4-Phenylbutyric acid *[1821-12-1]* **$C_{10}H_{12}O_2$, M 164.2, m 48°, 50°, 52°, 49-53°, b 165°/10mm, 340.4°/atm, pK^{25} 4.76.** Crystallise the acid from petroleum ether (b 40-60°). [*Beilstein* **9** IV 1811.]

O*-Phenyl chlorothionoformate** *[1005-56-7]* **C_7H_5ClOS, M 172.6, b 81-83°/6mm, 91°/10mm, d_4^{20} 1.276, n_D^{20} 1.585.** Purify it by dissolving in $CHCl_3$, washing with H_2O, drying ($CaCl_2$), filtering, evaporating and distilling twice under a vacuum to give a clear yellow liquid. **It is reactive and POISONOUS—work in a fume cupboard.** Store it in sealed ampoules under N_2. A possible impurity is ***O,O'-diphenyl thiocarbonate which has **m 106°** and remains behind in the distilling flask. [Bögemann et al. in *Methoden Der Organischen Chemie (Houben-Weyl)* 4th edn (E. Müller Ed.) **Vol 9** *Schwefel-Selen-Tellur Verbindungen* pp. 807-808 *1955*, Rivier & Schalch *Helv Chim Acta* **6** 605 *1923*, DOI: 10.1002/hlca.19230060163; Kalson *Chem Ber* **20**, 2384 *1887*, DOI: 10.1002/cber.18870200256; Rivier & Richard *Helv Chim Acta* **8** 490 *1925*, DOI: 10.1002/hlca.19250080174; Schönberg & Varga *Justus Liebigs Ann Chem* **483** 176 *1930*, DOI: 10.1002/jlac.19304830117; Schönberg & Vargha *Chem Ber* **64** 1390 *1931*, DOI: 10.1002/cber.19310640628; *Beilstein* **6** III 609.] Reagent for thionocarbonylation, and to form phenoxythiocarbonyl esters.

Phenyl cinnamate *[2757-04-2]* **$C_{15}H_{12}O_2$, M 224.3, m 75-76°, b 205-207°/15mm.** Crystallise the cinnamate from EtOH (2ml/g). It can also be distilled under reduced pressure. [Womack & McWhirter *Org Synth* Coll Vol **3** 714 *1955*, DOI: 10.15227/orgsyn.020.0077; *Beilstein* **9** H 583, **9** II 387, **9** III 2689, **9** IV 2011.]

α-Phenylcinnamic acid (2,3-diphenylprop-2-enoic acid) *[cis-E 91-48-5, trans-Z 91-47-4]* **$C_{15}H_{12}O_2$, M 224.3, m 174°(*cis*), m 138-139°(*trans*), pK^{25} 4.8 (60% aqueous EtOH).** Recrystallise the acid from Et_2O/petroleum ether. Crystallise the ***cis-isomer*** from petroleum ether or EtOH (**m 174°**) and has a pK^{25} of 4.44, and the ***cis-amide*** from aqueous Me_2CO (**m 174°**). Crystallise the ***trans-isomer*** from Et_2O/petroleum ether or EtOH (**m 140°**), and the ***trans-amide*** from $CHCl_3$/petroleum ether (**m 167-168°**). [*Beilstein* **6** H 691, **9** III 3414.]

o-**Phenylenediamine** *[95-54-5]* **$C_8H_8N_2$, M 108.1, m 100-101°, 102-104°, 103-104°, 252°/atm, d 1.03, pK_1^{25} 0.67 (aqueous H_2SO_4), pK_2^{25} 4.47 (4.85).** Crystallise the diamine from aqueous 1% sodium hydrosulfite (charcoal), wash it with ice-water and dry it in a vacuum desiccator, or sublime it *in vacuo*. It has been purified by recrystallisation from toluene and zone refined [Anson et al. *J Am Chem Soc* **108** 6593 *1986*, DOI: 10.1021/ja00281a024]. Purification by refluxing a CH_2Cl_2 solution containing charcoal is also carried out followed by evaporation and recrystallisation [Koola & Kochi *J Org Chem* **52** 4545 *1987*, DOI: 10.1021/jo00229a022], protect from light. The ***acetate*** has **m 186°**. [*Beilstein* **13** IV 38.]

m-**Phenylenediamine** *[108-45-2]* **$C_8H_8N_2$, M 108.1, m 61-63°, 62-63°, 62.5°, 63-64°, b 146°/22mm, 282-284°/760mm, 284-287°/atm, d_{10}^{10} 1.1422, $n_D^{57.7}$ 1.6340, pK_1^{25} 2.41, pK_2^{25} 4.98.** Purify the diamine by distillation under a vacuum followed by recrystallisation from EtOH (rhombs) and if necessary redistillation. It should be protected from light; otherwise it darkens rapidly. [Neilson et al. *J Chem Soc* 361 p371 *1962*, DOI: 10.1039/JR9620000361; IR: Katritzky & Jones *J Chem Soc* 3674 *1959*, DOI: 10.1039/JR9590003674; 2058 *1959*, DOI: 10.1039/JR9590002058; UV: Forbes & Leckie *Can J Chem* **36** 1371 *1958*, DOI: 10.1139/v58-202.] The ***hydrochloride*** has **m 277-278°**, and the ***bis-4-chlorobenzenesulfonyl*** derivative has **m 220-221°** from H_2O (**214-215°**, from MeOH/H_2O) [Runge & Pfeiffer *Chem Ber* **90** 1757 *1957*, DOI: 10.1002/cber.19570900910]. The ***acetate*** has **m 191°**. [*Beilstein* **13** IV 79.]

p-**Phenylenediamine** *[106-50-3]* **$C_8H_8N_2$, M 108.1, m 140°, 145-147°, b 267°/atm, pK_1^{25} 2.89, pK_2^{25} 6.16.** Crystallise the diamine from EtOH or *benzene, and sublime it *in vacuo*; protect it from light. The ***acetate*** has **m 304°**. [*Beilstein* **13** IV 104.] Useful for making polymers and composites.

o-**Phenylenediamine dihydrochloride** *[615-28-1]* **$C_8H_8N_2$. 2HCl, M 181.1, m 258°(dec).** Crystallise the salt from dilute HCl (60ml conc HCl, 40ml water, with 2g stannous chloride), after treatment of the hot solution with charcoal by adding an equal volume of concentrated HCl and cooling in an ice-salt mixture. The crystals are washed with a small amount of concentrated HCl and dried in a vacuum desiccator over NaOH. [*Beilstein* **13** IV 38.] It is a peroxidase substrate useful in ELISA procedures.

1-Phenyl-1,2-ethanediol *[R-(-)- 16355-00-3, S-(+)- 25779-13-9]* **$C_8H_{10}O_2$, M 138.2, m 64-67°, 65-66°, $[\alpha]_D^{24}$ (-) and (+) 40.5 (c 2.8, H_2O), $[\alpha]_D^{20}$ (-) and (+) 39 (c 3, EtOH).** Purify the diol by recrystallisation from *C_6H_6/ligroin and sublime it at 1-2mm. [Arpesella et al. *Gazetta* **85** 1354 *1955,* Prelog et al. *Helv Chim Acta* **37** 221 *1954*, DOI: 10.1002/hlca.19540370127; *Beilstein* **6** IV 5939.]

***dl*-1-Phenylethanol (*dl*-α-methylbenzyl alcohol)** *[98-85-1; 13323-81-4]* **$C_8H_{10}O$, M 122.2, m 19-20°, 20°, b 60.5-61.0°/3mm, 106-107°/22-23mm, 203-205°/atm, d_4^{20} 1.01, n_D^{20} 1.5254.** Purify the alcohol *via* its hydrogen phthalate. [See Houssa & Kenyon *J Chem Soc* 2260 *1930*, DOI: 10.1039/JR9300002260.] Shake it with a solution of ferrous sulfate, and the alcohol layer is washed with distilled H_2O, dried ($MgSO_4$) and fractionally distilled. [*Beilstein* **6** II 444.]

2-Phenylethanol *[60-12-8]* **$C_8H_{10}O$, M 122.2, m -27°, b 215-217°/atm, 219-221°/atm, d_4^{20} 1.020.** Purify the ethanol by shaking it with a solution of ferrous sulfate, and the alcohol layer is washed with distilled water and fractionally distilled. [*Beilstein* **6** IV 3067.] It is an antimicrobial antiseptic.

Phenyl ether (diphenyl ether) *[101-84-8]* **$C_{10}H_{12}O$, M 170.2, m 25.0° to 27.0°, 28°, b 83-84°/1mm, 138°/21mm, 257°/760mm, d_4^{20} 1.074, $n_D^{30.7}$ 1.57596.** Crystallise the ether from 90% EtOH. Melt it, wash it with 3M NaOH and water, dry it with $CaCl_2$ and fractionally distil it under reduced pressure. Fractionally recrystallise it from its melt and store over P_2O_5. [*Beilstein* **6** IV 562.] IRRITANT solvent with a fruity odour used to perfume soaps.

1-Phenylethyl isocyanate (α-methylphenyl isocyanate) *[R-(+)- 33375-06-3, S(-)- 14649-03-7]* **C_9H_9NO, M 147.2, b 82-83°/12-14mm, d_4^{20} 1.045, n_D^{20} 1.513, $[\alpha]_D^{24}$ (+) and (-) 2 (c 3.5, *C_6H_6), (+) and (-) 10.5 (neat)**. Purify the isocyanates by fractional distillation under a vacuum. With ammonia they give the ***ureido*** derivatives which crystallise from H_2O with **m 121-122°**, $[\alpha]_D^{25}$ (+) and (-) 48.8. [For the optical resolution of chiral amines, e.g. 2,3-dimethylethyleneimine see Cairns *J Am Chem Soc* **63** 871 *1941*, DOI: 10.1021/ja01848a504.] The ***racemate*** has **b 90-94°/3mm, 96°/18mm** [Seifkan *Justus Liebigs Ann Chem* **562** 75 *1949*, DOI: 10.1002/jlac.19495620202]. [*Beilstein* **12** IV 2443.]

(±)-*p*-α-Phenylethylphenol *[1988-89-2]* **$C_{14}H_{14}O$, M 198.3, m 56.0-56.3°, 64°, b 126°/0.4mm, 165-170°/5mm, 315-316°/742.2mm, pK_{Est} ~10.3.** Crystallise the phenol from petroleum ether. ***S-(+)-enantiomer*** has $[\alpha]_D$ +10.3 (*C_6H_6). [Okamoto et al. *Bull Chem Soc Jpn* **39** 299 *1966*, DOI:10.1246/bcsj.39.299.]

5-(α-Phenylethyl)semioxamazide *[93-95-8]* **$C_{10}H_{13}N_3O_2$, M 207.1, m 167-168° (*l*-), 157° (*dl*-).** Crystallise it from EtOH. The ***S(-)-l-enantiomer*** *[6152-25-6]* has $[\alpha]_D^{25}$ -102.5 (c 1, $CHCl_3$). [Leonard & Boyer *J Org Chem* **15** 42 *1950*, DOI: 10.1021/jo01147a007.]

Phenylhydrazine *[100-63-0]* **$C_6H_8N_2$, M 108.1, m 19.5°, 23°, b 71.8°/1mm, 137-138°/18mm, 241-242°/760mm, d_D^{20} 1.10, n_D^{20} 1.607, pK_1^{20} -5.2 (aqueous H_2SO_4), pK_2^{20} 5.27.** Purify phenylhydrazine by chromatography, then crystallise it from petroleum ether (b 60-80°)/*benzene. Store it in the dark under N_2 as it turns yellow, then red, on exposure to air. It is best stored as the *hydrochloride salt*; see below. [Coleman *Org Synth* Coll Vol **I** 442 *1941*, DOI: 10.15227/orgsyn/02.0071; Shaw & Stratton *J Chem Soc* 5004 *1962*, DOI: 10.1039/JR9620005004; *Beilstein* **15** IV 50.]

Phenylhydrazine hydrochloride *[59-88-1]* **$C_6H_8N_2$. HCl, M 144.5, m 244°, 250-254°(dec).** Dissolve 100g of phenylhydrazine hydrochloride in 200ml of warm H_2O (60-70°) during 1-3 hours, then add 1L of boiling EtOH. The solution is filtered, while still hot, through Whatman No 2 filter paper and cooled in a refrigerator. The precipitate is collected on a medium sintered-glass filter and recrystallised twice this way, then washed with cold EtOH, dried thoroughly and stored in a stoppered brown bottle. [Peterson et al. *Anal Chem* **29** 144 *1957*, DOI: 10.1021/ac60121a042.] Hough, Powell and Woods [*J Chem Soc* 4799 *1956*, DOI: 10.1039/JR9560004799] boiled the hydrochloride with three times its weight of water, filtered hot (charcoal), added one-third volume of concentrated HCl and cooled to 0°. The crystals were washed with acetone, and dried over P_2O_5 under vacuum. The salt has also been crystallised from 95% EtOH, and it can be sublimed. [Coleman *Org Synth* Coll Vol **1** 442 *1941*, DOI: 10.15227/orgsyn/02.0071; *Beilstein* **15** III 71.]

Phenylhydroxylamine (*N*-hydroxyaniline) *[100-65-2]* **C_6H_7NO, M 109.1, m 81°, 82°, 83-84°, pK^{25} 3.2.** Impure base deteriorates rapidly. Crystallise it from H_2O, *C_6H_6 or *C_6H_6/petroleum ether (40-60°). The ***picrate*** has **m 186°** (from EtOH), and the ***benzenesulfonate salt*** has **m 70°** (**dec**)(EtOH/*C_6H_6). [*Beilstein* **15** H 2, **15** I 3, **15**, II 4, **15** III 5. **15** IV 4.]

2-Phenyl-1,3-indandione *[83-12-5]* **$C_{15}H_{10}O_2$, M 222.2, m 144-148°, 149-151°, pK^{20} 4.12 (1% aqueous MeOH).** Crystallise the dione from EtOH (**m 156°**) or $CHCl_3$ (**m 148-150°**). [*Beilstein* **7** H 808, **7** III 4100, **7** IV 2570.]

Phenylisocyanate *[103-71-9]* **C_7H_5NO, M 119.1, m -30°, b 45-47°/10mm, 162-163°/atm, d_4^{20} 1.093, n_D^{24} 1.536.** Distil phenylisocyanate under reduced pressure from P_2O_5. [*Beilstein* **12** IV 864.] Used for derivatisation.

8-Phenylmenthol *[1R,2S,5R-(-)- 65253-04-5, 1S,2R,5S-(+)- 57707-91-2]* **$C_{16}H_{24}O$, M 232.4, $[\alpha]_D^{20}$ (–) and (+) 26 (c 2, EtOH).** Dissolve the menthol in toluene, dry (Na_2SO_4), evaporate and chromatograph it on a silica gel column and eluting with 5% Et_2O in petroleum ether to give an oil with the desired rotation. Its IR has ν_{max} at 3420cm^{-1} (OH) with consistent ^1H NMR [Ensley et al. *J Org Chem* **43** 1610 *1978*, DOI: 10.1021/jo00402a037; Whitesell et al. *Tetrahedron* **42** 2993 *1986*, DOI: 10.1016/S0040-4020(01)90590-3; Bednarski & Danishefsky *J Am Chem Soc* **108** 7060 *1986*, DOI: 10.1021/ja00282a035].

2-Phenylnaphthalene *[612-94-2]* **$C_{16}H_{12}$, M 204.3, m 102-103°, 103.5°, 103-104°, 105°, b 185-190°/5mm, 357-358°/760mm.** Chromatograph it on alumina in *benzene and crystallise it from aqueous EtOH or MeOH/EtOH. It has been sublimed. It has λ_{max} at 248 and 286nm (methylcyclohexane). The ***2,4,7-trinitrofluoren-9-one*** has **m 169.5-170.5°** (from EtOH/*C_6H_6). [*Beilstein* **5** H 687, **5** II 603, **5** III 2231, **5** IV 2412.]

***N*-Phenyl-1-naphthylamine** *[90-30-2]* **$C_{16}H_{13}N$, M 219.3, m 60-62°, 63.7-64.0°, b 226°/15mm, pK_{Est} ~0.1.** Crystallise it from EtOH, petroleum ether or *C_6H_6/EtOH. Dry it under vacuum in an Abderhalden pistol. It has λ_{max} at 252nm [*Beilstein* **12** H 1224.]
***N*-Phenyl-2-naphthylamine** *[135-88-6]* has **m 107.5-108.5°, 110°, b 395°/atm, pK_{Est} ~0.5.** Crystallise it from EtOH, MeOH, glacial acetic acid or *benzene/hexane. [*Beilstein* **12** H 1275, **12** I 535, **12** II 716, **12** III 2991.]

4-Phenylphenacyl bromide *[135-73-9]* **$C_{14}H_{11}BrO$, M 275.2, m 126°, b 370°/atm, d 1.379.** Crystallise (charcoal) the bromide from EtOH (15ml/g), or ethyl acetate/petroleum ether (b 90-100°). [*Beilstein* **7** III 2137.] **IRRITANT.**

(±)-2-Phenylpropanal *[93-53-8]* **$C_9H_{10}O$, M 134.2, b 92-94°/12mm, 206°/760mm, d_4^{20} 1.001, n_D^{20} 1.5183.** It may contain up to 15% of acetophenone. Purify it *via* the bisulfite addition compound [Lodge & Heathcock *J Am Chem Soc* **109** 3353 *1987,* DOI: 10.1021/ja00245a027] and see Chapter 2 for preparation and decomposition of bisulfite adducts. [*Beilstein* **7** IV 695.]

Phenylpropiolic acid *[637-44-5]* **$C_9H_6O_2$, M 146.2, m 136°, 137°, 137.8-138.4°, pK^{25} 2.23.** Crystallise the acid from *benzene, CCl_4 (**m** 136°) or aqueous EtOH. The ***S-benzylisothiuronium salt*** has **m 184-186°** (from EtOH). [*Beilstein* **9** II 436, **9** III 3061, **9** IV 2327.]

***RS*-2-Phenylpropionic acid** *[492-37-5]* **$C_9H_{10}O_2$, M 150.2, m 16-16.5°, b 153-155°/20mm, 189°/48mm, 260-262°/760mm, d_4^{20} 1.10, n_D^{20} 1.522, pK^{25} 4.3.** Fractionally distil the acid, or recrystallise it from petroleum ether (b 40-60°) with strong cooling (see references below). [*Beilstein* **9** II 348.]
2-Phenylpropionic acid *[R-(-)- 7782-26-5, S-(+)- 7782-24-3]* has **m 30.3-31°, 30-32°, b 115°/1-2mm, 142°/12mm, $[\alpha]_D^{20}$ (-) and (+) 99.7 (l = 1 dcm, neat), (-) and (+) 89.1 (c 1.7, EtOH), (-) and (+) 75 (c 1.6, $CHCl_3$)**. Purify the acids by vacuum distillation and by recrystallisation from petroleum ether. The ***S-anilide*** has **m 103-104°** (from H_2O or $CHCl_3$/*C_6H_6), $[\alpha]_D^{25}$ +47 (c 9, Me_3CO) [Argus & Kenyon *J Chem Soc* 916 *1939*, DOI: 10.1039/JR9390000916; Campbell & Kenyon *J Chem Soc* 25 *1946*, DOI: 10.1039/JR9460000025;

Levene et al. *J Biol Chem* **88** 27, 34 *1930*]. [*Beilstein* **9** III 2417, **9** IV 1779.]
3-Phenylpropionic acid **(hydrocinnamic acid)** *[501-52-0]* has **m 45-48°, 48-48.5°, pK^{25} 4.56.** Crystallise the acid from *benzene, $CHCl_3$ or petroleum ether (b 40-60°). Dry it in a vacuum. [*Beilstein* **9** H 508.] Food flavour and fragrance agent.

3-Phenylpropyl bromide *[637-59-2]* **$C_9H_{11}Br$, M 199.1, b 110°/12mm, 128-129°/29mm, d $^{20}_4$ 1.31.** Wash the bromide successively with concentrated H_2SO_4, water, 10% aqueous Na_2CO_3 and again with water, then dry it with $CaCl_2$ and fractionally distil it just before use. [*Beilstein* **5** IV 982.]

Phenylpyruvic acid *[156-06-9]* **$C_9H_8O_3$, M 164.2, m 152°, 150-154°, 155°, 158-159°, pK$_{Est}$ ~2.1.** Recrystallise the acid from *C_6H_6. The ***phenylhydrazone*** has **m 173°** [Zeller *Helv Chim Acta* **26** 1614 *1943*, DOI: 10.1002/hlca.19430260524; Hopkins & Chisholm *Can J Research* [B] **24** 89 *1946*, DOI: 10.1139/cjr46b-016]. The ***2,4-dinitrophenylhydrazone*** has **m 162-164°** (**189°, 192-194°**) [Fones *J Org Chem* **17** 1534 *1952*, DOI: 10.1021/jo50011a022]. [*Beilstein* **10** IV 2760.]

Phenyl salicylate (Salol) *[118-55-8]* **$C_{13}H_{10}O_3$, M 214.2, m 41.5°, 41.8-42.6°, 43°, 173°/atm, d 1.25, pK$_{Est}$ ~9.9.** Fractionally crystallise salol from its melt, then crystallise it from *benzene. [*Beilstein* **10** IV 154.]

3-Phenylsalicylic acid *[304-06-3]* **$C_{13}H_{10}O_3$, M 214.3, m 186°, 186-187.5°, pK$_{Est(1)}$~2.8 (CO_2H), pK$_{Est(2)}$~11.0 (OH).** Dissolve the acid in *ca* 1 equivalent of saturated aqueous Na_2CO_3, filter and precipitate it by adding 0.8 equivalents of M HCl. Crystallise it from ethylene dichloride (charcoal), and sublime it at 0.1mm. [Brooks et al. *J Chem Soc* 661 *1961*, DOI: 10.1039/JR9610000661.]

1-Phenylsemicarbazide *[103-03-7]* **$C_7H_9N_3O$, M 151.2, m 171-174°, 172°, 173.5°, 174-176°.** Crystallise it from water and dry it in a vacuum over KOH. Store at -20°. [*Beilstein* **15** H 287, **15** II 106, **15** III 184, **15** IV 180.]

4-Phenylsemicarbazide *[537-47-3]* **$C_7H_9N_3O$, M 151.2, m 122°, 122-125°.** Crystallise it from water and dry it in a vacuum over KOH. Store at -20°. [*Beilstein* **12** II 221, **12** III 822.]

Phenylsuccinic acid *[R-(-)- 46292-93-7, S-(+)- 4036-30-1]* **$C_{10}H_{10}O_4$, M 194.2, m 173-176°, 178.5-179°, 179-180°, [α] $^{25}_D$ (-) and (+) 171 (c 2, Me_2CO), [α] $^{26\text{-}30}_D$ (-) and (+) 148 (c 0.27-5, EtOH), pK $^{25}_1$ 3.78, pK $^{25}_2$ 5.55.** Purify the acids by re-precipitation from alkali and recrystallisation from H_2O. [Naps & Johns *J Am Chem Soc* **62** 2450 *1940*, DOI: 10.1021/ja01866a053; Fredga & Matell *Bull Soc Chim Belg* **62** 47 *1953*, DOI: 10.1002/bscb.19530620108; Wren & Williams *J Chem Soc* **109** 572 *1916*, DOI: 10.1039/CT9160900572.] The ***racemate*** *[635-51-8]* has **m 166-168°, 168°** after recrystallisation from H_2O or MeCN. Its ***S-benzylisothiuronium salt*** has **m 164-165°** (from EtOH) [Friediger & Pedersen *Acta Chem Scand* **9** 1425 *1955*, DOI: 10.3891/acta.chem.scand.09-1425]. [*Beilstein* **9** IV 3351.]

Phenyltoloxamine [2-(2-dimethylaminoethoxy)-diphenylmethane] hydrochloride *[6152-43-8]* **$C_{17}H_{21}NO$. HCl, M 291.8, m 119-120°, pK^{25} 9.3 (free base).** Crystallise the salt from isobutyl methyl ketone. The ***free base*** *[92-12-6]* M 255.4, has **b 144°/1mm**. [*Beilstein* **6** III 3351, **6** IV 4630.] It is an antihistamine with sedative and analgesic properties.

Phenyl 4-tolylcarbonate *[13183-20-5]* **$C_{14}H_{12}O_3$, M 228.2, m 94°.** Purify the carbonate by preparative GLC with 20% Apiezon on Embacel, and sublime it *in vacuo*. [*Beilstein* **6** H 398.]

1-Phenyl-2,2,2-trifluoroethanol *[R-(-)- 10531-50-7, S-(+)- 340-06-7]* **$C_8H_7F_3O$, M 176.1, b 74-76°/10mm, 125-127°/760mm, d $^{20}_4$ 1.301, n $^{20}_D$ 1.4632, [α] $^{20}_D$ (-) and (+) 31 (neat).** Purify the chiral alcohols by fractional distillation preferably in a vacuum. [Morrison & Ridgeway *Tetrahedron Lett* 573 *1969*, DOI: 10.1016/S0040-4039(01)87751-0; NMR: Pirkle & Beare *J Am Chem Soc* **90** 6250 *1968*, DOI: 10.1021/ja01024a073.] The ***racemate*** *[340-05-6]* has **b 52-54°/2mm, 57-59°/2mm, 64-65°/5mm**, d $^{20}_4$ 1.293, n $^{20}_D$ 1.457, and the ***2-carbobenzoyl*** derivative has **m 137-138°** [Mosher et al. *J Am Chem Soc* **78** 4374 *1956*, DOI: 10.1021/ja01598a049]. [*Beilstein* **6** IV 3043.]

Phenylurea *[64-10-8]* **$C_7H_8N_2O$, M 136.2, m 145-147°, 147°, 148°, b 238°/atm, pK^{25} -1.45 (aqueous H_2SO_4).** Crystallise the urea from boiling water (10ml/g) or amyl alcohol (**m 149°**). Dry it in a steam oven at 100°. The **1:1 *resorcinol complex*** has **m 115°** (from EtOAc/*C_6H_6). [*Beilstein* **12** H 346, **12** II 204, **12** III 760, **12** IV 734.]

Phloretin [2',4',6'-trihydroxy-3-(*p*-hydroxyphenyl)propiophenone] *[60-82-2]* **$C_{15}H_{14}O_5$, M 274.3, m 260°(dec), 264-271°(dec), $pK_{Est(1)}$~7.5, $pK_{Est(2)}$~8.0, $pK_{Est(3)}$~10, $pK_{Est(4)}$~12 (phenolic OH's).** Crystallise phloretin from aqueous EtOH. [Zemplen & Bognár *Chem Ber* **75** 1040 *1942*, DOI: 10.1002/cber.19420750903; Zemplén et al. *Chem Ber* **76** 386 *1943*, DOI: 10.1002/cber.19430760412; *Beilstein* **8** IV 3518.] Inhibits active transport of glucose into certain cells. It is an antioxidant which inhibits elastase activity, and affect Ca^{2+} channels.

Phloroacetophenone ($2H_2O$) (2',4',6'-trihydroxyacetophenone) *[480-66-0]* **$C_8H_8O_4$, M 186.2, m 218-219°, 219-221°, 218-223°, $pK_{Est(1)}$~7.9, $pK_{Est(2)}$~12.0.** Crystallise the ketone from hot H_2O/charcoal (35ml/g). Dry the colorless to pale yellow needles in an oven at 130°, but they pick up water readily on exposure to air. They give a wine-red colour with $FeCl_3$, compare with violet colour with phloroglucinol (below) [Gulati *et al*. *Org Synth* **15** 70 *1935*, DOI: 10.15227/orgsyn.015.0070]. [*Beilstein* **8** IV 2729.] It lowers plasma cholesterol in animals, and is used as a matrix for laser desorption/ionisation in acidic glycans and glycopeptide negative ion analysis.

Phloroglucinol ($2H_2O$) (benzene-1,3,5-triol) *[6099-90-7 ($2H_2O$), 108-73-6 (anhydrous)]* **$C_6H_6O_3$, M 126.1, m 217-219°, 219°, 117° (anhydrous), pK_1^{25} -7.74 ($HClO_4$), pK_2^{20} 7.97 (8.43), pK_3^{20} 9.23.** Crystallise the triol from water, and store it in the dark under nitrogen. [Clarke & Hartmann *Org Synth* Coll Vol **1** 455 *1941*, DOI: 10.15227/orgsyn.009.0074; *Beilstein* **6** IV 7361.] It has antispasmotic properties.

o-**Phthalic acid** *[88-99-3]* **$C_8H_6O_4$, M 166.1, m 205°(dec), 210-211°(dec), 211-211.5°(dec), d 1.593, pK_1^{25} 2.76 (3.05), pK_2^{25} 4.92 (4.73).** Crystallise phthalic acid from water. [*Beilstein* **9** IV 3167.]

Phthalic anhydride *[85-44-9]* **$C_8H_4O_3$, M 148.1, m 130.8°, 131°, 132°, 130-134°, b 295°/atm, d 1.53.** Distil the anhydride under reduced pressure. Purify it from the acid by extracting with hot $CHCl_3$, filtering and evaporating. The residue is crystallised from $CHCl_3$, CCl_4 or *benzene, or sublimed (295 °/atm). Fractionally crystallise it from its melt. Dry it under vacuum at 100°. [Saltiel et al. *J Am Chem Soc* **108** 2674 *1986*, DOI: 10.1021/ja00270a028; *Beilstein* **17/11** V 253.]

Phthalide *[87-41-2]* **$C_8H_6O_2$, M 134.1, m 72-73°, 75-77°, b 290°/atm, pK -7.98 (aqueous H_2SO_4).** Crystallise phthalide from water (75ml/g) and dry it in air on filter paper. [Synthesis see Gardner & Naylor *Org Synth* Coll Vol **2** 526 *1943*, DOI: 10.15227/orgsyn.016.0071; *Beilstein* **17/10** V 7.]

Phthalimide *[85-41-6]* **$C_8H_5NO_2$, M 147.1, m 234°, 235°, 238°, b 336°/atm, pK 8.30.** Crystallise the imide from EtOH (20ml/g) (charcoal), or sublime it. For potassium phthalimide see entry in 'Metal-organic Compounds', Chapter 4. [*Beilstein* **21/10** V 270.]

Phthalonitrile (1,2-dicyanobenzene) *[91-15-6]* **$C_8H_4N_2$, M 128.1, m 138°, 140°, 141°, b 304°/atm.** Crystallise the nitrile from EtOH, toluene or *benzene. It has also been distilled under high vacuum. It is steam volatile. [*Beilstein* **9** H 815, **9** II 602, **9** III 4199, **9** IV 3268.]

Phthalylsulfacetamide *[131-69-1]* **$C_{16}H_{14}N_2O_6S$, M 362.3, m 196°, 304°.** It is prepared by hydrolysis of N-acetamidosulfophenylphthalimide by boiling for 3 hours in 15% aqueous KOH followed by treatment with Norit, filtration and acidification with AcOH. Crystallise the phthalamide from hot H_2O, aqueous EtOH, or EtOH. [Jain et al. *J Indian Chem Soc* **24** 174 *1947*, Basu *J Indian Chem Soc* **26** 130 *1949*, and several patents.] It is antibacterial. [*Beilstein* **14** III 2073.]

Phthiocol (2-hydroxy-3-methylnaphtha-1,4-quinone) *[483-55-6]* **$C_{11}H_8O_3$, M 188.1, m 173-174°, 173.5°, pK_{Est} ~4.2.** Crystallise the quinone from diethyl ether/petroleum ether. [*Beilstein* **8** III 2568, **8** IV 2375.] It is

hemostatic.

Physodic acid [4,4',6'-trihydroxy-6-(2-oxoheptyl)-2'-pentyl-2,3'-oxydibenzoic acid 1,5-lactone] *[84-24-2]* **$C_{26}H_{30}O_8$, M 470.5, m 205°, $pK_{Est(1)}$~3.0, $pK_{Est(2)}$~10, $pK_{Est(3)}$~13.** Crystallise the acid from MeOH. The ***methyl ester***, **m** 156-157°, crystallises from EtOH/H_2O (4:1) in prisms. The ***diacetate*** has **m 155-156°** (from Me_2CO/CS_2). [*Beilstein* **19** II 329, **19** III/IV 3988.]

Picene (dibenzo[*a,i*]phenanthrene, 3,4-benzchrysene) *[213-14-3, 213-46-7]* **$C_{22}H_{14}$, M 278.3, m 364°, 366-367°, 367-369°.** Crystallise picene from isopropylbenzene/xylene. After sublimation at 300°/2mm followed by crystallisation from xylene (charcoal), it gives white glistening leaflets with **m 366-366.5°** [Newman *J Org Chem* **09** 518 *1944*, DOI: 10.1021/jo01188a005]. The ***2,4,7-trinitrofluoren-9-one*** has **m 257-257.8°** (from *C_6H_6). [*Beilstein* **5** H 735, **5** I 369, **5** III 2555, **5** IV 2724.]

Picric acid *[88-89-1]* **$C_6H_3N_3O_7$, M 229.1, m 122-123°(dried material), d 1.76, pK^{25} 0.33 (0.37).** Crystallise the acid first from acetic acid, then acetone, toluene, $CHCl_3$, aqueous 30% EtOH, 95% EtOH, MeOH or H_2O. Dry it in a vacuum for 2 hours. *Alternatively*, dry it over $Mg(ClO_4)_2$ or fuse (**CARE**) and allow it to solidify under a vacuum three times. Because it is **EXPLOSIVE**, picric acid should be stored moistened with H_2O, and only small portions should be dried at any one time. The dry acid should **NOT** be heated. [*Beilstein* **6** IV 1388.]

Picryl chloride (2-chloro-1,3,7-trinitrobenzene) *[88-88-0]* **$C_6H_2ClN_3O_6$, M 247.5, m 83°, d 1.797.** Crystallise the chloride from $CHCl_3$ or EtOH (**m 83-84°**). The **2:1 *C_6H_6-complex*** has **m 39°** (from *C_6H_6). It forms a **1:1 *hexamethylbenzene complex*** which has orthorhombic orange-yellow crystals [Ross et al. *J Am Chem Soc* **76** 69 *1954*, DOI: 10.1021/ja01630a018]. [*Beilstein* **5** II 205, **5** III 645, **5** IV 757.]

Picryl iodide (2-iodo-1,3,7-trinitrobenzene) *[4436-27-5]* **$C_6H_2IN_3O_6$, M 339.0, m 164-165°.** Crystallise the iodide from *benzene. [*Beilstein* **5** III 647, **5** IV 758.]

Piperic acid [*trans,trans*-5-(3,4-methylenedioxyphenyl)-2,4-pentadieneoic acid] *[136-72-1, 5285-18-7]* **$C_{12}H_{10}O_4$, M 218.2, m 215°, 217°, 220-221°, pK_{Est} ~4.7.** Crystallise the acid from EtOH. It turns yellow in light. It sublimes with partial decomposition. It has UV with λ_{max} at 340nm (MeOH). [*Beilstein* **19** H 281, **19** II 30, **19** III/IV 3565.]

Piperonal *[120-57-0]* **$C_8H_6O_3$, M 150.1, m 37°, b 140°/15mm, 263°/760mm.** Crystallise piperonal from aqueous 70% EtOH or EtOH/water. [*Beilstein* **19/4** V 225.] It is a food-grade flavour ingredient.

Piperonylic acid *[94-53-1]* **$C_8H_6O_4$, M 166.1, m 229°, pK^{25} 4.50.** Crystallise the acid from EtOH or water. [Synthesis see Shriner & Kleiderer *Org Synth* **10** 82 *1930*, DOI: 10.15227/orgsyn.010.0082; *Beilstein* **19/7** V 300.]

Polystyrene (PS) *[9003-53-6]* **$(C_8H_8)_n$, m ~240°.** Precipitate polystyrene repeatedly from $CHCl_3$ or toluene solution by addition of MeOH. Dry it *in vacuo*. [Miyasaka et al. *J Phys Chem* **92** 249 *1988*, DOI: 10.1021/j100313a001.]

Procaine [4-(2-diethylaminomethoxycarbonyl)aniline] *[59-46-1]* **$C_{13}H_{20}N_2O_2$, M 236.3, m 51° (dihydrate), 61° (anhydrous), pK_1^{15} 2.45, pK_2^{15} 8.91.** Procaine crystallises as the ***dihydrate*** from aqueous EtOH and as the *anhydrous* material from petroleum ether or diethyl ether. The latter is *hygroscopic*. [*Beilstein* **14** IV 1138.] It is a sympathomimetic anti-inflammatory drug. See *hydrochloride* in 'Physiologically Active….' In Chapter 6.

p-**(1-Propenyl)phenol** *[cis/trans 6380-21-8, trans 85960-8-2, 539-12-8]* **$C_9H_{10}O$, M 134.2, m 93-94°, b (*trans*) 229.6°/760mm, pK_{Est} ~10.2.** Crystallise the phenol from water. [*Beilstein* **6** III 2394, **6** IV 3796.]

***n*-Propyl gallate** *[121-79-9]* **$C_{10}H_{12}O_5$, M 212.2, m 147°, 148°, 150°, d 1.21.** Crystallise the ester from aqueous EtOH or *C_6H_6 (**m** 146-146.5°). [*Beilstein* **10** III 2078, **10** IV 2003.]

Protocatechualdehyde (3,4-dihydroxybenzaldehyde) *[139-85-5]* **$C_7H_6O_3$, M 138.1, m 153°, 150-157°.** Crystallise the aldehyde from water or toluene and dry it in a vacuum desiccator over KOH pellets or shredded wax respectively. [*Beilstein* **8** IV 1762.]

***1S,2S*-Pseudoephedrine (1-hydroxy-1-phenyl-2-methylaminopropane)** *[90-82-4]* **$C_{10}H_{15}NO$, M 165.2, m 118-119°, $[\alpha]_D^{20}$ +53.0 (EtOH), +40.0 (H_2O), pK^{25} 9.71.** Crystallise the amine from dry diethyl ether, or from water and dry it in a vacuum desiccator. [*Beilstein* **13** IV 1878.]

***1S,2S*-Pseudoephedrine hydrochloride** *[345-78-8]* **$C_{10}H_{15}NO$. HCl, M 210.7, m 181-182°, 185-188°, $[\alpha]_D^{20}$ +61 (c 1 H_2O).** Crystallise the salt from EtOH. [*Beilstein* **13** IV 1878.]

Purpurin (1,2,4-trihydroxy-5,10-anthraquinone) *[81-54-9]* **$C_{14}H_8O_5$, M 256.2, m 253-256°, $pK_{Est(1)}$~7.0 (2-OH), $pK_{Est(2)}$~9.0 (4-OH), $pK_{Est(3)}$~11.1 (1-OH).** Crystallise purpurin from aqueous EtOH (orange needles with 1 H_2O), dry it at 100°. Sublimation at ~150°/<2mm provides red needles of the anhydrous dye. It has λ_{max} at 515nm and 521nm; and complexes with metal salts to produce coloured complexes (e.g. 'lakes'). It stains nuclear material in histology. [*Beilstein* **8** IV 3568.]

Pyrene (benzo[*def*]phenanthrene) *[129-00-0]* **$C_{16}H_{10}$, M 202.3, m 145-148°, 149-150°.** Crystallise pyrene from EtOH, glacial acetic acid, *benzene or toluene. Purify it also by chromatography of CCl_4 solutions on alumina, with *benzene or *n*-hexane as eluent. [Backer & Whitten *J Phys Chem* **91** 865 *1987*, DOI: 10.1021/j100288a021.] It can also be zone refined and purified by sublimation. Marvel and Anderson [*J Am Chem Soc* **76** 5434 *1954*, DOI: 10.1021/ja01650a051] refluxed pyrene (35g) in toluene (400ml) with maleic anhydride (5g) for 4 days, then added 150ml of aqueous 5% KOH and refluxed for 5 hours with occasional shaking. The toluene layer was separated, washed thoroughly with H_2O, concentrated to about 100ml and allowed to cool. Crystalline pyrene was filtered off and recrystallised three times from EtOH or acetonitrile. [Chu & Thomas *J Am Chem Soc* **108** 6270 *1986*, DOI: 10.1021/ja00280a026; Russell et al. *Anal Chem* **58** 2961 *1986*, DOI: 10.1021/ac00127a014.] The material is free from anthracene derivatives. Another purification step involves passage of pyrene in cyclohexane through a column of silica gel. It can be sublimed in a vacuum and zone refined. The ***picrate*** has **m 224°**. [Kano et al. *J Phys Chem* **89** 3748 *1985*, DOI: 10.1021/j100263a032; *Beilstein* **5** IV 2467.]

