1126/science.270.5240.1335; Murray et al *Annu Rev Mater Sci* **30** 545 *2000*, DOI: 10.1146/annurev.matsci.30.1.545].

A similar protocol was used by Alivisatos and coworkers [Owen et al. *J Am Chem Soc* **130** 12279 *2008*, DOI: 10.1021/ja804414f] for preparing nanocrystalites of ***CdSe capped with ODPA*** (*n*-octadecylphosphonic acid) in the presence of TOPO with ~4nm diameter, fluorescence max = 580nm, fluorescence *fwhm* ~30nm after 7min at 315°. ***CdSe/ZnS-ODPA capped crystallites*** were prepared in a closed system by adding, *via* syringe Et_2Zn (1.0g, 0.49nmol Zn, see *[557-20-0]* below) to a mixture of TOPO (10.0g, 25.86mmol) and ODPA (0.197g, 1.2 equiv/Zn) [previously heated at 100°/30min with vigorous stirring under Ar, then at 275° (measured with a thermocouple)] and the temperature was lowered to 250°. Dry CdSe-ODPA-capped, prepared as before, dissolved in TOP (1.0g, 2.70mmol) was then injected into the mixture under Ar, the temperature was set to 235°, followed immediately by a solution of $(Me_3Si)_2S$ (1.0g, 0.246mmol S, 1 part, see *[3385-94-2]* in 'Miscellaneous As, B, P, Si, S, Se and Te Compounds,' Chapter 3) in TOP (100 parts) using a syringe pump (at 0.015ml/min), and allowed to cool slowly to <100°, and the cleaning process was started. This involved injecting dry degassed Me_2CO (50ml) under argon in a glovebox into the mixture; a milky precipitate was formed, collected by centrifugation, and redissolved in $CHCl_3$ (15ml) to give a dark solution which readily formed a layer of foam on shaking. *n*-Octylamine (5ml) was then added followed by Me_2CO (50ml) and the white milky precipitate was removed by centrifugation leaving a thin layer of nanocrystals and a clear or cloudy supernatant. The film of nanocrystals was dissolved in hexane (15ml) and Me_2CO added until solids start to separate, which will redissolve on strong shaking or sonication but addition of more Me_2CO causes precipitation of solids, and this is repeated until no more solids separate. The solids are removed by centrifugation, discarded, and the deeply coloured supernatant was treated further with Me_2CO to precipitate the nanocrystals which were isolated by centrifugation. This step was repeated a second time to ***produce CdSe/ZnS-ODPA*** capped nanocrystalites which exhibited variable fluorescence quantum efficiencies (24 to 55%), and are freely soluble in hexane, toluene, $CHCl_3$ and other non-polar solvents. Their ^1H and ^{31}P NMR did not have sharp signals characteristic of non-bound ligands. The caps can be exchanged with MeSiCl, *n*-tridecyltrimethylammonium chloride, *S*-trimethylsilyl-2,5,8,11-tetraoxatridecane-13-thiol in toluene at ~25 to give the bis trimethylsilyl (and related) ester of ODPA and the nanocrystallites with the respective de-trimethylsilyl ligand. The caps were characterised by their ESI-MS and XPS.

Stiegerwald and coworkers [*J Am Chem Soc* **110** 3046 *1988*, DOI: 10.1021/ja00218a008.] have isolated and derivatised nanometer-sized semiconductor cluster molecules of CdSe by ***arrested precipitation*** in reverse micelles to give bare semiconductor lattices which can be modified. They prepared surfactant-stabilised CdSe nanoparticles thus: a typical AOT/H_2O/heptane microemulsion was first prepared by dissolving the dried surfactant bis(2-ethylhexyl)sulfosuccinate (AOT, 33.3g, 75mmol, see *[577-11-7]* below) in heptane (1.3L) and deoxygenated H_2O (4.3ml) and magnetically stirred until homogeneous (with W = 3.2; W was defined as the molar ratio of H_2O/AOT). Then Cd^{2+} solution (1.12ml, of stock 1.0M $Cd(ClO_4)_2\ 2H_2O$ in deoxygenated H_2O) was added with stirring until optically homogeneous (emulsion with W = 4.0), and was followed by injecting $(Me_3Si)_2Se$ (210µl, 0.93mmol) in heptane (50ml) rapidly *via* syringe. As the semiconductor particles were formed, the emulsion developed colour with absorption spectra shifting to its final persistent form with time; from seconds (for large W, e.g. ~ 5.4, red) to minutes (for small W, e.g. ~2, blue). The surfactant-stabilised colloids collected were treated in three ways: (a) for further surface modification (see below), (b) evaporation to dryness or (c) for flocculation. (b) Produced coloured surfactant particles with embedded CdSe which can be dissolved in hydrocarbon solvents to give optically homogeneous solutions that are quite stable in air or room light, although some deterioration was observed in solution after ~8—10 months. If the solvent was not removed as in (c) flocculation occurs within hours, but addition of large amounts of H_2O resulted in immediate flocculation and the precipitate did not re-dissolve in organic or inorganic solvents. In typical further capping preparations these authors used material in (a) and coated the surfactant-stabilised CdSe particles with Cd^{2+} by adding 0.5ml of above stock 1.0M $Cd(ClO_4)_2\ 2H_2O$ in deoxygenated H_2O, stirring till homogeneous then excess of ***phenyl trimethylsilyl selenide*** (350µl, 1.5mmol, see *[33861-17-5]* below) in heptane (50ml) was injected *via* syringe when the cloudy mixture precipitated a coloured solid which was collected by centrifugation or filtration, washed with petroleum ether and dried to give a free-flowing powder of crystallites (~260mg). The yields of ***phenyl capped crystallites*** from preparation ($0<W<10$) were ~55% based on input mass, or ~75% based on Cd as limiting reagent. These should be completely soluble in pyridine; if not, the pyridine solution was filtered to remove any flocculated colloidal material from proper molecular crystallites which were then re-precipitated with petroleum ether, and the ***purification*** process was repeated until complete solubility in pyridine was achieved. The amount of insoluble flocculated material was an indication of the extent of capping. The particles were shown to be of molecular size (10-100 Å).

Preparation and purification of CdSe and CdTe Quantum Nano-Dots (QDs) by Chemical Aerosol Flow Synthesis (CAFS) devised by Didenko & Suslick [*J Am Chem Soc* **127** 12186 *2005*, DOI: 10.1021/ja054124t, PMID: 16131177]. In this beautiful new technology various combinations of Cd (e.g. CdO, CdCO, Cd naphtheate or acetate) and Se (with TOP to form TOPSe *in situ*) precursors in toluene are placed in an ultrasonic nebulizer which produces an aerosol under argon flow that is allowed to flow through a tube furnace whose temperature can be altered from ~300° to ~180° where the toluene is rapidly vapourised and the CdSe-capped nano Q-dots are formed (with sizes varying with the furnace temperature) and collected by bubbling through toluene in a quencher trap. The Q-dots are then *purified* by precipitation with dry MeOH, redissolved in $CHCl_3$ and precipitated again with MeOH. This process is repeated at least four times to remove precursors and solvents. The size of the dots can be fine tuned by careful adjustment of furnace temperature, flowrate and precursors. The CdSe/stearic acid or hexadecylamine (HDA) particles are tunable from 2 to 4nm and the sizes are confirmed by TEM, and XRD, and fluoresce in different colours, e.g. with CAFS at furnace temperatures of 320°, 300°, 280°, 260°, 240°, 220° and 180° the fluorescences of CdSe/hexadecylamine Q-dots were red, orange, light yellow-green, green, deep green, light blue and deeper blue respectively. Experimental details of these reactions can be found in the above reference of Didenko and Suslick. Surfactant systems that proved successful include TOP/TOPO, in the presence or absence of octadecylamine, steric acid, hexadecylamine (HDA) or oleic acid (OLA). Similar procedures can be used successfully with S for ***CdS Q-dots*** (by using thiourea) and Te for ***CdTe Q-dots*** (by using TOPTe). Highly fluorescent ***CdTe Q-dot*** were produced by CAFS from a mixture of CdO/octadecylphosphonic acid (ODPA), octadecene and TOPTe in toluene which had quantum yields of fluorescence of 40% with fwhm ~30nm. When formed in the gas phase these high quality CdTe nanoparticles could be deposited directly on surfaces to ***produce solar cells***, ***LEDs*** or other ***Q-dot composites***. The above authors state that CAFS can be extended to the preparation of nanostructured metals, metal oxides and other materials. and can be used for larger quantities. It is superior to the earlier batch process.

Highly luminescent capped colloidal CdS quantum dots with efficient NIR electroluminescence in light emitting diodes have been described by I.D.W. Samuel and coworkers [Bansal et al. *J Phys Chem C* **120** 1871

2016, DOI: 10.1021/acs.jpcc.5b09109]. They injected, *via* syringe, a solution of cadmium bis(octanethiol) (480mg, see preparation below) in TOP (15.4ml) under N_2 to hot TOPO (24g, heated at 120º under a 50mbar vacuum with stirring for 30 minutes then brought to 220º under N_2 for an additional 30 minutes) whereby the temperature dropped to 180º, then the temperature is raised within 5-10min to a stable temperature of 220º. At this point 5ml aliquots are withdrawn after 30, 60, 75, 90, 120, 150, 180 and 240 minutes (as the CdS QDs are being formed) and the reactions stopped by cooling the aliquots to ~20º with external cold H_2O. Each aliquot is poured into Me_2CO (40ml), kept at -20º for 20 minutes and the QDs are collected by centrifugation at 4000rpm for 20 minutes. The pelleted QDs are ***purified*** by dissolving them in $CHCl_3$ (200µl) and for duplicate analyses half portions (100µl) are treated with Me_2CO (1.2ml) and the precipitated QDs are obtained by centrifugation at 14,000rpm for 10 minutes, and the dissolution/precipitation repeated twice. The final pellets are dissolved in $CHCl_3$ (0.5ml) for optical and structural characterisation. In the same vain, but with some modification, CdS and cadmium bis(octanethiol) with TOP, diphenylphosphine (DPP), octadecene (ODE), and/or oleic acid (OLA), produce capped CdS QDs with these ligand. ***Purification of the CdS QDs*** is generally as stated above, but in some cases (e.g. with ODE) they were purified by pouring into Me_2CO (~40ml, as above) then a volume of MeCN (2-5ml) was added as soon as the solution became cloudy, centrifuged at 4000rpm for 20 minutes, the pellet was re-dissolved in $CHCl_3$ (0.2-0.4ml) and transferred into Eppendorfs. To each $CHCl_3$ volume of 0.2ml, Me_2CO/MeCN (1.2ml, 1:1 v/v) was added and the mixture was centrifuged at 14,000rpm for 10 minutes. The pellet was washed again with Me_2CO/MeCN (1.2ml, 1:1 v/v), centrifuged at 14,000rpm for 10 minutes, and re-suspended (dissolved) in $CHCl_3$ (0.5ml) and characterised. For the special procedure that was reported for the ***fabrication of Thin Films and Devices*** for analyses by see I.D.W. Samuel and coworkers (above). The *highest photoluminescence* (quantum yield 68.7 —3.7%, PL_{max} 676 ±12nm) was found in the *DPP capped CdS QD* in TOPO solvent, and quantum yield 34.7 ±3.1%, PL_{max} 622 ±17 in *OLA/DPP capped CdS QD* in neat thin films in the NIR range. deMello and coworkers [*Lab Chip* **11** 1221 *2011*, DOI: 10.1039/C0LC00507j] reported a versatile capillary-based droplet ***microfluidic*** reactor for the synthesis of ***CdSe oleate NP*** by highly controlled nanoparticle growth up to temperatures of 250º. This droplet reactor was very stable during one day's continuous use under constant flow-rates and temperatures producing well defined particles. It was successfully applied to the preparation of ***metal (Ag) and metal oxide (TiO_2) NPs***.
Skrabalak and Brutchey [*Chem Mater* **28** 1003 *2016*, DOI: 10.1021/acs.chemmater.6b00472] recently reviewed all the ***Continuous Flow Routes to Colloidal Inorganic Nanoparticles***, and included ***microfluidic reactors*** [see Laboratory on a Chip/microfluidics in Chapter 1, and gold and platinum nanoparticles below].