Pyrene-1-aldehyde *[3029-19-4]* **$C_{17}H_{10}O$, M 230.3, m 123-126°, 125-126°.** Recrystallise the aldehyde three times from aqueous EtOH. [*Beilstein* **7** IV 1821.]

1-Pyrenebutyric acid *[3443-45-6]* **$C_{20}H_{16}O_2$, M 288.4, m 184-186°, pK_{Est} ~4.1.** Crystallise the butyric acid from *benzene, EtOH, EtOH/water (7:3 v/v) or *C_6H_6/AcOH. Dry it over P_2O_5. [Chu & Thomas *J Am Chem Soc* **108** 6270 *1986*, DOI: 10.1021/ja00280a026; *Beilstein* **9** IV 2731.]

1-Pyrenecarboxylic acid *[19694-02-1]* **$C_{17}H_{10}O_2$, M 230.3, m 270-272°, 273-274°, pK_{Est} ~3,2.** Crystallise the acid from *C_6H_6, chlorobenzene, nitrobenzene or 95% EtOH. [*Beilstein* **9** H 712, **9** III 3575.]

***p*-Quaterphenyl** *[135-70-6]* **$C_{24}H_{18}$, M 306.4, m 312-314°, 316-318°, 317°, 320°, b 428°/18mm.** Recrystallise *p*-quaterphenyl from dimethyl sulfoxide at *ca* 50°. [*Beilstein* **5** II 669.]

Quinalizarin (1,2,5,8-tetrahydroxy-9,10-anthraquinone) *[81-61-8]* **$C_{14}H_8O_6$, M 272.2, m 275°, ~300°, $pK_{Est(1)}$~7.1 (1-OH), $pK_{Est(2)}$~9.9 (8-OH), $pK_{Est(3)}$~11.1 (5-OH), $pK_{Est(4)}$~11.8 (2-OH).** Crystallise the red quinone from acetic acid or nitrobenzene. It can be sublimed *in vacuo*. The Cu salt forms red crystals. [*Beilstein* **8** H 549, **8** I 755, **8** II 584.]

Quinhydrone (1:1 complex of hydroquinone and benzoquinone) *[106-34-3]* **$C_{12}H_{10}O_4$, M 218.2, m 168°, 167-172°, 168-171°, 172°, 173-174°.** Crystallise quinhydrone from H_2O at 65°, then dry it *in vacuo*. [*Beilstein* **7** H 617, **7** IV 2069.]

Quinizarin (1,4-dihydroxy-9,10-anthraquinone, Solvent orange 86) *[81-64-1]* **$C_{14}H_8O_4$, M 240.2, m 198-199°, 200-202°, b 450°/atm, pK_1^{25} 9.90 (9.5), pK_2^{25} 11.18.** Crystallise quinizarin (orange or red-brown crystalline powder) from glacial acetic acid. It forms 'lake' pigments with Ca, Ba and Pb salts. [*Beilstein* **8** H 450, **8** IV 3260.]

p-**Quinquephenyl (*p*-pentaphenyl)** *[3073-05-0, 61537-20-0]* **$C_{30}H_{22}$, M 382.5, m 388.5°, 385-390°.** Recrystallise *p*-pentaphenyl from boiling dimethyl sulfoxide (**b** 189°, lowered to 110°). The solid obtained on cooling is filtered off and washed repeatedly with toluene, then with concentrated HCl. The final material is washed repeatedly with hot EtOH. It is also recrystallised from pyridine or Me_2SO (well defined leaflets), then sublimed *in vacuo*. [Campbell & McDonald *Org Synth* Coll Vol **5** 985 *1973*, DOI: 10.15227/orgsyn.040.0085; *Beilstein* **5** II 709, **5** III 2680, **5** IV 2874.]

Resorcinol *[108-46-3]* **$C_6H_6O_2$, M 110.1, m 110°, 111.2-111.6°, b 277°/atm, d 1.28, pK_1^{25} 9.23, pK_2^{25} 13.05.** Recrystallise resorcinol from *benzene, toluene or *benzene/diethyl ether. The ***benzoate*** has **m 117°**. [*Beilstein* **6** IV 2069.]

Retene (1-methyl-7-*iso*propylphenanthrene) *[483-65-8]* **$C_{18}H_{18}$, M 234.3, m 89°, 90°, 98.5°, 99°, 100.5-101°, b 208°/10mm, 390°/atm.** Crystallise retene from EtOH. The ***picrate*** has **m 126°** (from EtOH). The 1:1 ***1,3,5-trinitrobenzene-complex*** has **m 144°** (from EtOH). [*Beilstein* **5** H 683, **5** II 598, **5** III 2199.]

Para*Rosaniline (4,4',4"-triaminotrityllium [triphenylmethane] carbonium ion, para-fuschin, paramagenta)** *[467-62-9]* **$C_{19}H_{19}N_3O$, M 305.4, m 205°, pK^{25} 7.57 and free base has pK >13.** Dissolve the dye in EtOH (1.16g in 30ml), filter and add aqueous NH_3 till neutral (colourless) and precipitate it by adding H_2O giving 0.8g, **m** 247°(dec, sintering at 230°). Dissolve it in EtOH, neutralise with NH_3 till colourless, add 0.1g of charcoal, filter, and repeat, then add H_2O (100ml) to precipitate the colourless ***carbinol (pseudo-base) and dry it *in vacuo*, **m 257°(dec**, also **205°**, **sintering at 232°**). [Weissberger & Theile *J Chem Soc* 148 *1934*, DOI: 10.1039/JR9340000148.] The ***carbinol*** is slightly soluble in H_2O but is soluble in acids (e.g. HCl to give the coloured *chloride [569-61-9]*) and EtOH [pK: Goldacre & Phillips *J Chem Soc* 1724 *1949*, DOI: 10.1039/JR9490001724]. The ***perchlorate*** (dark red with a green shine) has **m 300°** and explodes at **317°** [Dilthey & Dinklage *J Prakt Chem* [2] **129** 24 *1931*, DOI: 10.1002/prac.19311290102]. [*Beilstein* **13** IV 2283.]
***Rosaniline HCl* (Magenta I, Fuschin)** *[632-99-5]* **$C_{19}H_{18}ClN_3$, M 337.9,** has **m >200°(dec).** Purify the dye by dissolving it in EtOH (1mg/ml), filtering and adding H_2O. Filter or centrifuge it and wash the precipitate with Et_2O and dry it in air. It has also been recrystallised from water and dried *in vacuo* at 40°. The crystals have a metallic green lustre. It has UV with λ_{max} in EtOH at 543nm (ε 93,000). Its solubility in H_2O is 0.26%. A carmine red colour is obtained in EtOH. It is paraRosaniline with a methyl group. [Scalan *J Am Chem Soc* **57** 887 *1937*, DOI: 10.1021/ja01308a029.]

p-**Rosolic acid (4-[bis-{4-hydroxyphenyl}methylene]-2,5-cyclohexadien-one, 4',4"-di-hydroxy-fuschson, aurin, corallin)** *[603-45-2]* **$C_{19}H_{14}O_3$, M 290.3, m 292°, 295-300° (dec with liberation of phenol), 308-310°(dec), pK_1 3.11, pK_2 8.62.** It forms green crystals with a metallic luster, but the colour depends on the solvent used. When recrystallised from brine (saturated aqueous NaCl) acidified with HCl, it forms red needles, but when recrystallised from EtO/AcOH, the crystals have a beetle iridescent green colour. It has been recrystallised from Me_2CO (although it dissolves slowly), methyl ethyl ketone, 80-95% AcOH and from AcOH/*C_6H_6. An aqueous KOH solution is golden yellow, and a 70% H_2SO_4 solution is deep red in colour. An *alternative* purification is to dissolve this triphenylmethane dye in 1.5% of aqueous NH_3, filter, and heat to 70-80°, then acidify with dilute AcOH by adding it slowly with vigorous stirring, whereby the aurin separates as a brick-red powder or as purplish crystals depending on the temperature and period of heating. Filter off the solid, wash it with H_2O and a little dilute AcOH, then H_2O again. Stir this solid with Et_2O to remove any ketones and allow it to stand overnight in the Et_2O, then filter and dry it in air then in a vacuum. [Gomberg & Snow *J Am Chem Soc* 47 298 *1925*, DOI: 10.1021/ja01678a029; Baines & Driver *J Chem Soc* **123** 1214 *1923*, DOI: 10.1002/prac.19311290102, UV: Burawoy *Chem Ber* **64** 462 *1931*, DOI: 10.1002/cber.19310640243; *Beilstein* **8** IV 2646.] It is an indicator whose aqueous solutions are pink-red below pH 5.0 and yellow above pH 6.8 (see pKa and above).

Salicylaldehyde (*o*-**hydroxybenzaldehyde**) *[90-02-8]* **$C_7H_6O_2$, M 122.1, m -7°, 1-2°, b 93°/25mm, 195-197°/760mm, d_4^{20} 1.167, n_D^{20} 1.574, pK^{25} 8.37.** It is precipitated as the bisulfite addition compound by pouring the aldehyde slowly and with stirring into a 25% solution of $NaHSO_3$ in 30% EtOH, then standing for 30 minutes. The precipitate, after filtering at the pump, and washing with EtOH, is decomposed with aqueous 10% $NaHCO_3$, and the aldehyde is extracted into diethyl ether, dried with Na_2SO_4 or $MgSO_4$, and distilled, under reduced pressure. *Alternatively*, salicylaldehyde is precipitated as its Cu complex by adding it to warm, saturated aqueous $Cu(OAc)_2$, shaking and standing in ice. The precipitate is filtered off, washed with EtOH, then Et_2O, and decomposed with 10% H_2SO_4; the aldehyde is extracted into Et_2O, dried and vacuum distilled. It was also purified by dry column chromatography on Kieselgel G [Nishiya et al. *J Am Chem Soc* **108** 3880 *1986*, DOI: 10.1021/ja00274a003]. The ***acetyl*** derivative has **m 38-39°** (from petroleum ether or EtOH) and **b 142°/18mm, 253°/atm**. The ***oxime***, *[94-67-7]* **M 137.1**, crystallises $CHCl_3$/petroleum ether (b 40-60°) with **m 57°**. [*Beilstein* **8** IV 176, 203.]

Salicylamide *[65-45-2]* **$C_7H_7NO_2$, M 137.1, m 140-144°, 142-144°, pK^{20} 8.37.** Crystallise the amide from water or repeatedly from $CHCl_3$ [Nishiya et al. *J Am Chem Soc* **108** 3880 *1986*, DOI: 10.1021/ja00274a003]. [*Beilstein* **10** IV 169.] The ***anilide*** *[87-17-2]* **M 213.2**, **m 135°** crystallises from H_2O. [*Beilstein* **12** H 500, **12** I 268, **12** II 256, **12** 944.] Analgesic.

Salicylhydroxamic acid *[89-73-6]* **$C_7H_7NO_3$, M 153.1, m 177°(dec), 179-180°(dec), pK_1^{30} 2.15, pK_2^{30} 7.46, pK_3^{30} 9.72.** Crystallise the hydroxamic acid from acetic acid. [*Beilstein* **10** H 98.] Irreversible inhibitor of bacterial (and plant) urease and useful in urinary tract infections. [Opperdoes et al. *Exptl Parasitol* **40** 198 *1976*, DOI: 10.1016/0014-4894(76)90082-5].

Salicylic acid (2-hydroxybenzoic acid) *[69-72-7]* **$C_7H_8O_3$, M 138.1, m 157-159°, 158-160°, 158.6°, 159°, 159.5°, 159-160°, 162°, b 211°/20mm, pK_1^{25} 3.01, pK_2^{25} 13.43 (13.01).** It has been purified by steam distillation, by recrystallisation from H_2O (solubility is 0.22% at room temperature and 6.7% at 100°), absolute MeOH, or cyclohexane and by sublimation in a vacuum at 76°. The ***acid chloride*** (needles) has **m 19-19.5°**, **b 92°/15mm**, the ***O-acetyl*** derivative has **m 135°** (rapid heating and the liquid resolidifies at 118°), and the ***O-benzoyl*** derivative has **m 132°** (aqueous EtOH). [IR: Hales et al. *J Chem Soc* 3145 *1954*, DOI: 10.1039/JR9540003145; Bergmann et al. *J Chem Soc* 2351 *1950*, DOI: 10.1039/JR9500002351]. [*Beilstein* **10** IV 125.]

cis*-Stilbene** (Z*-1,2-diphenylethylene**) *[645-49-8]* **$C_{14}H_{12}$, M 180.3, m 1-2°, b 145°/12mm, 307°/atm.** Purify it by chromatography on alumina using hexane and distil it under vacuum. (The final product contains *ca* 0.1% of the *trans*-isomer.) [Lewis et al. *J Am Chem Soc* **107** 203 *1985*, DOI: 10.1021/ja00287a037; Saltiel et al. *J Phys Chem* **91** 2755 *1987*, DOI: 10.1021/j100295a022; *Beilstein* **5** H 630.]
trans*-Stilbene** (E*-1,2-diphenylethylene**) *[103-30-0]* has **m 122-124°, 125.9°, 126°, b 305-307°/744mm, d_4^{20} 0.970.** Purify it by vacuum distillation. (The final product contains about 1% of the *cis* isomer.) Crystallise it from EtOH. It has also been purified by zone melting. The ***styphnate*** (see next entry) has **m 142°**. [Lewis et al. *J Am Chem Soc* **107** 203 *1985*, DOI: 10.1021/ja00287a037; Bellucci et al. *J Am Chem Soc* **109** 515 *1987*, DOI: 10.1021/ja00236a032; Saltiel *J Phys Chem* **91** 2755 *1987*, DOI: 10.1021/j100295a022; *Beilstein* **5** IV 2156.]

Styphnic acid (2,4,6-trinitroresorcinol) *[82-71-3]* **$C_6H_3N_3O_8$, M 245.1, m 177-178°, 179-180°, 180°, d 1.83, pK_1^{25} 0.06 (1.74), pK_2^{25} 4.23 (4.86).** Crystallise the phenol from ethyl acetate or water containing HCl **[EXPLODES violently on rapid heating.]** Its solubility in H_2O is 0.7% at 20° and 3% at 100°. It forms ***addition compounds*** with aromatic hydrocarbons, e.g. naphthalene (**m 168°**), anthracene (**m 180°**), phenanthrene (**m 142°**), fluorene (**m 134°**) and retene (**m 141°**). [*Beilstein* **6** H 830, **6** III 4354, **6** IV 5699.]

Styrene (vinylbenzene) *[100-42-5]* **C_8H_8, M 104.2, m -30°, b 41-42°/18mm, 145.2°/760mm, d_4^{20} 0.907, n_D^{20} 1.5469, n_D^{25} 1.5441.** Styrene is difficult to purify and keep pure. Usually it contains added inhibitors (such as a trace of hydroquinone). Wash it with aqueous NaOH to remove inhibitors (e.g. *tert*-butanol), then with water, dry it for several hours with $MgSO_4$ and distil it at 25° under reduced pressure in the presence of an inhibitor (such as 0.005% *p-tert*-butylcatechol). It can be stored at -78°. It can also be stored and kept anhydrous with Linde type 5A molecular sieves, CaH_2, $CaSO_4$, BaO or sodium, being fractionally distilled, and distilled in a

vacuum line just before use. ***Alternatively***, styrene (and its deuterated derivative) are passed through a neutral alumina column before use [Woon et al. *J Am Chem Soc* **108** 7990 *1986*, DOI: 10.1021/ja00285a018; Collman *J Am Chem Soc* **108** 2588 *1986*, DOI: 10.1021/ja00270a016]. [*Beilstein* **5** IV 1334.]

(±)-Styrene glycol (±-1-phenyl-1,2-ethanediol) *[93-56-1]* **$C_8H_{10}O_2$, M 138.2, m 67-68°, 67.5°, 68°, 272-274°/755mm.** Crystallise the diol from petroleum ether, Et_2O, Et_2O/*C_6H_6 (**m 69-70°**) or *C_6H_6. The ***dibenzoyl dervative*** has **m 96-97°**. [*Beilstein* **6** H 907, **6** I 444, **6** II 887, **6** III 4572, **6** IV 5939.]

Sudan II [Solvent Orange 7, 1-(2,4-xylylazo)-2-naphthol)] *[3118-97-6]* **$C_{18}H_{16}N_2O$, M 276.3, m 156-158°, CI 12140, λ_{max} (420nm sh) 493, 604 nm, pK_{Est} ~9.0.** Crystallise the red dye from EtOH, EtOH/water or *benzene/absolute EtOH (1:1). This fat-soluble dye stains triglycerides and protein bound lipids in frozen paraffin sections. [*Beilstein* **16** H 168.]

Sudan III [Solvent Red 23, 1-(*p*-phenylazo-phenylazo)-2-naphthol] *[85-86-9]* **$C_{22}H_{16}N_4O$, M 352.4, m 199°(dec), CI 26100, λ_{max} 354, 508 nm, pK_{Est} ~9.0.** Crystallise this red lysochrome dye from EtOH, EtOH/water or *benzene/absolute EtOH (1:1). It stains fatty substances, e.g. oils, fats, waxes, greases etc. [*Beilstein* **16** II 75, **16** III 148, **16** IV 248.]

Sudan IV [Solvent Red 24, 1-(4-*o*-tolylazo-*o*-tolylazo)-2-naphthol] *[85-83-6]* **$C_{24}H_{20}N_4O$, M 380.5, m ~184°(dec), 199°(dec), CI 26105, λ_{max} (357nm sh) 520nm, pK_{Est} ~9.0.** Crystallise this red-brown lysochrome dye from EtOH/water or acetone/water. [*Beilstein* **16** IV 249.]

Sudan Blue II (Solvent Blue 35, 1,4-bis-(butylamino)-9,10-anthraquinone) *[17354-14-2]* **$C_{22}H_{26}N_2O_2$, M 350.5, m 121-122°, 122°, λ_{max} 604, 652nm, pK_{Est} ~9.5 (OH).** It is formed from quinizarin (2g see *[81-64-1]*), 33% EtOH/*n*-$BuNH_2$ (20ml) and $Na_2S_2O_4$ (2g) at 140°/8 hours, evaporate, extract with toluene, chromatograph (Al_2O_3), the intense blue band in toluene is evaporated, and the residue gave purple needles (Cu lustre) from petroleum ether (b 60-80°) (1.1g, 38%) [Peters & Walker *J Chem Soc* 1429 *1956*, DOI: 10.1039/JR9560001429; *Beilstein* **14** IV 460]. It forms Cu and Ni salts.

Syringaldehyde (3,5-dimethoxy-4-hydroxybenzaldehyde) *[134-96-3]* **$C_9H_{10}O_4$, M 182.2, m 110-113°, 112°, 113°, b 192°/14mm, d 1.01, pK_{Est} ~8.** Crystallise syringaldehyde from petroleum ether. [*Beilstein* **8** H 391, **8** IV 2718.]

Syringic acid (3,5-dimethoxy-4-hydroxybenzoic acid) *[530-57-4]* **$C_9H_{10}O_5$, M 198.2, m 204-205°, 206.5°, 206-209°, 209-210°, b 192-193°/14mm, pK_1^{25} 4.34, pK_2^{25} 9.49**. Recrystallise syringic acid from H_2O using charcoal [Bogert & Coyne *J Am Chem Soc* **51** 571 *1929*, DOI: 10.1021/ja01377a030; Anderson & Nabenhauer *J Am Chem Soc* **48** 3001 *1926* DOI: 10.1021/ja01690a037.] The ***methyl ester*** has **m 107°** (from MeOH), the ***4-acetyl*** derivative has **m 190°** and the ***4-benzoyl*** derivative has **m 229-232°**. [Hahn & Wassmuth *Chem Ber* **67** 696 *1934*, DOI: 10.1002/cber.19340670430; UV: Lemon *J Am Chem Soc* **69** 2998 *1947*, DOI: 10.1021/ja01204a018 and Pearl & Beyer *J Am Chem Soc* **72** 1743 *1950*, DOI: 10.1021/ja01160a092; *Beilstein* **10** IV 1995.]

Terephthalaldehyde *[623-27-8]* **$C_8H_6O_2$, M 134.1, m 112-115°, 114-117°, 116°, 117°, b 245-248°/771mm, d 1.06.** Crystallise terephthalaldehyde from water. [*Beilstein* **7** IV 2140.]

Terephthalic acid (benzene-1,4-dicarboxylic acid) *[100-21-0]* **$C_8H_6O_4$, M 166.1, m sublimes >300° without melting, d 1.52, pK_1^{20} 3.4, pK_2^{20} 4.34.** Purify the acid *via* the sodium salt which, after crystallisation from water, is re-converted to the acid by acidification with mineral acid. Filter off the solid, wash it with H_2O and dry it in a vacuum. The ***S-benzylisothiuronium salt*** has **m 204°** (from aqueous EtOH). [*Beilstein* **9** IV 3301.] Used for making PET polyesters, e.g. for plastic bottles, clothing and related materials.
Terephthaloyl chloride **(benzene-1,4-dicarbonyl chloride)** *[100-20-9]* **$C_8H_4Cl_2O_2$, M 203.0,** has **m 79-83°, 81°, 80-82°, 83.5°, b 265°/atm, d 1.34.** Crystallise the acid chloride from dry hexane. The ***diamide*** *[3010-82-0]* **$C_8H_8N_2O_2$**, M 164.1, has **m 332°** (from aqueous NH_3). [*Beilstein* **9** IV 3318.]

***o*-Terphenyl (1,2-diphenylbenzene)** *[84-15-1]* **$C_{18}H_{14}$, M 230.3, m 54-57°, 56.2°, 57°, 58-59°, b 332°/atm, 337°/atm, d 1.24.** Crystallise *o*-terphenyl from EtOH. Also purify it by chromatography of CCl_4 solution on alumina, with petroleum ether as eluent, followed by crystallisation from petroleum ether (b 40-60°) or petroleum ether/*C_6H_6. It also distils under vacuum. [*Beilstein* **5** III 2292, **5** IV 2478.]
***m*-Terphenyl (1,3-diphenylbenzene)** *[92-06-8]* **$C_{18}H_{14}$, M 230.3,** has **m 86°, 87°, 88-89°, b 363°/atm, 379°/atm, d ^{25} 1.24g/ml.** Purify it as for *o*-terphenyl above. [*Beilstein* **5** IV 2480.]
***p*-Terphenyl (1,4-diphenylbenzene)** *[92-94-4]* **$C_{18}H_{14}$, M 230.3,** has **m 212.7°, b 389°/atm.** Crystallise *p*-terphenyl from nitrobenzene or trichlorobenzene. It is also purified by chromatography on alumina in a darkened room, using petroleum ether, and then crystallising from petroleum ether (b 40-60°) or petroleum ether/*benzene. It is a fluorophore for scintillation counting and has λ_{ex} 286nm : λ_{em} 343nm in DMF, and λ_{max} at 277nm (logε 4.50). [*Beilstein* **5** IV 2483.]

3',3",5',5"-Tetrabromophenolphthalein ethyl ester *[1176-74-5]* **$C_{22}H_{14}Br_4O_4$, M 662.0, m 208-211°, 212-214°.** Crystallise the yellow to red ester from *benzene, dry at 120°, and keep it under vacuum or store at -20°. [*Beilstein* **10** III 4490.] Useful stain in microscopy.

2,3,4,5-Tetrachloroaniline *[634-83-3]* **$C_6H_3Cl_4N$, M 230.9, m 117-118°, 119-120°, pK_{Est} ~-0.26.** Crystallise it from EtOH. Analytical standard available in MeCN (100mg.ml), and it store at +4°. The ***acetyl*** derivative has **m 165-166°** (from EtOH). [*Beilstein* **12** H 630, **12** I 313, **12** II 340, **12** IV 1286.]
2,3,5,6-Tetrachloroaniline *[3481-20-7]* has **m 106°, 106-108°, 107-108°, pK_{Est} ~-1.8.** Crystallise it from EtOH. The ***acetyl*** derivative has **m 213-214°** (from EtOH). [*Beilstein* **12** II 340, **12** III 1414, **12** IV 1287.]

1,2,3,4-Tetrachlorobenzene *[634-66-2]* **$C_6H_2Cl_4$, M 215.9, m 42-45°, 45-46°, 47°, 47.5°, b 254°/761mm.** Crystallise it from EtOH. [*Beilstein* **5** H 204, **5** II 156, **5** III 550, **5** IV 667.]
1,2,3,5-Tetrachlorobenzene *[634-90-2]* has **m 50-51°, 51°, 54-55°, b 246°/760mm, d^{10} 1.7344.** Crystallise it from EtOH. [*Beilstein* **5** II 157, **5** III 551, **5** IV 668.]
1,2,4,5-Tetrachlorobenzene *[95-94-3]* has **m 139°, 139.5°, 139.5-140.5°, 139-142°, b 240°/760mm, 245°/760mm, d 1.86.** Crystallise it from EtOH, ether, *benzene, *benzene/EtOH or carbon disulfide. [*Beilstein* **5** IV 668.]

3,4,5,6-Tetrachloro-1,2-benzoquinone (*o*-chloranil) *[2435-53-2]* **$C_6Cl_4O_2$, M 245.9, m 126° to 129°, 130°, 133°.** Crystallise *o*-chloranil from AcOH. Dry it in vacuum desiccator over KOH. A useful dehydrogenating and oxidising agent [Fieser **1** 128]. [Brook *J Chem Soc* 5035, Note p 5040, *1952*, DOI: 10.1039/JR9520005035; *Beilstein* **7** IV 2065.]

3,4,5,6-Tetrachloro-*N*-methylphthalimide *[14737-80-5]* **$C_9H_3Cl_4NO_2$, M 298.9, m 209.7°.** Crystallise the imide from absolute EtOH. [*Beilstein* **21** H 505, **17/11** V 260.]

2,3,4,6-Tetrachloronitrobenzene (1,2,3,5-tetrachloro-4-nitrobenzene) *[879-39-0, 3714-62-3]* **$C_6HCl_4NO_2$, M 260.9, m 41-42°, 42°.** Crystallise it from aqueous EtOH. [*Beilstein* **5** II 187, **5** III 617, **5** IV 728.]
2,3,5,6-Tetrachloronitrobenzene **(1,2,4,5-tetrachloro-3-nitrobenzene)** *[117-18-0, 28804-67-3]* has **m 98-101°, 99-100°, b 304°/760mm,** Crystallise it from aqueous EtOH or H_2O. [*Beilstein* **5** III 617, **5** IV 728.]

2,3,4,5-Tetrachlorophenol *[4901-51-3]* **$C_6H_2Cl_4O$, M 231.9, m 116.5°, 116-117°, pK^{25} 6.95 (6.35).** Crystallise the phenol from petroleum ether. The ***benzoate*** has **m 110°** (from EtOH). [*Beilstein* **6** II 182, **6** III 729, **6** IV 1020.]

2,3,4,6-Tetrachlorophenol *[58-90-2]* **$C_6H_2Cl_4O$, M 231.9, m 63-67°, 70°, b 150°/15mm, 164°/23mm, d 1.839, pK^{25} 5.38.** Crystallise the phenol from petroleum ether and/or distil it under vacuum. The ***benzoate*** has **m 116°** (from EtOH). [*Beilstein* **6** H 193, **6** III 729, **6** IV 1021.] Pesticide against insects, fungi and bacteria, but is a potential carcinogen.
2,3,5,6-Tetrachlorophenol *[935-95-5]* has **m 114-116°, 115°, pK^{25} 5.48 (5.09).** Recrystallise the phenol from petroleum ethers. It is soluble in *C_6H_6 (very), H_2O (slightly), and ligroin. It irritates eyes, skin, mucous memberanes and respiratory tract. The ***benzoate*** has **m 136°** (from EtOH). [*Beilstein* **6** III 730, **6** IV 1025.]

Tetrachlorophthalic acid *[632-58-6]* **$C_8H_2Cl_4O_4$, M 303.9, m 98° (anhydrous), 439°/760mm.** Crystallises from hot water as the *hemihydrate* in colourless thin monoclinic plates. [For crystal structure of hemihydrate see Ito et al. *Bull Chem Soc Jpn* **48** 3078 *1975*, DOI: 10.1246/bcsj.48.3078.]
Tetrachlorophthalic anhydride *[117-08-8]* **$C_8Cl_4O_3$, M 285.9, m 253-256°, 254.5°, 255-256°, 255-257°, 254-258°, b 371°/760mm.** Crystallise the anhydride from chloroform or *benzene, then sublime it in a vacuum. It forms a phenanthrene adduct *[3178-32-3]* [*Beilstein* **17/11** V 260, Fieser **15** 300] ***Tetrtachlorophthalimide*** *[1571-13-7]* **$C_8HCl_4NO_2$, M 284.9**, crystallises as colourless blades **m 338-339°** (from hot AcOH, solubility 1g/100ml); **m 336-337°** (from nitrobenzene); and yellow needles **m 345-347°** (from DMF) and is a **teratogen**. [Al-Mughaid & Grindley *e-EROS Encyclopedia of Reagents for Organic Synthesis* DOI: 10.1002/047084289X.rn00333; *Beilstein* **21** 505.]

1,2,4,5-Tetracyanobenzene *[712-74-3]* **$C_{10}H_2N_4$, M 178.1, m 270-272°, 275-280° (280°).** The tetranitrile can be prepared by dehydration of ***1,2,4,5-benzenetetracarboxamide (pyromellitimide)*** *[6183-35-5]* **$C_{10}H_{10}N_4O_4$, M 250.2, m >450-454°**, with $SOCl_2$/DMF**.** Crystallise the tetra-nitrile from EtOH (fine needles) and sublime it *in vacuo*. It crystallises from AcOH in colourless plates (**m 267-269°**), and recrystallisation from $MeOCH_2CH_2OH$, EtCOMe and again from AcOH provided crystals with **m 270-272°**. Its IR (KBr pellet) has ν_{max} at 2,240 (4.5μ, CN), 3,125 and 3,030(3.2μ and 3.3μ, CH), and 926 (10.8μ, 1,2,4,5-benzene substitution) cm^{-1}. It forms distinct molecular complexes with a variety of aromatic 'donor' molecules such as durene (**m 267-270°**), anthracene (**m 277-280°**), pyrene (**m 268-270°**), 2-naphthol (**m 265-270°**), 2,7-dimethoxynaphthalene (**m 267-270°**), dimethylaniline (**m 266-268°**), 1,5-diaminonaphthalene (**m >360°**), quinolone (**m** 262-265°) and isoquinoline (**m 194-196°**). [Lawton & McRitchie *J Org Chem* **24** 26 *1959*, DOI: 10.1021/jo01083a008; Bailey et al. DOI: 10.1016/0040-4020(63)80018-6; **19** 161 *1963*, *Beilstein* **9** IV 3804.]

7,7,8,8-Tetracyanoquinodimethane (TCNQ) *[1518-16-7]* **$C_{12}H_4N_4$, M 204.2, m 287-289°(dec), 289-291°, 293.5-296°.** It is prepared by condensation of cyclohexane-1,4-dione and malononitrile**,** bromination followed by dehyrobromination with pyridine. It is purified by sublimation above 250° at atmospheric pressure or at ~200° under vacuum giving rust coloured crystals. It also crystallises nicely from EtOAc, tetrahydrofuran or MeCN in rust-coloured crystals. When the crystals are crushed between soft glass melting point cover glasses and heated, a beautiful blue film forms on the glass plates at ~200° due to the reaction of TCQN with the bases in the glass to give the TCNQ anion-radical. Its has IR bands at ν_{max} 1540 cm^{-1} (conjugated C=C for a cycloölefine) and 2220 cm^{-1} (conjugated nitrile). The UV in EtOH is complicated by the presence of the TCNQ radical anion (among other products), and the absorption from TCNQ is best determined by using a KBr wafer or measuring it in MeCN solution which has λ_{max} at 395nm (ε 63,600). Polarographic reduction of TCNQ in 0.2M NaOAc is at +0.15 to +0.16V reversibly to form $TCNQH_2$. TCNQ is a strong Lewis acid which forms π–complexes; the charge-transfer complex with anthracene is black. The association constants of the radical anions in CH_2Cl_2 were determined with durene (5.6), hexamethylbenzene (14.5) and pyrene (78.4) which compare with those of TCNE (tetracyanoethylene) that are 54.2, 263 and 29.5 respectively. [Acker & Hertler *J Am Chem Soc* **84** 3370 *1962*, DOI: 10.1021/ja00876a028; Melby et al. *J Am Chem Soc* **84** 3374 *1962*, DOI: 10.1021/ja00876a029; Fieser **1** 1136, **12** 464.]

Tetrahydroxy-*p*-benzoquinone ($2H_2O$) *[5676-48-2; 123334-16-7 $2H_2O$]* **$C_6H_4O_6.2H_2O$, M 172.1 + xH_2O, m ~300°, pK_1^{30} 4,80, pK_2^{30} 6.8.** Crystallise the quinone from water. [*Beilstein* **8** H 534, **8** II 572, **8** III 4204, **8** IV 3604.] It is an indicator for sulfate titrations.

Tetralin (1,2,3,4-tetrahydronaphthalene) *[119-64-2]* **$C_{10}H_{12}$, M 132.2, m –35.79° (from CF_2Cl_2), b 65-66°/5mm, 207.6°/760mm, d_4^{20} 0.968, n_D^{20} 1.5413.** Wash tetralin with successive portions of concentrated H_2SO_4 until the acid layer is no longer coloured, then wash it with aqueous 10% Na_2CO_3, and then distilled water. Dry ($CaSO_4$ or Na_2SO_4), filter, reflux and fractionally distil it under under reduced pressure from sodium or BaO. It can also be purified by repeated fractional freezing. Bass [*J Chem Soc* 3475(3498) *1964*, DOI: 10.1039/JR9640003475 (note)] freed tetralin, purified as above, from naphthalene and other impurities by conversion to ammonium tetralin-6-sulfonate. Concentrated H_2SO_4 (150ml) is added slowly to stirred tetralin (272ml) which is then heated on a water bath for about 2 hours for complete solution. The warm mixture, when poured into aqueous NH_4Cl solution (120g in 400ml water), gives a white precipitate which, after filtering off, is crystallised from boiling water, washed with 50% aqueous EtOH and dried at 100°. Evaporation of its boiling

aqueous solution on a steam bath removes traces of naphthalene. The pure salt (229g) is mixed with concentrated H_2SO_4 (266ml) and steam distilled from an oil bath at 165-170°. An ether extract of the distillate is washed with aqueous Na_2SO_4, and the ether is evaporated, prior to distilling the tetralin from sodium. Tetralin has also been purified *via* barium tetralin-6-sulfonate, converted to the sodium salt and decomposed in 60% H_2SO_4 using superheated steam. [*Beilstein* **5** H 491, **5** III 1219, **5** IV 1388.]

Tetralin hydroperoxide *[771-29-9]* **$C_{10}H_{12}O_2$, M 164.2, m 55.7-56°, 56°.** Crystallise the tetralin hydroperoxide from hexane, toluene at -30° (**m 54.0-54.5°**). The oxygen content should be ~9.70%. [Knight & Swern *Org Synth* Coll Vol **4** 895 *1963*, DOI: 10.15227/orgsyn.034.0090.]

α-Tetralone (1,2,3,4-tetrahydro-1-oxonaphthalene) *[529-34-0]* **$C_{10}H_{10}O$, M 146.2, m 2-7°, 7.8-8.0°, b 75-85°/0.3mm, 89°/0.5mm, 94-95°/2mm, 132-134°/15mm, 143-145°/20mm, d_4^{20} 1.0695, n_D^{20} 1.5665.** Check the IR first. Purify α-tetralone by dissolving 20ml in Et_2O (200ml), washing with H_2O (100ml), 5% aqueous NaOH (100ml), H_2O (100ml), 3% aqueous AcOH (100ml), 5% $NaHCO_3$ (100ml) then H_2O (100ml) and dry the ethereal layer over $MgSO_4$. Filter, evaporate and fractionate the residue through a 6in Vigreux column under reduced pressure to give a colourless oil (~17g) with **b 90-91°/0.5-0.7mm**. [Snyder & Werber *Org Synth* Coll Vol **3** 798 *1955*, DOI: 10.15227/orgsyn.020.0094.] It has also been fractionated through a 0.5metre packed column with a heated jacket under reflux using a partial take-off head. It has λ_{max} at 247.5 and 290nm (hexane). The ***phenylhydrazone*** has **m 83°.** The ***2,4,6-trinitrophenylhydrazone*** has **m 247.5-248°** (from EtOH). [Olson et al. *Org Synth* Coll Vol **4** 898 *1963I*, DOI: 10.15227/orgsyn.035.0095; *Beilstein* **7** III 1416, **7** IV 1015.]
β-Tetralone* (1,2,3,4-tetrahydro-2-oxonaphthalene)** *[530-93-8]* has **m 17-18°, ~18°, b 93-95°/2mm, 104-105°/4mm, 114-115°/4-5mm, 140°/18mm, d_4^{20} 1.1000, n_D^{20} 1.5598.** If reasonably pure, then fractionate it through an efficient column. Otherwise purify it *via* the ***bisulfite adduct. To a solution of $NaHSO_3$ (32.5g, 0.31mol) in H_2O (57ml) is added 95% EtOH (18ml) and set aside overnight. Any bisulfite-sulfate that separated is removed by filtration, and the filtrate is added to the tetralone (14.6g, 0.1mol) and shaken vigorously. The adduct separates in a few minutes as a white precipitate and is kept on ice for ~3.5 hours with occasional shaking. The precipitate is collected, washed with 95% EtOH (13ml), then with Et_2O (4 x 15ml, by stirring the suspension in the solvent, filtering and repeating the process). The colourless product is dried in air and stored in air tight containers in which it is stable for extended periods (yield is ~17g). This bisulfite (5g) is suspended in H_2O (25ml), and $Na_2CO_3.H_2O$ (7.5g) is added (pH of solution is ~10). The mixture is then extracted with Et_2O (5 x 10ml, i.e. until the aqueous phase does not test for tetralone — see below). Wash the combined extracts with 10% aqueous HCl (10ml), H_2O (10ml, i.e. until the washings are neutral), dry ($MgSO_4$), filter, evaporate and distil the residual oil using a Claisen flask under reduced pressure and in a N_2 atmosphere. The pure tetralone is a colourless liquid **b 70-71°/0.25mm** (see also above). The yield is ~2g. **Tetralone test:** Dissolve a few drops of the tetralone solution (ethereal or aqueous) in 95% EtOH in a test tube and add 10 drops of 25% NaOH down the side of the tube. A deep blue colour develops at the interface with air. [Soffer et al. *Org Synth* Coll Vol **4** 903 *1963*, DOI: 10.15227/orgsyn.032.0097; Cornforth et al. *J Chem Soc* 689 *1942*, DOI: 10.1039/JR9420000689; UV: Soffer et al. *J Am Chem Soc* **74** 1556 *1952*, DOI: 10.1021/ja01126a063.] The ***phenylhydrazone*** has **m 108°** [Crowley & Robinson *J Chem Soc* 2001 *1938*, DOI: 10.1039/JR9380002001]. [*Beilstein* **7** H 370, **7** II 295, **7** III 1422, **7** IV 1018.]

1,2,3,4-Teteramethylbenzene (prehnitine) *[488-23-3]* **$C_{10}H_{14}$, M 134.2, m -6.3°, b 79.4°/10mm, 204-205°/760mm, d_4^{20} 0.905, n_D^{20} 1.5203.** Dry it over sodium and distil under reduced pressure. The ***picrate*** has **m 92-95°** (EtOH). [*Beilstein* **5** H 430, **5** I 206. **5** II 329, **5** III 974, **5** IV 1072.]
***1,2,3,5-Tetramethylbenzene* (isodurene)** *[527-53-7]* has **m -23.7°, -24°, b 74.4°/10mm, 198°/760mm, d_4^{20} 0.890, n_D^{20} 1.5130.** Reflux isodurene over sodium and distil it under reduced pressure. [Smith *Org Synth* Coll Vol **2** 248 *1943*, DOI: 10.15227/orgsyn.010.0032; *Beilstein* **5** H 430, **5** II 329, **5** III 976, **5** IV 1073.]
***1,2,4,5-tetramethylbenzene* (durene)** *[95-93-2]* has **m 77° to 80°, 79.5-80.5°, 191-192°/760mm, d^{81} 0.838.** Chromatograph durene on alumina, and recrystallise it from aqueous EtOH or *benzene. Dry it under vacuum. Zone-refining removes duroaldehydes. [Yamauchi et al. *J Phys Chem* **89** 4804 *1985*, DOI: 10.1021/j100268a029.] It is been prepared from xylene/MeCl/$AlCl_3$ under conditions which produce a high proportion of durene which is separated from other methylbenzenes by fractional distillation using a good column, then steam distilled, the durene is collected from the distillate, dried ($CaCl_2$), filtered, distilled through a good column, then dried over Na and redistilled. It is poorly soluble in H_2O but is steam volatile, and soluble in

organic solvents. It can be sublimed unchanged, but it is best to sublime it *in vacuo*. [Johnston et al. *J Am Chem Soc* **109** 1291 *1987*, DOI: 10.1021/ja00239a001; Smith *Org Synth* Coll Vol **2** 248 *1943*, DOI: 10.15227/orgsyn.010.0032; *Beilstein* **5** H 431, **5** I 207, **5** II 329, **5** III 979, **5** IV 1076.]

***N,N,N',N'*-Tetramethylbenzidine** *[366-29-0]* **$C_{16}H_{20}N_2$, M 240.4, m 193-195°, 195.4-195.6°, $pK_{Est(1)}$~3.4, $pK_{Est(2)}$~4.5.** Crystallise the benzidine from EtOH or petroleum ether, then from petroleum ether/*benzene, and sublime it in a vacuum. [Guarr et al. *J Am Chem Soc* **107** 5104 *1985*, DOI: 10.1021/ja00304a015.] Dry it *in vacuo* in a drying pistol, or a vacuum line. It has **m 195-196°** after sublimation. [*Beilstein* **13** H 221, **13** I 61, **13** II 97, **13** III 429, **13** IV 368.]

***p,p'*-Tetramethyldiaminodiphenylmethane [bis(*p*-dimethylaminophenyl)methane, Michler's base, (*p,p'*-methylene-bis-(*N,N*-dimethylaniline)]** *[101-61-1, 30135-64-9]* **$C_{17}H_{22}N_2$, M 254.4, m 89-90°, b 155-157°/0.1mm, $pK_{Est(1)}$~5.8, $pK_{Est(2)}$~5.1.** Crystallise the base from EtOH (2ml/g) or 95% EtOH (*ca* 12ml/g). It sublimes on heating. [*Beilstein* **13** IV 390.] Used in fixing latent fingerprints developed with iodine [Trowell *J Forensic Sci Soc* **15** 189 *1975*, DOI:10.1016/S0015-7368(75)70984-2].

***N,N,N',N'*-Tetramethyl-1,8-naphthalenediamine [Proton sponge, 1,8-bis-(dimethylamino)-naphthalene** *[20734-58-1]* **$C_{14}H_{18}N_2$, M 214.3, m 45-48°, 47-48°, 47-51°, b 144-145°/4mm, pK_1 -10.5 (from half protonation in 86% aqueous H_2SO_4, diprotonation), pK_2 12.34 (monoprotonation).** It is prepared by methylating 1,8-diaminonaphthalene, and likely impurities are methylated products. The tetramethyl compound is a stronger base than the unmethylated, di and trimethylated derivatives. The pKa values are: 1,8-$(NH_2)_2$ = 4.61, 1,8-$(NHMe)_2$ = 5.61, 1-NHMe-8-$NHMe_2$ = 6.43 and 1,8-$(NMe_2)_2$ = 12.34. The mixture is then treated with H_2O at pH 8 (where all but the required base are protonated) and extracted with Et_2O or $CHCl_3$. The dried extract (K_2CO_3) yields the tetramethyldiamine on evaporation which can be distilled. It is a strong base with weak nucleophilic properties, e.g. it could not be alkylated by refluxing with EtI in MeCN for 4 days; and on treatment with methyl fluorosulfonate only the fluorosulfonate salt of the base is obtained. [NMR: Adler et al. *Chem Commun* (London) 723 *1968*, DOI: 10.1039/C19680000723; Brown & Letang *J Am Chem Soc* **63** 358 *1941*, DOI: 10.1021/ja01847a009; Brzezinski et al. *JCS Perkin Trans 2* 857 *1991*, DOI: 10.1039/P29910000857.] *Alternatively*, crystallise *proton sponge* from EtOH and dry it in a vacuum oven. Store it in the dark in a CO_2-free atmosphere. [Benoit et al. *Can J Chem* **65** 996 *1987*, DOI: 10.1139/v87-170; *Beilstein* **13** IV 344.] Also used as a matrix for MALDI-MS, and traces of the cations of Ba(at ≈5mg/kg), Cd(at ≈5mg/kg), Co(at ≈5mg/kg), Cr(at ≈5mg/kg), Cu(at ≈5mg/kg), Fe(at ≈100mg/kg), K(at ≈20mg/kg), Mg(at ≈5mg/kg), Mn(at ≈5mg/kg), Na(at ≈50mg/kg), Ni(at ≈5mg/kg), Pb(at ≈5mg/kg), Zn(at ≈5mg/kg) can be detected, as well as lipids and metabolites.

***N,N,N',N'*-Tetramethyl-1,4-phenylenediamine (TMPD, Wurster's blue)** *[100-22-1]* **$C_{10}H_{16}N_2$, M 164.3, m 51°, b 135°/14mm, 260°/760mm, pK_1^{20} 2.29, pK_2^{20} 6.35.** Crystallise the amine from petroleum ether or water. It can be sublimed or dried carefully in a vacuum line, and stored in the dark under nitrogen. It has been recrystallised from its melt. It loses two electrons stepwise upon oxidation; the radical-cation has a characteristic blue-violet colour, and is used in studies of electron transport for oxidase tests of biological electron transport systems [Michaelis et al. *J Am Chem Soc* **61** 1981 *1939*, DOI: 10.1021/ja01877a013]. Tetraphenylethylene *[632-51-9]* **$C_{26}H_{20}$, M 332.4, m 223-224°, 224°, 225°, b 415-425°/760mm.** Crystallise the ethylene from dioxane or from EtOH/*C_6H_6. Sublime it under high vacuum. [*Beilstein* **5** IV 2780.]

Tetraphenylhydrazine *[632-52-0]* **$C_{24}H_{20}N_2$, M 336.4, m 147°, pK_{Est} ~0.** Crystallise the hydrazine from 1:1 $CHCl_3$/toluene, 1:5 $CHCl_3$/EtOH (**m 149°**), *C_6H_6 or *C_6H_6/petroleum ether. Store it in a refrigerator, in the dark. [*Beilstein* **15** H 125, **15** I 29, **15** III 77, **15** IV 59.]

***trans*-1,1,4,4-Tetraphenyl-2-methylbutadiene** *[20411-57-8]* **$C_{29}H_{24}$, M 372.5.** Crystallise it from EtOH or AcOH. [Wittig & Obermann *Chem Ber* **68** 2214 *1935*, DOI: 10.1002/cber.19350681210; *Beilstein* **5** IV 2816.]

5,6,11,12-Tetraphenylnaphthacene (Rubrene) *[517-51-1]* **$C_{42}H_{28}$, M 532.7, m>315°, 322°, 330-335°, d_4^{20} 1.255.** Rubrene forms orange crystals on sublimation at 250-260°/3-4mm [UV Badger & Pearce *Spectrochim Acta* **4** 280 *1950*, DOI: 10.1016/0371-1951(51)80073-0]. It has also been recrystallised from *benzene under red light because it is chemiluminescent and light sensitive. [*Beilstein* **5** IV 2968.]

1,2,3,4-Tetraphenylnaphthalene *[751-38-2]* **$C_{34}H_{24}$, M 432.6, m 199-201°, 204-204.5°.** Crystallise the naphthalene from MeOH or EtOH. [Fieser & Haddadin *Org Synth* **46** 107 *1966*, DOI: 10.15227/orgsyn.046.0107; *Beilstein* **5** IV 2918.]

Thymol (2-isopropyl-5-methylphenol) *[89-83-8]* **$C_{10}H_{14}O_2S$, M 150.2, m 49-51°, 51.5°, b 232°/atm, d^{25} 0.965, n_D^{25} 1.5204, pK^{20} 10.62.** It occurs in the volatile oils of *Thymus vulgaris* and *Moranda punctate* L. from which it was first isolated [Arppe *Justus Liebigs Ann Chem* **58** 41 *1846*, DOI: 10.1002/jlac.18460580107]. It is quite volatile at 100°, and is steam volatile, separating as white crystals which have a characteristic pungent odour, with a caustic taste. It should be stored in the dark, preferably under N_2 as it oxidises slowly in air. It possesses antimould properties, is an internal and external antiseptic, and has nematode anthelmintic activity. The ***acetate*** *[528-93-2]* is a yellow irritating oil, **b 243.5-245.5°/atm, d^0 1.009**, with the odour of thymol, and is soluble in most organic solvents, but almost insoluble in H_2O. [*Beilstein* **6** IV 3334.] Antimicrobial.

Thymolphthalein complexone {TPC, 3,3'-bis[*N*,*N*-di(carboxymethyl)aminomethyl]thymolphthalein} *[1913-93-5]* **$C_{38}H_{44}N_2O_{12}$, M 720.8, m 190°(dec), 191°, $pK_1^{18.2}$ 7.35, $pK_2^{18.2}$ 12.25.** Purify it as for phthalein complexone except that it is synthesised from thymolphthalein instead of cresolphthalein. It has absorption maxima at 600-605nm ($A_{1cm}^{1\%}$ 350-345) in aqueous 0.1NaOH. [*Beilstein* **18/4** V 194.]

o-**Tolidine (3,3'-dimethylbenzidine)** *[119-93-7]* **$C_{14}H_{16}N_2$, M 212.3, m 129°, 131-132°, b 300.5°/atm, d 1.23, pK^{25} 4.45.** Dissolve the tolidine in *benzene by percolation through a column of activated alumina and crystallise it from *benzene/petroleum ether. [*Beilstein* **13** IV 410.]

p-**Tolualdehyde** *[104-87-0]* **C_8H_8O, M 120.2, m -6°, b 83-85°/0.1mm, 199-200°/atm, 205°/760mm, d_4^{20} 1.018, n_D^{20} 1.5479.** Steam distil the aldehyde, dry it with $CaSO_4$, then fractionally distil it. [*Beilstein* **7** IV 672.]

o-**Toluamide** *[527-85-5]* **C_8H_9O, M 135.2, m 141°, 142°, 144-145°, 147°.** Crystallise *o*-toluamide from hot water (10ml/g) and dry in air. [Noller *Org Synth* Coll Vol **2** 586 *1943*, DOI: 10.15227/orgsyn.013.0094; *Beilstein* **9** H 465, **9** II 319, **9** III 2304.]

Toluene *[108-88-3]* **C_7H_8, M 92.1, m -93°, -94.9°, -95°, b 110.6°/760mm, 111°/760mm, d_4^{10} 0.87615, d_4^{25} 0.86231, n_D^{20} 1.49693, n_D^{25} 1.49413.** Dry toluene with $CaCl_2$, CaH_2 or $CaSO_4$, and dry further by standing with sodium, P_2O_5 or CaH_2. It can be fractionally distilled from sodium or P_2O_5. Unless specially purified, toluene is likely to be contaminated with methylthiophenes and other sulfur-containing impurities. These can be removed by shaking with concentrated H_2SO_4, but the temperature must be kept below 30° if sulfonation of toluene is to be avoided. A typical procedure consists of shaking toluene twice with cold concentrated H_2SO_4 (100ml of acid per L), once with water, once with aqueous 5% $NaHCO_3$ or NaOH, again with H_2O, then drying successively with $CaSO_4$ and P_2O_5, with final distillation from P_2O_5 or over $LiAlH_4$ after refluxing for 30 minutes. ***Alternatively***, $NaHCO_3$ can be replaced by boiling under reflux with 1% sodium amalgam. Sulfur compounds can also be removed by prolonged shaking of the toluene with mercury, or by two distillations from

$AlCl_3$, the distillate then being washed with water, dried with K_2CO_3 and stored with sodium wire. Other purification procedures include refluxing and distillation of sodium dried toluene from diphenylpicrylhydrazyl, and from $SnCl_2$ (to ensure freedom from peroxides). It has also been co-distilled with 10% by volume of ethyl methyl ketone, and again fractionally distilled. [Brown & Pearsall *J Am Chem Soc* **74** 191 *1952*, DOI: 10.1021/ja01121a049.] For removal of carbonyl impurities see **benzene*. Toluene has been purified by distillation under nitrogen in the presence of sodium benzophenone ketyl. Toluene has also been dried with $MgSO_4$, after the sulfur impurities have been removed, and then fractionally distilled from P_2O_5 and stored in the dark [Tabushi et al. *J Am Chem Soc* **107** 4466 *1985*, DOI: 10.1021/ja00301a016]. Toluene can be purified by passage through a tightly packed column of Fuller's earth.
Rapid purification: Alumina, CaH_2 and 4A molecular sieves (3% w/v) may be used to dry toluene (6 hours stirring and standing). Then the toluene is distilled, discarding the first 5% of distillate, and is stored over molecular sieves (3A, 4A) or Na wire. [*Beilstein* **5** H 280, **5** I 144, **5** II 209, **5** III 651, **5** IV 766.]

Toluene-2,4-diamine (4-methyl-*m*-phenylenediamine) *[95-80-7]* **$C_7H_{10}N_2$, M 122.2, m 99°, b 148-150°/8mm, 292°/760mm, $pK_{Est(1)}$~2.5, $pK_{Est(2)}$~4.4.** Recrystallise the diamine from water (solubility is 0.75w/v%) containing a very small amount of sodium dithionite (to prevent air oxidation), and dry it under vacuum. It also crystallises from *benzene. [*Beilstein* **13** IV 235.]

Toluhydroquinone (1,4-dihydroxy-2-methylbenzene) *[95-71-6, 96937-50-7]* **$C_7H_8O_2$, M 124.1, m 125°, 126°, 128-129°, d 1.34, pK_1^{20} 10.15, pK_2^{20} 11.75.** Crystallise the quinone from EtOH. [*Beilstein* **6** IV 5866.]

o-**Toluic acid** *[118-90-1]* **$C_8H_8O_2$, M 136.2, m 102-103°, 104-105°, b 258-259°/760mm, d 1.06, pK^{25} 3.91.** Crystallise the acid from *benzene (2.5ml/g) and dry in air. The ***S-benzylisothiuronium salt*** has **m 146°** (from aqueous EtOH). [*Beilstein* **9** IV 1697.]

m-**Toluic acid** *[99-04-7]* has **m 108.7°, 108-110°, 112°, 111-113°, b 263°/760mm, d 1.05, pK^{25} 4.27.** Crystallise the acid from water. [*Beilstein* **9** IV 1712.] Aromatic acid impurities (to <0.05%) can be removed *via* the (±)-α-methylbenzylamine salt as described for 2,4-dichlorobenzoic acid [Ley & Yates *Organic Process Research & Development* **12** 120 *2008*, DOI: 10.1021/op7001547]. The ***S-benzylisothiuronium salt*** has **m 140°** (from aqueous EtOH).

p-**Toluic acid** *[99-94-5]* has **m 178.5-179.5°, 180°, 181°, 178-182°, d 1.06, b 274-275°/760mm, pK^{25} 4.37.** Crystallise the acid from water, water/EtOH (1:1), MeOH/water or *benzene. [*Beilstein* **9** IV 1724.] Aromatic acid impurities (to <0.05%) can be removed *via* the (±)-α-methylbenzylamine salt as described for 2,4-dichlorobenzoic acid [Ley & Yates *Organic Process Research & Development* **12** 120 *2008*, DOI: 10.1021/op7001547]. The ***S-benzylisothiuronium salt*** has **m 164°** (from aqueous EtOH).

o-**Toluidine (2-methylaniline)** *[95-53-4, 162607-18-3]* **C_7H_9N, M 107.2, m -24°, -16.3°, -14.4°, b 80.1°/10mm, 200.3°/760mm, d_4^{20} 0.999, n_D^{20} 1.57246, n_D^{25} 1.56987, pK^{25} 4.45.** In general, methods similar to those for purifying aniline can be used, e.g. distillation from zinc dust, at reduced pressure, under nitrogen. Berliner and May [*J Am Chem Soc* **49** 1007 *1927*, DOI: 10.1021/ja01403a017] purified it *via* the oxalate. Twice-distilled *o*-toluidine is dissolved in four times its volume of diethyl ether, and the equivalent amount of oxalic acid needed to form the di-oxalate is added as its solution in diethyl ether. (If *p*-toluidine is present, its oxalate precipitates and can be removed by filtration.) Evaporation of the ethereal solution gives crystals of ***o*-toluidine di-oxalate** [*Beilstein* **12** III 1494, **12** IV 1817]. These are filtered off, recrystallised five times from water containing a small amount of oxalic acid (to prevent hydrolysis), then treated with dilute aqueous Na_2CO_3 to liberate the amine which is separated, dried ($CaCl_2$) and distilled under reduced pressure. The ***benzoyl*** derivative has **m 144°** (from EtOH). [*Beilstein* **12** H 772, **12** I 372, **12** II 429, **12** III 1837, **12** IV 1744.]
m*-Toluidine (3-methylaniline)** *[108-44-1]* has **m -30.4°, -31.3°, b 82.3°/10mm, 203.4°/ 760mm, d_4^{20} 0.989, n_D^{20} 1.56811, n_D^{25} 1.56570, pK^{25} 4.71.** It can be purified as for aniline. Twice-distilled, *m*-toluidine is converted to the hydrochloride using a slight excess of HCl, and the salt is fractionally crystallised from 25% EtOH (five times), and from distilled water (twice), rejecting, in each case, the first material that crystallised out. The amine is regenerated and distilled as for *o*-toluidine. The ***benzoyl derivative has **m 125°** (from EtOH). [Berliner & May *J Am Chem Soc* **49** 1007 *1927*, DOI: 10.1021/ja01403a017; *Beilstein* **12** II 463, **12** III 1949, **12** IV 1813.]

p-**Toluidine (4-methylaniline)** *[106-49-0]* has **m 42-46°, 43°, 43.6°, 44°, 44.8°, b 79.6°/10mm, 200.5°/760mm, d_4^{20} 0.962, n_D^{20} 1.5636, $n_D^{59.1}$ 1.5534, pK^{25} 5.08.** In general, methods similar to those for purifying aniline can be used. It can be separated from the *o*- and *m*-isomers by fractional crystallisation from its melt. *p*-Toluidine has been crystallised from hot water (charcoal), EtOH, *benzene, petroleum ether or EtOH/water (1:4), and dried in a vacuum desiccator. It can also be sublimed at 30° under vacuum. For further purification, use has been made of the oxalate, the sulfate and acetylation. The ***oxalate***, formed as described for *o*-toluidine, is filtered, washed and recrystallised three times from hot distilled water. The base is regenerated with aqueous Na_2CO_3 and recrystallised three times from distilled water. [Berliner & May *J Am Chem Soc* **49** 1007 *1927*, DOI: 10.1021/ja01403a017.] *Alternatively*, *p*-toluidine is converted to its ***acetyl*** derivative which, after repeated crystallisation from EtOH, is hydrolysed by refluxing (50g) in a mixture of 500ml of water and 115ml of concentrated H_2SO_4 until a clear solution is obtained. The amine sulfate is isolated, suspended in water, and NaOH is added. The free base is distilled twice from zinc dust under vacuum. The *p*-toluidine is then recrystallised from petroleum ether and dried in a vacuum desiccator or in a vacuum for 6 hours at 40°. The ***benzoyl*** derivative has **m 158°** (from EtOH). [Berliner & Berliner *J Am Chem Soc* **76** 6179 *1954*, DOI: 10.1021/ja01652a092; Moore et al. *J Am Chem Soc* **108** 2257 *1986*, DOI: 10.1021/ja00269a022; *Beilstein* **12** H 880, **12** I 140, **12** II 482, **12** III 2017, **12** IV 1866.] *p-**Toluidine hydrochloride** [540-23-8]* **C_7H_9N.HCl, M 143.6,** has **m 243-245°, 245.9-246.1°.** Crystallise the salt from MeOH containing a few drops of concentrated HCl or aqueous EtOH. Dry it under vacuum over paraffin chips. [*Beilstein* **12** II 587, **12** III 2021, **12** IV 1869.]

o-**Tolunitrile** *[529-19-1, 25550-22-5]* **C_8H_7N, M 117.2, m -14°, -13.5°, -13°, b 205.2°/atm, d_4^{20} 0.992, n_D^{20} 1.5279.** Fractionally distil the nitrile, wash it with concentrated HCl or 50% H_2SO_4 at 60° until the smell of isonitrile has gone (this also removes any amines), then wash it with saturated $NaHCO_3$ and dilute NaCl solutions, then dry it with K_2CO_3 and redistil it. [*Beilstein* **9** IV 1703.]
*m-**Tolunitrile** [620-22-4]* has **m -23°, b 99-101°/20mm, 209.5-210°/773mm, d_4^{20} 0.986, n_D^{20} 1.5250.** Dry the nitrile with $MgSO_4$, fractionally distil it, then wash it with aqueous acid to remove possible traces of amines, dry and redistil it. [*Beilstein* **9** H 477, **9** I 191, **9** II 325, **9** III 2324, **9** IV 1717.]
*p-**Tolunitrile** [104-85-8]* has **m 26-29°, 27°, 28°, 29.5°, b 104-106°/20mm, 217°/atm, 218°/atm, d_4^{20} 0.981.** Melt the nitrile, dry it with $MgSO_4$, fractionally crystallise it from its melt, then fractionally distil it under reduced pressure in a 6-in spinning band column. [Brown *J Am Chem Soc* **81** 3232 *1959*, DOI: 10.1021/ja01522a018.] It can also be crystallised from *benzene/petroleum ether (b 40-60°). [*Beilstein* **9** H 489, **9** I 194, **9** II 330, **9** III 2348, **9** IV 1738.]

4-Tolyl-2-benzoic acid (4'-methylbiphenyl-2-carboxylic acid) *[7148-03-0]* **$C_{14}H_{12}O_2$, M 212.2, m 138-139°, 146-148°, 148-152°, pK^{25} 3.64.** Crystallise the acid from toluene or $*C_6H_6$ (**m** 147-148°). [*Beilstein* **9** H 677, **9** IV 2523.]

p-**Tolyl carbinol (4-methylbenzyl alcohol)** *[589-18-4]* **$C_8H_{10}O$, M 122.2, m 58-61°, 59.5-60°, 61°, b 116-118°/20mm, 217°/760mm.** Recrystallise the alcohol from petroleum ether (b 80-100°, 1g/ml), Et_2O, pentane or H_2O (**m 61-62.1°**). It can also be distilled in a vacuum. [*Beilstein* **6** H 498, **6** I 248, **6** II 469, **6** III 1779.]

Tolylene-2,4-diisocyanate (toluene-2,4-diisocyanate) *[584-84-9]* **$C_9H_6N_2O_2$, M 174.2, m 19.5-21.5°, 21.8°, 20-22°, 28°, b 126°/11mm, 124-126°/18mm, 251°/760mm, d^{25} 1.214g/ml.** It is purified by fractionation in a vacuum and should be stored in a dry atmosphere. It is soluble in organic solvents but reacts with H_2O, alcohols (slowly) and amines, all of which could cause explosive polymerisation. It darkens on exposure to light. It has a sharp pungent odour, is **TOXIC** and is **IRRITATING TO THE EYES.** [Siefken *Justus Liebigs Ann Chem* **562** 75, 96, 127 *1949*, DOI: 10.1002/jlac.19495620202; Bayer *Angew Chem* **59** 257 *1947*, DOI: 10.1002/ange.19470590901] It is a reagent for covalent crosslinking of proteins [Wold *Methods Enzymol* **25** 623 *1972*, DOI: 10.1016/S0076-6879(72)25061-3.] [*Beilstein* **13** IV 243.]

Tolylene-2,6-diisocyanate (2-methyl-*m*-phenylenediisocyanate) *[91-08-7]* **$C_9H_6N_2O_2$, M 174.2, m 13°, b 129-133°/18mm, 246-247°/760mm, d_4^{20} 1.225, n_D^{20} 1.5715.** It is purified by fractional distillation in a vacuum. Store it under N_2 in sealed dark ampoules as it is water and light sensitive. Like the preceding 2,4-isomer, it has a sharp pungent odour, is **TOXIC** and is **IRRITATING TO THE EYES.** [*Beilstein* **13** IV 259.]

p-**Tolyl urea** *[622-51-5]* **$C_8H_{10}N_2O$, M 150.2, m 177-184°, 181°, 182°, 182-83°.** Crystallise the urea from H_2O (**m** 186°), EtOH/water (1:1) or aqueous AcOH (**m** 184°). [*Beilstein* **12** H 941, **12** I 425, **12** II 512, **12** III 2084, **12** IV 1923.]

Tribenzylamine *[620-40-6]* **$C_{21}H_{21}N$, M 287.4, m 91.5°, 93°, 93-94°, b 230°/13mm, 417.2°/760mm, pK_{Est} <0.** Crystallise the amine from absolute EtOH or petroleum ether. Dry it in a vacuum over P_2O_5 at room temperature. The ***hydrochloride*** has **m 226-228°** (from EtOH) and the ***picrate*** has **m 191°** (from H_2O or aqueous EtOH). [*Beilstein* **12** IV 2183.]

***sym*-Tri-*tert*-butylbenzene (1,3,5-tri-*tert*-butylbenzene)** *[1460-02-2]* **$C_{18}H_{30}$, M 246.4, m 67° to 72°, 73.4-73.9°, b 121-122°/12mm.** Crystallise it from EtOH. [*Beilstein* **5** IV 1206.]

2,4,6-Tri-*tert*-butylphenol *[732-26-3]* **$C_{18}H_{30}O$, M 262.4, m 125-130°, 129-132°, 131°, 131-131.2°, b 131°/1mm, 147°/10mm, 278°/760mm, pK^{25} 12.19.** Distil the phenol under reduced pressure and/or recrystallise it from *n*-hexane or several times from 95% EtOH until the EtOH solution is colourless [Balasubramanian & Bruice *J Am Chem Soc* **108** 5495 *1986*, DOI: 10.1021/ja00278a021]. It has also been purified by sublimation [Yuan & Bruice *J Am Chem Soc* **108** 1643 *1986*, DOI: 10.1021/ja00267a039; Wong et al. *J Am Chem Soc* **109** 3428 *1987*, DOI: 10.1021/ja00245a039]. Purification has also been achieved by passage through a silica gel column followed by recrystallisation from *n*-hexane [Kajii et al. *J Phys Chem* **91** 2791 *1987*, DOI: 10.1021/j100295a029]. [*Beilstein* **6** III 2094, **6** IV 3539.]

2',2',2'-Trichloroacetanilide *[2563-97-5]* **$C_8H_6Cl_3NO$, M 238.5, m 93.5-94°, 95°.** Crystallise the anilide from *benzene or 90% EtOH (**m 93.5-95.5°**). [Sukornick *Org Synth* Coll Vol **5** 1074 *1973*, DOI: 10.15227/ orgsyn.040.0103; *Beilstein* **12** H 224, **12** I 193, **12** II 142, **12**III 464, **12** IV 377.]

2,3,4-Trichloroaniline *[634-67-3]* **$C_6H_4Cl_3N$, M 196.5, m 65-67°, 67.5°, b 292°/774mm, pK_{Est} ~1.3.** Recrystallise it from ligroin. The ***acetanilide*** has **m 120-122°** (from EtOH or *C_6H_6). [*Beilstein* **12** H 626.]

2,4,5-Trichloroaniline *[636-30-6]* **$C_6H_4Cl_3N$, M 196.5,** has **m 93-95°, 96.5°, b 270°/760mm, pK 1.09.** Crystallise the aniline from ligroin. [*Beilstein* **12** H 627, **12** IV 1277.]

2,4,6-Trichloroaniline *[634-93-5]* **$C_6H_4Cl_3N$, M 196.5,** has **m 73-75°, 75-79°, 74°, 77°, 78°, 78.5°, b 127°/14mm, 262°/746mm, pK^{25} 0.03.** Crystallise the aniline from ligroin. The ***benzoyl*** derivative has **m 174°** (from EtOH). [*Beilstein* **12** H 627, **12** IV 1281.]

1,2,3-Trichlorobenzene *[87-61-6]* **$C_6H_3Cl_3$, M 181.5, m 51-55°, 52.6°, 53°, 54°, 55°, 218-219°/740mm, d 1.69.** Crystallise it from EtOH. [*Beilstein* **5** IV 664.]

1,2,4-Trichlorobenzene *[120-82-1]* **$C_6H_3Cl_3$, M 181.5,** has **m 16.9°, 17°, b 210°/atm, 214.6°/760m, d 1.454.** Separate it from isomers by washing with fuming H_2SO_4, then water, drying with $CaSO_4$ and slowly fractionally distilling. [Jensen et al. *J Am Chem Soc* **81** 3303 *1959*, DOI: 10.1021/ja01522a038; *Beilstein* **5** IV 664.]

1,3,5-Trichlorobenzene *[108-70-3]* **$C_6H_3Cl_3$, M 181.5, m 62-65°, 63°, 64°, 64-65°, 208°/740mm.** Recrystallise it from dry *benzene or toluene. [*Beilstein* **5** IV 666.]

3,4,5-Trichloro-*o*-cresol (3,4,5-trichloro-2-methylphenol) *[608-92-4]* **$C_7H_5Cl_3O$, M 211.5, m 77°, pK_{Est} ~7.6.** Crystallise the cresol from petroleum ether.
***2,3,5-Trichloro-p-cresol* (2,3,5-trichloro-4-methylphenol)** *[608-91-3]* has **m 66-67°, pK_{Est} ~6.9.** Crystallise the cresol from petroleum ether. [Datta & Mitter *J Am Chem Soc* **41** 2028 *1919*, DOI: 10.1021/ja02233a020; *Beilstein* **6** I 204.]

2,4,5-Trichloro-1-nitrobenzene (1,2,4-trichloro-5-nitrobenzene) *[89-69-0]* **$C_6H_2Cl_3NO_2$, M 226.5, m 52-57°, 57°, 288°/740mm, d^{25} 1.79g/ml.** Crystallise it from EtOH. Its solubility in H_2O is 0.27w/v% at 20°. [*Beilstein* **5** IV 728.]

3,4,6-Trichloro-2-nitrophenol *[82-62-2, 4524-78-1]* **$C_6H_2Cl_3NO_3$, M 226.5, m 92-93°, pK_{Est} ~4.1.** Crystallise the nitro-phenol from petroleum ether or EtOH. [*Beilstein* **6** III 842.]

2,4,5-Trichlorophenol *[95-95-4]* **$C_6H_3Cl_3O$, M 197.5, m 67°, 67-69°, b 72°/1mm, 248°/740mm, d^{25} 1.79g/ml, pK^{25} 7.0.** Crystallise the phenol from EtOH or petroleum ether. [*Beilstein* **6** IV 962.]
2,4,6-Trichlorophenol *[88-06-2]* has **m 67-68°, 69°, b 246°/760mm, d^{25} 1.675g/ml, pK^{25} 6.23.** Crystallise the phenol from *benzene, EtOH or EtOH/water. [*Beilstein* **6** IV 1005.] It is an environmental pollutant.
3,4,5-Trichlorophenol *[609-19-8]* has **m 100°, d^{25} 1.80g/ml, pK^{25} 7.84.** Crystallise the phenol from petroleum ether/*benzene mixture. [*Beilstein* **6** III 729.]

2,4,5-Trichlorophenoxyacetic acid (2,4,5-T) *[93-76-5]* **$C_8H_5Cl_3O_3$, M 255.5, m 153°, 155-158°, pK^{25} 2.83.** Crystallise this phenoxyacid from *benzene. **[***Beilstein* **6** III 721.] It is a herbicide, and **CANCER SUSPECT.**

1,2,4-Triethylbenzene *[877-44-1]* **$C_{12}H_{18}$, M 162.3, b 96.8-97.1°/12.8mm, 215°/atm, d_4^{20} 0.8738, n_D^{20} 1.5015.** For separation from a commercial mixture see Dillingham and Reid [*J Am Chem Soc* **60** 2606 *1938*, DOI: 10.1021/ja01278a014]. [*Beilstein* **5** IV 1133.]
1,3,5-Triethylbenzene *[102-25-0, 102-49-0, 25340-18-5]* has **m -67.1°, -66°, -65.5°, b 136.85-137.15°, 215.9°/atm, 217.5°/760mm, d_4^{20} 0.8631, n_D^{20} 1.4957.** For separation from a commercial mixture see Dillingham and Reid [*J Am Chem Soc* **60** 2606 *1938*, DOI: 10.1021/ja01278a014]. The separation was done by fractionation at atmospheric pressure in a 125-plate miniature Hyper-Cal column and the middle fraction containing about 80% of the distillate was collected and found to be free from isomeric and other impurities (purity is 99.0-99.5 mole% from freezing point data). The IR (film) has ν_{max} 865 cm^{-1}. [McCaulay et al. *J Am Chem Soc* **76** 2354 *1954*, DOI: 10.1021/ja01638a020; *Beilstein* **5** IV 1133.]

4-(Trifluoromethyl)acetophenone *[709-63-7]* **$C_9H_7F_3O$, M 188.2, m 29-35°, 31°, 32°, 31-33°, b 79-81°/9mm, 81-84°/8-9mm, d^{25} 0.924g/ml.** Purify the ketone by distillation or sublimation *in vacuo*. [*Beilstein* **7** IV 1404.]

3-Trifluoromethyl-4-nitrophenol (TFN) *[88-30-2]* **$C_7H_4F_3NO_3$, M 162.1, m 81°, b 135-138°/0.01mm, pK_{Est} ~6.1.** Crystallise the nitrophenol from *benzene or from petroleum ether/*benzene mixture. [*Beilstein* **6** III 1328.] It is a lampricide and is poisonous to amphibians— an environmental hazard.

α,α,α-Trifluorotoluene (benzotrifluoride) *[98-08-8]* **$C_7H_5F_3$, M 146.1, m -29°, b 102.5°/atm, d_4^{20} 1.190, n^{30} 1.4100.** Purify benzotrifluoride by repeated treatment with boiling aqueous Na_2CO_3 (until no test for chloride ion is obtained), dry it with K_2CO_3, then with P_2O_5, and fractionally distil it. [*Beilstein* **5** IV 802.]

2,3,4-Trihydroxybenzoic acid *[610-02-6]* **$C_7H_6O_5$, M 170.1, m 207-208°, 210°(dec), 221°, $pK_{Est(1)}$~3.4, $pK_{Est(2)}$~7.8, $pK_{Est(3)}$>12.** Crystallise the acid from water. [*Beilstein* **10** IV 1971.]

2,4,6-Trihydroxybenzoic acid *[83-30-7]* **$C_7H_6O_5$, M 170.1, m 205-212°(dec), $pK_{Est(1)}$~1.5, $pK_{Est(2)}$~8.0, $pK_{Est(3)}$>12.** Crystallise the acid from water which provides crystals of a *monohydrate* [*Beilstein* **10** IV 1987.]

3,4,5-Triiodobenzoic acid *[2338-20-7]* **$C_7H_3I_3O_2$, M 499.8, m 289-290°, 292.5°, 293°, pK^{25} 0.65.** Crystallise the acid from aqueous EtOH or water. [*Beilstein* **9** H 367, 9 III 1475.]

3,4,5-Triiodobenzyl chloride *[52273-54-8]* **$C_7H_4Cl_3$, M 504.4, m 138°.** Crystallise the chloride from CCl_4/petroleum ether (charcoal).

Trimellitic (benzene-1,2,4-tricarboxylic) acid *[528-44-9]* **$C_9H_6O_6$, M 210.1, m 218-220°, pK_1^{25} 2.42, pK_2^{25} 3.71, pK_3^{25} 5.01.** Crystallise the acid from acetic acid or aqueous EtOH. [*Beilstein* **9** IV 3746.]

1,2,3-Trimethoxybenzene *[634-36-6]* **$C_9H_{12}O_3$, M 168.2, m 43-47°, 45-46°, b 241°/atm, d^{25} 1.112.** Sublime it under vacuum. Used for studies of the solvent effects on photoinduced electron-transfer reactions [Niwa et al. *J Phys Chem* **97** 11960 *1993*, DOI: 10.1021/j100148a019]. [*Beilstein* **6** I 540, **6** II 1066, **6** III 6265, **6** IV 7329.]
1,3,5-Trimethoxybenzene *[621-23-8]* has **m 50-53°, 53°, b 255°/atm,** Sublime it under vacuum. Its solubility in MeOH is ~0.1g/ml at ~20°. [*Beilstein* **6** III 635, **6** IV 7362.]

3,4,5-Trimethoxyphenol (Antiarol) *[642-71-7]* **$C_9H_{12}O_4$, M 184.2, m 146°, 145-149°, pK_{Est} ~9.4.** Recrystallise the phenol from 10 times its weight of H_2O (white needles, **m** 148°). The ***acetyl*** derivative crystallises as elongated prisms from EtOH with **m 74°.** [Chapman et al. *J Chem Soc* 3028 *1927*, DOI: 10.1039/JR9270003015; Shriner et al. *J Am Chem Soc* **61** 2322 *1939*, DOI: 10.1021/ja01878a017; *Beilstein* **6** H 1154, **6** II 1118, **6** III 6656.]

1,2,4-Trimethylbenzene (pseudocumene) *[95-63-6]* **C_9H_{12}, M 120.2, m -43.78°, b 51.6°/10mm, 167-168°/760mm, d_4^{20} 0.889, n_D^{20} 1.5048.** Reflux pseudocumene over sodium and distil it under reduced pressure. [*Beilstein* **6** H 1088, **6** I 542, **6** II 1072, **6** III 6278, **6** IV 7339.]

2,4,6-Trimethylbenzoic acid (mesitoic acid) *[480-63-7]* **$C_9H_{12}O_2$, M 164.2, m 152°, 153-155°, 154°, 155°, pK^{25} 3.45.** Crystallise mesitoic acid from water, ligroin or carbon tetrachloride [Ohwada et al. *J Am Chem Soc* **108** 3029 *1986*, DOI: 10.1021/ja00271a036]. [*Beilstein* **9** H 553, **9** I 214, **9** II 360, **9** III 2489, **9** IV 1854.]

Trimethyl-1,4-benzoquinone *[935-92-2]* **$C_9H_{10}O_2$, M 150.1, m 29-30°, 36°, b 98°/10mm, 108°/18mm, 215.3°/760mm, d 1.1, n 1.501.** Distil the quinone in a vacuum or sublime it *in vacuo* before use. It is prepared in 96-100% yield by oxidation of 2,3,6-trimethylphenol with H_2O_2 over Ti(I) grafted on commercial mesoporous silica [Kholdeeva et al. *Green Chem* **9** 731 *2007*, DOI: 10.1039/B617162A]. A quantitative structure-activity relationship of trimethylbenzoquinone, among many other quinones, in the two-electron reduction by *Enterobacter cloacae* NAD(P)H:nitroreductase was evaluated by Nivinskas et al. [*Arch Biochem Biophys* **403** 249 *2002*, DOI: 10.1016/S0003-9861(02)00228-X]. [*Beilstein* **7** H 161, **7** III 3407, **7** IV 2098.]

Trimethyl-1,4-hydroquinone (2,3,5-trimethylbenzene-1,4-diol) *[700-13-0]* **$C_9H_{12}O_2$, M 152.2, m 169-174°, 173-174°, b 298.3°/760mm, d^{25} 1.126g/ml, $pK_{Est(1)}$~ 11.1, $pK_{Est(2)}$~ 12.7.** Recrystallise the hydroquinone from water, under anaerobic conditions. [*Beilstein* **6** H 931, **6** IV 5997.]

2,3,5-Trimethylphenol *[697-82-5]* **$C_9H_{12}O$, M 136.2, m 92-95°, 95-96°, b 233°/760mm, d^{25} 0.763g/ml, pK^{25} 10.67.** Crystallise the phenol from water or petroleum ether. [*Beilstein* **6** IV 3248.]
2,4,5-Trimethylphenol *[496-78-6]* has **m 70.5-71.5°, 72°, b 232°/760mm, d^{25} 1.00g/ml, n_D^{20} 1.55, pK^{25} 10.57.** Crystallise the phenol from water. [*Beilstein* **6** H 509, **6** I 255, **6** II 482, **6** III 1831, **6** IV 3247.]
2,4,6-Trimethylphenol *[527-60-6]* has **m 69°, 70-74°, 72°, 73°, b 220-221°/760mm, pK^{25} 10.86.** Crystallise the phenol from water and sublime it *in vacuo*. [*Beilstein* **6** IV 3253.]
3,4,5-Trimethylphenol *[527-54-8]* has **m 104-108°, 107°, b 248-249°/760mm, pK^{25} 10.25.** Crystallise the phenol from petroleum ether. [*Beilstein* **6** IV 3245.]