CdSe quantum dots have been implemented in a wide range of applications including solar cells. When CdSe nanocrystals are molecularly linked with TiO_2, the films formed are capable of harvesting light energy and are used for making ***Quantum Dot solar cells*** [Robel et al. *J Am Chem Soc* **128** 2385 *2006*, DOI:10.1021/ja056494n]. CdSe can be modified by producing two phase materials, e.g. with ZnS coating, whose surface can be further modified with e.g. mercaptoacetic acid to *confer* solubility [for review on '*CdSe nanocrystal based chem-/bio- sensors*' see Somers et al. *Chem Soc Rev* **36** 579 *2007*, DOI: 10.1039/B517613C]. Other applications include light emitting diodes [for '*Light-emitting diodes made from CdSe nanocrystals and a semiconducting polymer*' see Colvin et al. [*Nature* **370** (6488): 354 *1994*, DOI:10.1038/370354a0]; and M Krüger and coworkers reported that the improved efficiency of bulk heterojunction hybrid solar cells can be achieved by utilising *CdSe quantum dot-graphene nanocomposites*. [Eck et al. *Phys. Chem. Chem. Phys.* **16** 12251 *2014*, DOI: 10.1039/ C4CP01566e.]

Cobalt *[7440-48-4]* **Co, M 58.9, m 1495º, b 2870º, d ^{20} 8.71, resistivity 6.24 µΩcm/20º, Brinell hardness 125. Cobalt nanoparticles** for use in ***magnetic fluids*** **(MFs)** are available commercially with an average particle size of 10-12nm. It is in the form of a black powder, and is prepared by a ***thermolysis process*** using a strict formula. Thus, to dicobalt octacarbonyl {$Co_2(CO)_8$, 17.1g, 100mmol, see *[10210-68-1]*} under flowing argon is added $Al(C_8H_{17})_3$ (4.4ml, 10mmol) [Co:Al = 10.1] dissolved in toluene (300ml) in one portion, and the mixture is stirred and heated at 110º under a reflux condenser for 18 hours. The reaction is carried out in an efficient fume cupboard because **POISONOUS** carbon monoxide evolution occurs. The colour of the solution changes to dark brown and a black precipitate separates from the clear solution. The mixture is cooled to 20º, and still under argon a further amount of $Al(C_8H_{17})_3$ (1.2ml, ~30% of the initial quantity) is added, the temperature is raised to 110º and is heated for 3 hours more. The mixture is cooled to 20º, and stirred further for 16 hours. Smooth oxidation is carried out by bubbling (use a capillary) air through the mixture for 6 hours. The product is stirred overnight and the precipitated Co is allowed to settle during 2 hours. The supernatant is

decanted and the solid is isolated in ***toluene wet form***, or by drying *in vacuo* to give an air stable ***Co nano-powder*** (5.2g); both of which can be handled under laboratory conditions. The particle size of the Co, as determined by TEM and HRTEM is ~10±1.1nm (see further, however). The particle size is sensitive to the thermolysis conditions and to the $Al(alkyl)_3$. With alkyl = Me, Et or *n*-octyl (C_8H_{17}) and a Co:Al ratio of 10:1 as above, the nanoparticle sizes are 3-4, 5-8 or ~10nm respectively. Moreover, with $Al(C_8H_{17})_3$ and a Co:Al ratio of 1:2 the particle size was always ~5.4nm.

Peptisation of Co nanoparticles*:** The Co particles are suspended in toluene and peptised by adding 2ml of Korantin SH (BASF, *N*-oleylsarcosine + AOT, an excellent emulsifying, solubilising corrosion inhibitor), oleic acid, LP-4 (a fatty acid condensation polymer, or AOT (sodium dioctylsulfosuccinate, see [577-11-7] below) as surfactants and sonicated in an ultrasound bath for 10 minutes to give a clear dark brown ***Co-MF. After drying a sample *in vacuo* elemental analysis indicated the presence 67.8% of Co and 0.98% of Al. These MFs were found to be stable for more than 5 months [by X-ray absorption near edge structure (XANES) measurements] under air. It should be pointed out that if the $Al(C_8H_{17})_3$ is washed away from the Co particles immediately after the synthesis, the magnetic properties are markedly reduced after exposure to air. The chemical nature of the analysed nanoparticles shows that the stability of the local electronic and geometric structure is significantly affected by the surfactant used. Peptised Co nanoparticles can also be dispersed in kerosene or mineral oil as precursors for MFs.

Cobalt nanoparticles (surface modified with L-cysteine ethyl ester) ethanol wet are available as ~10nm black powder (wet with EtOH) which is best used within 3 months. The material can be easily transferred into stable aqueous suspensions, and can be used as a starting material for surface modifications (e.g. dextran coating) or the preparation of magnetic polymer microspheres.

Carbon coated cobalt nanoparticles (magnetic cobalt) with particle size >50nm (TEM ≥99%, magnetization is >150emu/g, mass saturation), 6.24μΩcm/20°, *[*7440-48-4*]* M 58.9, [MDL number MFCD00010935**]** are commercially available. The carbon shell (<8 wt%) has *ca* three graphitic layers covering the cobalt particle which can be functionalised, using the SDS/diazotisation reactions of Dyke & Tour [*Nano Lett* **3** 1215 *2003*, DOI: 10.1021/nl034537x, see functionalised SWCNTs above] which consequently place a variety of *p*-substituted (e.g. with Cl, NO_2, etc) aryl groups on the carbon surface. The functionalised particles are collected *via* their magnetic properties and used for whatever purpose they are intended. [Grass et al. *Angew Chem Int Ed* **46** 4909 *2007*, DOI: 10.1002/anie.200700613].

Copper zinc iron oxide, 98.5% trace metal basis (zinc copper ferrite, copper zinc ferrite) *[66402-68-4, 228402-49-1]* **$CuZnFe_4O_4$, [**MDL number MFCD06200729, PubChem CID 24883132**] M 416.3 d_4^{25} 5.5g/ml.** It is a nano powder with particle size <100nm (BET). The actual particle size is <50nm (XRD) and is commercially available.

Gold nanoparticles stabilised by gum Arabic (GA-AuNP). AuNPs have been widely used for a variety of purposes and water soluble composites with gum Arabic (GA) are commercially available. Gum Arabic [9000-01-5] from *Acacia* gum is a branched polymer of galactose, rhamnose, arabinose and glucuronic acid as the Ca, Mg and K salts with M ~250,000, and is a non-toxic and physiologically compatible substance. ***GA-AuNP*** has been developed by Kannan, Katti and coworkers [Kattumuri et al. *Small* **3** 333 *2007*, DOI: 10.1002/smll.200600427]. It is prepared simply by mixing $NaAuCl_4$ with an aqueous solution of a non-toxic phosphine amino acid [$P(CH_2NHCHCH_3COOH)_3$ ***THPAL**, see preparation below] reducing agent in the presence of a 0.2% aqueous solution of gum Arabic. This resulted in an immediate reaction which produced GA-labeled AuNPs in over 98% yield. The aqueous solutions are stable for months. ***Note*** that if GA is omitted, the reaction is also instantaneous but the solutions agglomerate within 4-6 hours. TEM images showed that the size of ***GA-AuNPs*** thus produced is 15-20nm. It is stable in the presence of cysteine, bovine and human serum albumins and does not agglomerate in 25% NaCl solution. Formulations of it can be readily administered site specifically (*intravenously*), for diagnostic imaging (***computer tomography* CT**), and is bio-compatible for therapeutic applications in ***nanomedicine***. GA-AuNPs are also suitable for ***nanoelectronics*** which include sensor design, MEMS applications, spin coating, self-assembly and formation of monolayers.

K.V. Katti and coworkers [Raghuraman et al. *J Am Chem Soc* **125** 6955 *2003*, DOI: 10.1021/ja034682c] prepared the reducing agent ***tris[N-(R or S)-alaninylmethylene]phosphine** (***THPAL**) by adding tris(hydroxymethyl)phosphine (0.50g, 4.03mmol, see *[2767-80-8]*) in H_2O (5ml) dropwise to *R*- or *S*- alanine (1.08g, 12mmol) in H_2O (10ml) at 25° with stirring under N_2 for 1 hour. Evaporation *in vacuo* gave a white solid which, after washing with MeOH and drying *in vacuo* was pure product (90% yield). The ^1H NMR (300

MHz, D_2O) has δ at 1.38 (d, J = 6.0Hz, 9H, NCH(C***H*****$_3$**)COOH), 3.47 (d, 6H, PC***H*****$_2$**), 3.65 (m, 3H, NC***H***(CH_3)COOH); the ^{13}C NMR (75MHz, D_2O) has δ at 14.84 (s, NCH(***C***H_3)COOH), 42.65 (d, $J_{p\text{-}c}$ = 12.82Hz, P***C***H_2), 59.35 (d, $J_{p\text{-}c}$ = 5.77 Hz, N***C***H(CH_3)COOH), 174.10 (s, NCH(CH_3)***C***OOH); and the ^{31}P NMR (121.5MHz, D_2O) has δ at -39.9 (s); and the ESI-MS has calculated for $C_{12}H_{24}N_3O_6P$ 337.3, found *m/z* 337.6. The X-ray crystal structure analysis of the ***S-enantiomer*** (4 H_2O) revealed that the alanine portions were packed to form two-dimensional bilayers running parallel to (001). [See also Kannan et al. *J Am Chem Soc* **128** 11342 *2006*, DOI: 10.1021/ja063280c.]