Trimethylphenylammonium benzenesulfonate *[3426-74-2, 16093-66-6]* **$C_{15}H_{19}NO_3S$, M 293.3.** Crystallise it repeatedly from MeOH (charcoal). [*Beilstein* **12** IV 249.]

2,4,6-Trinitroanisole *[606-35-9]* **$C_7H_5N_3O_7$, M 243.1, m 68°, d^{25} 1.632g/ml.** Recrystallise it from EtOH or

MeOH. Dry it *in vacuo*. [*Beilstein* **6** H 288, **6** I 140, **6** II 280, **6** III 968, **6** IV 1456.]

1,3,5-Trinitrobenzene *[99-35-4]* **$C_6H_3N_3O_6$, M 213.1, m 122°, 122-123°.** Crystallise it from glacial acetic acid, $CHCl_3$, CCl_4, EtOH aqueous EtOH or EtOH/*benzene, after (optionally) heating with dilute HNO_3. Dry it in air. Fuse it and crystallise it under vacuum. [*Beilstein* **5** H 271, 5 I 140, **5** II 203, **5** III 643, **5** IV 754.]

2,4,6-Trinitrobenzoic acid *[129-66-8]* **$C_7H_3N_3O_8$, M 257.1, m 227-228°, 229°, pK^{25} 0.65.** Crystallise the acid from distilled H_2O. Dry in a vacuum desiccator. The ***amide*** has **m 264°** (from EtOH). [*Beilstein* **9** H 417, **9** I 168, **9** II 285, **9** III 1956, **9** IV 1362.]

2,4,6-Trinitro-*m*-cresol *[602-99-3]* **$C_7H_5N_3O_7$, M 243.1, m 107.0-107.5°, b 320.9°/760mm, d^{25} 1.74g/ml, pK^{25} 2.8.** Crystallise the yellow cresol successively from H_2O, aqueous EtOH and *benzene/cyclohexane, then dry at 80° for 2 hours. [Davis & Paabo *J Res Nat Bur Stand* **64A** 533 *1960*, DOI:org/10.6028/jres.064A.055; *Beilstein* **6** H 387, **6** I 194, **6** II 363, **6** III 1331, **6** IV 2079.]

2,4,7-Trinitro-9-fluorenone *[129-79-3]* **$C_{13}H_5N_3O_7$, M 315.2, m 176°, 176-178°.** Crystallise it from nitric acid/water (3:1), wash it with water and dry it under vacuum over P_2O_5, or recrystallise it from dry *benzene. [*Beilstein* **7** II 410, **7** III 2348, **7** IV 1638.]

2,4,6-Trinitrotoluene (TNT) *[118-96-7]* **$C_7H_5N_3O_6$, M 227.1, m 80°, 80.35°, 81.0-81.5°, b 295°/760mm (decomposes, avoid distilling due to possible explosive nature), d^{25} 1.65g/ml.** Crystallise TNT from *C_6H_6 or EtOH. Then fuse **(CARE)** and allow to crystallise under vacuum. Gey, Dalbey and Van Dolah [*J Am Chem Soc* **78** 1803 *1956*, DOI: 10.1021/ja01590a008] dissolved TNT in acetone and added cold water (1:2:15), the precipitate was filtered off, washed free from solvent and stirred with five parts of aqueous 8% Na_2SO_3 at 50-60° for 10 minutes. This was filtered, washed with cold water until the effluent was colourless, and air dried. The product was dissolved in five parts of hot CCl_4, washed with warm water until the washings were colourless and TNT was recoverd by cooling and filtering. It was recrystallised from 95% EtOH and carefully dried over H_2SO_4. The dry solid should not be heated without taking precautions for a possible **EXPLOSION**. Work with small quantities. Irritates skin, mucous membrane, causes liver damage, jaundice; cyanosis, sneezing, cough, sore throat and muscle pain — **do not inhale it**. [*Beilstein* **5** H 347, **5** I 172, **5** II 268, **5** III 767, **5** IV 873.]

2,4,6-Trinitro-*m*-xylene *[632-92-8]* **$C_8H_7N_3O_6$, M 241.2, m 182.2°.** Crystallise the xylene from ethyl methyl ketone. [*Beilstein* **5** H 381, **5** I 185, **5** II 295, **5** III 845, **5** IV 950.]

Triphenylamine *[603-34-9]* **$C_{18}H_{15}N$, M 245.3, m 123-126°, 125-129°, 125-127°, 127°, 127.3-127.9°, b 347-348°/atm, 365°/atm, d^{25} 0.77g/ml, pK^{25} -5.0 (in fluorosulfuric acid).** Crystallise the amine from EtOH or from *benzene/absolute EtOH, diethyl ether and petroleum ether. It is sublimed under vacuum and carefully dried in a vacuum line. Store it in the dark under nitrogen. [*Beilstein* **12** IV 276.]

1,3,5-Triphenylbenzene *[612-71-5]* **$C_{24}H_{18}$, M 306.4, m 171-172°, 173-175°, 176°, 460°/atm, d$_4^0$ 1.205.** Purify it by chromatography on alumina using *benzene or petroleum ether as eluents. Crystallise the triphenylbenzene from EtOH (**m 174°**). [*Beilstein* **5** H 737, **5** I 370, **5** II 670, **5** III 2563, **5** IV 2732.]

Triphenylene (9,10-benzophenanthrene) *[217-59-4]* **$C_{18}H_{12}$, M 228.3, m 195-198°, 198°, b 425°/atm, 438°/atm.** Purify triphenylene by zone refining or crystallisation from EtOH or $CHCl_3$ and sublimation. Its fluorescence has λ_{ex} at 265nm and λ_{em} at 372nm in cyclohexane. [*Beilstein* **5** IV 2556.]

***RS*-(±)-1,1,2-Triphenyl-1,2-ethanediol** *[6296-95-3]*, ***R*-(+)-1,1,2-triphenyl-1,2-ethanediol** *[9506-46-4]*, and ***S*-(-)-1,1,2-triphenyl-1,2-ethanediol** *[108998-83-0]* **$C_{20}H_{18}O_2$, M 290.4, m 167-167.5°, 167-168° for *RS*, m 126°, 128-129° for *R*-enantiomer, $[\alpha]_D^{25}$ +213.8 to 214.6 (c 1, EtOH), $[\alpha]_D^{25}$ +220 (c 1, 95% EtOH), m 128-129° for *S-enantiomer* and $[\alpha]_D^{25}$ -214.6 (EtOH), -217(c 1, EtOH).** The racemate is prepared by condensation of benzophenone, thus benzaldehyde (10.6g, 0.1 mole) in dry Et_2O (50ml) is added to a stirred solution of disodio-benzophenone (0.1 mole prepared from benzophenone and Na in liquid NH_3) in liquid NH_3 (250ml), whereby the black solution turned to light blue. The NH_3 is evaporated off and replaced by Et_2O, and the susp-

ension is then poured into Et_2O (100ml) containing glacial acetic acid (30ml) to which is added H_2O and the two layers are separated. The organic layer is washed with saturated $NaHCO_3$ and dried (Drierite), then evaporated to give a white solid which is dissolved in hot *C_6H_6 (25ml) and diluted with 4 volumes of petroleum ether (b 30-60°) whereby white crystals deposited (26.5g, 91%) with **m 167-168°**. [Hamrick & Hauser *J Am Chem Soc* **81** 493 *1959*, DOI: 10.1021/ja01511a058] The ***RS*-diol**, prepared by a crossed pinacol reaction, has **m 167-168°** (from hexane/EtOAc 6:1) and IR (CH_2Cl_2) with ν_{max} at 3550, 3440 (OH), 3050, 3015, 1590 and 1480 (HC=C) cm^{-1}, and ^1H NMR with δ at 1.45 (1H, d, *J* = 3.2Hz, CHO*H*), 3.14 (1H, s, CO*H*), 5.60 (1H, d, *J* = 3.2Hz, C*H*O), 7.02-7.17, 7.24-7.32, 7.36-7.41 (15H 4m, ArH); ^{13}C NMR with δ at 77.95 (*C*HO), 80.75 (*C*O), 126.15, 126.7, 127.0, 127.35, 127.45, 127.6, 127.7, 128.05, 128.45, 138.75, 143.35 and 145.05 (Ar*C*); and MS with *m/z* 183 (M^+ -107, 15%), 105 (61%), 78 (28%) and 77 (100%). [Guijarro et al. *Tetrahedron* **49** 1327 *1993*, DOI: 10.1016/S0040-4020(01)85822-1]

The optical isomers, e.g. ***R*-(+)-1,1,2-triphenyl-1,2-ethanediol**, are prepared from their respective chiral methyl mandelates {see [*R*-(-)-methyl mandelate *[20698-91-3]* above} where the configuration at the chiral center is retained. Thus *R*-(-)-methyl mandelate (15.og 500mmol) in dry THF (100ml) is added, slowly during 20-30 minutes, to a stirred solution under N_2 of phenylmagnesium bromide [prepared from Mg powder (12.15g, 500mmol) in THF (100ml) and bromobenzene (3ml) to start the reaction, followed by more bromobenzene (39ml) in THF (200ml) and boiled under reflux for 3 hours, then cooled to 5-10°], stirred for 2 hours below 10° then refluxed for 3 to 5 hours. The stirred mixture is cooled in an ice bath, treated with saturated aqueous NH_4Cl (200ml) and neutralised with 5% aqueous HCl. The organic layer is collected, the aqueous phase is extracted with $CHCl_3$, the combined organic phases and washed with H_2O, dired (Na_2SO_4), filtered and the filtrate is evaporated to dryness under vacuum. The residue is recrystallised from CH_2Cl_2 (50ml) to give the ***R*-diol** (17.0-18.6g, 65-71% yield) with **m 126°**, **$[\alpha]_D^{25}$ +213.8 to +214.6 (c 1 EtOH)** and IR (KBr) with ν_{max} at 3500—3300, 1495, 1450, 1170 1060, 1005, 770, 750, 735 and 695 cm^{-1}, and ^1H NMR (90MHz, $CDCl_3$, TMS) has δ at 2.42 (1H, d, *J* = 4Hz, PhCHO***H***), 3.11 (1H, s, *J* = 4Hz, Ph_2CO***H***), 5.64 (1H, d, *J* = 4Hz, PhC***H***OH), 6.97—7.48 (13H, m, Ar-***H***), 7.60-7.77 (2H, m, Ar-***H***); and MS (70eV) has *m/z* (%): 272 (1), 256 (3), 243 (6), 183 (100), 165 (10), 105 (70), 77 (36). [For the synthesis of *R*(+)- and *S*(-)- diols and acetates see Devant et al. *Chem Ber* **121** 397 *1988*, DOI: 10.1002/cber.19881210303; and Braun et al. *Org Synth* **72** 32 *1995*, DOI: 10.15227/ orgsyn.072.0032; Braun e-EUROS 15 April 2001, DOI: 10.1002/047084289X.rt363; *Beilstein* **6** I 510.] The optically acive diols form 2:1 inclusion compounds with racemic compounds to form diastereoisomeric complexes which have very different solubilities and therefore effect clean optical resolutions, see for example *Lansoprazole* obtained in 99.9%ee see in 'Physiologically Active Compounds', Chapter 6.

For the 2-acetates and their stereospecific aldol condensations *via* the doubly deprotonated acetate methyl group see **2-Hydroxy-1,2,2-triphenylacetate** above.

1,2,3-Triphenylguanidine *[101-01-9]* **$C_{19}H_{17}N_3$, M 287.3, m 144°, 144-147°, d ^{25} 1.16g/ml, , pK^{25} 9.10.** Crystallise the guanidine from EtOH or EtOH/water. Dry it *in vacuo*. It is a fairly strong base, store in the absence of CO_2. [*Beilstein* **12** H 451, **12** I 261, **12** II 246, **12** III 907, **12** IV 866.]

Triphenylmethane *[519-73-3]* **$C_{19}H_{16}$, M 244.3, m 90-92°, 92-93°, 93°, 94°, 358-359°/atm, d ^{25} 1.014g/ml.** Crystallise triphenylmethane from EtOH or *benzene (with one molecule of *benzene of crystallisation which is lost on exposure to air or by heating on a water bath). It can also be sublimed under vacuum. It has been given a preliminary purification by refluxing with tin and glacial acetic acid, then filtered hot through a glass sinter disc, and precipitated by addition of cold water. [*Beilstein* **5** H 698, **5** IV 2495.]

Triphenylmethanol (triphenylcarbinol) *[76-84-6]* **$C_{19}H_{16}O$, M 260.3, m 161-164°, 162°, 163°, 164°, 164.2°, b 360-380°/atm (without dec), d ^{25} 1.189g/ml, pK^{25} -6.63 (aqueous H_2SO_4).** Crystallise the carbinol from EtOH, MeOH, CCl_4 (4ml/g), *benzene, hexane or petroleum ether (b 60-70°). Dry it at 90°. [Ohwada et al. *J Am Chem Soc* **108** 3029 *1986*, DOI: 10.1021/ja00271a036; *Beilstein* **6** IV 5014.]

Triphenylmethyl chloride (trityl chloride) *[76-83-5]* **$C_{19}H_{15}Cl$, M 278.8, m 109-112°, 110-112°, 111-112°, b 230-235°/20mm, d ^{25} 1.141g/ml.** Crystallise trityl chloride from iso-octane. Also crystallise it from 5 parts of petroleum ether (b 90-100°) and 1 part of acetyl chloride using 1.8g of solvent per g of chloride. Dry it in a desiccator over soda lime and paraffin wax, and store it under N_2 in aliquots. Its solubility in $CHCl_3$ is 0.1g/ml at ~20°. [Bachman *Org Synth* Coll Vol **3** 841 *1955*, DOI: 10.15227/orgsyn.023.0100; Thomas & Rochow *J Am*

Chem Soc **79** 1843 *1957*, DOI: 10.1021/ja01565a021; Meisel et al. *J Am Chem Soc* **108** 4706 *1986*, DOI: 10.1021/ja00276a004; *Beilstein* **5** H 750, **5** I 346, **5** II 615, **5** III 2315, **5** IV 2497.] It is moisture sensitive, store in a well sealed container. It is used to introduce a trityl protecting group. **LACHRYMATORY**.

dl*-Tropic [(3-hydroxy-2-phenylpropionic) acid, Tropaic acid]** *[529-64-6, 552-63-6, 28845-94-5]* **$C_9H_{10}O_3$, M 166.2, m 116-117°, 118°, pK^{25} 4.12.** Tropic acid crystallises from H_2O or *C_6H_6 in needles or plates. Its solubility in MeOH is 0.1g/ml at ~20°. It is the (±)-acid component (*dl*-tropyl ester) of atropine *[51-55-8]*. It is best prepared from acetophenone cyanohydrin *via* atrolactic acid *[515-30-0]* **m** 94.5° (anhydr), atropic acid *[492-38-6]* **m 106-107°**, ***chlorohydratropic acid followed by hydrolysis of the latter in boiling aqueous 1.73N Na_2CO_3 in high yielding steps. No racemisation occurred when chiral intermediates were used (see next entry). [McKenzie & Wood *J Chem Soc* **115** 828 *1919*, DOI: 10.1039/CT9191500828; McKenzie & Strathern *J Chem Soc* **127** 82 *1925*, DOI: 10.1039/CT9252700082.] [*Beilstein* **10** IV 664.]
***S*(–)-*Tropic acid* [(–)3-hydroxy-2-phenylpropionic acid]** *[16202-15-6]* has **m 128-129°, $[\alpha]_D^{13}$ –72.5 (c 2.6, EtOH), $[\alpha]_D^{15}$ –79.0 (c 1.5, H_2O), $[\alpha]_D^{15}$ –83.3 (c 1.8, Me_2CO).** It is the (–)-acid component of ***l*-hyoscyamine** (i.e *l*-tropyl atropine, *[101-31-5]*). It has been prepared by optical resolution of (±)-tropic acid using the quinine diastereomeric salt for obtaining ***R*(+)-tropic acid** *[529-64-6]*, and then with the morphine diastereomeric salt for obtaining the **natural (–)-tropic acid**. The salts were hydrolysed with dilute H_2SO_4, extracted thoroughly into Et_2O, dried (Na_2SO_4), evaporated, and the residue was recrystallised from *C_6H_6 (in which it is sparingly soluble) to give lustrous needles **m 128-129°**. It also crystallises from H_2O in glassy needles and plates grouped in rosettes. The enantiomer, obtained in the same way, has identical properties except for opposite optical rotations. [McKenzie & Wood *J Chem Soc* **115** 828 *1919*, DOI: 10.1039/CT9191500828; McKenzie & Strathern *J Chem Soc* **127** 86 *1925*, DOI: 10.1039/CT9252700082]. The absolute configuration of the (–)-tropic acid was deduced as *S*- by conversion into (+)-alanine. [Fedor & Csepreghy *J Chem Soc* 3222 *1961*, DOI: 10.1039/JR9610003222; for enzymic kinetic resolution see Klomp et al. *Tetrahedron Asymmetry* **16** 3892 *2005*, DOI: 10.1016/j.tetasy.2005.10.032.]

Tropolone (2-hydroxycyclohepta-2,4.6-trien-1-one) *[533-75-5]* **$C_7H_6O_2$, M 122.1, m 49-50°, 50-52°, b 81-84°/0.1mm, pK$_1^{25}$ -0.53 (protonation of CO, aqueous H_2SO_4), pK$_2^{25}$ 6.67 (acidic OH).** Crystallise tropolone from hexane or petroleum ether and sublime it at 40°/4mm. Also distil it at high vacuum. Store it at 2-8°. [Pauson *Chem* Rev **55** 9 *1955*, DOI: 10.1021/cr50001a002; *Beilstein* **8** IV 159.] It complexes with Cu^{2+}, Ga^{3+}, In^{3+} among other metals.

Tropone (2,4,6-cycloheptatrien-1-one) *[539-80-0]* **C_7H_6O, M 106.1, m -7°, b 92-95°/0.25mm, 91-92°/4mm, 113°/15mm, d^{25} 1.094, n$_D^{20}$ 1.615.** Among the various syntheses, tropone was prepared by the oxidation of cycloheptatriene with SeO, and purified by bulb-to-bulb distillation (20-110°/0.05mm) with Dry-Ice cooling, then fractionally redistilled at 0.25mm as a pale yellow oil. Its IR ($CHCl_3$) has ν_{max} at 3000, 1630, 1580, 1515, 1470, 1210 cm^{-1}, and ^1H NMR ($CDCl_3$, 300MHz) with δ at 6.88-7.11 (several multiplets, 6H). [Dahnke & Paquette *Org Synth* Coll Vol **9** 396 *1998*, DOI: 10.15227/orgsyn.071.0181; *Beilstein* **7** IV 501.]

Tyramine (4-hydroxyphenethylamine) *[51-67-2]* **$C_8H_{11}NO$, M 137.2, m 160-162°, 164-165°, b 166°/2mm 175-181°/8mm, 205-207°/25mm pK$_1^{25}$ 9.74 (OH), pK$_2^{25}$ 10.52 (NH_2).** Crystallise tyramine from *benzene or EtOH; and/or distil it in a vacuum. Its solubility (~15°) in H_2O is 1.1w/v%, and in EtOH it is 10/v%. It is a strong base and should be stored under N_2 away from CO_2, or better to keep it as the hydrochloride salt (see below). [*Beilstein* **13** IV 1788.] It can enter the catecholamineric terminals and be released as a false transmitter [Bunzow et al. *Mol Pharmacol* **60** 1181 *2001*, DOI: 10.1124/mol.60.6.118] ***Tyramine hydrochloride*** *[60-19-5]* **$C_8H_{11}NO.HCl$, M 173.6,** has **m 269°, 271-274°, 274°, 274-276°.** Crystallise the hydrochloride from EtOH by addition of diethyl ether, or from concentrated HCl. An aqueous solution has a pH of ~7. [*Beilstein* **3** II 355.] See previous entry for pharmacological activity.

Vanillin (4-hydroxy-3-methoxybenzaldehyde) *[121-33-5]* **$C_8H_8O_3$, M 152.2, m 81-83°, 81-84°, 81.5°, 82°, 83°, b 170°/15mm, 285°/atm, pK^{25} 7.40.** Crystallise vanillin from water or aqueous EtOH, or by distillation *in vacuo*. [*Beilstein* **8** IV 1763.] It is a food flavouring substance.

Veratraldehyde (vanillin methyl ether) *[120-14-9]* **$C_9H_{10}O_3$, M 166.2, m 40-43°, 42-43°, b 281°/atm,** Crystallise the ether from diethyl ether, petroleum ether, CCl_4 or toluene. [*Beilstein* **8** IV 1765.] It is a flavor and fragrance agent.

Variamine Blue RT [4-aminodiphenylamine diazonium HSO_4, 4-(phenylamino)benzenediazonium sulfate (1:1)] *[4477-28-5]* **$C_{12}H_{10}N_3.HSO_4$, M 293.3, m (of the chloride) 120°(dec), 168-170° (dec), CI 37240, λ_{max} 377 nm.** Dissolve 10g of the dye in 100ml of hot water. Sodium dithionite (0.4g) is then added, followed by active carbon (1.5g) and is filtered hot. To the colourless or slightly yellow filtrate a solution of saturated NaCl is added, and the mixture is cooled. The needles are filtered off, washed with cold water, dried at room temperature, and stored in a dark bottle (light sensitive). [Anderson & Steedly *J Am Chem Soc* **76** 5144 *1954*, DOI: 10.1021/ja01649a043.] This diazonium salt is used in the spectrophotometric determination of uric acid in urine (or serum) based on an enzymatic method with Uricase which liberates H_2O_2 that reacts with the diazonium salt and changes its colour from yellow to pale yellow-green. The assay is performed in a pH 9.0 buffer, and the change in absorption at 269nm is measured, with a limit of sensitivity of 0.5—13mM. [Hamzah et al. *J Anal Bioanal Tech* **S7:011** 2155 *2013*, DOI: 10.4172/2155-9872.S7-011.] [For *Variamine blue as a gravimetric reagent: Determination of tungsten* see Erdey et al. *Talanta* **14** 515 *1967*, DOI: 10.1016/0039-9140(67)80078-X; Erdey *Chemist-Analyst* **48** 106 *1959*, *Beilstein* **16** H 602, **16** I 371, **16** II 307, **16** III 575.]

9-Vinylanthracene *[2444-68-0]* **C_9H_{12}, M 204.3, m 61-64°, 62-65°, 64°, 65-67°, b 61-66°/10mm.** Purify it by vacuum sublimation. It has also been purified by chromatography on silica gel with cyclohexane as eluent, and recrystallised from EtOH [Werst et al. *J Am Chem Soc* **109** 32 *1987*, DOI: 10.1021/ja00235a005]. [*Beilstein* **5** IV 2415.]

4-Vinylbenzyl chloride (VBC, 4-chloromethylstyrene) *[1592-20-7]* **C_9H_9Cl, M 152.6, b 58-62°/0.4mm, 75.5-79°/2mm, 229°/760mm, d^{25} 1.083, n_D^{20} 1.572.** Purify 4-vinylbenzyl chloride by dissolving it in Et_2O, washing it with 0.5% of aqueous NaOH, separating, drying the organic layer (Na_2SO_4), evaporating and distilling the residual oil under N_2 *in vacuo*. Add 0.05% of 4-*tert*-butylcatechol as stabiliser. Store it at 4°. It is **lachrymatory.** [Nishikubo et al. *Tetrahedron Lett* **22** 3873 *1981*, DOI: 10.1016/S0040-4039(01)91332-2; Tanimoto et al. *Synth Commun* **4** 193 *1974*, DOI:10.1080/00397917408062071; *Beilstein* **6** IV 3818.]

1-Vinylnaphthalene *[826-74-4, 92529-36-7]* **$C_{14}H_{10}$, M 154.2, b 68-69°/0.4mm, 100-101°/3.7mm, 124-125°/15mm, 135-138°/atm, d^{25} 1.040g/ml, n_D^{20} 1.653.** Commercial material can contain up to 2% of poly-1-vinylnaphthalene. Fractionally distil it under reduced pressure using a spinning-band column, dry it with CaH_2 and again distil it under vacuum. Store it in sealed ampoules in a freezer. It has λ_{max} (cyclohexane) at 210nm and 320nm. The ***picrate*** has **m 105-106°**. [*Beilstein* **5** H 585, **5** III 1773, **5** IV 1833.] It reacts nicely with quinones [Corbett et al. *Aust J Chem* **18** 1775 *1965*, DOI: 10.1071/CH9651775]. It is an **irritant**.
2-Vinylnaphthalene *[827-54-3]* has **m 60-62°, 62-65°, 62-67°, 65-68°, 65°, 66°, b 76-81°/2.5mm, 128-131°/13mm, 135-137°/18mm.** Commercial material can contain up to 5% of MeOH as stabiliser. The flammable solid can be fractionally distilled under reduced pressure using a spinning-band column; dry it with CaH_2 and again distil it under vacuum. It crystallises from aqueous MeOH, EtOH (**m 66°**) or petroleum ether (**m 66-66.5°**). Store it in sealed ampoules in a freezer. The ***picrate*** has **m 91-92°** (from EtOH). [*Beilstein* **5** III 1775, **5** IV 1833.] It is an **irritant**.

Violanthrene (dibenzanthrene, 5,10-dihydroviolanthrene A) *[81-31-2]* **$C_{34}H_{20}$, M 428.5.** Purify violanthrene by vacuum sublimation over Cu in a muffle furnace at 450°/25mm in a CO_2 atmosphere [Scholl & Meyer *Chem Ber* **67** 1229 *1934*, DOI: 10.1002/cber.19340670722]. [*Beilstein* **5** I 392.] ***Violanthrene A* (anthro[9,1,2-*cde*]benzo[*rst*]pentaphene)** *[188-87-4]* **M** 426.5 has **m 506°.** [Clar *Chem Ber* **76** 458 *1943*, DOI: 10.1002/cber.19430760504; *Beilstein* **5** III 2778; for *Violanthrene B (violanthrone)* see *Beilstein* **7** I 466, **7** II 818, **7** III 4539.]

Xylene (dimethylbenzene) *[1330-20-7]* **C_8H_{10}, M 106.1 (mixed isomers).** Usual impurities are ethylbenzene, paraffins, traces of sulfur compounds and water. With a very efficient still, *o*-xylene can be fractionally distilled from a mixture of isomers. Purify (and dry) by fractional distillation from $LiAlH_4$, P_2O_5,

CaH_2 or sodium. This treatment can be preceded by shaking successively with concentrated H_2SO_4, water, aqueous 10% NaOH, water and mercury, and drying with $CaCl_2$ for several days. [*Beilstein* **5** H 360.]

o-Xylene *[95-47-6]* has **m -25.2°, -24°, b 84°/14mm, 144.4°/760mm, d_4^{20} 0.88020, d_4^{25} 0.87596, n_D^{20} 1.50543, n_D^{25} 1.50292.** The general purification methods listed under xylene are applicable [Clarke & Taylor *J Am Chem Soc* **45** 830 *1923*, DOI: 10.1021/ja01656a043]. *o*-Xylene (4.4Kg) is sulfonated by stirring for 4 hours with 2.5L of conc H_2SO_4 at 95°. After cooling, and separating the unsulfonated material, the product is diluted with 3L of water and neutralised with 40% NaOH. On cooling, sodium *o*-xylene sulfonate separates and is recrystallised from half its weight of water. [A further crop of crystals is obtained by concentrating the mother liquor to one-third of its volume.] The salt is dissolved in the minimum amount of cold water, then mixed with the same amount of cold water, and with the same volume of concentrated H_2SO_4 and heated to 110°. *o*-Xylene is regenerated and steam distils. The distillate is saturated with NaCl, the organic layer is separated, dried and redistilled. [*Beilstein* **5** H 362, **5** I 179, **5** II 281, **5** III 807, **5** IV 917.]

m-Xylene *[108-38-3, 1330-20-7]* has **m -48°, -47.9°, b 139.1°/760mm, d_4^{20} 0.86417, d_4^{25} 0.85990, n_D^{20} 1.49721, n_D^{25} 1.49464.** The general purification methods listed under *xylene* are applicable. The *o*- and *p*-isomers can be removed by their selective oxidation when a *m*-xylene sample containing them is boiled with dilute HNO_3 (one part concentrated acid to three parts water). After washing with water and alkali, the product can be steam distilled, collected as for *o*-xylene, then distilled and purified further by sulfonation. [Clarke & Taylor *J Am Chem Soc* **45** 831 *1923*, DOI: 10.1021/ja01656a043.] *m*-Xylene is selectively sulfonated when a mixture of xylenes is refluxed with the theoretical amount of 50-70% H_2SO_4 at 85-95° under reduced pressure. By using a still resembling a Dean and Stark apparatus, water in the condensate can be progressively withdrawn while the xylene is returned to the reaction vessel. After cooling, then adding water, unreacted xylenes are distilled off under reduced pressure. The *m*-xylene sulfonic acid is subsequently hydrolysed by steam distillation up to 140°, the free *m*-xylene is washed, dried with silica gel and again distilled. It is stored over molecular sieves Linde type 4A. [*Beilstein* **5** H 370, **5** I 182, **5** II 287, **5** III 823, **5** IV 932.]

p-Xylene *[106-42-3]* has **m 13.3, b 138.3°/760mm, d_4^{20} 0.86105, d_4^{25} 0.85669, n_D^{20} 1.49581, n_D^{25} 1.49325.** The general purification methods listed for *xylene* above are applicable. *p*-Xylene can readily be separated from its isomers by crystallisation from such solvents as MeOH, EtOH, isopropanol, acetone, butanone, toluene, pentane or pentene at low temperatures. It can be further purified by fractional crystallisation by partial freezing, and stored over sodium wire or molecular sieves Linde type 4A. [Stokes & French *JCS Faraday Trans 1* **76** 537 *1980*, DOI: 10.1039/F19807600537; *Beilstein* **5** H 382, **5** I 185, **5** II 296, **5** III 845, **5** IV 951.]

HETEROCYCLIC COMPOUNDS

Acetaldehyde ammonia trimer (hexahydro-2,4,6-trimethyl-1,3,5-triazine trihydrate) *[58052-80-5 ($3H_2O$), 76231-37-3, 638-14-2, 108-74-7 ($2H_2O$)]* **($C_2H_7NO)_3$, $C_6H_{15}N_3$. $3H_2O$, M 183.3, m 94-96°, 94-95°, 95-97°, 97°, b 110°/atm (partly dec).** It crystallises from EtOH/Et_2O. When prepared (MeCHO + 15M aqueous NH_3 at ~0°, then -25°), it separates as the ***trihydrate*** which can be dried in a vacuum over $CaCl_2$ at room temperature to give finally the ***anhydrous*** compound with the same melting point. Store away from light <8°. The intermediate ***dihydrate*** melts at 25-28°, then resolidifies and melts again at 94-95°. On gentle warming (40° to 80°) it loses NH_3 to give $MeCH(N=CHMe)_2$. It is used as a source of acetaldehyde in syntheses. The ***monomer*** *[75-39-8]* **C_2H_7NO, M 61.2,** is the intermediate in its preparation. Do not breathe in vapours — *IT IRRITATES THE EYES AND MUCOUS MEMBRANES*. [Prepn & NMR: Nielson et al. *J Org Chem* **38** 3288 *1973*, DOI: 10.1021/jo00959a010; *Beilstein* **26** III/IV 25.]

2-Acetamido-5-nitrothiazole (Acinitrazole) *[140-40-9]* **$C_5H_5N_3O_3S$, M 187.2, m 262-265°, 263°, 264-265°**. Recrystallise acinitrazole from hot absolute EtOH (charcoal) then cool to -10°, or AcOH. [Hurd & Wehrmeister *J Am Chem Soc* **71** 4007 *1949*, DOI: 10.1021/ja01180a038; *Beilstein* **27** III/IV 4676.] Used as a prophylactic in aminal feeds. An analytical procedure was devised for estimating 0.03 to 0.07% in medicated feeds using λ_{max} at 340nm ($A^{1\%}_{cm}$ 650) for Acinitrazole [Brown *Analyst* **91** 672 *1966,* DOI: 10.1039/AN9669100672].

4-Acetamido-2,2,6,6-tetramethylpiperidine-1-oxyl (acetamidoTEMPO) *[14691-89-5]* **$C_{11}H_{21}N_2O_2$, M 213.3, m 144-146°, 146-147°**. Dissolve the 1-oxyl in CH_2Cl_2, wash it with saturated K_2CO_3, then saturated aqueous NaCl, dry (Na_2SO_4), filter and evaporate. The red solid is recrystallised from aqueous MeOH, **m 147.5°**. [Ma & Bobbitt *J Org Chem* **56** 6110 *1991*, DOI: 10.1021/jo00021a027; Rozantsev & Kokhanov *Bull Acad Sci USSR, Div Chem Sci* **15** 1422 *1966*, DOI: 10.1007/BF01151392; *Beilstein* **22/8** V 174.]

5-Acetamido-1,3,4-thiadiazole-2-sulfonamide (Acetazolamide) *[59-66-5]* **$C_4H_6N_4O_3S_2$, M 222.3, m 256-259° (dec), 258-259° (dec).** It is recrystallised from water. It is soluble in M NH_4OH (50mg/ml), Me_2SO, MeOH but slightly in EtOH. It is a carbonic anhydrase inhibitor. [Roblin & Clapp *J Am Chem Soc* **72** 4890 *1950*, DOI: 10.1021/ja01167a011; *Beilstein* **27** III/IV 8219.]

Acetoacetylpiperidide *[1128-87-6]* **$C_9H_{15}NO_2$, M 169.2, b 88.9°/0.1mm, 88-91°/0.1mm, n_D^{25} 1.4983.** Dissolve it in *benzene, extract with 0.5M HCl to remove basic impurities, wash with water, dry, and distil it at 0.1mm [Wilson *J Org Chem* **28** 314 *1963*, DOI: 10.1021/jo01037a009]. [*Beilstein* **20** IV 1121.]

4-Acetoxy-2-azetidinone *[28562-53-0]* **$C_5H_7NO_3$, M 129.1, m 38-40°, 38-41°.** Dissolve it in $CHCl_3$, dry ($MgSO_4$), concentrate at 40°/70mm, or better at room temperature to avoid decomposition. Wash and stir the residual oil with hexane by decantation and discard the wash. Dry the oil at high vacuum when it should solidify, **m 34°**. It can be distilled at high vacuum, 80-82°/10^{-3}mm, but this results in extensive losses. The purity can be checked by TLC using Merck Silica Gel F_{254} and eluting with EtOAc. The azetidinone has R_F 0.38 (typical impurities have R_F 0.67). The spots can be detected by the **TDM spray**. This is prepared from (A) 2.5g of 4,4'-tetramethyldiaminodiphenylmethane (TDM) in 10ml AcOH and diluted with 50ml of H_2O, (B) 5g KI in 100ml of H_2O and (C) 0.3g ninhydrin in 10ml of AcOH and 90ml of H_2O. The spray is prepared by mixing (A) and (B) with 1.5ml of (C) and stored in a brown bottle. [Clauβ et al. *Justus Liebigs Ann Chem* 539 *1974*, DOI: 10.1002/jlac.197419740403; Mickel et al. *Org Synth* **65** 135 *1987*, DOI: 10.15227/orgsyn.065.013; *Beilstein* **21/12** V 4.]

***N*-Acetylcaprolactam (1-acetylazepan-2-one, 1-acetylhexahydro-2*H*-azepin-2-one)** *[1888-91-1]* **$C_8H_{11}NO$, M 155.2, b 85-86°/0.05mm, 119.5-222° /11mm, 134-135° /26mm, d_4^{25} 1.094, n_D^{20} 1.489.** Distil the lactam in a vacuum, but if the IR has broad OH bands (*ca* ν_{max} at ~3300cm^{-1}), then add *ca* one half volume or more of Ac_2O, reflux for 2 hours and distil or dissolve it in toluene add MeCOCl heat at 100°/2 hours and distil in a vacuum. Its IR has ν_{max} at 1730cm^{-1} (film). [Stoll & Griehl *Helv Chim Acta* **48** 1805 *1965*, DOI: 10.1002/hlca.19650480742; Bose et al. *Tetrahedron* **30** 3 *1974*, DOI: 10.1016/S0040-4020(01)97208-4; *Beilstein* **21** III/IV 3210, **21/6** V 460.]

3-Acetyl-2,5-dimethylthiophene *[2530-10-1]* **$C_8H_{10}OS$, M 154.2, b 62°/0.25mm, 105-108°/15mm, 224°/atm, d_4^{25} 1.086, n_D^{20} 1.544.** Distil the thiophene in a vacuum, or dissolve it in *C_6H_6, shake this with 6M HCl, then wash with H_2O, dry the organic layer, evaporate, and distil the residue preferably in a vacuum. [Glaze et al. *JCS Perkin Trans 1* 957 *1985*, DOI: 10.1039/P19850000957; *Beilstein* **17** H 298.]

***N*-Acetylimidazole** *[2466-76-4]* **$C_5H_6N_2O$, M 110.1, m 99-105°, 101.5-102.5°, pK^{25} 3.6.** It is recrystallised from isopropenyl acetate and dried in a vacuum over P_2O_5. [Riordan & Vallee *Methods Enzymol* **25** 500 *1972*, DOI: 10.1016/S0076-6879(72)25045-5, Beilstein **23/4** V 218.]

1-Acetylindole *[576-15-8]* **$C_{10}H_9NO$, M 159.2, b 123-125°/8mm, 148-150°/10mm, 152-153°/15mm, d_4^{25} 1.387, n_D^{20} 1.6100.** It has been prepared by phase transfer catalysis of a mixture of AcCl/NaOH and Indole [Illi *Synthesis* 387 *1979*, DOI: 10.1055/s-1979-28695]. Purify it by distillation in a vacuum, but if it is very discoloured, then distil it in steam, separate the layers, dry the organic layer (Na_2SO_4), filter it, and distil it in a vacuum. The ***picrate*** has **m 98-99°**. ***1,3-Diacetylindole*** is formed when indole is treated with Ac_2O at 180-200°, and distils with 1-acetylindole. The latter distils in steam, whereas the diacetylindole remains behind. It is hydrolysed by boiling alkali to yield indole, and can be acetylated further to ***1,3-diacetylindole*** **m 151°**. [For NMR see Elguero et al. *Org Magn Res* **7** 445 *1975*, DOI: 10.1002/mrc.1270070910; Ciamician & Zatti *Chem Ber* ***22*** 1976 *1889*, DOI: 10.1002/cber.1889022025; Zatti & Ferratini *Chem Ber* **23** 1359 *1890*, DOI: 10.1002/cber.189002301214; Plieninger & Werst *Chem Ber* **89** 2783, 2788 *1956*, DOI: 10.1002/cber.19560891220; *Beilstein* **20** H 309, **20** II 200, **20** III/IV 3182, **20/7** V 19.]
3-Acetylindole *[703-80-0]* has **m 189°, 188-190°, 188-192°, 191-193°, 194°, pK^{25} 12.99 (acidic NH).** It is formed by reaction of indole-MgCl and AcCl, and also by hydrolysis of 1,3-diacetylindole (see above). It is purified by recrystallisation from MeOH, *C_6H_6 containing a little EtOH or *C_6H_6; and by sublimation *in vacuo*. The ***phenylureido*** derivative has **m 154°**. The ***(E)-oxime*** has **m 144-145°** (also **149°** reported) (from H_2O) [Kostyuchenko et al. *J Org Chem USSR (Engl Trans)* **8** 2471 *1972*], and the ***(Z)-oxime*** has **m 95°** [Kostyuchenko et al. *J Org Chem USSR (Engl Trans)* **8** 2469, 2473 *1972*]. The ***(E)-O-methyloxime*** crystallises from EtOH with **127-129°**. [Oddo & Sessa *Gazz Chim Ital* **41** 234 *1911*, Baker *J Chem Soc* 461 *1946*, DOI: 10.1039/JR9460000461; *Beilstein* **21** H 316, **21** I 300, **21** II 264, **21** III/IV 3775, **21/8** V 297.]