Gold nanoparticles stabilised by agarose (A-AuNP). K.V. Katti and coworkers [Kattumuri *et al*. **88** 153114 2006, http://dx.doi.org/10.1063/1.2192573] prepared this similarly, but replacing GA by agarose. A-AuNPs were used for surface-enhanced Raman spectroscopic detection of DNA nucleosides as well as the other applications stated above.

Gold nanoparticles functionalised with dodecylthiol in solution (particle size 2-4nm DLS, 2w/v% in toluene) Au-S$CH_2(CH_2)_{10}CH_3$, d ^{25} 0.9308g/cm^3, [MDL number MFCD09953506, PubChem CID 24884475]**.** It has been found useful for the self-assembly of gold monolayers (Au—SAMS) for nanoelectronics. [Fendler et al. *Chem Mater* **13** 3196 *2001*, DOI: 10.1021/cm010165m] Similar AuNPs with secondary amines, e.g. diocylamine, didodecylamine and dioctadecylamine which are effectively transferred to gold nanoparticles [Solwoda et al. *Langmuir* **30** 6684 *2014*, DOI: 10.1021/la501135q]. They are useful as a ruler for measuring the thickness of vertically self assembled gold monolayers, e.g. with vertical heights of 0.9, 1.5 and 2.1nm for matrix reference molecules of hexylthiol, dodecylthiol and octadecylthiol respectively [Kelly et al. *Langmuir* **26** 3040 *2010*, DOI: 10.1021/la9026128].

Gold (~1%) nanoparticles on titanium oxide extrudates (AURO*lite*, Au/TiO_2), on aluminium oxide extrudates (Au/Al_2O_3), on zinc oxide granulates (Au/ZnO), and on manganese oxide and carbon (Au/MnO_x/C). These are available commercially and used to catalyse some reactions. A 1% AuNP(~2nm) preparation on TiO_2 is used for catalytic purposes in ***'Green'*** processes, e.g. in the presence of NaOMe in alcohols as solvents it catalyses the oxidation of aldehydes to esters using air as oxidant at ambient or lower temperatures [Marsden et al. *Green Chem* **10** 168 *2008*, DOI: 10.1039/B712171G]. It also catalyses the oxidation of CO and H_2 using O_2 or NO as oxidants [Walther et al. *J Catal* **260** 86 *2008*, DOI: 10.1016/j.jcat.2008.09.003]. Au/Al_2O_3, Au/ZnO and Au/Mn_xO/C are active catalysts for low temperature oxidation of CO and/or of CH_4 [Grisel & Nieuwenhuys *Catal Today* **64** 69 *2001*, DOI: 10.1016/S0920-5861(00)00510-1; Ma et al. *J Catal* **252** 119 *2007*, DOI: 10.1016/j.jcat.2007.08.013; see also Freund *Catal Today* **117** 6 *2006*, DOI: 10.1016/j.cattod.2006.05.043]. The preparations, properties and identification of these and related 'Gold on support' substances will be found in these references; and in Hugon et al. *Gold Bull* **41** 127 *2008*, WOS:000257937100007, ISSN: 0017-1557; Supansomboon et al. *Gold Bull* **41** 296 *2008*, Steyn et al. *Gold Bull* **41** 318 *2008*, Murdoch et al. *Nature Chemistry* **3** 489 *2011*, DOI: 10.1038/nchem.1048; and for a review on *Catalytically active gold on ordered titania supports* see Chen & Goodman [*Chem Soc Rev* **37** 1860 *2008*, DOI: 10.1039/b707318f].

Murphy and coworkers [Lohse et al. *ACS Nano*, **7** 4135 *2013*, DOI: 10.1021/nn4005022] constructed a simple ***microfluidic reactor*** [see Laboratory on a Chip/microfluidics in Chapter 1] which allowed the aqueous gram-scale synthesis of a variety of functionalised ***gold nanoparticles*** including ***gold nanospheres*** with controlled core diameters, ***gold nanorods*** (aspect ratios ~1.5 to 4.0) and ***gold nanocubes*** which can be tailored to requirements. The reactor can be interfaced with existing purification and monitoring techniques to produce high-throughput functionalisation/purification of gold nanoparticle products. A system which could be applied to the preparation of *monodispersed, hydrophilic functionalised metal nanoparticles* and be an integral part of chemical nanotechnology research laboratories. Marmstadt and coworkers [Lazarus et al. *Lab Chip* **10** 3377 *2010*, DOI: 10.1039/C0LC00297f] had also described a ***microfluidic platform*** for the flow-focused synthesis of monodispersed gold nanoparticles (4.38 ±0.53nm) rapidly and reproducibly using an imidazolium ionic liquid.

Indium-tin oxide nanopowder (ITO) *[50926-11-9]* **M 264.9, surface resistivity of 100Ωcm.** Available in particle size <50nm. It is coated on glass for making transparent electrodes for screens (e.g. touch screens). However, graphene electrodes have better transparency and are tougher (see above) [Bae et al. *Nature Nanotechnol* **5** 574 *2010,* DOI: 10.1038/nnano.2010.132].

Lead sulfide (Galena) *[1314-87-0]* **PbS, M239.3, nanocrystals (NCs),** (see PbS in 'Inorganic Compounds', Chapter 4)**.** The following synthesis is a literature procedure [for PbS NCs: Hines & Scholes *Adv Mater* **15** 1844 *2003*, DOI: 10.1002/adma.200305395] as described by R.D. Robinson and coworkers [Zhang et al. *Nano Lett* **11** 5356 *2011*; DOI: 10.1021/nl202892p] for preparing ***6nm PbS NCs***. To a mixture of PbO (0.45g) and oleic acid (20ml, OLA, see *[112-80-1]* in 'Aliphatic Compounds', Chapter 3) which is heated under N_2 at 150° for 15min until clear, the temperature is then decreased to 110°, evacuated to remove any H_2O and then reheated to 130°; was added BTSS-ODE [10ml, of a mixture of bis(trimethylsilyl)sulfide (252ml, BTSS, see *[3385-94-2]* in 'Miscellaneous As, B, P, Si, S, Se and Te Compounds' Chapter 3) in octadecene (12ml, ODE, see *[112-88-9]* in 'Aliphatic Compounds', Chapter 3)] *via* a syringe in a glovebox and allowed to react for 40 seconds. The mixture is rapidly cooled with H_2O and then EtOH is added to precipitate the NCs which are separated by centrifugation and purified twice by dissolving in hexanes and precipitating with EtOH. The size of PbS NCs can be controlled by changing the reaction temperature and time. PbSe (6.3 ±0.6nm), CdSe with oleate ligand (4.7 ±0.4nm), CdSe with stearate ligand (8.1 ±1nm), CdS with oleate ligand (3.5nm ±03nm), CdS with oleate ligand (7.6 ±0.7nm) and CdSe/CdS coreshell with oleate NCs were synthesised in a similar way.

A new procedure for de-capping was discovered where treating with 0.004M $(NH_4)_2S$ in MeOH for 30 seconds, then washing excess salt with MeOH which removed the ligands completely, and converted the NC metal-rich shells into metal sulfides. The now bare metal sulfide NCs were shown to have metal sulfide bonding to form a larger NC film assembly and still retain quantum confinement. This makes these new NCs promising new materials for ***electronic*** and ***photoelectronic applications***. The capped and de-capped NCs were characterised in detail by elemental analysis, FTIR, optical spectroscopy, X-ray photoelectron spectroscopy (XPS), wavelength dispersive X-ray spectroscopy (WDS), small angle X-ray scattering (SAXS), High-Angle Annular Dark-Field (HAADF) imaging and Electron Energy Loss Spectroscopic (EELS) mapping in an aberration-corrected electron microscope. [Zhang et al. *Nano Lett* **11** 5356 *2011*; DOI: 10.1021/nl202892p.]

In elegant work, Tisdale and coworkers [Wiedman et al. *ACS Nano* **8** 6363 *2014*, DOI: 10.1021/nn5018654] found that the Pb to S ratio of the precursor during nucleation is a critical parameter that affects growth and monodispersity of PbS—NCs. They succeeded in synthesising highly monodispersed PbS—NCs (of size dispersivity <5%) over a range of sizes and exciton energies in the range 0.70—1.25eV (1000—1800nm), without use of size-selective precipitations. Ensembles close to the homogeneous limit with absorption peak half width at half maximum values (HWHM) as small as 20meV were obtained. Correspondingly narrow photoluminescence emission that have small Stokes shifts and quantum efficiencies of 30-60% were achieved. These PbS—NCs are stable in air for several months and readily self assemble into ordered superlattices.

The synthetic procedures described briefly here are along the lines developed by Tisdale and coworkers (see above). PbS—NCs have been synthesised at high temperature 120° and at the low temperatures of 40° and 80°. All work is done using air-free Schlenk techniques (see Chapter 1) in N_2 atmospheres. For the ***120° synthesis*** the Pb solution is prepared by adding $PbCl_2$ (2.50g, 9mmol) to oleylamine (7.5ml), degassed for 10min (Schlenk vacuum line) with stirring to a pressure of ~150mm, then re-pressurised with N_2 and the temperature set at 120° (using a controller). A sulfur solution is prepared by heating a mixture of S (0.040g) with oleylamine to 120° and while stirring, N_2 is bubbled through for 20 minutes to give a clear amber coloured solution, then cooled to ~25° while still under N_2. To the Pb solution at 120°/N_2, is swiftly injected 0.357ml of the above sulfur solution, whereby a nucleation burst takes place with immediate change from colourless to black occurs. The solution is kept at 120°, while ~1ml aliquots (syringe) are removed at various growth times so as to track the reaction progress and provide increasing number of data points per synthesis. The aliquots are then treated as described below. At the end of the synthesis, i.e. when as many aliquots as required are collected, heating is removed and the reaction is quenched by injecting cold hexanes (20ml), and the reaction flask immersed in a water bath. A typical synthesis yield is ~75mg of product (see further for isolation). The process can be scaled up 10-fold with the proviso that the injection of the S solution is as close to instantaneous as possible. This necessitates the reduction of the S solution volumes by concentrating (e.g. to ~5ml) instead of injecting large volumes in the scale up. The procedure is for a 24:1 Pb/S ratio, for other ratios the weight of Pb precursor is altered but that of the S precursor is unaltered. For the ***40° and 80 ° syntheses*** the Pb solution is prepared as above at 120° then allowed to cool to the lower temperatures before injecting the S solution. In this case the nucleation burst takes a few seconds longer to occur.