4-Acetylmorpholine *[1696-20-4]* **$C_6H_{11}NO_2$, M 129.2, m 13.8-14°, 14°, 14.5°, b 96-97°/6mm, 113-128°/22mm, 242-247°/760mm, d_4^{20} 1.0963, n_D^{20} 1.4830.** Distil it through an 8inch Fenske (glass helices packing) column with a manual take-off head. Purify it by fractional distillation. The ***hydrobromide*** has **m 172-175°**. [Brace *J Am Chem Soc* **75** 357 *1953*, DOI: 10.1021/ja01098a030; deBenneville et al. *J Org Chem* **21** 1072 *1956*, DOI: 10.1021/jo01116a006; *Beilstein* **27** III/IV 274.]

1-Acetylpiperazine *[13889-98-0]* **$C_6H_{12}N_2O$, M 128.2, m 31-34°, 32-34°, 52°, pK^{25} 7.94.** Purify 1-acetylpiperazine by recrystallisation from 40% aqueous EtOH or from EtOH/Et_2O. It is an **irritant**, and is ***hygroscopic***. The ***hydrochloride*** has **m 191°** (from EtOH), and the ***tosylate salt*** has **m 148-149°** (from EtOH/EtOAc, 1:16). The free base, however, cannot be isolated by basifying the tosylate salt and extraction with CH_2Cl_2. [Jacobi *Chem Ber* **66** 113 *1933*, DOI: 10.1002/cber.19330660206; Mosher et al. *J Am Chem Soc* **75** 4949 *1953*, DOI: 10.1021/ja01116a020; Hall *J Am Chem Soc* **78** 2570 *1956*, DOI: 10.1021/ja01592a066; *Beilstein* **23** IV 201.]

1-Acetyl-4-piperidone *[32161-06-1]* **$C_6H_{12}NO_2$, M 141.2, b 124-128°/0.2mm, 218°/760mm, d_4^{25} 1.1444, n_D^{20} 1.5023.** Purify it by fractional distillaton through a short Vigreux column (15mm). The ***2,4-dinitrophenylhydrazone*** has **m 212-213°** (from EtOH). It is freely soluble in H_2O but insoluble in Et_2O. [McElvain & McMahon *J Am Chem Soc* **71** 901 *1949*, DOI: 10.1021/ja01171a038; *Beilstein* **21/6** V 426.]

3-Acetylpyridine *[350-03-8]* **C_7H_7NO, M 121.1, m 13-14°, b 65-66°/1mm, 92-95°/8-9mm, 105°(113°)/16mm, 219-221°/760mm, d_4^{20} 1.1065, n_D^{20} 1.1065, pK^{25} 3.18.** It is purified by dissolving in HCl, extracting with Et_2O to remove the possible impurity of nicotinic acid, basified with NaOH and extracted with Et_2O. The dried extract is filtered, evaporated and the residual oil is distilled. If the NMR spectrum indicates further impurities, then convert it to the ***phenylhydrazone*** (**m 137°**, yellow needles from EtOH). This is hydrolysed with HCl [Engler & Kiby *Chem Ber* **22** 597 *1889*, DOI: 10.1002/cber.188902201132], the phenylhydrazine HCl is removed by filtration, $NaNO_2$ is added, the solution is basified with aqueous NaOH and

extracted with Et_2O as before and distilled at atmospheric pressure to give 3-acetylpyridine as a colourless oil. Purification can also be achieved by shaking with 50% aqueous KOH, extracting with Et_2O, drying the extract and distilling it at atmospheric pressure or *in vacuo*. [Kloetzel & Chubb *J Am Chem Soc* **79** 4226 *1957*, DOI: 10.1021/ja01572a064.] The ***hydrochloride*** has **m 180-181°** (from MeOH/EtOH), the ***picrate*** has **m 133.8-134.8°** (from H_2O), and the ***phenylhydrazone*** has **m 137°** (**129-130°**)(needles, from EtOH) [Webb & Webb *J Am Chem Soc* **71** 2285 *1949*, DOI: 10.1021/ja01175a003]. The ***ketoxime*** has **m 112°** (from EtOH or *C_6H_6). [Strong & McElvain *J Am Chem Soc* **55** 816 *1933*, DOI: 10.1021/ja01329a062; Kolloff & Hunter *J Am Chem Soc* **63** 490 *1941*, DOI: 10.1021/ja01847a036; *Beilstein* **21/7** V 394.]

2-Acetylthiazole *[24295-03-2]* **C_5H_5NOS, M 127.2, b 89-91° (90-95°)/12mm, 95-105°/15mm, d_4^{20} 1.23, n_D^{20} 1.55.** Check NMR spectrum; if it is not too bad, distil it through an efficient column in a vacuum. Otherwise purify it *via* the oxime. The ***oxime*** sublimes at 140-145°, **m 159°**, and when crystallised from H_2O has **m 163-165.5°**. [Erlenmeyer et al. *Helv Chim Acta* **31** 1142 *1948*, DOI: 10.1002/hlca.19480310421; Waisvisz et al. *J Am Chem Soc* **79** 4524 *1957*, DOI: 10.1021/ja01573a074; Menassé et al. *Helv Chim Acta* **40** 554 *1957*, DOI: 10.1002/hlca.19570400306; *Beilstein* **27** IV 2617.]

2-Acetylthiophene (methyl 2-thienyl ketone) *[88-15-3]* **C_6H_6OS, M 126.2, m 9.2-10.5°, 10.45°, 10-11°, b 77°/4mm, 89-91°/9mm, 94.5-96.5°/13mm, 213-214°/atm, d_4^{20} 1.17, n_D^{20} 1.5666.** Fractionally distil the thiophene through a 12-plate column, and fraction **b 77°/4mm** is collected. Also wet the acetylthiophene in order to remove and free thiophene which forms an azeotrope with H_2O, **b** 68°. Store it in a brown bottle, and the clear colourless liquid remains thus for extended periods. [Kosak & Hartough *Org Synth* Coll Vol **3** 14 *1955*, DOI: 10.15227/orgsyn.028.0001; Hartough & Kosak *J Am Chem Soc* **69** 3093 *1947*, DOI: 10.1021/ja01204a049.] The red ***4-nitrophenylhydrazone*** crystallises from EtOH with **m 181-182°**. [*Beilstein* **17/9** V 387.]

3-Acetylthiophene (methyl 3-thienyl ketone, acetothienone) *[1468-83-3]* **C_6H_6OS, M 126.2, m 57°, 60-63°, b 106-107°/25mm, 208-210°/748mm.** Recrystallise the thiophene from petroleum ether (b 30-60°) or EtOH. The ***2,4-dinitrophenylhydrazone*** crystallises from $CHCl_3$, **m 265°**, and the ***semicarbazone*** crystallises from EtOH, **m 174-175°**. [Campaigne & Le Suer *J Am Chem Soc* **70** 1555 *1948*, DOI: 10.1021/ja01184a078; *Beilstein* **17/9** V 399.]

Aconitine *[302-27-2]* **$C_{34}H_{47}NO_{11}$, M 645.8, m 198°, 204°, $[\alpha]_{546}$ +20° (c 1, $CHCl_3$), pK^{15} 8.35.** Crystallise it from EtOH, $CHCl_3$ or toluene. Its slightly soluble in H_2O (0.3mg/ml) and EtOH (35mg/ml). It is a very POISONOUS toxin from the *Aconitum* plant (devil's helmet or monkshood) and used against pain in Chinese herbal medicine. [*Beilstein* **21/6** V 310.]

Aconitine hydrobromide *[6034-57-7]* **$C_{34}H_{47}NO_{11}$. HBr, M 726.7, m 207°.** Crystallise the salt from water or EtOH/ether. [*Beilstein* **21/6** V 310.]

Acridine (2,3-benzoquinoline) *[260-94-6]* **$C_{13}H_9N$, M 179.2, m 107-110° (sublimes), 111° (sublimes), b 346°/atm, pK^{25} 5.58 (pK^{25} of excited state 10.65).** Acridine has been crystallised twice from *benzene/cyclohexane, or from aqueous EtOH (pale yellow crystals), then sublimed, removing and discarding the first 25% of the sublimate. The remainder is again crystallised and sublimed, discarding the first 10-15% [Wolf & Anderson *J Am Chem Soc* **77** 1608 *1955*, DOI: 10.1021/ja01611a060]. Acridine can also be purified by crystallisation from *n*-heptane and then from ethanol/water after pre-treatment with activated charcoal, or by chromatography on alumina with petroleum ether in a darkened room. *Alternatively*, acridine can be precipitated as the hydrochloride from *benzene solution by adding HCl, after which the base is regenerated, dried at 110°/50mm, and recrystallised to constant melting point from petroleum ether [Cumper et al. *J Chem Soc* 4518 *1962*, DOI: 10.1039/JR9620004518]. The ***free base*** may be chromatographed on basic alumina/ C_6H_6, then vacuum-sublimed and zone-refined. Its UV has λ_{max}(log ε) 249(5.25), 338(3.83), 346(3.83), 354(4.02)nm at pH 8.0, and 255(5.10), 324(3.50), 338(3.99), 354(4.34), 386(3.50), 402(3.48) at pH 3.0. [Williams & Clarke, *JCS Faraday Trans 1* **73** 514 *1977*, DOI: 10.1039/F19777300514; Albert, *The Acridines* Arnold Press *1966*.] It can exist in five crystalline forms and is steam volatile. It is a strong IRRITANT to skin and mucous membranes and can become a chronic irritant— handle it with CARE. [*Beilstein* **20/8** V 199.]

***N*-(9-Acridinyl)maleimide (NAM)** *[49759-20-8, 49761-68-4]* **$C_{17}H_{10}N_2O_2$, M 274.3, m 248°, 255-258°.** Purify NAM by chromatography on silica gel using CH_2Cl_2 as eluant. Evaporation of pooled fractions that gave the correct NMR spectra gave a solid which was crystallised from Me_2CO as pale yellow prisms. Its IR(nujol) has ν_{max} at 1710 (imide); the UV (MeOH) has λ_{max} (nm) (ε $M^{-1}cm^{-1}$) at 251 (159 500), 343 shoulder (7 700), 360 (12 400) and 382shoulder (47 000). It is used in fluorimetric assays and as a fluorescent tag. [Machida et al. *Chem Pharm Bull Jpn* **26** 596 *1978*, DOI: org/10.1248/cpb.26.596; Schuldiner et al. *Eur J Biochem* **25** 64 *1972*, DOI: 10.1111/j.1432-1033.1972.tb01667.x; Schäfer et al. *Analyt Biochem* **209** 53 *1993*, DOI: 10.1006/abio.1993.1081.]

Acridone (9,10-dihydro-9-oxoacridine, 9-hydroxyacridine) *[578-95-0]* **$C_{13}H_9NO$, M 195.2, m >300°, pK_1 -0.32 (basic), pK_2 12.80 (14.0, acidic, proton loss).** Dissolve ~1g in *ca* 1% NaOH (100ml), add 3M HCl to pH 4 when acridone separates as a pale yellow solid with **m** just above **350°** (sharp). It can be recrystallised from large volumes of H_2O to give a few mg. It is soluble in 160 parts of boiling EtOH (540 parts at 22°) [Albert & Phillips *J Chem Soc* 1294 *1956*, DOI: 10.1039/JR9560001294]. A few decigms are best crystallised as the ***hydrochloride*** from 400 parts of 10N HCl (90% recovery) from which the free base is obtained by washing the salt with H_2O. A small quantity can be recrystallised (as the neutral species) from boiling AcOH. Larger quantities are best recrystallised from a mixture of 5 parts of freshly distilled aniline and 12.5 parts of glacial acetic acid. Acridone distils unchanged at atmospheric pressure, but the boiling point was not recorded, and some sublimation occurs below 350°. Commercial acridone has been recrystallised three times from EtOH and dried at 70°/0.5mm. It has UV with λ_{max}(log ε) at 250(4.52), 294(3.36), 400(3.95)nm in EtOH. [see Albert, *The Acridines* Arnold Press pp 201, 372 *1966*; for pKa see Kalatzis *J Chem Soc (B)* 96 *1969*, DOI: 10.1039/J29690000096; *Beilstein* **23/9** V 7.]

Acriflavine *[8048-52-0]* **$C_{13}H_{11}N_3$, M 196.2, pK^{25} >12.** Treat acriflavin twice with freshly precipitated AgOH to remove proflavine, then recrystallise it from absolute methanol [Wen & Hsu *J Phys Chem* **66** 1353 *1962*, DOI: 10.1021/j100813a501]. [*Beilstein* **22** III/IV 218.] (See following entry and the 3,6-diaminoacridine hydrochloride and sulfate below).

Acriflavin Mixture (Euflavin, Proflavin, 3,6-diamino-10-methylacridinium chloride + 3,6-diaminoacridine) *[8048-52-0]* **$C_{14}H_{14}ClN_3$. $C_{13}H_{11}N_3$, M 259.7, m 179-181°.** Purify it by dissolving in 50 parts of H_2O, shaking with a small excess of freshly precipitated and washed Ag_2O. The mixture is set aside overnight at 0° and filtered. The cake is not washed. The pH of the filtrate is adjusted to 7.0 with HCl and evaporated to dryness. The residue is then crystallised twice from MeOH, twice from H_2O and dried at 120°. Its UV has λ_{max} at 452nm and a logε value of 4.67. It is a red powder which readily absorbs H_2O. The solubility is increased in the presence of proflavin. The ***dihydrochloride (Panflavin)*** *[8063-24-9]* is a deep red crystalline powder. It is available as a mixture of 3,6-diaminoacridinium chloride (35%) and its 10-methochloride (65%). [See Albert, *The Acridines* Arnold Press p 346 *1966*, Benda *Chem Ber* **45** 1787 *1912*, DOI: 10.1002/cber.19120450251]. [*Beilstein* **22** III/IV 5488, **23** I 650.] These are antiseptics.

Adrenochrome (3-hydroxy-1-methyl-5,6-indoline-dione) *[54-06-8]* **$C_9H_9NO_3$, M 179.2, m 125-130° (dec).** It was crystallised from MeOH/formic acid, as bright red crystals of the ***hemihydrate*** (**m ~115-120°**), and stored in a vacuum desiccator. The much more stable ***oxime sesquihydrate*** *[6055-73-8]* **$C_9H_{10}N_2O_4.1.5\ H_2O$, m 278°**, crystallises in orange crystals from hot H_2O. The ***mono-semicarbazone (Carbazochrome)*** [69-81-8] M 236.2, crystallises as orange-red crystals from dilute EtOH with **m ~203°(dec)** and is haemostatic. [Heacock *Chem Rev* **59** 181 *1959*, DOI: 10.1021/cr50026a001; *Beilstein* **21** III/IV 6434.]

Aetioporphyrin I (Etioporphyrin, I 2,4,6,8-tetraethyl-1,3,5,7-tetramethylporphyrin) *[448-71-5]* **M 478.7, m 360-363°, pK^{25} 18.** Purify it by chromatography on an Al_2O_3 column (300g/300mg of porphyrin) and elute with CH_2Cl_2, evaporate the eluate and crystallise the residue from CH_2Cl_2/MeOH, pyridine or $CHCl_3$/petroleum ether (purple prisms, **m > 300°**) [Smith *JCS Perkin Trans 1* 1471 *1972*, DOI: 10.1039/P19720001471]. The copper salt crystallises as red needles from pyridine/AcOH. It complexes with metals. The ***dihydrobromide*** *[69150-58-9]* **M** 640.5 separates from aetioporphyrin I in Et_2O on addition of 10% of aqueous HBr after 2 days [Fischer & Treibs *Justus Liebigs Ann Chem* **457** 209 *1927*, DOI: 10.1002/jlac.19274570108; Treibs & Dieter *Justus Liebigs Ann Chem* **513** 65 *1934*, DOI: 10.1002/jlac.19345130105]. [*Beilstein* **26** III/IV 1915.]

Agroclavin *[548-42-5]* **$C_{16}H_{18}N_2$, M 238.3, m 198-203°(dec), 205-206°, 210-212°, $[\alpha]_D^{20}$ -155 (c 1, $CHCl_3$), pK_{Est} ~8.0.** This ergot alkaloid crystallises from diethyl ether (colourless rods) or Me_2CO (needles). The ***hydrochloride*** crystallises from H_2O and has **m 265-266°**, $[\alpha]_D^{20}$ -110 ($CHCl_3$). [Plieninger et al. *Justus Liebigs Ann Chem* **743** 95 *1971*, DOI: 10.1002/jlac.19717430111; *Beilstein* **23** III/IV 1623.]

***RS*-Allantoin (5-ureidoimidazol-2,4-dione)** *[97-59-6]* **$C_4H_6N_4O_3$, M 158.1, m 230°(dec), 238°(dec).** This purine metabolite in the uric acid pathway crystallises from water or EtOH [Hartman et al. *Org Synth* Coll Vol **II** 21 *1943*, DOI: 10.15227/orgsyn.013.0001]. It reacts with free radicals and is a useful biomarker for oxidative stress. [*Beilstein* **25** III/IV 4071.]

Alloxan [2,4,5,6(1*H*,3*H*)pyrimidine tetrone, 5,6-dihydroxyuracil] *[50-71-5]* **$C_4H_2N_2O_4$, M 142.0, m ~170°(dec), pK^{25} 6.64.** Crystallisation from water gives the ***tetrahydrate***. ***Anhydrous*** crystals are obtained by crystallisation from acetone, glacial acetic acid or by sublimation *in vacuo*. [See below and *Beilstein* **24** H 500, **24** I 428, **24** II 301, **24** III/IV 2137.]

Alloxan monohydrate *[2244-11-3]* **$C_4H_2N_2O_4.H_2O$, M 160.1,** has **m 255°(dec), pK^{25} 6.64.** Recrystallisation from H_2O gave the ***tetrahydrate*** in large prisms or rhombs. On heating at 100°, or on exposure to air, this is converted to the ***monohydrate***. Dissolve it in its own weight of boiling H_2O and cool it for several days below 0°; the ***tetrahydrate*** crystallises from solution much more slowly when free from HNO_3. It is less soluble in bicarbonate solutions than in H_2O. Drying the solid over H_2SO_4 yields the ***monohydrate***. The ***anhydrous*** crystals can be obtained by recrystallisation from dry Me_2CO or AcOH followed by washing with dry Et_2O, or by sublimation in a vacuum. On heating it turns pink at 230° and decomposes at *ca* 256°. It is acidic to litmus. [Hartman & Sheppard *Org Synth* Coll Vol **3** 37 *1955*, DOI: 10.15227/orgsyn.023.0003.] It forms a compound with urea which crystallises from H_2O in yellow needles that become red at 170° and decompose at 185-186°. [*Beilstein* **24** H 500, **24** I 428, **24** II 301, **24** III/IV 2137.]

Alloxantin (5,5'-dihydroxy-5,5'-bibarbituric acid) *[76-24-4]* **$C_8H_6N_4O_8$, M 286.2, m 253-255°(dec) (yellow at 225°).** Alloxantin crystallises from water or EtOH and is kept under nitrogen. It turns red in air. It can be obtained from uric acid [Nightingale *Org Synth* Coll Vol **3** 42 *1955*, DOI: 10.15227/orgsyn.023.0006], or from alloxan hydrate [Tipson et al. *Org Synth* Coll Vol **4** 25 *1963*, DOI: 10.15227/orgsyn.033.0003]. [*Beilstein* **26** III/IV 2782.]

Alloxazine (6,7-benzopteridin-2,4(1*H*,3*H*)-dione) *[490-50-5]* **$C_{10}H_6N_4O_2$, M 214.2, dec > 300°, $pK_{Est(1)}$ ~-2.0 (proton gain), $pK_{Est(2)}$~7.92 (proto loss), $pK_{Est(3)}$~12.00 (proton loss).** Prepared by cyclisation of 2-carbethoxyaminoquinoxaline-3-carboxamide with NaOMe/MeOH which deposits the bright yellow ***sodium salt*** that dissolves in hot 2% aqueous NaOH and deposits the Na salt as yellow needles in high yield. When the salt is dissolved in aqueous EtOH and acidified with AcOH, alloxazine separates as a pale yellow powder which decomposes without melting above 300°. It turns greyish-green on standing in light. It can be recrystallised from 50% aqueous AcOH. It is sparingly soluble in EtOH, insoluble in H_2O or Et_2O The UV (EtOH) has λ_{max} 322nm (ε 5,900) and 246 (ε 19,000). It is characterised by conversion into ***1,3-dimethylalloxazine*** which crystallises from MeOH in bright yellow prisms with **m 238-240°** (**234-236°**), and has UV (EtOH) with λ_{max} 378nm (ε 7,200), 234.5nm (ε 6,900) and 245nm (ε 32,200). [Gowenlock et al. *J Chem Soc* 517 *1948*, DOI: 10.1039/JR9480000517; Tishler et al. *J Am Chem Soc* **67** 215 *1945*, DOI: 10.1021/ja01228a031; *Beilstein* **26** H 498.]

1-Allyl-6-amino-3-ethyluracil (Aminometradine) *[642-44-4]* **$C_9H_{13}N_3O_2$, M 195.2, m 143-144° (anhydrous).** It crystallises from water (as ***monohydrate***, **m 70-114°**). It is a diuretic. [*Beilstein* **24** III/IV 4133.]

1-*N*-Allyl-3-hydroxymorphinan (Levallorphan) *[152-02-3]* **$C_{19}H_{25}NO$, M 283.4, m 180-182°, $[\alpha]_D^{20}$ -89 (c 3, MeOH).** It crystallises from aqueous EtOH. It is a narcotic antagonist. [Schnider & Grüssner *Helv Chim Acta* **34** 2211 *1951*, DOI: 10.1002/hlca.19510340715; Hellerbach et al. *Helv Chim Acta* **39** 429 *1956*, DOI: 10.1002/hlca.19560390212.]

5-Allyl-5-*iso*butylbarbituric acid (Butalbital) *[77-26-9]* **$C_{11}H_{16}N_2O_3$, M 224.3, m 138-139°, 139°, 139-140°, 140-142°, pK^{18} 12.36.** It can be recrystallised from H_2O or dilute EtOH, and sublimes at 100-120°/8-

12mm. It is soluble in *C_6H_6, cyclohexane, tetralin and petroleum ether at 20°. It is a controlled substance, a depressant, hypnotic and a sedative. [Butler et al. *J Am Chem Soc* **77** 1486 *1955*, DOI: 10.1021/ja01611a024; *Beilstein* **24** III/IV 2006.]

9-Aminoacridine (9-acridineamine, Aminacrine) *[90-45-9]* **$C_{13}H_{10}N_2$, M 194.2, m 241°, pK^{20} 9.95.** It crystallises from EtOH or acetone and sublimes at 170-180°/0.04mm [Albert & Ritchie *Org Synth* Coll Vol **3** 53 *1955*, DOI: 10.15227/orgsyn.022.0005; for hydrochloride, see below]. [*Beilstein* **21** II 280, **21** III/IV 4174.]
9-Aminoacridine hydrochloride monohydrate **(Acramine yellow, Monacrin) $C_{13}H_{10}N_2.HCl.H_2O$,** *[52417-22-8 hydrate, 134-50-9 anhydrous]* **M 248.7,** has **m >355°, pK$_1^{20}$ 4.7, pK$_2^{20}$ 9.99.** Recrystallise it from boiling H_2O (charcoal; 1g in 300 ml) to give pale yellow crystals with a neutral reaction. It is one of the *most fluorescent substances known*. At 1:1000 dilution in H_2O it is pale yellow with only a faint fluorescence, but at 1:100,000 dilution it is colourless with an intense blue fluorescence. [Albert & Ritchie *Org Synth* Coll Vol **3** 53 *1955*, DOI: 10.15227/orgsyn.022.0005; Falk & Thomas *Pharm J* **153** 158 *1944*, *Beilstein* **22** H 463, **21** II 280, **21** III/IV 4174.] See previous entry for the free base.

2-Amino-5-(2-aminoethyl)-4-methylthiazole dihydrobromide (Amthamine dihydrobromide) *[142437-67-0 for free base]* **$C_6H_{11}N_3S$. 2HBr, M 319.1, m 275°(dec), pK$_{Est(1)}$ ~5.0, pK$_{Est(2)}$ ~9.7.** Prepared from 3-bromo-5-phthalimido-2-pentanone and thiourea in DMF at 120°/3hrs which converted to *2-amino-4-methyl-5-(2-phthalimidoethyl)thiazole hydrobromide* (55.% yield, **m 270.3-272.4°**, from absEtOH/EtOAc), and the amino group was deprotected by refluxing in 30% HBr solution for 5 hours, evaporated (80/20mm), HBr was chased with toluene to give a 75.2% yield of ***2-amino-5-(2-amino-methyl)-4-methylthiazole dihydrobromide*** after recrystallisation from hot EtOH/Et_2O. It has ^{1}H NMR (90MHz, DMSO-*d*6) with δ at 2.16 (s, 3H), 2.84-3.12 (br m, 4H), 8.08 (br s, 3H), 9.32 (br s, 2H) ppm; MS *m/z* (rel intensity) 158(5), 157(7), 104(31), 30(2); exact mass M^+ = 157.062, calc for $C_6H_{11}N_3S$ 157.067. [Eriks et al *J Med Chem* **35** 3239 *1992*, DOI: 10.1021/jm00095a021]. ***Amthamine*** is a highly selective H_2 agonist that is slightly more potent than histamine, but only a weak antagonist at H_3 but no activity at H_1 receptors. [Coruzzi et al. *Arch Pharmacol* **348** 77 *1993*, DOI: 10.1007/BF00168540; for allergy and Histamine see Poli et al. *Agents Actions* **40** 44 *1993*, DOI: 10.1007/BF01976750.]

2-Amino-4-anilino-*s*-triazine (Amanozine) *[537-17-7]* **$C_9H_9N_5$, M 187.2, m 235-236°, pK$_{Est}$ ~5.5.** It crystallises from dioxane or 50% aqueous EtOH. [*Beilstein* **26** III/IV 1195.]

4-Aminoantipyrine (Ampyrone, 4-amino-2,3-dimethyl-1-phenylpyrazol-5-one) *[83-07-8]* **$C_{11}H_{13}N_3O$, M 203.3, m 105-110°, 109°.** It crystallises from EtOH or EtOH/ether. It is antipyretic and an analgesic. [*Beilstein* **25** III/IV 3554.]

2-Aminobenzothiazole *[136-95-8]* **$C_7H_6N_2S$, M 150.2, m 126-129°, 132°, pK^{20} 4.48.** The thiazole cystallises from H_2O, aqueous EtOH, *C_6H_6 or petroleum ether. The ***hydrochloride*** crystallises from dilute HCl and has **m 240.5°**. [*Beilstein* **27** H 182, **27** III/IV 4824.]

6-Aminobenzothiazole *[533-30-2]* **$C_7H_6N_2S$, M 150.2, m 87°, 87-91°, pK$_{Est}$ ~3.** It crystallises from aqueous EtOH, petroleum ether or *C_6H_6/petroleum ether. The ***hydrochloride*** has **m 305°(dec)** from dilute HCl, and the ***picrate*** has **m 185°(dec)** from Me_2CO. [Boggust & Cocker *J Chem Soc* 355 *1949*, DOI: 10.1039/JR9490000355; *Beilstein* **27** III/IV 4884.]

3-*o*-Aminobenzyl-4-methylthiazolium chloride hydrochloride *[534-94-1]* **$C_{11}H_{14}N_2SCl_2$, M 277.2, m 213°(dec).** The ***hydrochloride*** crystallises from aqueous EtOH, and the ***iodide hydroiodide*** has **m 273°** (from aqueous HI). [*Beilstein* **27** III/IV 973.]

4-Amino-1-benzylpiperidine *[50541-93-0]* **$C_{12}H_{18}N_2$, M 190.3, b ~180°/20mm, d$_4^{20}$ 0.933, n$_D^{20}$ 1.543, pK$_{Est(1)}$~ 8.3 pK$_{Est(2)}$~ 10.4.** Purify it by distillation *in vacuo* and store it under N_2 because it absorbs CO_2. The ***dihydrochloride salt*** *[1205-72-7]* has **m 270-273°** (**255°**) after recrystallisation from MeOH/EtOAc or EtOH. [Brookes et al. *J Chem Soc* 3165, 3172 *1957*, DOI: 10.1039/JR9570003165.]
The ***4-methylamino-1-benzylpiperidine*** derivative has **b 168-172°/17mm**, n$_D^{20}$ 1.5367 [Reitsema & Hunter *J Am Chem Soc* **70** 4009 *1948*, DOI: 10.1021/ja01192a011].

The ***1-(1-benzyl-4-piperidinyl)-3-cyano-2-methylisothiourea*** derivative has **m 160°** from $CHCl_3/Et_2O$ [Preparation, IR, NMR: Ried et al. *Chem Ber* **116** 1547 *1983*, DOI: 10.1002/cber.19831160431; *Beilstein* **22** III/IV 3752].

2-Amino-4-chloro-6-methylpyrimidine *[5600-21-5]* **$C_5H_6ClN_3$, M 143.6, m 183-186°, 184-186°, pK_{Est} ~1.0.** Recrystallise it from EtOH. [*Beilstein* **24** H 84, **25** IV 2171.]

2-Amino-5-chloropyridine *[1072-98-6]* **$C_5H_5ClN_2$, M 128.6, m 135-136°, 135-138°, 127-128°/11mm, pK^{25} 4.38.** Recrystallise this base from petroleum ether. It sublimes at 50°/0.5mm. [*Beilstein* **22** II 332, **22/8** V 541.]

2-Amino-4-chloropyrimidine *[3993-78-0]* **$C_4H_4ClN_3$, M 129.55, m 168-169°, m 170°, pK_{Est} ~1.2.** The pyrimidine crystallises in glistening plates from EtOH (**m** 170°, sintering at 167°). It has also been purified by sublimation in a vacuum and recrystallisation from H_2O. [Hilbert & Johnson *J Am Chem Soc* **52** 1152 *1930*, DOI: 10.1021/ja01366a051]. Cf. Littke et al. *Org Lett* **9** 1711 *2007*, DOI: 10.1021/ol070372d for its use as a substrate in a palladium-catalysed cyanation with $Z(CN)_2$. [*Beilstein* **24** H 80, **25** III/IV 2117.]

2-Amino-3,5-dibromopyridine *[35486-42-1]* **$C_5H_4Br_2N_2$, M 251.9, m 103-104°, 104-105°, pK_{Est} ~2.4.** Steam distil it and recrystallise it from aqueous EtOH or petroleum ether. [*Beilstein* **22** II 333, **22** III/IV 4041.]

3-Amino-2,6-dichloropyridine *[62476-56-6]* **M 164.0, m 119°, b 110°/0.3mm, pK_{Est} ~2.0.** Recrystallise it from water. [*Beilstein* **22** III/IV 4093.]

2-Amino-4,6-dimethylpyridine (6-amino-2,4-lutidine) *[5407-87-4]* **$C_7H_{10}N_2$, M 122.2, m 63-64°, 69-70.5°, 235°/atm, pK^{25} 7.84.** Recrystallise this base from hexane, ether/petroleum ether or *benzene. Residual *benzene is removed over paraffin-wax chips in an evacuated desiccator. The ***dipicrate*** crystallises from EtOH and has **m 205-207°(dec)**. [*Beilstein* **22** III/IV 4210.]

2-Amino-4,6-dimethylpyrimidine *[767-15-7]* **$C_6H_9N_3$, M 123.2, m 151-153°, 152-153°, pK^{25} 4.95.** Recrystallisation from water gives the pyrimidine with **m 197°**, but recrystallisation from acetone gives **m 153°**. [*Beilstein* **25** III/IV 2205.]

2-(Aminomethyl)piperidine *[22990-77-8]* **$C_6H_{14}N_2$, M 114.2, b 66-67°/12mm, 80-81°/18mm, d_4^{20} 0.9406, n_D^{20} 1.4854, pK_1^{20} 6.33, pK_2^{20} 9.70.** Dry (over Na_2SO_4) and distil the piperidine under vacuum from KOH. It has been purified *via* the ***Reinekate salt*** (**m 173-174°**) and its ***dipicrate salt*** (**m 201°**, from H_2O). [Norton et al. *J Am Chem Soc* **68** 1330 *1946*, DOI: 10.1021/ja01211a071; Mortimer *Aust J Chem* **11** 82 *1958*, DOI: 10.1071/CH9580082; Augustine *J Am Chem Soc* **81** 4664 *1959*, DOI: 10.1021/ja01526a054; *Beilstein* **22** III/IV 3765.]

4-Amino-3-hydrazino-5-mercapto-1,2,4-triazole (Purpald) *[1750-12-5]* **$C_2H_6N_6S$, M 146.2, m 228-230°(dec), 234-235°(dec), $pK_{Est(1)}$~2, $pK_{Est(2)}$~3 (NH_2), $pK_{Est(3)}$~8 (SH).** Recrystallise Purpald from H_2O (0.6g in 300-400ml). The ***benzylidene*** derivative has **m 245-246°(dec)** from *i*-PrOH [Hoggarth *J Chem Soc* 4817 *1952*, DOI: 10.1039/JR9520004817; Dickinson & Jacobson *JCS Perkin Trans I* 975 *1975*. DOI: 10.1039/P19750000975; [*Beilstein* **26** III/IV 547.]

5-Amino-8-hydroxyquinoline hydrochloride *[3881-33-2]* **$C_9H_8N_2O.HCl$, M 196.7, pK_1^{20} 5.67, pK_2^{20} 11.24.** Dissolve the hydrochloride in the minimum volume of MeOH, then add Et_2O to initiate crystallisation. The crystals are filtered off and dried [Lovell et al. *J Phys Chem* **88** 1885 *1984*, DOI: 10.1021/j150653a042]. The ***dihydrochloride*** [21302-43-2] has **M 233.1, m 279°(dec).** [*Beilstein* **22** III/IV 5866.]

4-Aminoimidazole-5-carboxamide hydrochloride (AICAR HCl) *[72-40-2]* **$C_4H_6N_4O.HCl$, M 162.6, m 250-252°(dec), 255-256°(dec), $pK_{Est(1)}$ ~3.5, $pK_{Est(2)}$ ~9.4.** Recrystallise the hydrochloride from EtOH. [Kuroda & Suzuki *J Heterocycl Chem* **30** 593 *1993*, DOI: 10.1002/jhet.5570300302; Alhede et al. *J Org Chem* **56** 2139 1991, DOI: 10.1021/jo00006a033; Chern et al. *Heterocycles* **34** 1133 *1992*, DOI: 10.3987/COM-92-6000; *Beilstein* **25** II 221, **25** III/IV 4329.]

6-Aminoindazole *[6967-12-0]* **$C_7H_7N_3$, M 133.2, m 204-206°(dec), 210°, pK^{25} 3.99.** It is recrystallised from H_2O or EtOH and sublimes in a vacuum. [*Beilstein* **25** H 317.]

2-Amino-3-iodopyridine *[104830-06-0]* **$C_5H_5IN_2$, M 220.1, m 78-91°, 90-91.5°, pK_{Est} ~4.9.** Purify this pyridine by recrystallisation from hexane. The *N-Me* derivative *[113975-23-8]* has **m 50°,** and distils at **b 129°/14mm**. [Sakamoto et al. *Chem Pharm Bull, Japan* **33** 4764 *1985*, DOI: org/10.1248/cpb.33.4764; Estel et al. *J Org Chem* **53** 2740 *1988*, DOI: 10.1021/jo00247a016.]
2-Amino-4-iodopyridine *[552331-00-7]* has **m 163-164°, pK_{Est} ~5.1.** Purify this pyridine by recrystallisation from H_2O. The ***picrate*** has **m 253-254°** (from H_2O), the ***N-acetyl*** derivative has **m 150°** (from H_2O), and the ***N-benzoyl*** derivative has **m 167-168°** (from aqueous EtOH). [Graf *Chem Ber* **64** 21 (25) *1931*, DOI: 10.1002/cber.19310640103.]
2-Amino-5-iodopyridine *[20511-12-0]* has **m 128-131°, 129-130°, 130°, pK_{Est} ~4.5.** The pyridine can be purified by steam distillation. Separate the solid from the cooled distillate by filtration, acidify the filtrate, decolorise it with charcoal, concentrate it to ~200ml, make alkaline with KOH and cool. Filter the solid, add it to the original solid that was collected, and dry it *in vacuo*. It crystallises from *C_6H_6 in white needles. The ***picrate*** separates as yellow needles from hot EtOH or Me_2CO, **m 240°**. [Caldwell et al. *J Am Chem Soc* **66** 1479 *1944*, DOI: 10.1021/ja01237a018.] [*Beilstein* **22** II 334.]
5-Amino-2-iodopyridine *[29958-12-1]* has **m 63-65°, pK_{Est} ~2.6.** Purify it by recrystallisation from EtOH (white needles). [Caldwell et al. *J Am Chem Soc* **66** 1479 *1944*, DOI: 10.1021/ja01237a018.]

3-Amino-5-mercapto-1,2,4-triazole *[16691-43-3]* **$C_2H_4N_4S$, M 116.1, m 298°, ~300°, $pK_{Est(1)}$~ 3.0, $pK_{Est(2)}$~ 9.** Recrystallise the triazole from H_2O and dry it *in vacuo*. The ***acetyl*** derivative has **m 325°(dec)** after recrystallisation from H_2O. [*Beilstein* **26** III/IV 1351.] It has also been recrystallised from EtOH/H_2O (3:1, 1g in 50 ml, 50% recovery), **m 300-302°** (dec subject to heating rate), (λ_{max} 263nm, log ε 4.12). The ***S-benzyl*** derivative, when crystallised from *C_6H_6/EtOH (20:1), or $CHCl_3$/Et_2O has **m 109-111°** [Godfrey & Kurzer *J Chem Soc* 3437 *1960*, DOI: 10.1039/JR9600003437; *Beilstein* **26** III/IV 1351.]

2-Amino-4-methoxy-6-methylpyrimidine *[7749-47-5]* **$C_6H_9N_3O$, M 139.2, m 156-158°, 157-159°, 158-158.5°, 158-160°, pK_{Est} ~ 6.0.** Recrystallise it from H_2O. The ***picrate*** has **m 220-221°(dec)**. [Braker et al. *J Am Chem Soc* **69** 3072, 3075 *1947*, DOI: 10.1021/ja01204a044; Sirakawa et al. *Yakugaku Zasshi* **73** 598 *1953*, Backer & Grevenstuk *Recl Trav Chim Pays-Bas* **61** 291 *1942*, DOI: 10.1002/recl.19420610408; *Beilstein* **25** III/IV 3385.]

8-Amino-6-methoxyquinoline *[90-52-8]* **$C_{10}H_{10}N_2O$, M 174.2, m 41-42°, 51°, b 137-138°/1mm, $pK^{70.1}$ 3.38.** Distil it under N_2 and at high vacuum, then recrystallise it several times from MeOH (0.4ml/g). It remains colourless for several months when purified in this way [Elderfield & Rubin *J Am Chem Soc* **75** 2963 *1953*, DOI: 10.1021/ja01108a052]. The ***hydrobromide*** [312693-53-1] **M** 255.1 has **m 238°(dec)**. [*Beilstein* **22** III/IV 5934.]

7-Amino-4-methylcoumarin (Coumarin 120) *[26093-31-2]* **$C_{10}H_9NO_2$, M 175.2, m 223-226°, 224-229°(dec), pK_{Est} ~3.2.** Dissolve it in 5% HCl, filter and basify with 2M ammonia. The precipitate is dried in a vacuum and recrystallised from dilute EtOH. It yields a blue solution and is light sensitive. [Khammungkhune & Sigler *Synthesis* 614 *1980*, DOI: 10.1055/s-1980-29136; Kanaoka et al. *Chem Pharm Bull Jpn* **30** 1485 *1982*, DOI: org/10.1248/cpb.30.1485]. Useful laser dye with λ_{max} at 354nm, and in fluorescent labeling of trace enzymes [*Aldrichimica Acta* **15** 42 *1982*, for 7-amino-4-methyl-6-sulfocoumarin-3-acetic acid (AMCA-S), see Leung et al. *Biorg Med chem Lett* **9** 2229 *1999*, DOI: 10.1016/S0960-894X(99)00364-9]. [*Beilstein* **18/11** V 445.]