Purification of the PbS—NCs**: (a)** *with alcohols anti-solvents*. The above products are set aside overnight when white $PbCl_2$ precipitates out and is removed by centrifugation (4000rpm/30min). The quantum dots (QDs) are then precipitated from the supernatant by adding alcohol anti-solvents (5ml MeOH and 10ml BuOH), centrifuged as before and the supernatants are discarded. The QDs pellets are dried for several hours before re-

dispersing in hexanes (20ml). If turbid, centrifuge off any $PbCl_2$ that separates, then perform ligand exchange for better stability of the QDs. This is done by adding oleic acid (2ml) to the hexane dispersion and agitate for 1min, and precipitate the QDs by adding alcohol anti-solvents, collecting the QDs by centrifugation and dryng them. The oleic acid exchange and precipitation is repeated once more time before finally dispersing the QDs in the desired solvent.

(b) *with oleic acid*. The products from synthesis are precipitated by addition of butanol (10ml) and MeOH (5ml). The precipitates are collected by centrifugation as above and re-dispersed in hexanes (10ml) and 100% oleic acid by volume is added, the mixture is agitated for several minutes, and the QDs are precipitated *via* centrifugation as above. The supernatants may contain unreacted S (orange colour). The pellets are allowed to dry for several minutes, and the precipitation with oleic acid is repeated 3-5 times until the supernatant is colourless. The QD pellets are then re-dispersed in hexane and precipitated with BuOH and MeOH to remove unbound oleic acid to the nanocrystalline QDs. Finally the QDs are redispersed in the desired organic solvent and centrifuged if any $PbCl_2$ is present (as indicated by some turbidity).

The ~1ml ***aliquots*** isolated at intervals of time are quenched with cold hexanes (5ml). Their stabilities are less robust those of the above QDs, and as before they are kept in the centrifuge tubes overnight, centrifuged the following day to remove $PbCl_2$, the QDs are then precipitated with anti-solvents (~3ml BuOH and ~2ml MeOH) and centrifuged. The pellets are dried for several hours, the QDs are redispersed in hexanes and oleic acid (0.5ml) is added. Centrifuge if turbid, and precipitate the QDs with the alcohols, dry the pellets for several hours and finally redisperse in the desired organic solvent. The QDs are now ready for physical evaluation, i.e. absorption spectra from which the HWHM values are obtained for all QDs of the aliquots, by TEM images, solution phase small-angle X-ray scattering (SAXS), X-ray diffraction (XRD), X-ray photoelectron spectroscopy (XPS), wide angle X-ray scattering (WAXS) and obtaining the grazing-incidence small-angle X-ray scattering (GISAXS) patterns.

$Pd^{(0)}$ EnCat™ is obtained by reducing the *$EnPd(OAc)_2$ (0.4g, 0.4mmol/g, see below) in Et_2O (8ml) with formic acid (8ml) at 45º for 2 hours. The mixture is cooled and the solid microcapsules are filtered through a polyethylene frit (20 micron porosity), washed with distilled H_2O (3 x 30ml), Me_2CO (3 x 30ml) and Et_2O (3 x 30ml). The microcapsules are dried (at <0.5mm) at 45º for 5 hours to provide black **$Pd^{(0)}$ EnCat** microcapsules (0.35g, containing Pd nanoparticles of ~2nm size). It is an efficient catalyst for reductive ring-opening of epoxides to the respective alcohols which occurs in ~99% yields. The reaction requires either $HCOOH/Et_3N$ or H_2 as hydrogen donors, and the catalyst can be recycled ~10 times [Ley et al. *Org Lett* **5** 4665 *2003*, DOI: 10.1021/ol0358509].

***EnPd(OAc)$_2$ [Pd EnCat™]** is prepared from polymethylene polyphenylene di-isocyanate (SUPRASEC 5025, average functionality of 2.7) and $Pd(OAc)_2$ dissolved in $CHCl_3$ and then dispersed at 800rpm for 1 minute into an aqueous solution of Na lignosulfonate (Reax 100M), polyvinyl alcohol (Gohsenol GL 03) and the polyoxyethylene ether of butanol (Tergitol XD), using a mechanical overhead stirrer with a rotary blade. The resulting emulsion would have a particle size range of 20-250microns and the mixture is then gently shaken for 16 hours. The solid polyurea microcapsules formed are collected on a polyethylene frit (20 micron porosity), washed with de-ionised H_2O (5 x 50ml), Me_2CO (5 x 50ml), Et_2O (3 x 50ml) and dried at room temperature.

Encapsulated Pd catalysts such as **Pd EnCat™** are available commercially. These particles are defined by their matrix content e.g. 30% or 40%, the latter having the smaller pore size. [See also Bremeyer et al. *Synlett* 1843 *2002*, DOI: 10.1055/s-2002-34862; Yu et al. *Chem Commun* 678 *2003*, DOI: 10.1039/B300074P; Vickerstaffe et al. *Org Biomol Chem* **1** 2419 *2003*, DOI: 10.1039/B305713E.]

Platinum, gold and palladium nanoparticles on spherical polyelectrolyte brushes (SPB). Pt crystals (2-3nm) were deposited on SPB using the procedure of M. Ballauff and coworkers [Schrinner et al. *Science* **323** 617 *2009*, DOI: 10.1126/science.1166703]. The SPB consists of a polystyrene core (~100nm diameter) onto which a cationic polyelectrolyte ($^+H_3NCH_2CH_2OOC^-)_n$ is attached [Schrinner et al. *Adv Mater* **20** 1928 *2008*, DOI: 10.1002/adma.200702421]. A mixture of $AuCl_4^-$ and $PtCl_6^{2-}$ was reduced with $NaBH_4$ on the surface of the cationic SPB to form alloy nanoparticles ($Au_{45}Pt_{55}$ ratio) on the surface. The Au was removed with cyanide and O_2. Thus a solution of 1.9 x 10^{-5} M NaCN (4ml) was added dropwise within 25 minutes to a stirred suspension of AuPt-SPB (0.04 weight %) at room temperature under air. High dilution of the cyanide is crucial for avoiding complete dissolution of the NPs and coagulation. Air was bubbled through the solution to remove completely the Au atoms. After 3 hours the colour of the solution was blue due to the formation of pure Pt-NPs. [Schrinner et al. *Macromol Chem Phys* **208** 1542 *2007*, DOI: 10.1002/macp.200700161.] Detailed examination

of the composite particles by cryo-TEM, wide angle XRS and HR-TEM showed that the Pt-NPs are well-defined faceted single crystals embedded in the SPB-chain layer. This composite system has excellent colloidal stability, and high catalytic activity with turn over numbers of as high as 1580 ±50 sec^{-1} for the reduction of *p*-nitrophenol to *p*-aminophenol using $NaBH_4$, which is among the higher ever observed for this reaction.
Similar **Palladium (SPB)** nanoparticles encapsulated in spherical polyelectrolyte brushes and Core-Shell microgels have been prepared in much the same way by Ballauff and coworkers [Mei et al. *Chem Mater* **19** 1062 *2007*, DOI: 10.1021/cm062554s]. The metal in a varitey of composites exhibits powerful catalytic activities [as judged by the rates of catalytic reduction of *p*-nitrophenol with $NaBH_4$ to start the reaction, that are exceedingly fast (see above)] and the rates depended on the composite material and its shape. Comparison of the catalytic activities of these composites depended on the metal and showed that they increase in the order Au < Pt < Pd [see Schrinner et al. *Macromol Chem Phys* **208** 1542 *2007*, DOI: 10.1002/macp.200700161]. [See also Zaera and coworkers in Lee et al. *Nature Materials* **8** 132 *2009*, DOI: 10.1038/nmat2371; and for a review see H. Birch RSC *Chemistry World* **6** (3) 29 *2009*.]
Microfluidic (see Laboratory on a Chip/microfluidics in Chapter 1) ***continuous platforms*** have been devised by Riche, Roberts and coworkers [*Nat Commun* **7** 10780 *2016*, DOI: 10.1038/ncomms10780, PMCID: PMC4766398] whereby three dimensional droplet generating devices with robust flow invariant behaviour in which a droplet generator produces droplet volumes spanning four orders of magnitude can be used. With a parallel network, the platforms can be made to synthesise ***platinum nanoparticles*** reproducibly using an ionic liquid solvent, and after recycling an ionic solvent the yield of the reaction was doubled compared with similar batch syntheses.

Rhodium nanoparticles entrapped in Rh/AlO(OH) matrix (~5wt% Rh loading). The catalyst is prepared from a mixture of $RhCl_3.xH_2O$**,** Al(*sec*$BuO)_3$ and 2-butanol [compare with Ru/AlO(OH) below] at 100º for 3 hours, aging in air for 1 day, filtering, washing the solid with Me_2CO and drying in air at 25º. It is estimated by high resolution transmission electron microscopy (HRTEM) and X-ray diffraction that the Rh particle sizes in the matrix are 2.5-3.0nm. It is an efficient catalyst for the hydrogenation of arenes, e.g. benzene, naphthalene, quinoline, at low pressures of H_2 (~1 atmosphere) and room temperature in yields approaching 100% and with high turn over, with *ca* 1 mol% of Rh in the catalyst. [Park et al. *Chem Commun* 5667 *2005*, DOI: 10.1039/B511577A].

Ruthenium (nanoparticles) in aluminium oxide/hydroxide (~2.5wt% Ru loading). In this catalyst, Ru is encapsulated in an aluminium oxy-hydroxide matrix where the metal has been shown by energy dispersive X-ray analysis (EDX) and X-ray photoelectron spectroscopy (XPS) to exists mainly as Rh(0) in the matrix. It is prepared in a one-pot synthesis through nanoparticle generation and gelation. Thus $RuCl_3.xH_2O$ (52mg, 0.25mmol) and Al(*sec*$BuO)_3$ (2.5g, 10mmol) in EtOH (1.2ml, 20mmol) under a reflux condenser are heated, with stirring, at 100º for 1 hour, forming a black suspension to which H_2O (2.0ml) is rapidly added. The mixture is stirred for a further 30 minutes at 100º, filtered, the black solid is washed with Me_2CO and dried in air at 25º to give the catalyst as a grey powder (0.74g, 2.5wt% of Ru). It is used as a recyclable catalyst for efficient oxidant-free alcohol dehydrogenation see Chapter 5, Catalysts-Part 1. [Kim, Park and Park *Org Lett* **8** 2543 *2006*, DOI: 10.1021/ol060750z.]

Ruthenium nanoparticles stabilised in polymer ligands. A general procedure is used for making these colloids (agglomerates) which involve introducing ruthenium (1,5-cyclooctadiene)(1,3,5-cyclooctatetraene) (158mg, 0.5mmol, [Ru(COD)(COT)] see *[127382-91-6]*) in a Fischer-Parr bottle and left *in vacuo* for 30 minutes, then THF (25ml, degassed by freeze-pump cycles) is added and the yellow solution is cooled to -80º, after which the ligand (0.1mmol) in THF (~60ml) is introduced to the bottle. The bottle is pressurised under 3 bars of H_2 and allowed to warm to room temperature. After ~20 hours a brown-black suspension is obtained. Complete decomposition of the Ru complex is checked by eliminating the H_2 (e.g. by blowing N_2 through) and taking a 3ml aliquot through a small Al_2O_3 column when the filtrate should be colourless. The volume of the solution is then reduced to *ca* 15ml, pentane (50ml) is added, the resulting mixture is cooled to -80º at which temperature a brown precipitate is formed. This is filtered off (or centrifuged), washed with pentane and dried *in vacuo*. The ligands used are PVP (poly vinylpyrrolidone), *n*-alkyl (C8, C12 and C16) amines and *n*-alkyl (C8, C12 and C16) thiols in varying amounts (from 0.2 to 1 equivalent) giving Ru percentages of ~55 to 80%. The colloids are characterised by microanalysis, IR after CO absorption, high resolution EM and wide-angle X-ray scattering. In THF and in a polymer matrix (Ru/polymer ~5%) crystalline particles of uniform mean size

(1.1nm) and agglomerated particles (1.7nm) are thus obtained in PVP and cellulose acetate. The reaction with various concentrations of alkyl amines and alkyl thiols lead to agglomerate particles or particles dispersed in solution both displaying mean size of 2-3nm. In the case with the amine ligands the particles are generally elongated with the tendency of forming worm or rod like structures at high amine concentrations, whereas ^{13}C NMR studies show that the stabilised particles are not fluxional, but thiol groups are oxidised to disulfide groups probably by the Ru surface. Because of their chemically reactive groups they are potentially very useful in nanotechnology. [Pan et al. *J Am Chem Soc* **123** 7584 *2001*, DOI: 10.1021/ja003961m]. In a similar synthesis ruthenium nanoparticles are stabilised by organosilane fragments, by using *n*-octylsilane, giving particles of ~2.3nm diameter which is a very narrow distribution of size. They were characterised by TEM, as well as solid state ^{13}C MAS NMR. [Pelzer et al. *Chem Mater* **16** 4937 *2004*, DOI: 10.1021/cm049086b.]

Silver acetate *[563-63-3]* see also entry in Chapter 5, 'Catalysis-Part 1'. Among the current intense activities in the synthesis of hybrid materials, where an inorganic phase is present as nanometer-sized particles dispersed throughout an organic matrix, is the preparation of a *ca* 190nm uniform film of exceptionally reflective and surface conductive silver 'mirror' on a flexible poly(amic) matrix. The Ag-containing resin solutions are made first by dissolving AgOAc in a small volume of dimethylacetamide (DMAc, *[127-19-5]*) by adding 1.35 equivalents of 1,1,1-trifluoro-2,4-pentanedione (TFAH). As AgOAc is not very soluble in DMAc, addition of TFAH converts the acetate salt into the much more soluble AgTFAH complex. The poly(amic) matrix is prepared by co-polymerising 3,3',4,4'-benzophenonetetracarboxylic anhydride (BTDA, *[2421-28-5]*) with 4,4'-oxydianiline (APE, 4,4'-diaminodiphenyl ether, *[101-80-4]*), and making a 15%w/w solution in DMAc by stirring for 5 hours to give a viscosity of 1.7-1.8 dL/g at 35º. The poly(amic) solution is added to the Ag solution to give the desired Ag to BTDA/APE polymer ratio of 10.7 to 13.0% Ag, cast into films (onto soda lime glass plates) to give cured films of 20-25 mm thickness. Air (10% relative humidity) is slowly flowed over the film for 18 hours, then thermally cured in a forced air oven with a cycle involving heating at 135º for 20 minutes, holding for 1 hour, heating at 300º for 4 hours, and holding at 300º for 7 hours. This process reduces Ag(I) to the metal and releases all the volatiles. Uniform nanometer thin films of Ag metal (see above) are thus formed in the polymer matrix. Characterisation by X-ray diffraction, transmission (TEM) and scanning (SEM) microscopy, tapping mode atomic force microscopy, X-ray photoelectron microscopy (XPS), and conductivity, reflectivity, thermal and mechanical measurements showed that the films have excellent properties, and are stable in air below 325º. This ***'film-to-film' method*** minimises the amount of Ag used. The applications for these Ag-copolymer silvered films with exceptional reflectivity, thermal, and surface conductivity are immense. They include the fabrication of lightweight optical mirrors, sunshields (e.g. in space telescopes), radiofrequency antennas for management of electromagnetic signals in space, Ag coated tubing to deter catheter-induced urethritis, elastomeric devices, concentration of solar energy, flexible conductive patterned surfaces and tapes. [Southward et al. *Chem Mater* **11** 501 *1999*, DOI: 10.1021/cm981014v.]

Silver nanoparticles on spherical electrolyte brushes (SPB). Compare these with the above Pt-NPs on SPB. They were also developed by M. Ballauff and coworkers [Lu et al. *J Phys Chem C* **111** 7676 *2007*, DOI: 10.1021/jp070973m]. In this case Ag nanoparticles were synthesised onto the polystyrene (PS) core—poly(acrylic acid) (PAA) SPB particles *in situ* by ***photoemulsion polymerisation***. The PS core with a thin layer of photo initiator {2-[*p*-(2-hydroxy-2-methylpropiophenone)]-ethylene glycol-methacrylate} was made by standard emulsion polymerisation procedures also developed by M. Ballauff and coworkers [Guo et al. *Macromolecules* **32** 6043 *1999*, DOI: 10.1021/ma990609o]. The PS-PAA-Ag composite particles were prepared *in situ* by mixing diluted PS core solution (1 wt %) with a defined quantity of functional monomer silver acrylate (30 mol% of the amount of styrene), degassing and refilling with N_2 (5 times). Then the mixture was irradiated under N_2 with UV-VIS radiation at ~25º for 90 minutes while being vigorously stirred to keep the mixture homogeneous. Coagulum was removed by filtration through glass wool and the Ag nanocomposite particles were washed by dialysis against purified H_2O using a cellulose nitrate membrane (100nm pore size). DLS showed that the polyelectrolyte brushes were on the PS core; TEM, Cryo-TEM, and wide-angle XRS revealed that the AgNPs in the brushes were crystalline with a diameter of 3 ±1.2nm.
This ***Ag-composite*** is stable and has very good catalytic activity. Reduction of *p*-nitrophenol using $NaBH_4$ is very fast, albeit slightly slower that with Pt or Pd immobilised on related carriers.

Silver nanoparticles [AgNP], on gum Arabic, gelatin or starch. Available as yellow-brownish liquids. They are water soluble in the form of 5-10nm spheres (10-15nm for starch) and have UV with λ_{max} at 405-410nm.

The gum Arabic (GA), gelatin and starch stabilise these particles and can be used for sensor design applications, for *in vitro* as well as *in vivo* antimicrobial and antifungal purposes. Among the useful AgNPs are the commercially available ***decanethiol-functionalised silver nanoparticles*** **Ag-$SCH_2(CH_2)_8CH_3$,** in 3-7nm size (TEM) as a 0.1w/v & in hexane with 0.075-0.125% loading, **d ^{25} 0.672g/cm^3**, [MDL number MFCD08705344]. Also available are ***PVP(polyvinylpyrrolidone)-functionalised silver nanoparticles*** with 10nm average size as 0.02mg/ml solutions in H_2O. Apart from their anti-microbial and anti-fungal properties, the AgNPs have optical colour properties that depend on their shape and size brought about by their attachments. Their strong coupling with the wavelengths of incident light has been used to produce highly sufficient thermal absorbers and ultrabright reporter molecules with nanoscale ***antennae*** which could amplify the strengths of local magnetic fields.

Silver Nanostrings: Nanostrings are a way of enhancing the electrical connection between two nanoelectrodes. The formation of necklace-like silver strings can be achieved as follows: Mix thoroughly Triton X-100 *[92046-34-9]* [4-$(C_8H_{17})C_6H_4(OCH_2CH_2)_{n\sim10}OH$] (2ml, of 0.5 x 10^{-2}M) with $AgNO_3$ (0.2ml of 10^{-2}M) and ascorbic acid AA (5ml of 5.68 x 10^{-2}M) in a plastic or quartz cuvette and expose to UV light (from a germicidal 15W lamp) for 10min to generate a green sol. [A more powerful lamp requires less exposure time.] Ag_2SO_4 or $AgClO_4$ give similar reactions. The green sol can also be prepared in gelatin (2ml, 0.001%) with $AgNO_3$ (0.2ml of 10^{-2}M), and ascorbic acid AA (20ml of 5.68 x 10^{-2}M) under UV light for 20-30 minutes, and the cuvettes in all cases are kept at a distance of 3cm from the UV lamp. These concentrations and conditions are critical. In the absence of ascorbic acid (AA) no green sol was formed, at lower amounts than stated a yellow sol of silver is formed, and at very high concentrations of AA (e.g. >1.7 x 10^{-1}M, with TX-100 or gelatin) the solution becomes turbid and forms larger yellow to black particles. Slightly longer UV exposure times are not deleterious. At high concentrations of TX-100 (>10^{-2}M) or gelatin (>0.002%) the linear aggregation of silver sol is inhibited and a pink silver particle (~50nm) sol is produced. A very low concentration of TX-100 or gelatin produced a yellow sol which is not stable and precipitates black silver particles on standing for ~24hrs.
The UV spectrum of the green sol has bands at ~400nm (high absorbance) and a band at ~630nm of lower intensity. The latter band is ***indicative of nanostring formation*** (solutions of other colour did not possess this band) which is confirmed by studies of fluorescence quenching of 1-aminonaphthalene, TEM (transmission electron microscopy), SERS (Surface Enhanced Raman Scattering) spectral effects (e.g. enhancement of the Raman signal of pyridine) and TAFM (Tapping Mode Atomic Force Microscopy). The Ag-nanostrings, which have similarities with DNA strings, are composed of particles as small as 3-5nm covered with 0.1-0.2mm thick layers of micelle or polymer. ***Note*** that SERS studies predict that linear aggregates of Ag will be produced in a green coloured sol. [Pal et al. *J Mater Sci Lett* **18** 1391 *1999*, DOI: 10.1023/A:1006659021058.]

Silver-tin alloy nanoparticles [MDL number MFCD00801108, PubChem Substance ID 24885373**] Ag-Sn_{25}, M 118.3.** These particles are available in <150nm in size and contain 3.5% Ag with the formula $Ag_{0.035}Sn_{0.965}$. They have a surface area >5.4 m^2/g. For the *Synthesis of tin, silver and their alloy nanoparticles for lead-free interconnect applications* see Hongjin Jiang: PhD thesis April 2008, School of Chemistry and Biochemistry, Georgia Institute of Technology, GA, USA, https://smartech.gatech.edu/bitstream/handle/1853/22636/Jiang, and is available in public domain.