2-Amino-3-methylpyridine (2-amino-3-picoline) *[1603-40-3]* **$C_6H_8N_2$, M 108.1, m 29-31°, 33.2°, b 221-222°/atm, d_4^{25} 1.073, n_D^{20} 1.5823. pK^{25} 7.24.** Recrystallise the picoline three times from *benzene, most of the residual *benzene being removed from the crystals by standing over paraffin wax chips in an evacuated desiccator. The amine is also transferred to a separating funnel under N_2, and left in contact with NaOH pellets for 3 hours with occasional shaking. It is then placed in a vacuum distilling flask where it is refluxed gently in a

stream of dry N_2 before fractionally distilling it. [Mod et al. *J Phys Chem* **60** 1651 *1956*, DOI: 10.1021/j150546a013; *Beilstein* **22/9** V 212].

2-Amino-4-methylpyridine (2-amino-4-picoline) *[695-34-1]* **$C_6H_8N_2$, M 108.1, m 96-99°, 99.2°, 100-100.5°, b 115-117°/11mm, 230°/atm, pK^{25} 7.48.** Crystallise it from EtOH, a 2:1 *benzene/acetone mixture, or petroleum ether, and dry it under vacuum as in the prevous entry. Sublimes in a vacuum. It is cardiotonic. [*Beilstein* **22/9** V 325.]
2-Amino-5-methylpyridine **(6-amino-3-picoline)** *[1603-41-4]* has **m 76-77°, 76.5°, b 227°/atm, pK^{25} 7.22.** Crystallise it from acetone, and/or distil it. [*Beilstein* **22/9** V 289.]
2-Amino-6-methylpyridine **(6-amino-2-picoline)** *[1824-81-3]* has **m 40-44°, 44.2°, b 208-209°/atm, pK^{25} 7.41.** Crystallise it three times from acetone and dry it under vacuum at *ca* 45°. *Alternatively*, keep it in contact with NaOH pellets for 3 hours, with occasional shaking, decant and fractionally distil it [Mod et al. *J Phys Chem* **60** 1651 *1956*, DOI: 10.1021/j150546a013]. It also recrystallises from CH_2Cl_2 on addition of petroleum ether. [Marzilli et al. *J Am Chem Soc* **108** 4830 *1986*, DOI: 10.1021/ja00276a021; *Beilstein* **22/9** V 210.]

2-Amino-4-methylpyrimidine *[108-52-1]* **$C_5H_7N_3$, M 109.1, m 158-160°, 159-160°, 161°, pK^{20} 4.15.** Crystallise the pyrimidine from H_2O or EtOH and sublime it in a vacuum. The ***picrate*** crystallises from EtOH and has **m 235-236°(dec)**. **[***Beilstein* **24** H 84, **25** III/IV 2152.]
2-Amino-5-methylpyrimidine *[50840-23-8]* has **m 193.5°, pK_{Est} ~4.0.** Crystallise it from water or *benzene/petroleum ether and sublime it at 50°/0.5mm. [*Beilstein* **24** H 87.]

4-Amino-2-methylquinoline (4-aminoquinaldine) *[6628-04-2]* **$C_{10}H_{10}N_2$, M 158.2, m 162-166°, 168°, b 333°/760mm, pK^{20} 9.42.** Recrystallise it from *benzene/petroleum ether. [*Beilstein* **22/10** V 347.]

6-Aminonicotinic acid *[3167-49-5]* **$C_6H_6N_2O_2$, M 138.1, m 312°(dec), $pK_{Est(1)}$ ~2.2 (CO_2H), $pK_{Est(2)}$ ~6.5.** Crystallise the acid from aqueous acetic acid. Dry it *in vacuo* at 70°. It decarboxylates cleanly above its melting point to give 2-amiopyridine. [*Beilstein* **22** III/IV 6726.]

(+)-6-Aminopenicillanic acid *[551-16-6]* **$C_8H_{12}N_2O_3S$, M 216.3, m 198-200°(dec), 208-209°, $[\alpha]_D^{22}$ +267.3 (c 1.2, 0.1M HCl), $[\alpha]_{546}$ +327 (in 0.1M HCl), pK_1^{25} 2.30, pK_2^{25} 4.90.** This acid crystallises from water or aqueous HCl. [Kleppe & Strominger *J Biol Chem* **254** 4856 *1979*, http://www.jbc.org/content/254/11/4856; *Beilstein* **27** III/IV 2858.]

2-Aminoperimidine *[28832-64-6]* **$C_{11}H_9N_3$, M 183.1, m 239°, b 170-175°/1.5mm, pK_{Est} ~7.9 (free base).** It crystallises from EtOH/H_2O (1:1). It precipitates as the ***hydrochloride*** with dilute HCl which has **m 282°**. [Dasgupta et al. *Anal Chim Acta* **94** 205 *1977*, DOI: 10.1016/S0003-2670(01)83651-5; *Beilstein* **24** H 193, **25** III/IV 2677.] ***2-Aminoperimidine hydrobromide*** *[40835-96-9, 313223-13-1 hydrate]* **$C_{11}H_9N_3.HBr.xH_2O$, M 264.1(anhydr),** has **m 299°, pK_{Est} ~7.9 (free base).** Purify the hydrobromide by boiling a saturated aqueous solution with charcoal, filtering and leaving the salt to crystallise. Store this ***dihydrate salt*** in a cool, stoppered flask in the dark place. The ***anhydrous salt*** is obtained by heating at 80°/4 hours, and it is hygroscopic. The solubilities of the hydrobromide at 26° are 2.4% in EtOH, 0.6% in H_2O, 0.3% in Et_2O, 0.1% in Me_2CO and 0.003% in $*C_6H_6$. [Dasgupta et al. *Anal Chim Acta* **94** 205 *1977*, DOI: 10.1016/S0003-2670(01)83651-5; Dasgupta & West *Microchim Acta* **70** 505 *1978*, DOI: http://www.jbc.org/content/177/1/357; Dasgupta et al. *Anal Chem* **50** 1793 *1978,* DOI: 10.1021/ac50035a020; *Beilstein* **24** H 193, **25** III/IV 2677.]

2-Aminopyridine *[504-29-0]* **$C_5H_6N_2$, M 94.1, m 54-58°, 58°, 58.1°, b 204-210°/atm, 210.6°/atm, pK_1^{25} -7.6, pK_2^{25} 6.71.** It crystallises from *benzene/petroleum ether (b 40-60°) or $CHCl_3$ /petroleum ether. [*Beilstein* **22/8** V 280.] IRRITANT.
3-Aminopyridine *[462-08-8]* has **m 64°, b 248°/atm, 250-252°/atm, pK_1^{25} -1.5, pK_2^{25} 6.03.** It crystallises from *benzene, $CHCl_3$/petroleum ether (b 60-70°), or *benzene/petroleum ether (4:1). [Allen & Wolf *Org Synth* Coll Vol **4** 45 *1963*, DOI: 10.15227/orgsyn.030.0003; *Beilstein* **22/9** V 3.] IRRITANT.
4-Aminopyridine *[504-24-5]* has **m 155-158°, 158-159°, 160°, b 180°/12-13mm, 273°/atm, pK_1^{25} -6.55, pK_2^{25} 9.11 (9.18).** Crystallise the aminopyridine from *benzene/EtOH, then recrystallise it twice from water, then crush and dry it for 4 hours at 105° [Bates & Hetzer *J Res Nat Bur Stand* **64A** 427 *1960*, DOI:org/10.6028/jres.064A.044]. It has also been crystallised from EtOH, *benzene, *benzene/petroleum

ether, toluene and sublimes in a vacuum. It is a relatively strong organic base. [*Beilstein* **22/9** V 106.] It is of some effect in demyelinating nerve fibres and in multiple sclerosis.

2-Aminopyrimidine *[109-12-6]* **$C_4H_5N_3$, M 95.1, m 122-126°, 126-127.5°, pK^{20} 3.45.** Crystallise 2-aminopyrimidine from *C_6H_6, EtOH or H_2O. [*Beilstein* **25** III/IV 2071.]
4-Aminopyrimidine *[591-54-8]* has **m 149-151°, 151-152°, 154-156°, pK^{25} 5.69.** Recrystallise 10.6g of aminopyrimidine from hot EtOAc (200ml) to give 7.4g colourless needles as first crop; evaporation to 25ml gives a second crop of 1.7g. It also crystallises from ~200 parts of light petroleum (b 100-120°) or 50 parts of *iso*butyl methyl ketone (charcoal). The ***hydroiodide*** has **m 180°**. The ***picrate*** has **m 225°**, and the ***1-methyl-iodide*** has **m 204-205°** (crystallise from 20 parts of EtOH) [Brown et al. *J Chem Soc* 4035 *1955*, DOI: 10.1039/JR9550004035]. [Synth: Brown *J Soc Chem Ind* (London) **69** 353 *1950*; also prepared by decarboxylation of 4-amino-5-carboxypyrimidine Brown & Short *J Chem Soc* 331 *1953*, DOI: 10.1039/JR9530000331; *Beilstein* **24** H 81, **24** III/IV 2130.]
5-Aminopyrimidine *[591-55-9]* has **m 171-172° (with sublimation), pK^{25} 2.52.** It is purified by conversion to the $MgCl_2$ complex in a small volume of H_2O. The complex (~ 5g) is dissolved in the minimum volume of hot H_2O, passed through a column of activated Al_2O_3 (200g), and the column is washed with EtOH. Evaporation of the EtOH gives a colourless residue of the aminopyrimidine which is recrystallised from *C_6H_6 (toluene could also be used) which forms needles at first, then prisms. It melts with sublimation. Acetylation yields ***5-acetamidopyrimidine*** which crystallises from *C_6H_6, **m 148-149°**. The NH_2 group behaved more like the one in aniline. [Whittaker & Jones *J Chem Soc* 1565 *1951*, DOI: 10.1039/JR9510001565.]

Aminopyrine (4-dimethylaminoantipyrene) *[58-15-1]* **M 231.3, m 107-109°, 108°, pK_1^{25} -2.22, pK_2^{25} 4.94.** It crystallises from petroleum ether, sublimes between 80° and 90°, and forms metal complexes. [*Beilstein* **25** H 452, **25** III/IV 3555.]

3-Aminoquinoline *[580-17-6]* **$C_9H_8N_2$, M 144.2, m 91-92°, 93.5°, pK_1^{20} -0.58, pK_2^{20} 4.94.** It crystallises from *C_6H_6, toluene, hexane and aqueous EtOH. [*Beilstein* **22** III/IV 4605, **22/10** V 233.]
4-Aminoquinoline *[578-68-7]* has **m 155-155.5°, 158°, pK_1^{25} -7.11(5.99), pK_2^{20} 9.13.** It has been purified by zone refining and recrystallisation from *C_6H_6, EtOH or H_2O. The ***hydrochloride*** has **m 308°** (from MeOH), and the ***picrate*** has **m 277°** (from EtOH). [Albert et al. *J Chem Soc* 2240 *1948*, DOI: 10.1039/JR9480002240; *Beilstein* **22** III/IV 4611, **22/10** V 341.]
5-Aminoquinoline *[611-34-7]* has **m 106-109°,110°, b 184°/10mm, 310°/760mm, pK_1^{20} 0.97(0.49), pK_2^{20} 5.42.** It crystallises from pentane and from *benzene or EtOH. The ***picrate*** has **m 209-210°(dec)** (**202° dec**) (from aqueous EtOH). [*Beilstein* **22** III/IV 4669, **22/10** V 297.]
6-Aminoquinoline *[580-15-4]* has **m 115-119°, 117-119°, 120°, b 146°/0.3mm, 192-195°/14mm, pK_1^{20} 1.63, pK_2^{20} 5.59.** It is purified by column chromatography on a SiO_2 column using $CHCl_3$/MeOH (4:1) as eluent. It crystallises from *C_6H_6 or *C_6H_6/petroleum ether and is an **irritant**. The ***styphnate*** has **m 239-240°** (from EtOH) and **m 242-243°** (from aqueous Me_2CO). [Barrett et al. *J Chem Soc* 50, 57 1953, DOI: 10.1039/JR9530000050; *Beilstein* **22** III/IV 4681, **22/10** V 303.]

8-Aminoquinoline *[578-66-5]* **$C_9H_8N_2$, M 144.2, m 60-65°, 70°, b 140.5-141°/7mm, 123°/5mm, 174°/26mm, pK_1^{20} -0.52, pK_2^{20} 3.95.** 8-Aminoquinoline crystallises from EtOH, ligroin, octane or H_2O, and complexes with metals. [*Beilstein* **22** III/IV 4708, **22/10** V 316.]

2-Amino-5-sulfanilylthiazole (thiazolsulfone, Promizole) *[473-30-3]* **$C_9H_9N_3O_2S_2$, M 255.3, m 219-221°(dec), pK_{Est} ~4.5 (OH).** If too impure, it may contain some 'iron-mud', then extract it with Me_2CO, filter and evaporate the fitrate *in vacuo*. Dissolve the residue in boiling absolute EtOH, treat it with charcoal (*ca* 10% w/w) filter and allow to cool. Recrystallise the thiazole again from EtOH (needles). It possesses tuberculotherapeutic activity. [Bambas *J Am Chem Soc* **67** 671 *1945*, DOI: 10.1021/ja01220a050.]

2-Aminothiazole *[96-50-4]* **$C_3H_4N_2S$, M 108.1, m 91-93°, 93°, b 140°/11mm, pK^{20} 5.36.** It crystallises from petroleum ether (b 100-120°), or EtOH. It undergoes Ulmann coupling with 2-chlorobenzoic acid in the presence of ultrasonic irradiation [Pellón et al. *Synth Commun* ***37*** *1853* 2007, DOI:10.1080/00397910701319056]. [*Beilstein* **27** III/IV 4574.] It inhibits thyroid growth.

2-Amino-4-thiazoleacetic acid (2-amino-4-carboxymethylthiazoline) *[29676-71-9]* **$C_5H_6N_2O_2S$, M 158.2, m 130°(dec), $pK_{Est(1)}$ ~4.5 (COOH), $pK_{Est(2)}$ ~5.3(2-NH_2).** Purified by recrystallisation from hot H_2O (solubility is ~6.5g/L at ~20°) or EtOH. It has been prepared by mixing ethyl chloroacetoacetate and ammonium dithiocarbamate in H_2O for 5 hours at room temperature then refluxed for 2 hours which gives an 81% yield of the ***ethyl ester*** *[53266-94-7]* **$C_7H_{10}N_2O_2S$, M 186.2, m 92-94°,** recrystallised from di-*iso*-propyl ether, and hydrolysed by 2.5N NaOH at 55° for 1 hour followed by acidification. [Bolchi et al. *Bioorg Med Chem Lett* **21** 5408 *2011*, DOI: 10.1016/j.bmcl.2011.07.003; Steude *Justus Liebigs Ann Chem* **261** 22 *1891*, DOI: 10.1002/jlac.18912610103]. The acid and ester are **IRRITANTS**. They are used in the pharmaceutical industry and as pesticides. The acid forms Ni II [He et al. *Acta Crystalogr Sect E* **65** m666 *2009*, DOI: 10.1107/S1600536809017978, PMID: 21583027], $CdCl_2$ [with the ethyl ester Zhang et al. *Acta Crystalogr Sect E* **68** m788 *2012*, DOI: 10.1107/S1600536812021976, PMID: 22719339] and Zn II [Zhang et al. *Acta Crystalogr Sect E* **65** m1517 *2009*, DOI: 10.1107/S1600536809045589, PMID: 21578564] crystalline complexes. [*Beilstein* **27** H 336.]

The ***2-amino-4-thiazoleacetic acid fluoroborate salt*** *[110295-78-8 zwitterion]* **$C_5H_7N_2O_2SBF_4$**, prepared by hydrolysis of the ethyl ester with 34% aqueous fluoroboric acid overnight at ~25°, and the salt which crystallise upon addition of Et_2O to the mixture, had **m 180-185°** and ^{1}H NMR (Me_2SO-d_6, TMS) with δ at 3.55 (2H, s), 6.55 (1H, s), 7.8-8.2 NH_2, br) [Bouchet et al. *J Med Chem* **30** 2222 *1987*, DOI: 10.1021/jm00395a008].

2-Amino-4-thiazoleacetic acid hydrazide is prepared by boiling the ***ethyl ester*** (0.4mol, above) and hydrazine hydrate (0.4mol) in absolute EtOH (300ml) for 6 hours, cooled and allowed to crystallise over 3 days. The hydrazide is then recrystallised from EtOH and dried in a desiccator over silica gel. It has antifungal and antitubercular activities and it forms light brown crystals of the ***CuII complex***. [Enedoh *Int J Sci Eng Res* **6** (4) 110 *2015*, ISSN 2229-5518.]

2-Amino-5-thiazoleacetic acid ethyl ester **(2-amino-5-ethoxycarbonylmethyl-1,4-thazole)** *[62557-32-8]* **$C_7H_{10}N_2O_2S$, M 186.2,** has **m 100-101°.** The ester was prepared by condensing thiourea (1.4g) with β-bromo-β-aldehydo-propionic acid ethyl ester (5.2g, = bromosuccinic acid semialdehyde ethyl ester) in EtOH (25ml) during 3 hours (boiling water bath), evaporating *in vacuo*; the crystalline residue was dissolved in dilute HCl (2ml concentrated HCl and 25ml H_2O), extracted into Et_2O (2 x 5ml), washed with aqueous $NaHCO_3$, filtered and evaporated. The residue was recrystallised from *C_6H_6/petroleum ether or $CHCl_3$/petroleum ether to give pure ***ester*** as white plates (3.1g, 90%) which were fairly soluble in H_2O, Et_2O, EtOH, *C_6H_6 and $CHCl_3$ but insoluble in petroleum ether. The ***ester-picrate*** forms yellow needles from EtOH with **m 204-205°(dec)**, and the ***ester-picrolonate*** has **m 216-218°(dec)** (golden yellow plates from absolute EtOH). The ***amide*** was formed by shaking the ester with concentrated aqueous NH_3, evaporating to dryness (hot water bath), and the residual solid was purified by subliming at 140-150°/0.05mm or distilling at 180°/0.5mm to give white crystals **m 174-175°(dec)** of the amide which are slightly soluble in H_2O but insoluble in most organic solvents. [Mory & Schenkel *Helv Chim Acta* **33** 405 *1950*, DOI: 10.1002/hlca.19500330225.]

2-Amino-5-thiazoleacetic acid fluoroborate salt *[110295-83-5 zwitterion]* **$C_5H_7N_2O_2SBF_4$**, was prepared by hydrolysis of the ethyl ester with 34% aqueous fluoroboric acid overnight at ~25°, and the salt was crystallised by addition of Et_2O to the mixture. It had **m 215°** and ^{1}H NMR (Me_2SO-d_6) with δ at 3.72 (2H, s), 6.2-6.8 NH_2, br) and 7.0 (1H, s) [Bouchet et al. *J Med Chem* **30** 2222 *1987*, DOI: 10.1021/jm00395a008].

1-Amino-1,2,4-triazole *[24994-60-3]* **$C_2H_4N_4$, M 84.1, m 91-93°, pK_{Est} ~2.** The triazole crystallises from water. [Barszcz et al. *JCS Dalton Trans* 2025 *1986*, DOI: 10.1039/DT9860002025; Temple & Montgomery *1,2,4-Triazoles —The Chemistry of Heterocyclic Compounds* Vol 37 (Weissberger & Taylor eds.). Wiley & Sons NY *1981*, ISBN 0-471-0656-6.]

3-Amino-1,2,4-triazole **(3-AT, Amitrol)** *[61-82-5]* has **m 159°, pK_1^{20} 4.04, pK_2^{20} 11.08.** It crystallises from EtOH (charcoal), then three times from dioxane [Williams et al. *J Phys Chem* **61** 261 *1957*, DOI: 10.1021/j150549a002]. [*Beilstein* **26** H 137.] **Possible carcinogen.** [Sjostedt & Gringas *Org Synth* Coll Vol **3** 95 *1955*, DOI: 10.15227/orgsyn.026.0011; *Beilstein* **26** H 137, Temple & Montgomery *1,2,4-Triazoles —The Chemistry of Heterocyclic Compounds* Vol 37 (Weissberger & Taylor eds.). Wiley & Sons NY *1981*, ISBN 0-471-0656-6.] The ***hydrochloride***, **m 153°**, crystallises from EtOH, and has herbicidal activity. **IRRITANT**.

4-Amino-1,2,4(4H)-triazole *[584-13-4]* has **m 80-81°, 84-86°, pK^{25} 3.23.** It crystallises from EtOH/ Et_2O or H_2O. The ***hydrochloride*** has **m 151-152°** (from EtOH, 1g/10ml). [Allen & Bell *Org Synth* Coll Vol **3** 96 *1955*, DOI: 10.15227/orgsyn.024.0012; Barszcz et al. *JCS Dalton Trans* 2025 *1986*, DOI: 10.1039/DT9860002025; *Beilstein* **26** H 16, **26** II 7, **26** III/IV 40, Temple & Montgomery *1,2,4-Triazoles —The Chemistry of Heterocyclic Compounds* Vol 37 (Weissberger & Taylor eds.). Wiley & Sons NY *1981*, ISBN 0-471-0656-6.]

7-Amino-4-(trifluoromethyl)coumarin (Coumarin 151) *[53518-15-3]* **$C_{10}H_6F_3NO_2$, M 229.1, m 221-222°, 222°, pK_{Est} ~3.1.** Purify the coumarin by column chromatography on a C18 column, elute with acetonitrile/0.01M H_2O/HCl (1:1), and recrystallise it from isopropanol. *Alternatively*, it is eluted from a silica gel column with CH_2Cl_2, or by extracting a CH_2Cl_2 solution (4g/L) with 1M aqueous NaOH (3 x 0.1L), followed by drying ($MgSO_4$), filtration and evaporation. It is a suitable laser dye with λ_{max} at 207nm. [Bissell *J Org Chem* **45** 2283 *1980*, DOI: 10.1021/jo01300a003; Zimmermann et al. *Anal Biochem* **70** 258 *1976* DOI: 10.1016/S0003-2697(76)80066-8.]

4(6)-Aminouracil (4-amino-2,6-dihydroxypyrimidine) *[873-83-6]* **$C_4H_5N_3O_2$, M 127.1, m >350°, ~360°, pK_1^{20} 0.00 (basic), pK_2^{20} 8.69 (acidic), pK_3^{20} 15.32 (acidic)** Purify the aminouracil by dissolving it in 3M aqueous NH_3, filtering hot, and adding 3M formic acid until precipitation is complete. Cool, filter off (or centrifuge), wash well with cold H_2O, then EtOH and dry it in air. Dry it further in a vacuum at ~80°. [Barlin & Pfleiderer *J Chem Soc (B)* 1425 *1971*, DOI: 10.1039/J29710001425; *Beilstein* **25** III/IV 4107.]

Amodiaquin [SN 10,751; 4-(3-dimethylaminomethyl-4-hydroxyanilino)-7-chloroquinoline, Camoquin] *[86-42-0]* **$C_{20}H_{22}ClN_3O$, M 355.9, m 208°(dec).** Amodiaquin crystallises from 2-ethoxyethanol, *iso*PrOH or EtOH. It was prepared in various ways, e.g. by reacting 4,7-dichloroquinoline with 4-aminophenol in AcOH, and without isolating the intermediate, the mixture was treated with formaldehyde and Et_2NH in aqueous HCl. *Alternatively*, 4-acetaminophenol was converted, with formaldehyde and Et_2NH in aqueous HCl, into 4-amino-2-dimethylaminomethylphenol which was condensed with 4,7-dichloroquinoline in DMF/Na_2CO_3 then aqueous HCl, all in a 'one pot synthesis' in a *Green Chemistry* US Patent Synthesis [Burckhalter et al. US Patent 2474819, 2474821 *1949* to Parke Davis; WO 2013138200 A1, Kulkarni et al. Sep 19 *2013* Howard University]. It also crystallises in pale yellow crystals from H_2O with ***2HCl. 2H$_2$O*** *[6398-98-7]* **m 150-160°(dec)** (under the names Camoquin, CAM-AQ1 or Flavoquin); forms yellow crystals from Me_2CO/H_2O with ***2HCl. 1H$_2$O*****, m 183°(dec)**, and when recrystallised from MeOH it also forms yellow crystals with ***2HCl. 0.5H$_2$O*****, m 243°(dec)**. The ***free base*** is ***anhydrous*** as it crystallises from absolute EtOH with **m 208°(dec)**. They have UV with λ_{max} mn ($\mathbf{E}^{1\%}_{cm}$) at 342(349) in MeOH; 341.5(389) in H_2O and 342(396) in 0.1N HCl. They have some solubility in H_2O, more so in aqueous acid due to the dialkylamino group and 4-arylaminoquinoline moiety, also in alkaline medium due to the phenolic group; low solubility in alcohols, but quite insoluble in *C_6H_6, $CHCl_3$ or Et_2O. [Burckhalter et al. *J Am Chem Soc* **70** 1363 *1948*, DOI: 10.1021/ja01184a023; for UV spectra see Krácmar et al. *Pharmazie* **29** 773 *1974*, PMID: 4460004; *Beilstein* **22** III/IV 4647.]. They have antimatarial activity, and their activities, e.g. against *Gallinaceum* malaria in chicks are ~25 times those of quinine; and if the diethylamino groups are replaced by di-*iso*-propyl groups their activities can be up to ~75 times those of quinine.

2-*n*-Amylpyridine (2-*n*-pentylpyridine) *[2294-76-0]* **$C_{10}H_{15}N$, M 149.2, b 63.0°/2mm, 206.5-207°/~760mm, n_D^{26} 1.4861, pK^{25} 6.00.** Dry it with NaOH for several days, then distil it from CaO under reduced pressure, taking the middle fraction and redistilling it. The ***picrate*** has **m 72-72.8°** (from EtOH). [*Beilstein* **20** III/IV 2835.]

3-*n*-Amylpyridine *[1802-20-6]* **$C_{10}H_{15}N$, M 149.2, b 110-112°/20mm, 224-226°/748mm, pK_{Est} ~5.8.** Purify as the 2-isomer, and has the ***picrate*** has **m 79.5-80°**(from EtOH). [*Beilstein* **20** III/IV 2835.] Flavouring agent.

4-*n*-Amylpyridine *[2961-50-4]* **$C_{10}H_{15}N$, M 149.2, b 78.0°/2.5mm, 229-230°/~760mm, n_D^{20} 1.4908, pK_{Est} ~6.1.** It is dried with NaOH for several days, then distilled from CaO under reduced pressure, taking the middle fraction and redistilling it. The ***picrate*** has **m 104°** (from EtOH). [*Beilstein* **20** III/IV 2836.]

Antipyrine (2,3-dihydro-1,5-dimethyl-3-oxo-2-phenylpyrazole) *[60-80-0]* **$C_{11}H_{12}N_2O$, M 188.2, m 111-113°, 114°, b 319°, pK^{25} 1.45.** Antipyrine crystallises from EtOH/water mixture, *benzene, *benzene/petroleum ether or hot water (charcoal), and the crystals are dried under a vacuum. [*Beilstein* **24** H 27, **24** III/IV 75.] It is an analgesic.

Aspergillic acid [2-hydroxy-3-isobutyl-6-(1-methylpropyl)pyrazine 1-oxide] *[490-02-8]* **$C_{12}H_{20}N_2O_2$, M 224.3, m 97-99°, pK^{25} 5.5, $[\alpha]_D^{20}$ +13.3 (c 4, EtOH)**. It is recrystallised from MeOH (yellow needles), and is sublimed at 80°/10^{-3}mm. [Dutcher *J Biol Chem* **171** 321 *1947*, http://www.jbc.org/content/254/11/4856; *Beilstein* **24** III/IV 235.]

8-Azaadenine (7-amino-1-*v*-triazolo[*d*]pyrimidine) *[1123-54-2]* **$C_4H_4N_6$, M 136.1, m 345°(dec), pK_1^{20} 2.65, pK_2^{20} 6.29.** 8-Azaadenine crystallises from H_2O. Antimetabolite of purines. [See Cavalieri et al. *J Am Chem Soc* **70** 3875 *1948*, DOI: 10.1021/ja01191a102; for spectra, *Beilstein* **25** III/IV 4157.]

2-Azacyclotridecanone (laurolactam) *[947-04-6]* **$C_{12}H_{23}NO$, M 197.3, m 150-153°, 152°.** 2-Azacyclotridecanone crystallises from $CHCl_3$ and is stored over P_2O_5 in a vacuum desiccator. [*Beilstein* **26/1** V 566.]

8-Azaguanine (5-amino-7-hydroxy-1-*v*-triazolo[*d*]pyrimidine) *[134-58-7]* **$C_4H_4N_6O$, M 152.1, m >300°, pK_1^{20} 1.04, pK_2^{20} 6.29.** Dissolve it in hot M NH_4OH, filter, and cool whereby colourless crystals separate out. Recrystallise it, and wash it with water, then dry it in a vacuum. Antimetabolite of purines. [Roblin et al. *J Am Chem Soc* **67** 290 *1945*, DOI: 10.1021/ja01218a043; for spectra see Cavalieri et al. *J Am Chem Soc* **70** 3857 *1948*, DOI: 10.1021/ja01191a102; *Beilstein* **26** III/IV 4171.]

7-Azaindole (1*H*-pyrrolo[2,3b]pyridine) *[271-63-6]* **$C_7H_6N_2$, M 118.1, m 105-106°, pK^{20} 4.57.** Recrystallise it repeatedly from EtOH, then sublime it in a vacuum [Tokumura et al. *J Am Chem Soc* **109** 1346 *1987*, DOI: 10.1021/ja00239a010]. It is used as a pharmaceutical synthetic building block [Wang et al. *J Org Chem* **71** 4021 *2006*, DOI: 10.1021/jo0602571]. The ***N-acetate*** has **m 65-66°** (from $*C_6H_6$), and the ***picrate*** has **m 232-233°** (from Me_2CO) [Clemo & Swan *J Chem Soc* 603 *1945*, DOI: 10.1039/JR9450000603; *Beilstein* **23** III/IV 1105.]

1-Azaindolizine (1,7a-diazaindene, imidazo[1,2-a]pyridine) *[274-76-0]* **$C_7H_6N_2$, M 118.1, b 72-73°/1mm, 103°/1mm, d_4^{25} 1.165, n_D^{20} 1.626, pK^{20} 1.43. (in aqueous HCl).** 1-Azaindolizine is purified by distillation or gas chromatography. [Bower & Ramage *J Chem Soc* 4506 *1957*, DOI: 10.1039/JR9570004506; Armarego *J Chem Soc* 4226 *1964*, DOI: 10.1039/JR9640004226; *Beilstein* **23** II 1554, **23** III/IV 1104.]

8-Azapurine (1*H*-1,2,3-triazolo[4,5-*d*]pyrimidine, 1,2,3,4,6[3*H*]penta-azaindene) *[273-40-5]* **$C_4H_3N_5$, M 121.1, m 174-175° (effervescence, m depends on heating rate), pK_1^{20} 2.05 (equilib with covalent hydrate), pK_2^{20} 4.84.** Sublime 8-azapurine at 120-130°/0.01mm and recrystallise it from 3 parts of EtOH. [Albert *J Chem Soc(B)* 427 *1966*, DOI: 10.1039/J29660000427; *Beilstein* **26** III/IV 4108.]

Azetidine (trimethyleneimine) *[503-29-7]* **C_3H_7N, M 57.1, b 19°/132.5mm, 61.3-61.5°/760mm, d_4^{20} 0.846, n 1.432, pK^{25} 11.29.** Azetidine is a flammable, hygroscopic liquid smelling of ammonia, which absorbs CO_2 from air and should be kept under Argon. Purify it by drying it over solid KOH and distilling it through a short Vigreux column (p 11) at atmospheric pressure (under Argon) and keeping the pot temperature below 210°. It is moisture sensitive. The ***hydrochloride*** *[36520-39-5]* **M 93.6** has **m > 300°** and the ***hydroiodide*** has **m 146.5°**(from EtOH). The ***N-Me derivative*** has **m 112°** (from $*C_6H_6$/petroleum ether), and the ***N-phenylcarbamoyl derivative*** has **m 189-190°** (from EtOH). [Searles et al. *J Am Chem Soc* **78** 4917 *1956*, DOI: 10.1021/ja01600a029; *Beilstein* **20** H 2, **20** I 3, **20** II 3, **20** III/IV 53, **20/1** V 136.]

Aziridine (ethyleneimine) *[151-56-4]* **C_2H_5N, M 43.1, b 55-56°/756mm, 56°/760mm, d_4^{24} 0.8321, pK^{25} 8.00.** Redistil it in an argon or N_2 atmosphere in a fume hood, and store it over KOH in sealed bottles in a refrigerator. Commercial aziridine has been dried over sodium and distilled from the metal through an efficient column before use [Jackson & Edwards *J Am Chem Soc* **83** 355 *1961*, DOI: 10.1021/ja01463a023; Wenker *J Am Chem Soc* **57** 2328 *1935*, DOI: 10.1021/ja01314a504]. It is a weaker base than Me_2NH (pK^{25} 10.87) but is caustic to the skin. It should not be inhaled, causes inflammation of the eyes, nose and throat, and one may become sensitised to it. It is soluble in H_2O, has an ammoniacal smell and reacts with CO_2. Pure aziridine is comparatively stable but polymerises in the presence of traces of H_2O and is occasionally explosive in the presence of acids. CO_2 is sufficiently acidic to cause polymerisation (forms linear polymers) which is not free radical promoted. It is stable in the presence of bases. The violet *2:1* ***Cu complex*** crystallises from EtOH containing a few drops of aziridine and adding Et_2O, and has **m 142°**(**dec**). The ***picrate*** has **m 142°**. [O'Rourke et al. *J Am Chem Soc* **78** 2159 *1956*, DOI: 10.1021/ja01591a035.] It has also been dried over BaO and has been distilled from sodium under nitrogen. [Allen et al. *Org Synth* Coll Vol **4** 433 *1963*, DOI: 10.15227/orgsyn.030.0038; *Beilstein* **20** III/IV 1.] **TOXIC.**

Azuleno(1,2-b)thiophene *[25043-00-9]* **$C_{12}H_8S$, M 184.2.** It is crystallised from cyclohexane, then sublimed *in vacuo*. ***Azuleno(2,1-b)thiophene*** *[248-13-5]* is recrystallised from cyclohexane, then sublimed *in vacuo*.

Azure A (3-amino-7-dimethylaminophenazin-5-ium chloride) *[531-53-3]* **$C_{14}H_{14}ClN_3S$, M 291.8, CI 52005, m > 290°(dec), λ_{max} 633nm, pK^{25} 7.2.** This biological stain, Azure A, has been twice recrystallised from H_2O and dried at 100°/1 hour in an oven. The green crystals give a blue aqueous solution. [*Beilstein* **27** III/IV 5151.]
Azure B **(3-methylamino-7-dimethylaminophenazin-5-ium chloride)** *[531-55-5]* **$C_{15}H_{16}ClN_3S$, M 305.8, CI 52010,** has **m > 201°(dec), 205-210°(dec), λ_{max} 648nm, pK^{25} 7.4.** This biological stain, Azure B, has been twice recrystallised from H_2O and dried at 100°/1 hour in an oven. The green crystals give a blue aqueous solution. [*Beilstein* **27** III/IV 5151.]
Azure C **(3-amino-7-methylaminophenazin-5-ium chloride)** *[531-57-7]* **$C_{13}H_{12}ClN_3S$, M 277.8, CI 52002,** has **λ_{max} 616nm, pK^{25} 7.0.** This biological stain, Azure C, has been twice recrystallised from H_2O, and dried at 100°/1 hour in an oven. The green crystals give a blue aqueous solution. [*Beilstein* **27** III/IV 5151.]

Barbituric acid (6-hydroxypyrimidin-2,4-dione) *[67-52-7]* **$C_4H_4N_2O_3$, M 128.1, m 248-250°(dec), 250°(dec), pK_1^{25} 3.99, pK_2^{25} 12.5.** Recrystallise it twice from H_2O, then dry it for 2 days at 100°. [*Beilstein* **24** III/IV 1873.] It is used as a buffer reagent.

Benzimidazole *[51-17-2]* **$C_7H_6N_2$, M 118.1, m 169-171°, 170-172°, 172-173°, pK_1^{25} 5.53, pK_2^{25} 11.70.** It crystallises from boiling water (1g/15ml) or aqueous EtOH (charcoal) and is dried at 100° for 12 hours. [Wagner & Millett *Org Synth* Coll Vol **2** 65 *1943*, DOI: 10.15227/orgsyn.019.0012; *Beilstein* **23** H 131, **23/6** V 196.]

2-Benzimidazolylacetonitrile *[4414-88-4]* **$C_9H_7N_3$, M 157.2, m 200-205°(dec), 209.7-210.7°(corrected), 210°.** It is recrystallised from aqueous EtOH. It has also been recrystallised from hot H_2O using charcoal, and finally from aqueous EtOH. [Copeland & Day *J Am Chem Soc* **65** 1072 *1943*, DOI: 10.1021/ja01246a019; *Beilstein* **25** III/IV 820.]

Benzo-15-crown-5 *[14098-44-3]* **$C_{14}H_{20}O_5$, M 268.3, m 78-80°.** It is recrystallised from *n*-heptane. **IRRITANT.** [Vögtle ed, Host Guest Complex Chemistry in *Topics in Current Chemistry* **98** *1981*, DOI: 10.1007/BFb0111244; *Beilstein* **19/10** V 618.]
Benzo-18-crown-6 *[14098-24-9]* **$C_{16}H_{24}O_6$, M 312.2,** has **m 42-45°, 43-43.5°.** Purify it by passage through a DEAE cellulose column in cyclohexane. It recrystallises from *n*-hexane. Its ***thiourea complex*** has **m 127°** [5-6 mol of urea to ether, Pedersen *J Org Chem* ***36*** 1690 *1971*, DOI: 10.1021/jo00811a027]. The stability constants of the Na^+, K^+, Rb^+, Cs^+, Tl^+ and Ba^{2+} complexes are described in Hofmanova et al. *Inorg Chim Acta* **28** 73 *1978*, DOI:10.1016/S0020-1693(00)87416-2. [NMR: Live & Chan *J Am Chem Soc* **98** 3769 *1976*, DOI: 10.1021/ja00429a006]. [*Beilstein* **19/12** V 618.] **IRRITANT.**

Benzo[3,4]cyclobuta[1,2-*b*]quinoxaline *[259-57-4]* **$C_{14}H_8N_2$, M 204.2, m dec >250°.** It is purified by sublimation under reduced pressure. For the He(I) photoelectron spectra see Yamaguchi & Baumann *Spectrochim Acta Part A*: *Molecular Spectroscopy* **43** 683 *1987*, DOI: 10.1016/0584-8539(87)80151-4.

Benzofuran (coumarone) *[271-89-6]* **C_8H_6O, M 118.1, b 62-63°/15mm, 97.5-99.0°/80mm, 169°/760mm, 170-173°/atm, 173-175°/760mm, d_4^{20} 1.0945, n_D^{20} 1.565.** Benzofuran is steam distilled, dissolved in Et_2O, washed with 5% aqueous NaOH, saturated NaCl, dried (Na_2SO_4), evaporated and redistilled. The UV has λ_{max} at 245, 275, 282nm (log ε 4.08, 3.45, 3.48). The ***picrate*** has **m 102-103°**. [Burgstahler & Worden *Org Synth* Coll Vol **5** 251 *1973*, DOI: 10.15227/orgsyn.046.0028; NMR: Black & Heffernan *Aust J Chem* **18** 353 *1965*, DOI: 10.1071/CH9650353; *Beilstein* **17/2** V 3.]

2-Benzofurancarboxylic acid (Coumanilic acid) *[496-41-3]* **$C_9H_6O_3$, M 162.1, m 192-193°, 193-196°, b 310-315°/atm with some dec, pK_{Est} ~3.2.** Purified by reprecipitation from alkaline solution with acid, and crystallised from hot water. [Fuson et al. *Org Synth* Coll Vol **3** 209 *1955*, DOI: 10.15227/orgsyn.024.0033; *Beilstein* **18/6** V 419.]

Benzofurazan (benz[1,2,5]oxadiazole) *[273-09-6]* **$C_6H_4N_2O$, M 120.1, m 47-51°, 55°, 75-78°/20mm.** Purify benzofurazan by steam distillation from a dilute alkaline solution, crystallisation from EtOH (long white needles) and by sublimation. [Green & Rowe *J Chem Soc* **101** 2452 *1912*, DOI: 10.1039/CT9120102452; Green & Rowe *J Chem Soc* **111** 612 *1917*, DOI: 10.1039/CT9171100612; Ghosh et al. *J Med Chem* **15** 255 *1972*, DOI: 10.1021/jm00273a012; *Beilstein* **27** H 568, **27** I 573, **27** III/IV 7115.]