Stannic oxide nanopowder *[18582-10-5]* **Sn(IV)O_2 [**MDL number MFCD00011244, PubChem Substance ID 24874714**], M 150.7, d ^{25} 6.95g/cm^3.** It is available in particle size of <100nm, and is used for polishing metal or glass, used in coloured glass, enamels, as a mordant for colouring fabrics and in battery manufacture. It is toxic and should not be inhaled. The oxide is prepared by precipitation from tin acetate solution in AcOH, upon addition of 12.5% aqueous ammonia solution with stirring to cool it. The precipitated sol is centrifuged down, washed twice with de-ionised H_2O, then dried at 120^o for 15 hours. The total impurity content in the original acetate used did not exceed 1wt%. For '*Studies of thermal stability of nanocrystalline SnO_2, ZrO_2, and SiC for semiconductor and thermocatalytic gas sensors* and *comparison of long-term stability of the sensors' signal with the thermal stability of the nanopowders*' see Pavelco et al. [*Russ J Electrochem* **45**(4) 470 *2009*, DOI: 10.1134/S1023193509040181].

Zinc oxide nanoparticles *[10139-47-6]* **ZnO, M 81.4.** The preparation of ZnO-nanoparticales can be carried out as follows: A solution of $Zn(CH_3CO_2)_2.2H_2O$ (0.10g) in isoPrOH (25ml) is added to isoPrOH (125ml) in a bath at 65^o and chilled, then 0.050M NaOH (15ml in chilled isoPrOH) is added rapidly with stirring *via* a pipette. After addition is complete aliquots are withdrawn (e.g. after 1, 3, 5, 10, 15, 30, 60 and 120 minutes) and

the UV spectra are measured. A series of spectra between 303 to 375nm are thus obtained each having a steep rise in absorption at the shortest wavelength. From the x-axis intercepts of the tangents to the steep rise in absorptions, the average radii of the nanoparticles can be calculated. The longer the sampling time, the larger the nanoparticle sizes that are formed. [For Growth kinetics and modeling of ZnO nanoparticles see Hale et al. *J Chem Educ* **82** 775 *2005*, DOI: 10.1021/ed082p775.] It should be possible to collect the nanoparticles by centrifugation for 10min, wash three times with de-ionised H_2O followed by two washes with anhydrous MeOH (all by centrifugation), and dried in an oven at 100º [as described by Hasanpoor et al. who used a microwave method *Procedia Material Science* **11** 320 *2015*, DOI: 10.1016/j.mspro.2015.11.101].

In a ***room temperature synthesis of ZnO nanoparticles*** Bagabas, Alshammari, Aboud and Kosslick [*Nano Lett* **8** 516 *2013*, DOI: 10.1186/1556-276X-8-516.] prepared nanoparticles which were effective catalysts for the photochemical distruction of cyanide, a very poisonous ingredient and/or product in the chelating agents, pharmaceutical, electroplating and mining industries. At 25º, cyclohexylamine (60mmoles, see [108-91-8] in 'Alicyclic compounds', Chapter 3) in H_2O (20ml) was added to a solution of $Zn(NO_3)_2.6H_2O$ (30mmoles) in H_2O (60ml) with magnetic stirring followed by more H_2O (80ml), which formed a white precipitate that was stirred for 4 days. The precipitate was filtered (F-size fritted filter) off, washed with Milli-Q H_2O (100ml) and dried for 1 day *in vacuo*. It was then suspended in Milli-Q H_2O (300ml) to remove further impurities, magnetically stirred for 1 day, filtered off again and dried at 25º *in vacuo* to give ***pure oxide*** (2.43g 89.7% yield). Inductively coupled plasma (ICP) elemental analysis of this uncalcined oxide showed that it had the formula $ZnO.0.5H_2O$. This was calcined by raising the temperature at the rate of 1º/min up to 500º in air and maintained at this temperature for 3hrs, and was designated ZnO_W.

A similar reaction carried out in EtOH medium gave 2.572g (98.1% yield) of $ZnO.0.33H_2O$ (by CIP) and after similar calcination was designated ZnO_E. Uncalcined and calcined ZnO_W and ZnO_E were subjected to various analyses including: surface areas (BET-SA) and pore size distribution, diffuse reflectance infrared Fourier transformation (DRIFT), FTIR, X-ray diffraction (XRD), morphology studies with field-emission scanning electron microscopy equipped with an energy-dispersive X-ray (EDX), high-resolution transmission electron microscopy (HRTEM), solid state UV-Vis and UV/Vis/NIR spectroscopy.

Analytical studies showed that ZnO_E and ZnO_W are nanocrystallites respectively with: Ave area 7.5 and 12.41 m^2/g (BET-SA); pore size 0.02 and 0.05 cm^3/g; Ave crystallite 28.8nm (15.6nm uncalcined) and 28.8nm (33.9nm uncalcined); 0.281nm (0.263nm uncalcined) and 0.263nm (0.262nm uncalcined) for d-spacing from HRTEM); 0.281nm (0.260nm uncalcined) and 0.260nm (0.260nm uncalcined) for d-spacing in bulk ZnO; 100*hkl*(002*hkl* uncalcined) and 002*hkl*(002*hkl* uncalcined) for Miller indices assignment.

The catalytic photodecompositions of cyanide kinetics were performed in aqueous KCN (100ppm, 300ml) made to pH 8.5 with aqueous NH_3 at 25º by UV light irradiation at 365nm (18W lamp) with 0.01, 0.02, 0.03, 0.05, 0.07 or 0.09w% of suspensed calcined ZnO and aliquots taken at time intervals (0 to 360min), and the CN^- ion concentration determined by volumetric titration with standard $AgNO_3$. ZnO_E is a more efficient catalyst than ZnO_W by a factor of 1.5 at catalyst concentration of oxide = 0.02%. Increasing the catalyst concentration from 0.01 to 0.09 increased the photolytic decomposition efficiency from 85% to 100% after 180min with a doubling of the *pseudo* first order rate constant. The rate constants at catalyst concentrations of 0.01 and 0.07wt% were 19.2 x 10^{-3} and 42.9 x 10^{-3} min^{-1} respectively.

M.R. Hoffmann and coworkers [*J Phys Chem* **91** 3789 *1987*, DOI: 10.1021/j100298a015] had similarly described the preparation of ***ZnO quantum sized nanoparticles*** by precipitation from $Zn(OAc)_2$ solution in H_2O, 2-propanol or MeCN with 80% of the stoichiometric amount of NaOH. They characterised the particles in detail by spectroscopy studies. [For '*A comprehensive review of ZnO materials and devices*'see Özgür et al. *J Appl Phys* **98** 041301 *2005*, DOI: 10.1063/1.1992666; and Klingshirn in '*ZnO: Material, Physics and Applications*' *Chem Phys Chem* **8** 782 *2007*, DOI: 10.1002/cphc.200700002; also see ZnO [10139-47-6] in 'Inorganic Compounds', Chapter 4.]

SOME ORGANIC AND METAL-ORGANIC COMPOUNDS USED IN NANO-TECHNOLOGY

1-Adamantane thiol (tricyclo[3.3.1.1^{3,7}]decane-1-thiol) *[34301-54-7]* **$C_{10}H_{16}S$, M 168.3, m 95-97º, 100-102º, 99-106º, pK ~11.2.** This thiol was prepared by various methods namely by formation of 1-adamantylisothiourinium bromide from 1-adamanylbromide followed by alkaline hydrolysis [Geigy A.-G. **Belg. Pat** 629,370 *1963*, *Chem Abstr* **60** 9167 *1963*], by refluxing 1-adamantanol with Lawesson's reagent (see

[19172-47-5]) in toluene [Nishio *JCS Perkin Trans I* 1113 *1993,* DOI: 10.1039/P19930001113], and by photolysis of *N*-(1-adamanylcarbonyloxy)pyridin-2-thione [Barton reaction: Barton et al. *Tetrahedron Lett* **35** 6057 *1994*, DOI: 10.1016/0040-4039(94)88074-3]. The thiol is generally purified by drying over P_2O_5, dissolving in Skellysolve B (see Aliphatic Compounds, Chapter 3) or *n*-hexane, passing through a column of Alumina in *n*-hexane, and eluting with *n*-hexane/EtOAc (97:3). Store it dry under N_2 or argon. The IR (CCl_4) has ν_{max} at 2190, 2850, 1450 and 2565 (S-H) cm^{-1}, the ^1H NMR (CCl_4) has τ at 8.06 (s, 9, β and γ H), 8.29 (s, 6, δ H) and 8.57 (s, 1 S-H); and the MS has *m/z* (peak height) 168 (14, M^+), 136 (12), 135 (100), 93 (15), 79 (17). The ***S-2,4-dinitrophenylsulfenyl derivative*** gives yellow needles from MeOH with **m 159-160°**. [Tanner & Brownlee *J Canad Chem* **51** 3366 *1973*, DOI: 10.1139/v73-502]. The ***S-CH_2CO_2Et derivative*** (from $NaNH_2/BrCH_2CO_2Et$) has **b 117-118°/0.001mm**, and on hydrolysis (NaOH/EtOH, 5 hours) gave ***α-(adamant-1-ylthio)acetic acid*** **m 68-70°** (hexane/pentane). Similarly obtained are ***α-(adamant-1-ylthio)propionic acid*** **m 142-144°** (cyclohexane), ***α-(adamant-1-ylthio)butyric acid*** **m 113-114°**, ***α-(adamant-1-ylthio)isovaleric acid*** **m 134-145°** (cyclohexane), ***α-(adamant-1-ylthio)caproic acid*** **m 74-76°**, ***α-(adamant-1-ylthio)-α-phenylacetic acid*** **m 122-124°** (cyclohexane/hexane) as well as other acids that are reported [Geigy A.-G. **Belg. Pat** 629,370 *1963*, *Chem Abstr* **60** 9167 *1963*]. ***1-Adamantane-thioether*** is a good novel sialoside protecting group which is also used for coupling with adequately protected sugars [Crich & Li *J Org Chem* **72** 7794 *2007*, DOI: 10.1021/jo7012912]. ***1-Adamantanethiolate molecules*** have been used in a new patterning technique (microdisplacement printing) to form self-assembled mono-layers (SAMs) on an Au(111) surface for contact printing. The attached thiolate molecular film hinders lateral surface diffusion of the patterning molecules allowing the use of such molecules which are too mobile to pattern by other methods. It is used for SAMs Cat 659452-5G molecular spacer in nanotechnology [*J Org Chem* **72** 7794 *2007*, DOI: 10.1021/jo7012912; Dameron et al. *Nano Lett* **5** 1834 *2005*, DOI: 10.1021/nl050981j].

Aerosol-OT [AOT, DOSS, sodium bis(ethylhexyl)sulfosuccinate, sodium ducosate] *[577-11-7]* **$C_{20}H_{37}O_7SNa$, M 444.6, m 173-179°.** The surfactant can be prepared by stirring vigorously di(2-ethylhexyl)malate (1mol, obtained from maleic anhydride and 2-ethylhexyl alcohol) and sodium bisulfite (1.05mols) with H_2O (100 parts to ~250 parts of ester) and heating (preferably under pressure to avoid loss of SO_2) until a homogenous solution is formed. The moisture is removed *in vacuo*, and any residual salts are removed by dissolving in organic solvents such as toluene or petroleum ether, filtering and evaporating to dryness. For variations of this method see A.O. Jaeger [**US Patents** 2028091 *1936* and 2176423 *1939* to American Cyanamid & Chem Corp]. For the preparation of reverse micelles of semiconductor nanoparticles, AOT is purified and degassed by dissolving the solid in petroleum ether (b 35-60°), filtering and evaporating to dryness [Stiegerwald et al. *J Am Chem Soc* **110** 3046 *1988*, DOI: 10.1021/ja00218a008]. AOT is a waxy colourless solid which is stable at pH 7 and below, but hydrolyses slowly at pH >8. It is soluble in CCl_4, light petroleum, xylene, dibutyl phthalate, EtOH, Me_2CO and plant oils. Its solubilities in H_2O (w/v%) are 1.5 (25°), 2.3 (40°), 3.0 (50°) and 5.5 (70°). It is also used as a surfactant wetting agent, in tablet formulations and as a laxative. The ***potassium salt*** *[7491-07-0]* **$C_{20}H_{37}O_7SK$, M 460.7,** is prepared in a similar way and has similar properties. [Caryl *Ind En Chem* **33** 731 *1941*, DOI: 10.1021/ie50378a011; *Beilstein* **4** III 71; Fieser **15** 149.]

Cadmium bis(octanethiol) $C_{16}H_{34}S_2Cd$, M 398,9. A precursor for making quantum dots, is prepared by addition of 35% aqueous NH_4OH (~10-11ml) to a solution of $CdCl_2$ (1.83g, 10mmol) in 1:1 v/v EtOH/H_2O (100ml) until the white suspension dissolved to give a clear solution. To this solution is added 1-octanethiol (3.47ml, 20mmol) dropwise when a white precipitate forms, and the mixture is stirred at ~25 for 2hrs. The solid is collected by centrifugation (4000rpm/10min), resuspended in 1:1 v/v EtOH/H_2O (100ml), centrifuged (4000rpm/10min) again, and this washing is repeated twice. The white powder is then dried in air overnight (85% yield, analytically pure for **$C_{16}H_{34}S_2Cd$**). Its FTIR (KBr) has ν at 2955 (C-H_3 asymm str), 2872 (C-H_3 symm str), 2849 (-CH_2- symm str), 1466 (-CH_2- deform), 1738 (C-H_3 deform), 722 (-CH_2- rock) and 647 (-CH- deform) cm^{-1}. Because of its insolubility the ^{13}C (^1H) CPMAS solid state spectrum was measured and gave a duplicate set of 8 signals attributed to a mixture of crystalline and amorphous forms. [Bansal et al. *J Phys Chem C* **120** 1871 *2016*, DOI: 10.1021/acs.jpcc.5b09109].

Dimethylcadmium *[506-82-1]* **C_2H_6Cd, M 142.5, f.p. -2,4°(corrected), -4.5°, b 105.5°/758mm, 105.7°/760m (log *p* versus 1/*T* does not give a straight line), n_D^{25} 1.5488.** Prepared by siphoning an ethereal solution of MeMgI under N_2 into a flask at -10° with a hopper (design provided by Anderson and Taylor, see reference below) containing dried powdered anhydrous $CdCl_2$ which was added at a rate (at ~5min intervals) which

allowed gentle reflux. At the end of the reaction the supernatant Et_2O was siphoned off, the residue was washed with dry Et_2O which was removed also by siphoning. The combined Et_2O was siphoned into a fractionation unit (design also provided by Anderson and Taylor, see reference below), and purified by fractionation also under N_2. Extreme precaution should be exercised as the whole system is **highly flammable**. It has a disagreeable odour, highly flammable and should be stored in sealed tubes at <0°. It ignites if dropped on filter paper and can explode spontaneously if heated above 90° in air. It forms dense white fumes when exposed to moist air. Its physiological effects are serious as it causes irritation of the eyes on exposure to the vapour, with distortion of vision which can last a few hours and the eyes can see halos to bright light that may last a day or two. When using $CdMe_2$ for chemical reactions it is best to use the siphoned Et_2O solution, determine its concentration, and use the required volume without isolating it. [Gilman & Nelson *Recl Trav Chim Pays-Bas* **55** 518 *1936*, DOI: 10.1002/ recl.19360550607; for preparation (including design of equipment) and physical constants see Anderson & Taylor *J Phys Chem* **56** 161 *1952*, DOI: 10.1021/j150494a001; and for preparation from MeMgBr and $CdBr_2$ see Krause *Chem Ber* **50** 1813 *1917*, DOI: 10.1002/cber.19170500292; for the determination of Cd concentration see Vogel's *Textbook of Quantitative Chemical Analysis* by Jeffrey, Bassett, Mendham and Denney Eds, 5th Edition, pp 444 and **541** *1989*, Longman Scientific & Technical Ltd UK/John Wiley & Sons Inc, NY, ISBN 0-582-44693-7.]

6-Mercaptohexylferrocene *[134029-92-8]* **$C_{16}H_{22}SFe$, M 302.3, b 321-353°.** This thiol is prepared in four steps from ferrocene. Thus a mixture of 6-bromohexanoyl chloride (3.2g, 15mmol, see *[22809-37-6]*) and anhydrous $AlCl_3$ (2.0g, 15mmol) in cold (0°) CH_2Cl_2 (40ml), which is stirred (20 minutes) under argon, is added dropwise with stirring to ferrocene (2.79g, 15mmol) in CH_2Cl_2 (40ml) over a period of 20 minutes when the colour of the solution turns purple. After stirring for 2 hours, the stirring rate is increase while H_2O (20ml) is added slowly, and the solvent boils gently. The organic layer is collected after 10 minutes, washed with H_2O until the washings are neutral, dried ($MgSO_4$), filtered, concentrated *in vacuo*, and the residue is subjected to chromatography on silica-gel (230-400 mesh) with hexane/EtOAc (100:1) as eluent. The second orange band (the first is ferrocene) is collected and gives ***6-(ferrocenylcarbonyl)pentyl bromide*** (4.5g, 85%) on evaporation. A part of it (1.61g, 7.4mmol) and Zn/Hg amalgam (freshly prepared from 7.4g of granulated Zn and 0.5g of $HgCl_2$) in H_2O (25ml), 12M HCl (20ml) and toluene (30ml) are stirred vigorously so that the two liquid phases and the solids are in close contact, and are heated under reflux for 16 hours during which time 12M HCl (2 x5ml) is added. The mixture is cooled to ~25°, the organic layer is collected washed with H_2O, dried ($MgSO_4$), filtered, concentrated, and the residue is purified through a silica-gel column as before. The yellow-brown band provides the required ***6-ferrocenylhexyl bromide*** (2.33g, 90%). The bromide (1.11g, 3.2mmol) and thiourea (0.24g, 3.5mmol) in absolute EtOH (20ml) is then boiled under reflux in an atmosphere of argon. After boiling for 18 hours, the solvent is removed *in vacuo*, treated with aqueous KOH (0.20g, 3.5mmol, in 20ml of H_2O) and boiled under reflux in an atmosphere of argon for 2 hours. The orange-yellow oil that settles on cooling is extracted into Et_2O (3 x 50ml), the combined extracts are dried ($MgSO_4$), concentrated, and chromatographed as before. The first yellow band gives the desired ***6-ferrocenylhexanethiol*** (0.68g, 62%) on evaporation. It is identified by its ^1H NMR (300 MHz, $CDCl_3$) which has δ at 1.35 (t, 1H, S**H**), 1.39 (br, 4H, $FcCH_2C\mathbf{H}_2\mathbf{CH}_2$), 1.52 (q, 2H, $C\mathbf{H}_2CH_2CH_2SH$), 1.63 (q, 2H, $C\mathbf{H}_2CH_2SH$), 2.34 (t, 2H, $FcC\mathbf{H}_2$), 2.53 (q, 2H, $C\mathbf{H}_2SH$), 4.06 (t, 2H, $C_5\mathbf{H}_4$), 4.07 (t, 2H, $C_5\mathbf{H}_4$), 4.11 (s, 5H, $C_5\mathbf{H}_5$); and EI-MS *m/z* at 302 (M^+). The second yellow band contains the corresponding ***disulfide*** which can be reduced and used. [Creager & Rowe *J Electroanal Chem (Lausanne Switz)* **370** 203 *1994*, DOI: 10.1016/0022-0728(93)03173-M; *cf* Yu et al. *J Org Chem* **66** 2937 *2001*, DOI: 10.1021/jo001283g.] This and other related ferrocenyl-alkane thiols have been synthesised and characterised electrochemically in solution and in self-assembled monolayer (SAM) films on gold electrodes. The affinities of these on the electrode surface have been described in detail. These redox active thiols can be used for selective electrochemical sensing and preparing a new type of thiol self-assembled sensing devices (SAMs). [Creager & Rowe *J Electroanal Chem (Lausanne Switz)* **370** 203 *1994*, DOI: 10.1016/0022-0728(93)03173-M.]

Gold nanoparticles covered fully with 6-ferrocenylhexanethiolate ligands, with average composition Au_{225}(6-ferrocenylhexanethiolate)$_{42}$, were prepared, and had a unique combination of adsorption properties on Pt electrodes which were studied comprehensively. The adsorbed layers are so robust that sub, mono and multi nanoparticulate layers on the electrodes can be transferred to fresh electrolyte solutions in which they show stable ferrocene voltametry over long time periods. [Stiles et al. *J Am Chem Soc* **130** 1856 *2008*, DOI: 10.1021/ja074161f.]

NPs for drug delivery to tissues and particularly to brain, i.e. traverse the blood-brain-barrier, include conjugates of dextran, agarose, chitosan polyacetic acid (PLA), poly(lactic-co-glycolytic acid) (PLGA) and NPs with lipophilic moieties, e.g. polyethylene glycol (PEG) to which drugs can be bound have been explored by Fresta and co-workers [Celia et al. *Med Res Rev* **31** (3) 716-756 *2011*, DOI: 10.1002/med.20201], and shown to be useful devices.