Benzofuroxan (benzofurazan-1-oxide, benz[1,2,5]oxadiazol-1-oxide) *[480-96-6]* **$C_6H_4N_2O_2$, M 136.1, m 70-71°, 72-73°.** Purify the 1-oxide by dissolving 3.6g in 45ml of 95% EtOH + 15ml H_2O, boil, filter hot and cool to 25°. The yellow crystalline solid is steam volatile (but less so than benzofurazan, above) and has a peculiar pungent odour. Its UV has λ_{max} at 355nm (EtOH). It was used as a dehydrogenation oxidant (Pätzold et al. *Synth Commun* **22** 281 *1992*, DOI:10.1080/00397919208021304]. [Mallory *Org Synth* Coll Vol **4** 74 *1963*, DOI: 10.15227/orgsyn.037.0001; Boulton & Ghosh *Adv Heterocyclic Chem* **10** 1 *1969*, DOI:10.1016/S0065-2725(08)60494-8; Boyer et al. *J Am Chem Soc* **79** 1748 *1977*, DOI: 10.1021/ja01564a059; *Beilstein* **27** I 622, **27** II 629, **27** III/IV 7115.]

5,6-Benzoquinoline (benzo[*f*]quinoline) *[85-02-9]* **$C_{13}H_9N$, M 179.2, m 93°, 94°, b 350°/atm, pK^{20} 5.11.** Purify as for phenanthridine (benzo[*c*]quinoline) below. It forms an insoluble complex **$[(C_{13}H_9N)_2.H_2CdI_4]$** with Cd in the presence of KI and mineral acids. The ***picrate*** has **m 258.1-259°** (from EtOH or H_2O). [Albert et al. *J Chem Soc* 2240 *1948*, DOI: 10.1039/JR9480002240; *Beilstein* **20** III/IV 4009, **20/8** V 220.]
7,8-Benzoquinoline **(benzo[*h*]quinoline)** *[230-27-3]* has **m 48-50°, 52.0-52.5°, b 238°/719mm, pK^{20} 4.21.** Purify it as for phenanthridine (benzo[*c*]quinoline) below. The ***picrate*** has **m 196°**(from Me_2CO). [*Beilstein* **20** H 463, **20** III/IV 4003, **20/8** V 215.]

1,2,3-Benzothiadiazole *[273-77-8]* **$C_6H_4N_2S$, M 136.2, m 35°, 36-37°, b 63°/0.5mm, pK_{Est} ~<0.** 1,2,3-Benzothiadiazole crystallises from petroleum ether, and has λ_{max} at 264 and 306nm in hexane. [Overberger et al. *J Org Chem* **24** 1407 *1959*, DOI: 10.1021/jo01092a004; *Beilstein* **27** III/IV 7113.]
2,1,3(1,2,5)-Benzothiadiazole *[272-13-2]* has **m 42-44°, 44°, b 206°/760mm, pK_{Est} <0.** 2,1,3-Benzothiadiazole crystallises from petroleum ether and has UV with λ_{max} at 221-222, 304 and 330nm in EtOH. [Sawicki & Carr *J Org Chem* **22** 503 *1959*, DOI: 10.1021/jo01356a007; *Beilstein* **27** III/IV 7118.]

1-Benzothiophene (benzo[b]thiophene, thianaphthene) *[95-15-8]* **C_8H_6S, M 134.2, m 29-32°, 30°, 31-33°, 31-32°, 32°, b 100°/16mm, 103-105°/20mm, 221-222°/760mm, $d_4^{32.2}$ 1.1484, n_D^{39} 1.6306.** 1-Benzothiophene has the odour of naphthalene. If the IR spectrum is not very good, then suspend it in a faintly alkaline aqueous solution and steam distil it. Extract the distillate with Et_2O, dry the extract ($CaCl_2$), filter, evaporate the solvent and fractionate the residue. The distillate sets solid. The ***sulfoxide*** has **m 142°**, the ***picrate*** has **m 148-149°** (yellow crystals from EtOH) and the ***styphnate*** has **m 136-137°**. [Hansch & Lindwall *J Org Chem* **10**, 381 *1945*, DOI: 10.1021/jo01181a001; Meyer & Meyer *Chem Ber* **52B** 1249 *1919*, DOI: 10.1002/cber.19190520702; Weisgerber & Kruber *Chem Ber* **53** 1551 *1920*, DOI: 10.1002/cber.19200530836; Iddon & Scrowston *Adv Heterocycl Chem* **11** 177 *1970*, DOI: 10.1016/S0065-2725(08)60776-X; *Beilstein* **17/2** V 6.]

1,2,3-Benzotriazole *[95-14-7]* **$C_6H_5N_3$, M 119.1, m 96-97°, 97-99°, 98.5°, 100°, b 159°/0.2mm, 204°/15mm, pK_1^{20} 1.6, pK_2^{20} 8.64.** 1,2,3-Benzotriazole crystallises from toluene, $CHCl_3$, Me_2NCHO or a saturated aqueous solution, and is dried at room temperature or in a vacuum oven at 65°. Losses are less if the material is distilled in a vacuum. **CAUTION: may EXPLODE during distillation; necessary precautions must be taken.** [Damschroder & Peterson *Org Synth* Coll Vol **3** 106 *1955*, DOI: 10.15227/orgsyn.020.0016; *Beilstein* **26** III/IV 93.]

***O*-Benzotriazol-1-yl-*N,N,N',N'*-tetramethyluronium hexafluorophosphate (HBTU)** *[94790-37-1]* **$C_{11}H_{16}F_6N_5OP$, M 379.2, m 200° (dec), 250°, 254°(dec).** Wash the salt with H_2O (3x), CH_2Cl_2 (3x), dry and recrystallise it from MeCN. Dry it in a vacuum and store it cold in the dark [Dourtoglou et al. *Tetrahedron Lett* 1269 *1978*, DOI: 10.1016/0040-4039(78)80103-8; NMR: Dourtoglou et al. *Synthesis* 572 *1984*, DOI: 10.1055/s-1984-30895]. Useful coupling reagent for peptide synthesis [Carpino et al. *Angew Chem Int Ed* **41** 441 *2002*, DOI: 10.1002/1521-3773(20020201)41:3<441::AID-ANIE441>3.0.CO;2-N; Knorr et al. *Tetrahedron Lett* **30** 1927 *1989*, DOI: 10.1016/S0040-4039(00)99616-3.]

Benzoxazolinone (2-hydroxybenzoxazole) *[59-49-4]* **$C_7H_5NO_2$, M 135.1, m 137-139°, 142-143°(corrected), b 121-213°/17mm, 335-337°/760mm.** Benzoxazolinone is purified by recrystallisation from aqueous Me_2CO followed by distillation at atmospheric pressure, then in a vacuum. The ***methyl mercury salt*** recrystallises from aqueous EtOH and has **m 156-158°**. [Bywater et al. *J Am Chem Soc* **67** 905 *1945*, DOI: 10.1021/ja01222a008; *Beilstein* **27** III/IV 2677.]

S*-(+) and *R*-(-) 1-Benzoyl-2-*tert*-butyl-3-methyl-4-imidazolinone** *[R- 101055-57-6] [S-101055-56-5]* **M 260.3, m 142-143°, 145.6-146.6°, 145-147°, $[\alpha]_{546}^{20}$ (+) and (-) 155, $[\alpha]_D^{20}$ (+) and (-) 133 (c 1, $CHCl_3$).** Recrystallise these chiral imidazolinones from boiling EtOH (solubility is 1.43g/ml) or better by dissolving in CH_2Cl_2 and adding pentane, filtering and drying for at least 12 hours at 60°/0.1mm and sublime them at 135°/0.01mm. They have also been purified by flash column chromatography through Merck silica gel at 0.04-0.063mm and using Et_2O/petroleum ether/MeOH (60:35:5) as eluent. They are then recrystallised from EtOH/petroleum ether. [IR, NMR: Seebach et al. *Helv Chim Acta* **70** 237 *1987*, DOI: 10.1002/hlca.19870700129; Fitzi & Seebach *Angew Chem Int Ed* **25** 345 *1986*, DOI: 10.1002/anie.198603451.] The ***racemate is purified in a similar manner and has **m 104-105°** [NMR: Seebach et al. *Helv Chim Acta* **68** 949 *1985*, DOI: 10.1002/hlca.19850680418].

2-Benzoylpyridine *[91-02-1]* **$C_{12}H_9NO$, M 183.2, m 41-43°, 48-50°, 72°/0.02mm, 104-105°/0.01mm, 317°/atm, n_D^{24} 1.6032, pK_{Est} ~2.4.** Dissolve 2-benzoylpyridine in Et_2O, shake it with aqueous $NaHCO_3$, H_2O, dry it over $MgSO_4$ and evaporate. The residue solidifies on cooling. The solid can be recrystallised from petroleum ether. Its ***hydrochloride*** crystallises from Me_2CO, **m 126-127°**, and the ***2,4-dinitrophenylhydrazone*** has **m 193-195°**. It distils at high vacuum. [Pinkerton & Thames *J Organomet Chem* **24** 623 *1970*, DOI:10.1016/S0022-328X(00)84491-5; *Beilstein* **21/8** V 566.]

***N^6*-Benzyladenine** *[1214-39-7]* **$C_{12}H_{11}N_5$, M 225.3, m 230-233°, 231-232°, 232.5°(dec), $pK_{Est(1)}$~ 4.2, $pK_{Est(2)}$~ 10.1.** It is purified by recrystallisation from aqueous EtOH. It has λ_{max} at 207 and 270nm (H_2O), 268 nm (pH 6), 274nm (0.1 N HCl) and 275nm (0.1 N NaOH). [Daly & Christensen *J Org Chem* **21** 1553 *1956*, DOI: 10.1021/jo01118a630; Bullock et al. *J Am Chem Soc* **78** 3693 *1956*, DOI: 10.1021/ja01596a037; *Beilstein* **26** III/IV 3575.]

1-Benzyl-1-aza-12-crown-4 (10-benzyl-1,4,7-trioxa-10-azacyclododecane) *[84227-47-4]* **$C_{15}H_{23}NO_3$, M 265.4, 122-125°/0.03mm, 140-143°/0.05mm, d_4^{20} 1.09, n_D^{20} 1.52, pK_{Est} ~ 7.7.** Dissolve it in CH_2Cl_2 or CCl_4 (1g in 30ml), wash it with H_2O (30ml), brine (30ml), H_2O (30 ml) again, dry ($MgSO_4$ or Na_2SO_4), and evaporate. The residue in CH_2Cl_2 is chromatographed through Al_2O_3 (eluting with 10% EtOAc in hexane); evaporate, collect the correct fractions and distil (Kügelrohr) them. Log K_{Na} in dry MeOH at 25° for Na^+ complex is 2.08. Also a good complexing agent for Lithium ions. [White et al. *Tetrahedron Lett* **26** 151 *1985*, DOI:10.1016/S0040-4039(00)61866-X; Arnold et al. *J Org Chem* **53** 5652 *1988*, DOI: 10.1021/jo00259a008.]

It is an antimalarial and is antibacterial as well. [*Beilstein* **27** II 567, **27** III/IV 6539.]
Berberine chloride ($2H_2O$) **(Neutral Yellow 18)** *[633-65-8 (anhydrous), 5956-60-5 ($2H_2O$)]* **$C_{20}H_{18}NO_4.Cl$, M 407.9,** has **m 204-206°(dec), CI 75160, pK^{20} 2.47.** Berberine chloride crystallises from water to give the *dihydrate*. The anhydrous salt may be obtained by recrystallisation from $EtOH/Et_2O$, wash the crystals with Et_2O and dry them in a vacuum. The ***iodide*** has **m 250°(dec)** (from EtOH). [Perkin *J Chem Soc* **113** 492 *1918*, DOI: 10.1039/CT9181300492; Kametani et al. *J Chem Soc(C)* 2036 *1969*, DOI: 10.1039/J39690002036; *Beilstein* **27** I 515, **27** II 567.]

Bilirubin *[635-65-4]* **$C_{33}H_{36}N_4O_6$, M 584.7, m >360°, ε_{450nm} 55,600 in $CHCl_3$, pK_{Est} ~3.0.** An acyclic tetrapyrrole bile pigment with impurities which can be eliminated by successive Soxhlet extraction with diethyl ether and MeOH. It crystallises from $CHCl_3$ as deep red-brown rhombs, plates or orange-red prisms from chlorobenzene (**m 330° dec**) and is dried to constant weight at 80° under vacuum. [Gray et al. *J Chem Soc* 2264, 2276 *1961*, DOI: 10.1039/JR9610002264; *Beilstein* **26** III/IV 3268.]

Biliverdine *[114-25-0]* **$C_{33}H_{34}N_4O_6$, M 582.6, m >300°, pK^{25} 3.0.** This is the precursor of bilirubin (above) and forms dark green plates or prisms, with a violet reflection, from MeOH. The ***dimethyl ester***, when crystallised from MeOH has **m 215°(209°)**, and when crystallised from $CHCl_3$/petroleum ether gives blue-green crystals with **m 202°.** [Gray et al. *J Chem Soc* 2264 *1961*, DOI: 10.1039/JR9610002264; Sheldrick *JCS Perkin Trans 2* 1457 *1976*, DOI: 10.1039/P29760001457; *Beilstein* **26** III/V 3272.]

2-(4-Biphenylyl)-5-phenyl-1,3,4-oxadiazole (BPD) *[852-38-0]* **$C_{20}H_{14}N_2O$, M 298.4, m 166-167°, 167-169°, 167-170°.** BPD is recrystallised from toluene. It is a good scintillation material and is suitable as a laser dye. [Brown et al. *Discussion Faraday Soc* **27** 43 *1959*, DOI: 10.1039/DF9592700043]. [*Beilstein* **27** III/IV 7283.]

2,2'-Bipyridyl *[366-18-7]* **$C_{10}H_8N_2$, M 156.2, m 70-73°, 70.5°, b 273°/atm, pK_1^{25} -0.52, pK_2^{25} 4.44.** 2,2'-Bipyridyl crystallises from hexane, or EtOH, or (after charcoal treatment of a $CHCl_3$ solution) from petroleum ether. Also, it precipitates from a concentrated solution in EtOH by addition of H_2O. Dry it in a vacuum over P_2O_5. It can be further purified by chromatography on Al_2O_3 or by sublimation. Its UV (EtOH) has λ_{max} at 280nm (logε 4.13). It is a metalloprotease inhibitor and high affinity chelator of iron and other transition metal ions. [Airoldi et al. *JCS Dalton Trans* 1913 *1986*, DOI: 10.1039/DT9860001913; *Beilstein* **23/8** V 16.]
4,4'-Bipyridyl *[553-26-4]* has **m 73°(hydrate)** *[553-26-4, 123333-55-1]***, 109-112°, 114° (anhydrous), b 305°/760mm, 293°/743mm, pK_1^{20} 3.17, pK_2^{20} 4.82.** It crystallises from water, *benzene/petroleum ether, ethyl acetate and sublimes *in vacuo* at 70°. Also purify it by dissolving in 0.1M H_2SO_4 and twice precipitating by addition of 1M NaOH to pH 8. Then recrystallise it from EtOH. For the ***dihydrochloride*** see Viologen below. [Collman et al. *J Am Chem Soc* **109** 4606 *1987*, DOI: 10.1021/ ja00249a025; *Beilstein* **23** H 800, **23** III/IV 1371, **23/8** V 28.]

2,2'-Biquinolin-4,4'-dicarboxylic (2,2'-bicinchoninic) acid *[1245-13-2]* **$C_{20}H_{12}N_2O_4$, M 344.3, m 367°, $pK_{Est(1)}$ ~1.5, $pK_{Est(2}$ ~4.0.** Dissolve the acid in dilute NaOH and precipitate it with acetic acid, filter, wash swell with H_2O and dry it at 100° in a vacuum oven. Attempts to form a picrate failed. The ***methyl ester*** ($SOCl_2$-MeOH) has **m 165.6-166°**. [Lesesne & Henze *J Am Chem Soc* **64** 1897 *1942*, DOI: 10.1021/ja01260a041; Brown et al. *J Am Chem Soc* **68** 2705 *1946*, DOI: 10.1021/ja01216a087; *Beilstein* **25** III/IV 1148.] For the di-K salt see entry in 'Metal-organic Compounds' in Chapter 4.

2,2'-Biquinolyl (Cuproin, α,α'-diquinolyl) *[119-91-5]* **$C_{18}H_{12}N_2$, M 256.3, m 192-195°, 196°, pK_{Est} ~4.2.** Decolourise 2,2'-biquinolyl in $CHCl_3$ solution (charcoal), then crystallise it to constant melting point from EtOH or petroleum ether [Cumper et al. *J Chem Soc* 1188 *1962*, DOI: 10.1039/JR9620001188]. [*Beilstein* **23/10** V 8.]

2,5-Bis(4-aminophenyl)-1,3,4-oxadiazole (BAO) *[2425-95-8]* **$C_{14}H_{12}N_4O$, M 252.3, m 252-255°, 254-255°.** BAO is recrystallised from EtOH using charcoal and under N_2 to avoid oxidation. It is a fluorescent stain for DNA [Yataghanas et al. *Exptl Cell Res* **56** 59 *1969*, DOI: 10.1016/0014-4827(69)90394-2]. [*Beilstein* **27** III/IV 8158.]

2,5-Bis(2-benzothiazolyl)hydroquinone *[33450-09-8]* **$C_{20}H_{12}N_2O_2S_2$, M 376.2, m dec >200°.** Purify the hydroquinone by repeated crystallisation from dimethylformamide followed by sublimation in vacuum [Ernsting et al. *J Phys Chem* **91** *1404 1987*, DOI: 10.1021/j100290a026].

2,5-Bis(4-biphenylyl)-1,3,4-oxadiazole (BBOD) *[2043-06-3]* **$C_{26}H_{18}N_2O$, M 374.5, m 229-230°, 235-238°**. BBOD is recrystallised from heptane or toluene. It is a good scintillant. [Hayes et al. *J Am Chem Soc* **77** 1850 *1955*, DOI: 10.1021/ja01612a041.]

3,3-Bis(chloromethyl)oxacyclobutane (3,3-bis-[chloromethyl]oxetane) *[78-71-7]* **$C_5H_8Cl_2O$, M 155.0, m 18.9°, b 65°/5mm, 80°/10mm, 103°/30mm, 198°/atm, d_4^{20} 1.290, n_D^{20} 1.486**. Shake it with aqueous $NaHCO_3$ or $FeSO_4$ to remove peroxides, separate, dry with anhydrous Na_2SO_4, then distil it under reduced pressure from a little CaH_2 [Dainton et al. *Trans Faraday Soc* **56** 1784 *1960*, DOI: 10.1039/TF9605601784; Farthing *J Chem Soc* 3648 *1955*, DOI: 10.1039/JR9550003648]. The *3,3-bis-(phenoxymethyl)* derivative is described below. [*Beilstein* **17** III/IV 68.] **Lachrymatory.**

***N,N'*-Bis(nicotinic acid) hydrazide** *[840-78-8]* **$C_{12}H_{10}N_4O_2$, M 242.2, m dec 200°, pK_{Est} ~3.3.** The hydrazide crystallises from water; it is also soluble in hot EtOH but insoluble in *C_6H_6, petroleum ether or $CHCl_3$. [Graf *J Prakt Chem* [2] **138** 289 *1933*, DOI: 10.1002/prac.19331381101; *Beilstein* **22** III/IV 455.]

3,3-Bis(phenoxymethyl)oxacyclobutane (3,3-bis-[phenoxymethyl]oxetane) *[1224-69-7]* **$C_{17}H_{18}O_3$, M 270.3, m 67.5-68°, b 143°/0.05mm.** Distil it under high vacuum, then crystallise the solidified distillate from MeOH. [Farthing *J Chem Soc* 3648 *1955*, DOI: 10.1039/JR9550003648; *Beilstein* **17** III/IV 2010.]

Blue Tetrazolium (BTC, tetrazolium blue chloride) *[1871-22-3]* **$C_{40}H_{32}Cl_2N_8O_2$, M 727.7, m 254-255°(dec), 255°(dec).** Crystallise the chloride from 95% EtOH/anhydrous diethyl ether to constant absorbance at 254nm. [*Beilstein* **26** III/IV 1789.]

1-*N*-Boc-piperidine (*N-tert*-butoxycarbonylpiperidine, 1-piperidincarboxylic acid 1,1-dimethylethyl ester) *[75844-69-8]* **$C_{10}H_{19}NO_2$, M 185.3, b 79°/0.05mm, d_4^{25} 0.964, n_D^{20} 1.454.** It is purifed by bulb-to-bulb distillation at 65°/1mm. If it is discoloured then dissolve it in Et_2O, wash it with brine, separate, dry the Et_2O layer over K_2CO_3, filter, evaporate, and distil in a vacuum. Its IR has ν_{max} at 1695 (CO) cm^{-1} (film). [IR, NMR, MS: Dieter & Li *J Org Chem* **62** 7726 *1997*, DOI: 10.1021/jo970985b; Beak & Lee *J Org Chem* **58** 1109 *1993*, DOI: 10.1021/jo00057a024].

1-*N*-Boc-2-piperidone (1-*N-tert*-butoxycarbonyl-2-piperidone) *[85908-96-9]* **$C_{10}H_{17}NO_3$, M 199.3, m 29-36°, 30-33°, 32-34°, 33-35°, 36°, b 110°/0.1mm.** This useful synthetic starting material is prepared by using the same principles as for the 4-oxo isomer below. Thus to a solution of γ-valerolactam (2-piperidone, 6.0g, 60.5mmol, *[675-20-7]*), DMAP (1.85g, 15.1mmol, 0.2 equiv, [1122-58-3] and Boc_2O (26.6g, 121.0mmol, 2.0 equiv, *[24074-26-8]*) in CH_2Cl_2 (70ml) at ~25° is added Et_3N (17.8g, 127.7mmol, 2.1 equiv) and is stirred for 32 hours, then quenched with 1.2N HCl (10ml). The aqueous layer is extracted with CH_2Cl_2, the combined CH_2Cl_2 solutions are washed with saturated aqueous $NaHCO_3$ (20ml), brine (30ml), dried ($MgSO_4$), filtered and evaporated *in vacuo*. The crude product is purified by flash chromatography through Kieselgel 60 (230-240 mesh with cyclohexane/EtOAc 8:2 elution) to give ***1-N-Boc-2-piperidone*** (9.71g, 48.7mmol, 81%) as a colourless low melting solid **m 36°**. It has R_F 0.40 (TLC on Kieselgel $60F_{254}$, cyclohexane/EtOAc 7:3), and its IR (KBr) has ν_{max} at 1713, 1302, 1249, 1159 and 1138 cm^{-1}; the ^1H NMR (300MHz, $CDCl_3$, with residual $CHCl_3$ as internal standard at δ 7.27) has δ at 3.66 (m, 2H, H-6,6), 2.50 (m, 2H, H-3,3), 1.90-1.74 (4H, H-3,3,4,4) and 1.53 (s, 9H, *t*-Bu); the ^{13}C NMR (75MHz, $CDCl_3$, with residual $CDCl_3$ as internal standard at δ 77.1) has δ at 171.1 (s), 152.4 (s), 82.5 (s), 46.0 (t), 34.6 (t), 27.7 (q), 22.5 (t) and 20.2 (t); and the EI MS has *m/z* (relative intensity) at 199 ($M^{\cdot+}$ 0.3), 144 (52), 126 (21), 100 (38), 99 (31), 98 (31), 82 (24), 57 (100), 56 (38) and 55 (30). [Cossy et al. *New J Chem* **27** 475 *2003*.] This synthesis has also been carried out in MeCN/DMAP at ~25°/24 hours (74% yield) without further base [Moody & Taylor *JCS Perkin Trans 1* 721 *1989*, DOI: 10.1039/P19890000721].

1-N-Boc-2-piperidone is hydrolysed at ambient temperature by LiOH (30 minutes, 90%), or undergoes methanolysis by MeONa/MeOH (15 minutes, 94%) to provide γ-$BocNH(CH_2)_4CO_2H$ (after acidification) or γ-$BocNH(CH_2)_4CO_2Me$ without losing the Boc protecting group, respectively [Flynn et al. *J Org Chem* **48** 2424 *1983*, DOI: 10.1021/jo00162a028].

1-N-Boc-3-piperidone **(1-*N-tert*-butoxycarbonyl-3-piperidone)** *[98977-36-7]* has **m 35-40°, b 104-105°/0.4mm.** 3-Piperidone used to prepare the Boc derivative was obtained by hydrogenolysis of *N*-benzyl-3-piperidone hydrochloride hydrate (4.2g, 18.6mmol, *[50606-58-1]*) catalyzed by 10% Pd/C (0.8g) and H_2 at 55 psi while stirring for 16 hours in degassed MeOH (200ml). This was filtered (Celite) and evaporated *in vacuo*. The crude oily 3-piperidone was dissolved in THF (200ml), treated with Boc_2O (5.27g, 24.1mmol) and saturated aqueous Na_2CO_3 (50ml), stirred for 4 hours and evaporated *in vacuo*. The white solid was partitioned between EtOAc and 1N HCl, the organic layer was collected, washed with 1N NaOH and brine, dried ($MgSO_4$), filtered, and evaporated *in vacuo* to give an oil which was purified by flash chromatography (silica gel, hexane/EtOAc 3:1) to give ***1-N-Boc-3-piperidone*** (2.93g, ~100%) as a colourless oil. [Lucca et al. *J Med Chem* **48** 2194 *2005*, DOI: 10.1021/jm049530m.] Its ^1H NMR (300MHz, $CDCl_3$, TMS) has δ at 3.99 (s, 2H, 2,2-H), 3.58 (t, *J* = 6.3 Hz, 2H, 6,6-H), 2.46 (t, *J* = 6.3 Hz, 2H 4,4-H), 1.97 (t, *J* = 6.3 Hz, 2H, 5,5-H), and 1.45 (s, 9H, *t*-Bu); and the HRMS has *m/z* 200.1285 and calculated for $C_{10}H_{18}NO_3$ (M + H) was 200.1287. *Alternatively*, and almost similar preparation, was carried out except that saturated aqueous Na_2CO_3 was replaced by Et_3N (3 equiv) to give an 81% yield of ***1-N-Boc-3-piperidone*** which was distilled at high vacuum undecomposed. [Brehm et al. *J Med Chem* **29** 224 *1986*, DOI: 10.1021/jm00152a010.]

In a completely different synthesis, involving catalysed intramolecular cyclisation, ***(5-oxo-6-dimethyl-sulfoxonium-hexyl)-carbamic acid tert-butyl ester*** (250mg, 0.901mmol) in CH_2Cl_2 (8.0ml, purged with N_2 for 30 minutes) was added *via* a syringe pump over 18 hours to a solution of $[Ir(COD)Cl]_2$ (6.05mg, 9.01μmol, 0.01 equiv, [12112-67-3]) in degassed CH_2Cl_2 (4.0ml) at 70°. The mixture was then evaporated *in vacuo*, and the residue was purified through a silica gel column and eluting with hexanes/EtOAc (3:2) to afford *1-N-Boc-3-piperidone* (147mg, 82%) identical with the above. [Mangion et al. *Org Lett* **11** 3566 *2009*, DOI: 10.1021/ol901298p.]

1-N-Boc-4-piperidone* (1-*N*-*tert*-butoxycarbonyl-4-piperidone)** *[79099-07-3]* has **m 68-69°, 70-72°, 72°, 73-75°, 74-75°, 74.4-75.2°.** It is prepared by dissolving 4-piperidone (1g, 6.5mmol [41661-47-6]) and EtN(*iso*-Pr)$_2$ (2.8ml, 16mmol, DIPEA [7087-68-5]) in dioxane/H_2O (4:1, 10ml), adding Boc_2O (2.2g, 9.8mmol, *[24074-26-8]*) slowly with stirring at ~25° for 24 hours. The solvent is removed *in vacuo*, the residue is dissolved in CH_2Cl_2, washed with H_2O (3 x), dried ($MgSO_4$), filtered and evaporated *in vacuo*. The residue is triturated with Et_2O, the white residue is collected by filtration and recrystallised from hexane to give the ***Boc-piperidone (75%), **m 73.5°**. It also crystallises from petroleum ether**,** toluene or EtOAc and can be dried in a vacuum desiccator over shredded paraffin wax. It has R_F 0.74 (TLC on Kieselgel 60F_{254}, hexane/EtOAc 4:6), and its IR (KBr) has ν_{max} at 1715 and 1680 cm^{-1}. Its ^{1}H NMR (300MHz, $CDCl_3$) has δ at 3.72 (t, *J* = 6.3 Hz, 4H, 3,5-H), 2.44 (t, *J* = 6.3 Hz, 4H 2,6-H) and 1.50 (s, 9H, *t*-Bu); and the ^{1}H NMR (300MHz, DMSOd_6) has δ at 3.6 (t, 4H, 3,5-H), 2.4 (t, 4H, 2,6-H) and 1.4 (s, 9H, *t*-Bu). It has been used extensively to introduce a piperidine ring for making drugs because the 4-oxo group can be functionalised in various ways and deprotection of the nitrogen allows bonding to this atom. [Houssin et al. *J Med Chem* **45** 533 *2002*, DOI: 10.1021/jm010297r; Ellis et al. *J Med Chem* **51** 2170 *2008*, DOI: 10.1021/jm701435h.]

Brazilin (6a*S*-*cis*-7,11b-dihydrobenzo[b]indeno[1,2-d]pyran-3,6a,9,10(6*H*)-tetraol) *[474-07-7]* **$C_{16}H_{14}O_5$, M 286.3, m 130°(dec), 250°, $pK_{Est(1)}$ ~9.3, $pK_{Est(2)}$ ~10.0, $pK_{Est(3)}$ ~12.5 (all phenolic), CI 75280.** Brazilin crystallises from EtOH as yellow crystals which become orange when exposed to light and air, and is yellow in dilute acid but crimson in dilute alkali. When crystallised from H_2O, it has **m 247-248°**. It forms coloured metal salts and is oxidised in air to *Brazilein*, the quinonoid form. The *(±)-form has been resolved, and the (+)-enantiomer* has $[\alpha]_D^{20}$ +121° (c 1, MeOH). [Craig et al. *J Org Chem* **30** 1573 *1965*, DOI: 10.1021/jo01016a058; Morsingh & Robinson *Tetrahedron* **26** 281 *1970*, DOI: 10.1016/0040-4020(70)85029-3; *Beilstein* **17** H 194, **17** II 244, **17** III/IV 2711.]

Brilliant Cresyl Blue (*NN*-diethyl-3-imino-8-methyl-3*H*-phenoxazin-7-amine hydrochloride) *[4712-70-3]* **M 332.8, pK^{25} 3.2.** Crystallise the dye from petroleum ether. It has λ_{max} at 625nm (H_2O) and 622nm (95% aqueous EtOH). [*Beilstein* **27** H 400, **27** II 454, **27** III/IV 5160.]

5-Bromocytosine *[2240-25-7]* **$C_4H_4BrN_3O$, M 190.0, m 240-243°(dec), 245-255°(dec), 250°(dec), pK_1^{25} 3.04, pK_2^{25} 10.33.** 5-Bromocytosine is recrystallised from H_2O or 50% aqueous EtOH. *Alternatively*, dissolve *ca* 3g in conc HCl (10ml) and evaporate to dryness. Dissolve the residual hydrochloride in the minimum volume of warm H_2O and make faintly alkaline with aqueous NH_3. Collect the crystals and dry them in a vacuum at 100°. [Hilbert & Jansen *J Am Chem Soc* **56** 134 *1934*, DOI: 10.1021/ja01316a041; *Beilstein* **25** III/IV 3689.]

2-(2-Bromoethyl)-1,3-dioxane *[33884-43-4]* **$C_6H_{11}BrO_2$, M 195.1, b 67-70°/2.8mm, 71-72°/4mm, 95°/15mm, d_4^{20} 1.440, n_D^{20} 1.4219**. Purify it by vacuum fractionation. Also dissolve it in Et_2O, wash with aqueous $NaHCO_3$, dry the extract (Na_2SO_4), filter and fractionate at high vacuum. Its ^{1}HNMR in CCl_4 has δ at 1.3 (m, 1H), 2.1 (m, 3H), 3.36 (t, 2H), 3.90 (m, 4H) and 4.57 (t, H). [Stowell *J Org Chem* **41** 560 *1976*, DOI: 10.1021/jo00865a034; NMR, MS: Schwarz et al. *Tetrahedron* **35** 1969 *1979*, DOI: 10.1016/0040-4020(70)85029-3; Kriesel & Gisvold *J Pharm Sci* **60** 1250 *1971*, DOI: 10.1002/jps.2600600833; *Beilstein* **19/1** V 69; Fieser **7** 37, **11** 78.]

2-(2-Bromoethyl)-1,3-dioxolane *[18742-02-4]* **$C_5H_9BrO_2$, M 181.1, b 68-70°/8mm, 68-73°/10mm, 78-80°/20mm, d_4^{20} 1.510, n_D^{20} 1.479.** Dissolve it in pentane, wash with 5% aqueous $NaHCO_3$, dry (Na_2SO_4), and evaporate. Distil the residue. [NMR: Buechi & Wuest *J Org Chem* **34** 1122 *1969*, DOI: 10.1021/jo01256a076; Kriesel & Gisvold *J Pharm Sci* **60** 1250 *1971*, DOI: 10.1002/jps.2600600833; *Beilstein* **19/1** V 69; Fieser **7** 37.]

6-Bromo-5-fluoro-1*H*-indole *[259860-08-7]* **C_8H_5BrFN, M 214.0, m 82-84°, 83-84°, $pK_{Est(1)}$ ~ −4.05 (basic), $pK_{Est(2)}$ ~ 15.9 (acidic).** There are several preparations of this indole. In a patent (to Vernallis Research Ltd, US6380238, *2002*] *N,N*-dimethylformamide dimethylacetal (8.5ml, 60mmol) was added to a stirred solution of 4-bromo-5-fluoro-2-nitrotoluene (11.8g, 50mmol) in DMF (30ml) in one portion under argon at ~25°, then heated at 120° for 16 hours and evaporated *in vacuo*. The residual oil crystallised from MeOH/CH_2Cl_2 (4:1) to give a purple solid (4.5g) which was dissolved in MeOH/THF (1:1, 30ml), mixed with Raney Ni (1g), cooled to 0° and $N_2H_4.H_2O$ (0.8ml, 16mmol) was added all at once. After stirring for 90min,

more $N_2H_4.H_2O$ (0.8ml) was added and stirred at 0° for 30 minutes. The mixture was filtered through Celite and the filter cakes was washed with THF. The combined filtrates were evaporated *in vacuo*, and the residue was purified by chromatography [SiO_2 with heptane/CH_2Cl_2 (4:1) as eluent] to give the ***indole*** (1.7g, 16%) as an off-white solid. In a second patent [to M.P. Dillon et al. US2004/224973, *2004*, see also Batcho & Leimgruber *Org Synth* **63** 214 *1985*, DOI: 10.15227/orgsyn.063.0214] crude [2-(4-bromo-5-fluoro-2-nitrophenyl)vinyl]-dimethylamine and Raney Ni in THF gave after flash chromatography through a silica gel column (eluting with 10% EtOAc in hexane) which gave the indole as a light green solid (61%). However, when the same enamine (1.89g, 4.38mmol) in EtOH (35ml) was treated with a mixture of Fe (4.42g, 79mmol) in AcOH (35ml) and stirred at 90° overnight, then filtered, evaporated and the residue purified by chromatography as above, pure ***6-bromo-5-fluoro-1H-indole*** (0.83g, 89%) was obtained as a yellow solid [Patent to the Board of Trustees of the University of Illinois; WO2008/77138 *2008*]. It had IR (nujol) with ν_{max} at 3395, 2925, 2855, 1570, 1469, 1451, 1408, 1314, 1145, 1105, 865, 763 and 505 cm^{-1}; and the ^1H NMR (400MHz, $CDCl_3$) had δ at 7.85 (br s, 1H), 7.55 (dd, 1H, *J* = 5.6 and 0.9 Hz), 7.34 (d, 1H, *J* = 9.0 Hz), 7.23 (t, 1H, *J* = 2.8 Hz) and 6.45-6.51 (m, 1H).
6-Bromo-5-fluoro-1-methylindole was obtained as a colourless solid in 99% yield by converting the indole above to its ***N-sodio- derivative*** with NaH (1.5mol) in DMF at 0°/30 minutes, followed by MeI (1.2mol) for 1 hour at ~25°, then purified by column chromatography as above. Its ^1H NMR (400MHz, $CDCl_3$) had δ at 3.66 (s, 3H, *N*-Me), 6.43 (d, 1H, *J* = 2.7 Hz), 7.05 (d, 1H, *J* = 2.7 Hz), 7.34 (d, 1H, *J* = 9.3 Hz) and 7.44 (d, 1H, *J* = 5.4 Hz) [Patent to the Board of Trustees of the University of Illinois; WO2008/77138 *2008*].

3-Bromofuran *[22037-28-1]* **C_4H_3BrO, M 147.0, b 38.5°/40mm, 50°/110mm, 102.5-103°/atm, d_4^{20} 1.661, n_D^{20} 1.4970.** Purify 3-bromofuran by two steam distillations and dry it over fresh CaO. It can be dried over Na metal (no obvious reaction) and fractionated. It is not very soluble in H_2O but is soluble in organic solvents. When freshly distilled, it is a clear oil, but darkens on standing and eventually resinifies. It can be stored for long periods by covering the oil with an alkaline solution of hydroquinone and is redistilled when required. It forms a characteristic ***maleic anhydride adduct***, **m 131.5-132°**. [Shepard et al. *J Am Chem Soc* **52** 2083 *1930*, DOI: 10.1021/ja01368a057; Hughes & Johnson *J Am Chem Soc* **53** 737 *1931*, DOI: 10.1021/ja01353a044; adduct: van Campen & Johnson *J Am Chem Soc* **55** 430 *1933*, DOI: 10.1021/ja01328a512; *Beilstein* **17/1** V 295.]

5-Bromoindole *[10075-50-0]* **C_8H_6BrN, M 196.1, m 90.5-91°, 90-92°, pK^{25} 16.13 (NH).** Purify it by steam distillation from a faintly alkaline solution. Cool the aqueous distillate, collect the solid, dry it in a vacuum desiccator over P_2O_5 and recrystallise it from aqueous EtOH (35% EtOH) or petroleum ether/Et_2O. Its UV in MeOH has λ_{max} at 279, 287 and 296nm (logε 3.70, 3.69 and 3.53). The ***picrate*** has **m 137-138°(dec)** (from Et_2O/petroleum ether). [UV: Thesing et al. *Chem Ber* **95** 2205 *1962*, DOI: 10.1002/cber.19620950917; UV and NMR: Lallemand & Bernath *Bull Soc Chim Fr* 4091 *1970*, *Beilstein* **20/7** V 36.]

5-Bromoisatin *[87-48-9]* **$C_8H_4BrNO_2$, M 226.0, m 245°, 247-152°, 251-153°, 255-256°.** 5-Bromoisatin forms red prisms or needles from EtOH. The ***N-acetate*** crystallises as yellow prisms from *C_6H_6, **m 170-172°**, and the ***N-methyl derivative*** forms orange-red needles from MeOH, **m 172-173°**. [Heller *Chem Ber* **53** 1545 *1920*, DOI: 10.1002/cber.19200530835; Buu-Hoi *Recl Trav Chim Pays-Bas* **73** 197 *1954*, DOI: 10.1002/recl.19540730305; Baker et al. *Tetrahedron Lett* 219 *1978*, DOI: 10.1016/S0040-4039(01)85088-7; *Beilstein* **21** H 453, **21** III/IV 5009.]
6-Bromoisatin *[6326-79-0]* has **m 270°, pK^{25} 10.35.** 6-Bromoisatin recrystallises from AcOH (yellow needles). It is a plant growth substance. Its IR ($CHCl_3$) has ν_{max} at 1320 and 3440cm^{-1}. [Sadler *J Org Chem* **21** 169 *1956*, DOI: 10.1021/jo01108a004; *Beilstein* **21** III/IV 5012.]