Phenyl trimethylsilyl selenide *[33861-17-5]* **$C_9H_{14}SeSi$, M 229.3, b 93-95°/9-10mm, 92-93°/5mm.** Prepared under positive pressure of N_2, a solution of diphenyl diselenide (15.7g, 50mmol; Reich et al. *Org Synth* **59** 141 *1979*, Coll Vol **6** 533 *1979*, DOI: 10.15227/orgsyn.059.0141) in THF (50ml) is treated with finely cut Na (2.76g, 120mmol) at ~25°, heated under gentle reflux until the metal dissolves, cooled to ~25°, then trimethylsilyl chloride (15.2ml, 120mmol) is added slowly to the brown mixture with stirring for 1hr at ~25° (orange-yellow solution) followed by refluxing for 30min whereby a copious white precipitate of NaCl is formed. The mixture (containing the NaCl) is evaporated to dryness, and distilled directly *in vacuo* with vigorous stirring to give a colourless liquid which was redistilled to give ***phenyl trimethylsilyl selenide*** (16.6g, 72%). It has IR (film): ν_{max} 1250, 840 and 739 cm^{-1}, ^1H NMR (CCl_4) with δ at 0.34 [s, 9H, $(CH_3)_3Si$)], 7.18-7.42 [m, 5H, SeC_6H_5] ppm, ^{13}C NMR ($CDCl_3$) with δ at 1.49 $(CH_3)_3Si$) and MS (70eV) has *m/e* = 230 ($M^{+\cdot}$), 215 ($M^{+\cdot}$ - CH_3), 73 [$M^{+\cdot}$ - $(CH_3)_3Si$)]. [Miyoshi et al. *Synthesis* 300 *1979,* DOI: 10.1055/s-1979-28659]. It is soluble in $*C_6H_6$, Et_2O, THF and MeCN, but is rather sensitive to moisture and should be handled *via* a syringe using Schlenk-type techniques (see Chapter 1). It can be stored indefinitely under dry argon or N_2 and all reactions should be carried out in efficient fume hoods. [See also Ogawa e-EROS *Encyclopedia of Reagents for Organic Synthesis* published on line on 15 April 2001, DOI: 10.1002/047084289X.rp145.]

Tetra-*n*-propylammonium perruthenate (TPAP, tetrapropyl tetraoxoruthenate) *[114615-82-6]* **$C_{16}H_{28}NO_4Ru$, M 351.4, m 160°(dec).** This oxidant (at 5 mol%) acts catalytically in oxidising 2-substituted *N-1, N-3*-dihydroxy-imidazolidines (1mol) in CH_2Cl_2 at room temperature in 1-12 hours in the presence of *N*-methylmorpholine *N*-oxide (1.1mol) to provide the respective 2-substituted imidazoline-1-nitronyl-3-nitroxide radicals (NNRs) in 44-90% yields. NNRs have found applications in Physics, Chemistry and Nanotchnology for the development of ***organic molecular magnets*** [Palacio et al. *Phys Rev Lett* **79** 2336 *1997*, http://dx.doi.org/10.1103/PhysRevLett.79.2336] and ***single chain magnets*** [Caneschi et al. *Angew Chem Int Ed* **40** 1760 *2001*, DOI: 10.1002/1521-3773(20010504)40:9<1760]. Gorini et al. *Synlett* 948 *2006*, DOI: 10.1055/s-2006-939045; for further reading see TPAP entries in Chapter 4, 'Metal-Organic Compounds'; and in Chapter 5, 'Catalysis-Part 1', and for applications see Fieser **14** 302, **16** 325.]

SAFETY ISSUES

Materials of nanometer size have been present on earth almost since its formation ~4.6 billion (eon) years ago, as well as in the universe. Recently J. Cami, and coworkers have discovered large clouds in the planetary nebula Tc1 in which C_{60} and C_{70} fullerenes were identified by infra red spectroscopy [*Science* **329** (Issue 5996) 1180 *2010*, DOI: 10.1126/science.1192035, reviewed by A. Extance RSC *Chemistry World* **7** (9) 21 *2010*, and L. Howes RSC *Chemistry World* **8** (1) 34 *2011*.] During the past 30 years or so the development of nanomaterials and their wide ranging applications have avalanched, and progress is continuing. The safety aspects of nanomaterials have been of concern for many years, and it is generally accepted that conscious efforts have to be made to protect the individual workers in the field, the general public and the environment. Research on safety aspects is slowly gaining pace, and it has already been shown in mice that carbon nanotubes (CNTs) exhibit asbestos-like pathogenicity when inhaled. [K. Donaldson and coworkers: Poland et al. *Nature Nanotechnol* **3** 423 *2008*, DOI: 10.1038/nnano.2008.111; J.C. Bonner and coworkers: Ryman-Rasmussen et al. *Nature Nanotechnology* **4** 747 *2009*, DOI: 10.1038/nnano.2009.305; Reviewed by H. Birch RSC *Chemistry World* **6** (12) 24 *2009*.] The movement of nanomaterials from lungs to lymph nodes to the blood stream and clearance through the kidneys has been demonstrated by J.V. Frangioni and A. Tsuda and their coworkers [Choi et al. *Nature Biotechnol* **28** 1300 *2010*, DOI: 10.1038/nbt.1696; reviewed by L. Howes RSC *Chemistry World* **7** (12) 24 *2010*.] More recently W. Wohlleben and coworkers have subjected two thermoplastic materials and two cement materials infused with different nanoparticles (i.e. nanotubes and nanoparticle in polymer filters and in inorganic matrices) to gentle abrasion, high speed sanding and UV radiation. They did not find significant release of nanopowders into the atmosphere in which the sizes of the nanoparticles were very different from

those in control powders. Moreover, rats exposed to the dust fared no worse than those exposed to dust that contained nanocomponents. However, further studies are in progress. [Wohlleben et al. *Small* **7** (16) 2384 *2011*, DOI: 10: 1002/smll.201002054; reported by K. McAlpine *Chemistry World* **8** (8) 28 *2011*.]
Safety was rather slack in the early days, but it is being realised that nanomaterials should be treated differently from hazardous chemicals due to their unknown long-term effects. Nano-enabled hoods and nano-enabled-gear for personnel are being used, but only to a small extent. Safety protocols have been written and updated, but nano-regulation is only slowly creeping in [see special report by V. Gill RSC *Chemistry World* **6** (4) 10 *2009*.]
A comprehensive report on nanosafety practices in research laboratories worldwide was compiled by J. Santamaria and coworkers recently, where they detail an up-to-date account of the present situation regarding to safety issues. [Balas et al. *Nature Nanotechnol* **5** 93 *2010*, DOI: 10.1038/nnano.2010.1; Reviewed by K. McAlpine RSC *Chemistry World* **7** (3) 15 *2010*.]

Advice in this regard is that in the manipulation and disposal of nanomaterials the same guidelines for asbestos handling should be used. In addition, further precautions should be exercised which should consider the known toxicity and the chemical nature of the nanomaterials in use.

CAS Registry Numbers Index

HOW TO VALIDATE CHEMICAL ABSTRACTS SERVICE REGISTRY NUMBERS

Almost all chemical and biochemical entries in this book have CAS (Chemical Abstract Service) Registry Numbers to identify them and have been entered for each substance. The registry numbers are an efficient way for identifying substances and are independent of the nomenclature of substances. Unlike chemical names which may have more than one synonymous name, there is only one CAS Registry Number for each substance (with only a few exceptions, e.g. where a substance may have another number before purification, or before determination of absolute configuration).

The registry numbers are made up of three sets of digits separated by two hyphens with the general form: $n\mathrm{N}_n + \ldots\ldots + 4\mathrm{N}_4 + 3\mathrm{N}_3 - 2\mathrm{N}_2 + 1\mathrm{N}_1 - R$ where the Ns are sequential numbers and *R* is the *check digit*. The first set can be up to eight digits (at this point in time, but not less than two), and the second is made of two digits (zeros are included as a digits) and the third is a single digit which *checks* the validity of the sequential numbers, e.g. 379669-72-4 for *but-3-enylboronic acid* or 83-32-9 for *acenaphthene*. The validity of a registry number can be checked by the following formula (computer generated):

$$\frac{n\mathbf{N}_n + \ldots\ldots + 4\mathbf{N}_4 + 3\mathbf{N}_3 + 2\mathbf{N}_2 + 1\mathbf{N}_1}{10} = \mathbf{Q} + \boldsymbol{R}/10$$

where the **N**s include all numbers except the last *check* digit, **Q** represents an integer (fractions not included) which, although it is disregarded, does give the value of ***R*** equal to the *check digit* in a **valid** Registry Number.

The following are three examples demonstrate the application of the formula and the validity of the Registry Number:

1. 1,5-Dihydroxynaphthalene 83-56-7

$$\frac{(4\mathrm{x}\mathbf{8}) + (3\mathrm{x}\mathbf{3}) + (2\mathrm{x}\mathbf{5}) + (1\mathrm{x}\mathbf{6})}{10} = \frac{\mathbf{57}}{10} = 5 + \frac{\mathbf{7}}{10}$$

[Note: *the last (check) digit of the CAS number 7 is not included*.]

When the value of **Q** is made to equal 5, the *check* digit *R* becomes equal to 7; thus the Registry Number is **valid**. In this case the value of **Q** is in fact the digit(s) (**5**), before the last *check* digit (**7**).

2. 4,5-Diamino-6-hydroxypyrimidine hemisulfate 102783-18-6

$$\frac{(8\mathrm{x}\mathbf{1}) + (7\mathrm{x}\mathbf{0}) + (6\mathrm{x}\mathbf{2}) + (5\mathrm{x}\mathbf{7}) + (4\mathrm{x}\mathbf{8}) + (3\mathrm{x}\mathbf{3}) + (2\mathrm{x}\mathbf{1}) + (1\mathrm{x}\mathbf{8})}{10} = \frac{\mathbf{106}}{10} = 10 + \frac{\mathbf{6}}{10}$$

When the value of Q is made to 10, the *check* digit *R* becomes equal to 6; thus the Registry Number is **valid**. In this case the value of **Q** is in fact the digit(s) (**10**), before the last *check* digit (**6**).

3. 1,4-Bis(pentafluorobenzyl)[C_{60}]fullerene 1260376-31-5

$$\frac{(9\text{x}\mathbf{1}) + (8\text{x}\mathbf{2}) + (7\text{x}\mathbf{6}) + (6\text{x}\mathbf{0}) + (5\text{x}\mathbf{3}) + (4\text{x}\mathbf{7}) + (3\text{x}\mathbf{6}) + (2\text{x}\mathbf{3}) + (1\text{x}\ \mathbf{1})}{10} = \frac{13\mathbf{5}}{10} = 13 + \frac{\mathbf{5}}{10}$$

When the value of Q is made to 13, the check digit *R* becomes equal to 5; thus the Registry Number is **valid**. In this case the value of **Q** is in fact the digit(s) (**13**), before the last *check* digit (**5**).

The CAS Registry Handbook (Number Section) and supplements should be consulted for obtaining the substance name and elemental formula corresponding to a Registry Number.

To facilitate the method for locating the purification of a substance, a CAS Registry Number Index of the numbers of the entries with their respective page numbers is included here. This will also provide the reader with a rapid way to see if the purification of a particular substance has been reported in the book.