2-Bromo-3-methylindole (2-bromoskatole) *[1484-28-2]* **C_9H_8BrN, M 210.1, m 102-104°, pK_{Est} <0.** Purify 2-bromoskatole by chromatography on silica gel in $CHCl_3$/petroleum ether (1:2) followed by crystallisation from aqueous EtOH. [Phillips & Cohen *J Am Chem Soc* **108** 2023 *1986*, DOI: 10.1021/ja00268a049; cf. *Beilstein* **20** III/IV 3205.]

4-(Bromomethyl)-7-methoxycoumarin *[35231-44-8]* **$C_{11}H_9BrO_3$, M 269.1, m 208-209°, 213-215°, 216-218°.** The coumarin is crystallised from boiling AcOH, the crystals are washed with AcOH, EtOH and dried in a vacuum. The ^{1}HNMR (TFA) has δ at 3.97s, 4.57s, 6.62s, 6.92-7.19m and 7.80d. A useful fluorescent label,

e.g. for a wide range of acids. [Secrist et al. *Biochem Biophys Res Commun* **45** 1262 *1971*, DOI: 10.1016/0006-291X(71)90154-9; Duenges *Anal Chem* **49** 442 *1977*, DOI: 10.1021/ac50011a028; *Beilstein* **18** III/IV 348.]

5-Bromonicotinic acid *[20826-04-4]* **$C_8H_4BrNO_2$, M 202.0, m 178-180°, 178-182°, 189-190°, pK_{Est} ~4.4, pK^{25} 4.02 (50% aqueous EtOH).** The acid is recrystallised from H_2O and then from EtOH using charcoal. The ***amide*** has **m 219-219.5°** (from aqueous EtOH), and the ***methyl ester***, prepared by addition of ethereal diazomethane, can be purified by sublimation in a vacuum and has **m 98-99°**. The ***acid chloride*** also can be sublimed in *vacuo* and has **m 74-75°** and gives the ***methyl ester*** in MeOH. [Graf *J Prakt Chem* **138** 244 *1933*, DOI: 10.1002/prac.19331380904; Bachman & Micucci *J Am Chem Soc* **70** 2381 *1948*, DOI: 10.1021/ja01187a020; Garcia et al. *J Am Chem Soc* **82** 4430 *1960*, DOI: 10.1021/ja01501a079; Misic-Vokovic et al. *JCS Perkin Trans 2* 34 *1978*, DOI: 10.1039/P29780000034; *Beilstein* **22/2** V 181.]

2-Bromopyridine *[109-04-6]* **C_5H_4BrN, M 158.0, b 49.0°/2.7mm, 192-194°/atm, d_4^{20} 1.660, n_D^{20} 1.5713, pK^{25} 0.90.** Dry 2-bromopyridine over KOH for several days, then distil it from CaO under reduced pressure, and taking the middle fraction. [*Beilstein* **20/5** V 422.]

8-Bromotheophylline (bromo-1,3-dimethyl-2,6(1*H*,3*H*)-purinedione) *[10381-75-6]* **M 259.1, m 309°, 315-320° (with browning and dec), $pK_{Est(1)}$ ~5.5, $pK_{Est(2)}$ ~9.2.** It is purified by dissolving in the minimum volume of dilute NaOH (charcoal), filtering and acidifying to pH *ca* 3.5-4. The solid that separates is collected, dried *in vacuo* at 100° and stored in a dark container. It has also been recrystallised from EtOH or AcOH. [Blitz & Beck *J Prakt Chem* [2] **118** 149 *1928*, DOI: 10.1002/prac.19281180116; Fischer & Ach *Chem Ber* **28** 3135 *1895*, DOI: 10.1002/cber.189502803156; *Beilstein* **26** H 476, **26** II 227, **26** III/IV 2447.]

5-Bromothiazole *[3034-55-7]* **C_3H_2BrNS, M 164.0, b 62-63°/15mm, d_4^{20} 1.835, n_D^{20} 1.5955, n_D^{25} 1.5976, pK_{Est} ~2.0.** If bromothiazole is too coloured, then suspend it in dilute NaOH and steam distil it. Add NaCl to the aqueous distillate, extract it with Et_2O, dry it (Na_2SO_4), evaporate and fractionate the residue in a vacuum. The ***$HgCl_2$ salt*** crystallises from EtOH with **m 148°** (**dec**). [Beyerman et al. *Recl Trav Chim Pays-Bas* **73** 325 *1954*, DOI: 10.1002/recl.19540730405; *Beilstein* **27** III/IV 962.]

2,3-(di)-Bromothiophene *[3140-93-0]* **$C_4H_2Br_2S$, M 241.9, m -17.5°, b 89-91°/13mm, 212-213°/atm, 218.6-219.6°/atm, d_4^{25} 2.137, n_D^{20} 1.632.** Purify the dibromothiophene by fractional distillation, preferably in a vacuum. Low temperature crystallisation from a small volume of petroleum ether (use Et_2O/CO_2 bath) removes the more soluble 2,4-dibromothiophene isomer. Nitration with Ac_2O/HNO_3 at 50-55° yields *2,3-dibromo-5-nitrothiophene* **m 75°** (from EtOH). [Steinkopf et al. *Justus Liebigs Ann Chem* **512** 136 *1934*, DOI: 10.1002/jlac.19345120113; Gronowitz et al. *Acta Chem Scand* **46** 654 *1992*, DOI: 10.3891/acta.chem.scand.46-0654; NMR: Fujiwara et al. *Bull Chem Soc Jpn* **32** 201 *1959*, DOI: org/10.1246/bcsj.32.201; *Beilstein* **17/1** III/IV 247, **17/1** V 308.]

4-*tert*-Butylcalix[4]arene *[60705-62-6]* **$C_{44}H_{56}O_4$, M 648.9, m >300°(dec), 380°(dec), 344-346°.** The calixarene recrystallises from $CHCl_3$ in large solvated prisms (**m** 380° dec); it effloresces on drying in air. Its ***tetra-acetate*** crystallises from Ac_2O in colourless prisms **m** 332-333°(dec). It crystallises from CCl_4 or chlorobenzene /EtOH (**m >300°**) and the ***tetra-acetate*** crystallises from $CHCl_3$/EtOH **m >290°**(**dec**). It also crystallises from toluene in white plates with toluene of crystallisation **m 344-346°** (**330-332°**); the ***tetra-acetate*** crystallises with 1AcOH of crystallisation **m 383-386°** (softening at **330-340°**, also **m 283-286°**), but acetylation with Ac_2O/NaOAc gives the ***triacetate*** which recrystallises from AcOH with 1AcOH of crystallisation **m 278-281°**. 4-*tert*-Butylcalix[4]arene (100mg) is unchanged after boiling for 4 hours with 10N KOH (0.04ml) in xylene (4ml). [Cornforth et al. *Br J Pharmacol Chemother* **10** 73 *1955*, PMCID: PMC1509476; Kämmerer et al. *Monatsh Chem* **109** 767 *1978*, DOI: 10.1007/BF00907297; Gutsche et al. *J Am Chem Soc* **103** 3782 *1981*, DOI: 10.1021/ja00403a028; see also Kluawer in *Calixarenes*, Vicens & Böhner eds Academic Press *1991*, *Beilstein* **6** IV 7858.]

4-tert-Butylcalix[6]arene *[78092-53-2]* **$C_{66}H_{84}O_6$, M 972.3,** has **m >300°, 380-381°.** It is recrystallised from $CHCl_3$ or $CHCl_3$/MeOH to give a white solid from the mother liquors of the calix[8]arene preparation. The ***hexa-acetate*** (Ac_2O/H_2SO_4) crystallises from $CHCl_3$/MeOH with **m 360-362°**(**dec**), and the ***($SiMe_3$)$_6$ derivative*** crystallises from $CHCl_3$/MeOH with **m** 410-412°. Its stability in KOH-xylene is the same as for the 4-*tert*-

butylcalix[4]arene. [Gutsche et al.*J Am Chem Soc* **103** 3782 *1981*, DOI: 10.1021/ja00403a028. See also Kluawer in *Calixarenes*, Vicens & Böhner eds Academic Press *1991*, *Beilstein* **6** IV 7858.]
4-tert-Butylcalix[8]arene *[68971-82-4]* **$C_{88}H_{112}O_8$, M 1297.8,** has **m 411-412°.** The calixarene recrystallises from $CHCl_3$ in fine colourless, glistening needles. It melts sharply between 400-401° and 411-412° depending on the sample and is sensitive to traces of metal ions. On TLC with silica gel (250μm thick) and elution with $CHCl_3$/hexane (3:4) it has R_F 0.75. The ***octa-acetate*** is prepared from 8g in Ac_2O (50ml) and 2 drops of concentrated H_2SO_4 and refluxed for 2 hours. On cooling, a colourless precipitate separates and is recrystallised from Ac_2O (1.2g 48%) with **m** 353-354°. The ***(SiMe$_3$)$_8$ derivative*** is prepared from 4-*tert*-butylcalix[8]arene (0.65g) in pyridine (4ml) with excess of hexamethyldisilazane (1ml) and trimethylchlorosilane (0.5ml) and refluxed under N_2 for 2 hours. Cool, evaporate the pyridine, triturate the gummy residue with MeOH. Chromatograph on silica gel using hexane/CH_2Cl_2 gave 0.5g (61%) with one spot on TLC. Recrystallise it from hexane/Me_2CO to give colourless needles **m** 358-360°. [Gutsche et al. *J Am Chem Soc* **103** 3782 *1981*, DOI: 10.1021/ja00403a028; Gutsche & Muthukrishnan *J Org Chem* **43** 4905 *1978*, DOI: 10.1021/jo00419a052; Muthukrishnan & Gutsche *J Org Chem* **44** 3962 *1979*, DOI: 10.1021/jo01336a045; Andretti et al. *JCS Chem Commun* 533 *1981*, DOI: 10.1039/C39810000533; see Kluawer in *Calixarenes*, Vicens & Böhner eds Academic Press *1991*.]

8-*sec*-Butylmetrazole *[25717-83-3]* **M 194.3, m 70°.** Crystallise it from petroleum ether and dry it for 2 days under vacuum over P_2O_5. [*Beilstein* **26** II 213 for Metrazole.]

***N*-(*n*-Butyl)-5-nitro-2-furamide** *[14121-89-2]* **M 212.2, m 89-90°, b 190°/10mm.** Distil the amide in a vacuum and recrystallise it twice from EtOH/water mixture or petroleum ether. [Gilman & Yale *J Am Chem Soc* **72** 3593 *1950*, DOI: 10.1021/ja01164a075; *Beilstein* **18** III/IV 3995.]

Butyloxirane (1-hexene oxide) *[1436-34-6]* **$C_6H_{12}O$, M 100.2, b 116-117°/atm, 116-119°/atm, 118-120°/atm, d_4^{20} 0.833, n_D^{20} 1.44051.** Purify it by fractional distillation through a 2ft helices-packed column atatmospheric pressure in a N_2 atmosphere. [Pasto & Cumbo *J Org Chem* **30** 1271 *1965*, DOI: 10.1021/jo01015a523; Emmons & Pagaro *J Am Chem Soc* **77** 89 *1955*, DOI: 10.1021/ja01606a029; ^{13}C NMR Davies & Whitham *JCS Perkin Trans 2* 861 *1975*, DOI: 10.1039/P29750000861; *Beilstein* **17/1** V 103.]

4-*tert*-Butylpyridine *[3978-81-2]* **$C_9H_{13}N$, M 135.2, m -44.4°, b 194-197°atm, 196-197°atm, 197°/765mm, d_4^{20} 0.923, n_D^{20} 1.495, pK^{25} 5.82.** Dry 4-*tert*-butylpyridine over solid KOH and purify it by fractional distillation through an efficient column under dry N_2. Its ***picrate*** has **m 153.9-154°**, and the ***hydrochloride*** has **m 151.7-154.8°** (from Me_2CO). Cacotheline **(2,3-dihydro-4-nitro-2,3-dioxo-9,10-*seco*strychnidin-10-oic acid)** *[561-20-6]* **$C_{21}H_{21}N_3O_7$, M 427.4, $pK_{Est(1)}$ ~4.4 (CO_2H), $pK_{Est(2)}$ ~10.2 (proton gain).** Cacotheline gives yellow crystals from H_2O. It is then dried over H_2SO_4 which gives the ***dihydrate***, and in a vacuum over H_2SO_4 at 105° it forms the ***anhydrous*** compound. The ***hydrochloride*** separates as the ***hydrate*** (on heating in vacuum at 80°) in orange-yellow prisms or plates, **m 250°(dec)** and forms a ***resorcinol complex*** which gives brown crystals from EtOH, **m 325°**; and a ***hydroquinone complex*** as dark red crystals from EtOH, **m 319°.** [Leuchs & Leuchs *Chem Ber* **43** 1042 *1910*, DOI: 10.1002/cber.191004301179; Teuber *Chem Ber* **86** 232, (UV: 242) *1953*, DOI: 10.1002/cber.19530860218; complexes: Gallo *Gazz Chim Ital* **85** 1441 *1955*.] It is used in the titrimetric estimation of Sn^{2+} ions [Szarvas & Lantos *Talanta* **10** 477 *1963*, DOI:10.1016/0039-9140(63)80055-7]. [*Beilstein* **27** III/IV 8014.]

1*S*-(-)-Camphorsulfonylimine {(7*S*)—10,10-dimethyl-5-thia-4-azatricyclo[5.2.1.03,7]dec-3-ene-5,5-dioxide} *[60886-80-8]* **$C_{10}H_{15}NO_2S$, M 213.3, m 228-230°, $[\alpha]_D^{20}$ -34 (c 1, $CHCl_3$).** The method described here is that of Davis and coworkers [*Org Synth* Coll Vol **8** 110 *1993*, *Org Synth* **69** 158 *1990*, DOI: 10.15227/orgsyn.069.0158]: Under N_2, and with stirring, 1*S*(+)-camphorsulfonamide (41.5g, see *[60933-63-3]* above) in toluene (500ml) and Amberlyst 15 ion-exchange resin (5g) are boiled under a Dean-Stark water separator and reflux for 4 hours, after which time H_2O separation was complete. While still warm (at 40-50°),

CH_2Cl_2 (200ml) is added slowly to dissolve any sulfonylimine that separated and the solution is filtered through a 150ml course porosity sintered glass funnel, and the funnel is washed with CH_2Cl_2 (75ml). The combined CH_2Cl_2 solutions (containing toluene) are evaporated and the solid residue being ***1S-(-)-camphorsulfonylimine*** is recrystallised from absolute EtOH (750ml) to provide white crystals (34.5-36.4g, 90-95% yield) with **m 225-228°**, $[\alpha]_D$ -32.7 (c 1.9, $CHCl_3$). Its IR ($CHCl_3$) has ν_{max} at 3030, 2967, 1366 cm^{-1}; ^1H NMR ($CDCl_3$) has δ at 1.03 (s, 3H, CH_3), 1.18 (s, 3H, CH_3), 1.45-2.18 (m, 6H), 2.65 (m, 1H), 3.10 and 3.28 (AB quartet, 2H CH_2-SO_2, *J* = 14Hz); ^{13}C NMR ($CDCl_3$) has δ at 19.01 (q, CH_3), 19.45 (q, CH_3), 26.64 (t), 28.44 (t), 35.92 (t), 44.64 (d), 48.00 (s), 49.46 (t), 64.52 (s), 195.52 (s). The **1*R*(+)-** ***enantiomer*** was similarly prepared. [*Beilstein* **27** III/IV 1007.]

2*R*,8a*S*-(+)-10-Camphorsulfonyloxaziridine {4H-4A,7-methanooxazirino[3,2-*i*][2,1]benzisothiazole, tetrahydro-9,9-dimethyl, 3,3-dioxide [4a*S*-(4aα,7α,8aR*)]} *[104322-63-6]* **$C_{10}H_{15}NO_3S$, M 229.3, m 165-167°, $[\alpha]_D^{20}$ +45 (c 2, $CHCl_3$).** The method described here is that of Davis et al. [*Org Synth* Coll Vol **8** 110 *1993*, *Org Synth* **69** 158 *1990*, DOI: 10.15227/orgsyn.069.0158]: To a stirred solution of the preceding ***1S-(-)-camphorsulfonylimine*** (39.9g, 0.187mol) in toluene (500ml) in a 5L three necked flask, a solution of anhydrous K_2CO_3 (543g, 7 equivalents based on oxone) in H_2O (750ml) is added with vigorous stirring, followed by a solution of ***oxone*** [345g, 0.56mol, 6 equivalents of $KHSO_5$, see *[37222-66-5, 70693-62-8 (triple salt)*] in 'Inorganic Compounds', Chapter 4] in H_2O (1250ml) dropwise in three volmes over 45 minutes. [***Note*** that the solution turns milky, and the reaction time depends on the activity of oxone; if it is below parr (e.g. if previously exposed to moisture, but if stored <0° under N_2 it should be stable for at least 6 months), then more oxone should be added making sure that the pH is maintained at ~9.] Completion of reaction should occur after all the oxone is added and should be checked by TLC. Thus an aliquot of the reaction mixture (~0.5ml) is spotted on a TLC silica gel plate (250μm thick), eluted with CH_2Cl_2 and developed with 10% molybdophosphoric acid in EtOH and heated for a few minutes in 100° oven, whereby the absence of a spot with R_F = 0.28 (for the *sulfonylimine*) indicates completion of reaction. {**Note** also, that if the reaction becomes brownish in colour and the addition of oxone is not complete after 30 minutes, the mixture should be filtered through a 150ml coarse porosity sintered glass funnel, the solids are washed with CH_2Cl_2 (50ml). The filtrate is returned to the original flask and stirred vigorously with more oxone (52g, 0.08mol, 1 equivalent of $KHSO_5$) added within 5 minutes and stirring is continued until the reaction is complete (~10-15 minutes).} At completion, the mixture is filtered through a 150ml coarse porosity sintered glass funnel to remove solids, the filtrate is transferred to a separating funnel (3L), the toluene phase is collected, the aqueous phase is washed with CH_2Cl_2 (100ml x 3). The solids together with the solids remaining in the original reaction flask are combined and washed with more CH_2Cl_2 (200ml). The combined organic liquids are washed with saturated sodium sulfite, dried ($MgSO_4$) for 15-20min, filtered and evaporated to dryness. The residual solid is recrystallised form hot *iso*-propanol (~500ml), which after drying *in vacuo* gave the **(+)-*oxaziridine*** (35.9g, 84% yield) as white needles with **m 165-167°**, $[\alpha]_D$ +44.7 (c 2.2, $CHCl_3$). Its ^1H NMR ($CDCl_3$) has δ at 1.03 (s, 3H, CH_3), 1.18 (s, 3H, CH_3), 1.45-2.18 (m, 6H), 2.65 (m, 1H), 3.10 and 3.28 (AB quartet, 2H, CH_2-SO_2, *J* = 14Hz); ^{13}C NMR ($CDCl_3$) has δ at 19.45 (q, CH_3), 20.42 (q, CH_3), 26.55 (t), 28.39 (t), 33.64(t), 45.78 (d), 48.16 (s), 48.32 (t), 45.07 (s), 98.76 (s).
The **(-)-*oxaziridine enantiomer*** *[104372-31-8]* was prepared similarly and had **m 166-167°**, $[\alpha]_D$ -43.6 (c 2.2, $CHCl_3$). ***Note the inversion of rotation on oxidation of the sulfonylimine***.

These oxaziridines are selective aprotic oxidising agents [see Davis & Jenkins on the chemistry of *N*-sulfonyloxaziridines in *Asymmetric Synthesis* Morrison Ed. *Academic Press* Vol 4 Chapter 4 *1984*, ISBN 10: 012431452X, 13: 978-0124314528; and Davis & Sheppard *Tetrahedron* **45** 5703 *1989*, DOI: 10.1016/S0040-4020(01)89102-X], and stereoselectively oxidise sulfides to sulfoxides [in 30-91% ee, Davis et al. *J Am Chem Soc* **109** 3370 *1987*, DOI: 10.1021/ja00245a030], selenides to selenoxides [8-9% ee, Davis et al. *Tetrahedron* **41** 4747 *1985*, DOI: 10.1016/S0040-4020(01)96713-4], sulfides to thiolsulfonates [2-13% ee, Davis et al. *J Am Chem Soc* **104** 5412 *1982*, DOI: 10.1021/ja00384a028], used in asymmetric epoxidation of alkenes [19-65% ee, Davis & Chattopadhyay *Tetrahedron Lett* **27** 5079 *1986,* DOI: 10.1016/S0040-4039(00)85137-0; Davis et al. *J Am Chem Soc* **105** 3123 *1983*, DOI: 10.1021/ja00348a029] and in the asymmetric oxidation of enolates [35-82% ee, Davis et al. *J Org Chem* **51** 2402 *1986*, DOI: 10.1021/jo00362a053; 51-84% ee, Davis & Haque *J Org Chem* **51** 4083 *1986,* DOI: 10.1021/jo00371a038, Davis et al. *J Org Chem* **54** 2021 *1989*, DOI: 10.1021/jo00269a054; 55-80% ee, Davis et al. *J Am Chem Soc* **112** 6679 *1990*, DOI: 10.1021/ja00174a035]. [Fieser **13** 64**, 14** 72, **16** 61, **17** 320.]

2,10-Camphorsultam [(3a*S*)-4,5,6,7-tetrahydro-8,8-dimethyl-1,2-dioxide-3*H*-3a,6-methano-2,1-benzisothiazole] *[1R-(+)- 108448-77-7, 1S-(-)- 94594-90-8]* **$C_{10}H_{17}NO_2S$, M 215.3, m 181-183°, 183-184 185-187°, $[\alpha]_D^{20}$ (+) and (-) 32 (c 5, $CHCl_3$).** The (-)-enantiomer has been prepared by reduction of **(-)-*camphorsulfonylimine*** (see above) with $LiAlH_4$. The (-)-enantiomer is recrystallised from 95% EtOH and dried in a vacuum desiccator. *Alternatively* dissolve the sultam (33.5g) in hot absolute EtOH (~60 mL), cool, collect the solid on a coarse porosity sintered glass funnel and dry it in a vacuum desiccator to give the pure sultam (31.1g, + 1.4g from the mother liquors) as white crystals. It dissolves in dilute aqueous NaOH and can be precipitated without hydrolysis by acidifying. It forms the ***N*-Na salt** in EtOH (by addition of Na to the EtOH solution), and the salt can be methylated with MeI to give the **(-)-*N-Me lactam*** with **m 80°** after recrystallisation from hot H_2O, and has $[\alpha]_D^{25}$ -59.6 (c 5, $CHCl_3$) [Shriner et al. *J Am Chem Soc* **60** 2794 *1938*, DOI: 10.1021/ja01278a072]. [Oppolzer et al. *Helv Chem Acta* **69** 1542 *1986*, DOI: 10.1002/hlca.19860690703; for prep and ^{1}H NMR see: Weismiller et al. *Org Synth* **69** 154 *1955*, Coll Vol **8** 110 *1993*, DOI: 10.15227/orgsyn.069.0154; *Beilstein* **27** III/IV 1007.]

ε-Caprolactam (azepan-2-one, aza-2-cycloheptanone, 2-oxohexamethyleneimine) *[105-60-2]* **$C_6H_{11}NO$, M 113.2, m 68-70°, 70°, 70.5-71.5°, 70-71°, 136-138°/10mm, 262.5°/760mm.** The lactam is distilled under reduced pressure, recrystallised from acetone or petroleum ether and redistilled. It can be purified by zone melting. It is very *hygroscopic* and discolours in contact with air unless small amounts (0.2g/L) of NaOH, Na_2CO_3 or $NaBO_2$ are present. It has been crystallised from a mixture of petroleum ether (185ml of **b** 70°) and 2-methyl-2-propanol (30ml), from acetone, or petroleum ether. It is then distilled under reduced pressure and stored under nitrogen. [Pellegata et al. *Synthesis* 614 *1978*, DOI: 10.1055/s-1978-24834; *Beilstein* **21/6** V 444.]

Caprylolactam (azanon-2-one, azacyclononan-2-one, 8-aminooctanoic acid lactam, cyclooctanone isooxime) *[935-30-8]* **$C_8H_{15}NO$, M 141.2, m 72°, 73°, 74-76°, 75°, 76-77°, b 119-122°/0.7mm, 150-151°/7-8mm, 164°/14mm, d_4^{73} 1.009, n_D^{73} 1.489, pK^{25} 0.55 (AcOH).** Dissolve it in $CHCl_3$, decolorise it with charcoal, evaporate to dryness and recrystallise it from $CHCl_3$/hexane. Sublime it at high vacuum. The ***oxime*** has **m 117°** (from *C_6H_6 or petroleum ether). [Guggisberg et al. *Helv Chim Acta* **61** 1050 *1978*, DOI: 10.1002/hlca.19780610314; Olah et al. *Synthesis* 537 *1979*, DOI: 10.1055/s-1979-28752; Behringer & Meier *Justus Liebigs Ann Chem* **607** 67 *1957*, DOI: 10.1002/jlac.19576070109; *Beilstein* **21** III/V 3260.]

Carbazole *[86-74-8]* **$C_8H_{15}NO$, M 167.2, m 240-243°, 243-246°, b 355°/atm, pK^{25} <0.** Dissolve carbazole (60g) in conc H_2SO_4 (300ml), extract with three 200ml portions of *benzene, then stir this into 1600ml of an ice-water mixture. The precipitate is filtered off, washed with a little water, dried, recrystallised from *benzene and then from pyridine/*benzene [Feldman et al. *J Am Chem Soc* **73** 4341 *1951*, DOI: 10.1021/ja01153a091]. It has also been recrystallised from EtOH or toluene, sublimed in vacuum, zone-refined, and purified by TLC. [UV: Armarego in *Physical Methods in Heterocyclic Chemistry* (Ed Katritzky, Academic Press, LCCC No 62-12037, Internet Public Domain) **Vol III** 158 *1971*; *Beilstein* **20/8** V 9.]

9-Carbazoleacetic acid *[524-80-1]* **$C_{14}H_{11}NO_2$, M 225.2, m 215°, pK_{Est} ~3.5.** Crystallise the acid from ethyl acetate. It yields ***9-methylcarbazole*** *[1484-12-4]* **$C_{13}H_{11}N$,** M 181.2, **m 90-92°**, on decarboxylation at **240-260°.** [Fan et al. *Anal Chim Acta* **367** 81 *1998*, DOI: 10.1016/S0003-2670(98)00125-1; *Beilstein* **20** III/IV 3841, and *Beilstein* **20** H 436 for 9-methylcarbazole] The ***ethyl ester***, $C_{16}H_{15}NO_2$, **m 97°**, crystallises from EtOH.

Carbazole-9-carbonyl chloride *[73500-82-0]* **M 300.0, m 100-103°, 103.5-104.5°**. Recrystallise the acid chloride from *C_6H_6. If it is not very pure (presence of OH or NH bands in the IR), dissolve it in pyridine, shake it with phosgene in toluene, evaporate and recrystallise the residue. Carry out this experiment in a good fume cupboard as $COCl_2$ is very **TOXIC**, and store the product in the dark. It is moisture sensitive. The ***amide*** has **m 246.5-247°**, and the ***dimethylaminoethylamide hydrochloride*** has **m 197-198°**. [Weston et al. *J Am Chem Soc* **75** 4006 *1953*, DOI: 10.1021/ja01112a038; *Beilstein* **20** III/IV 3841.]

1-Carbethoxy-4-methylpiperazine hydrochloride *[532-78-5]* **M 204.7, m 168.5-169°, pK^{25} 7.31.** Crystallise the hydrochloride from absolute EtOH. Its solubility is 280g/100g of H_2O at 25°. The ***free base ester*** has **b 97-98°/8mm**. [*Beilstein* **23** III/IV 223.]

γ–Carboline (9*H*-pyrido[3,4-b]indole) *[244-69-9]* **$C_{11}H_8N_2$, M 168.2, m 225°, 230-233°, pK^{25} ~0.** Crystallise it from water or EtOAc. [Robinson & Thornley *J Chem Soc* **125** 2169 *1924*, DOI: 10.1039/CT9242502169; Dalton et al. *Aust J Chem* **22** 185 *1969*, DOI: 10.1071/CH9690185; Staab & Wendel *Org Synth* **48** 44 *1968*, DOI: 10.15227/orgsyn.048.0044; *Beilstein* **23** II 223, **23** III/IV 1572.]

***N,N'*-Carbonyldiimidazole (CDI)** *[530-62-1]* **$C_7H_6N_4O$, M 162.2, m 115-122°, 115.5-116°, 117-122°.** Crystallise it from *benzene or tetrahydrofuran in a dry-box and store it dry. [*Beilstein* **23/4** V 245.] Very useful for activating acids (as imidazolides) for the synthesis of esters, amides, and ketones, and for immobilising enzymes on affinity ligands [Staab *Angew Chem* **74** 407 *1962*, DOI: 10.1002/ange.19620741203; Hearn *Methods Enzymol* **135** 102 *1987*, DOI: 10.1016/0076-6879(87)35068-2]. It has also been used as a carbonyl-transfer reagent for synthesising various heterocyclic compounds [Barluenga et al. *J Org Chem* **56** 6751 *1991*, DOI: 10.1021/jo00024a011; Kang et al. *Synth Commun* **23** 2219 *1993*, DOI: 10.1080/00397919308013776]. [*Beilstein* **23/4** V 245.]

1,1'-Carbonyldi(1,2,4-triazole) (CDT) *[41864-22-6]* **$C_5H_4N_6O$, M 164.1, m 134-136°, 145-150°.** Dissolve CDT in tetrahydrofuran and evaporate at 10mm until it crystallises. Wash the crystals with cold tetrahydrofuran and dry them in a vacuum desiccator over P_2O_5 in which it can be stored for months. Its applications are similar to those of CDI (see preceding entry). [Bergmann & van Den Brink *Recl Trav Chim Pays-Bas* **80** 1372 *1961*, DOI: 10.1002/recl.19610801209; Potts & Crawford *J Org Chem* **27** 2631 *1962*, DOI: 10.1021/jo01054a502; Staab *Justus Liebigs Ann Chem* **609** 75 *1957*, DOI: 10.1002/jlac.19576090108.] [*Beilstein* **24** IV 38.]

(±)-Catechin (3,3',4',5,7-pentahydroxyflavan) *[7295-85-4]* **$C_{15}H_{14}O_6$, M 290.2, m 177° (anhydrous).** Crystallise it from hot water or hot H_2O + AcOH, and dry it at 100° in a vacuum. **(-)-*Catechin*** *[18829-70-4]* has **m 93-96°** (hydrate from H_2O + AcOH) and **m 175-177°** (anhydrous) and $[\alpha]_D$ -16.8 (H_2O); and the enantiomer **(+)-*Catechin*** *[154-23-4]* (which occurs as the hydrate) has **m 93-96°** (hydrate from H_2O + AcOH) and **m 175-177°** (anhydrous) and $[\alpha]_D^{18}$ +16.8 to +18 (H_2O). [*Beilstein* **17/8** V 448, for stereochemistry see Clark-Lewis *J Chem Soc* 2433 *1960*, DOI: 10.1039/JR9600002433.]

Cetylpyridinium chloride (H_2O) (hexadecylpyridinium chloride) *[6004-24-6]* **$C_{21}H_{38}ClN$, M 358.0, m 80-83°.** Crystallise the chloride from MeOH or EtOH/diethyl ether and dry it *in vacuo*. 2-Chloro-4,6-dimethylpyrimidine *[4472-44-0]* **$C_6H_7ClN_2$, M 142.6, m 34-38°, 38°, b 223°/atm, pK^{20} -0.68.** The chloro-pyrimidine has been distilled at atmospheric pressure, and solidifies on cooling. Purify it by recrystallisation from petroleum ether (b 40-60°). The 2-chloro-substituent is readily subject to nucleophilic substitution, and the kinetics of reaction with morpholine and piperidine are reported in detail (cf. Chapman & Rees). It is a very weak base and requires 2N HCl to form the cation species. The UV has λ_{max} (logε) at 255 (3.65) and 263 (infl 3.49) nm at pH 2.0 (neutral species); and 261nm (3.87) in ~2N HCl (H_o -3.0, cation). [Boarland & McOmie *J Chem Soc* 1218 *1951*, DOI: 10.1039/JR9510001218; Boarland & McOmie 3722 *1952*, DOI: 10.1039/JR9520003722; Chapman & Rees *J Chem Soc* 1190 *1954*, DOI: 10.1039/JR9540001190; Brown & England *J Chem Soc, C* 1922 *1967*, DOI: 10.1039/J39670001922; Matsukawa & Ohta *J Pharm Soc, Jpn* **69** 491 *1949*, *Chem Abstr* **44** 3456 *1950,* Andrisano & Modena *Gazz Chem Ital* **81** 405 *1951*, Angerstein *Chem Ber* **34** 3956 *1901*, DOI: 10.1002/cber.190103403119; *Beilstein* **23** H 95, **23** IV 918.]

2-Chloro-5-nitropyridine *[4548-45-2]* has **m 105-108°, 108°, pK_{Est} ~-2.6.** It crystallises from *benzene or *benzene/petroleum ether. [*Beilstein* **20/5** V 452.]

N*-(3-Chlorophenyl)-6,7-dimethoxyquinazolinamine (Tyrphostin AG 1478)** *[175178-82-2 free-base; 153436-53-4 hydrochloride]* **$C_{16}H_{14}ClN_3O_2$, M 315.7 (free base), decoposes ≥ 275-280, pKa (very weak base).** This and related bio-active 4-anilinoquinazolines [see Barker & Davies EP 0520722 A1 *30 Dec 1992* to Zeneca; Hess US 3511836 A *12 May 1970* to Pfizer & Co] have been prepared from 4-chloro-6,7-dimethoxyquinazoline. The latter was obtained by the following sequence of reaction: veratole (4-hydroxy-3-methoxybenzaldehyde) + Me_2SO_4 → 3,4-dimethoxybenzaldehyde + HNO_3 → 4,5-dimethoxy-2-nitrobenzaldehyde + $KMnO_4$ → 4,5-dimethoxy-2-aminobenzoic acid + HNCHO → 6,7-dimethoxyquinazoline-4-one + $POCl_3$/Me_2NPh → 4-chloro-6,7-dimethoxyquinazoline, or some slight variations of this synthesis [Althuis & Hess *J Med Chem* **20** 146 *1977*, DOI: 10.1021/jm00211a031; see also Armarego & Reece *Aust J Chem* **34** 1561 *1981*, DOI: 10.1071/CH9811561]. The purity of the chloroquiazoline is important because impure material deteriorates rapidly. Stable material is best obtained by dissolving the residue, after evaporation of excess $POCl_3$, in CH_2Cl_2, placing the solution on an Al_2O_3 column and eluting with CH_2Cl_2 followed by increasingly polar mixtures of CH_2Cl_2 and EtOAc. The condensation of 4-chloro-6,7-dimethoxyquinazoline with 3-chloroaniline can be achieved by fusing equimolar amounts at ~100° for 5min whereby the mixture melts and then solidifies, dissolving this in the minimum volume of hot EtOH, heat at boiling point for 30min and cool to crystallise out the quinazolinamine hydrochloride which is recrystallised from EtOH or *iso*PrOH. ***Alternatively, equimolar amounts of reagents are stirred with *iso*PrOH which has been heated to 80° and stirred at this

temperature for 30 minutes. On cooling, the product separates and is recrystallised from the same solvent. In another variant Et_3N is added to the *iso*PrOH solution which provides similar yields (65-88%), but in this case the ***free base*** is formed because Et_3N consumes the HCl liberated from the reaction. **AG 1478** is soluble in 0.1M HCl (0.4w/v%), in EtOH (1.0w/v%), in DMSO-MeOH (1:1. 1w/v%) and in CH_2Cl_2, but insoluble H_2O and in 0.1N NaOH. ***N-(3-Chlorophenyl)-N-(6,7-dimethoxyquinazolin-4-yl)-N-methylamine hydrochloride*** has **m 220-222º** (**235-237º**), and ***N-(3-chlorophenyl)-N-(6,7-dimethoxyquinazolin-4-yl)-N-ethylamine hydrochloride*** has **m 261-263º** [See Myers et al. 2-Chlorothiophene (2-thienyl chloride) *[96-43-5]* **C_4H_3ClS, M 118.6, b 126-128°/atm, 127-129°/atm, 128°/~760mm, d_4^{20} 1.285, n_D^{20} 1.551.** Purify it by fractional distillation at atmospheric pressure or by gas chromatography. [Conde et al. *Synthesis* 412 *1976*, DOI: 10.1055/s-1976-24065; *Beilstein* **17/1** V 303.]

5-Chlorouracil (5-chloro-2,4(6)-dihydroxypyrimidine) *[1820-81-1]* **$C_4H_3ClN_2O_2$, M 146.5, m 314-418°(dec), 324-325°(dec), pK_1^{25} 7.95, pK_2^{25} >13.** It recrystallises from hot H_2O (4g/500ml) using charcoal. [Chesterfield et al. *J Chem Soc* 3478 *1955*, DOI: 10.1039/JR9550003478; West & Barrett *J Am Chem Soc* **76** 3146 *1954*, DOI: 10.1021/ja01641a009; *Beilstein* **24** III/IV 1231.]

4-Chromanone (2,3-dihydro-4*H*-1-benzopyran-4-one) *[491-37-2]* **$C_9H_8O_2$, M 148.2, m 35-37°, 39°, 41°, b 92-93°/3mm, 127-128°/13mm, 130-132°/15mm, 160°/50mm.** It has been recrystallised from petroleum ether, or purified by dissolving in *C_6H_6 washing with H_2O, drying ($MgSO_4$), evaporating and distilling in a vacuum,

then recrystallising the residue. The liquid has a pleasant lemon-like odour. The ***semicarbazone*** has **m 227°**. [Loudon & Razdan *J Chem Soc* 4299 *1954*, DOI: 10.1039/JR9540004299.] The ***oxime*** is prepared from 3g of chromanone, 3g $NH_2OH.HCl$ in EtOH (50ml), 6g K_2CO_3 and refluxed on a water bath for 6 hours. The solution is poured into H_2O, the solid is filtered off, dried and dissolved in hot $*C_6H_6$ which on addition of petroleum ether yields the ***oxime*** as glistening needles **m 140°**. Hydrolysis of this gives very pure chromanone. The ***benzal derivative*** is prepared from 3g of chromanone and 4g PhCHO in 50ml EtOH, heated to boiling, 10ml of conc HCl are added dropwise and set aside for several days. The derivative separates and is recrystallised from EtOH to give yellow needles, **m 112°** [Powell *J Am Chem Soc* **45** 2708 *1923*, DOI: 10.1021/ja01664a033]. Reaction with $Pb(OAc)_4$ yields the ***3-acetoxy derivative*** **m 74°** (from petroleum ether + trace of EtOAc) [Cavill et al. *J Chem Soc* 4573 *1954*, DOI: 10.1039/JR9540004573; *Beilstein* **17/10** V 14].

Cinnoline *[253-66-7]* **$C_8H_6N_2$, M 130.2, m 38°, 40-41°, b 114°/0.35, pK^{20} 2.37.** Distil at high vacuum, then recrystallised from petroleum ether. It forms an etherate **m 24-25°**. Keep under N_2 in sealed tubes in the dark at 0°. The ***hydrochloride*** *[5949-24-6]* **M** 166.6 has **m 156-158°** (yellow ***monohydrate***, from EtOH/Et_2O), and dehydrates on sublimation at 110-115°/3mm. The ***picrate*** has **m 196-196.5°**. [D.J. Brown *Cinnolines and Phthalazines* Suppl II *2005*, Wiley & Sons NJ. ISBN-13: 978-0-471-48587-2; *Beilstein* **23** III.IV 1217.]

Citrazinic acid (2,6-dihydroxyisonicotinic acid) *[99-11-6]* **$C_6H_5NO_4$, M 155.1, m >300°, pK_1 3.0, pK_2 4.76.** The acid is normally a yellow powder with a greenish shade, but is white when ultra pure and turns blue on long standing. It is insoluble in H_2O but slightly soluble in hot HCl and soluble in alkali or carbonate solutions. It is purified by precipitation from alkaline solutions with dilute HCl, and dried in a vacuum over P_2O_5. The ***ethyl ester*** has **m 232°** (evacuated tube) and a pKa of 4.81 in $MeOCH_2CH_2OH$ [IR: Pitha *Coll Czech Chem Commun* **28** 1408 *1963*, DOI: org/10.1135/cccc19631408]. [*Beilstein* **22/7** V 24.]

Clioquinol (5-chloro-8-hydroxy-7-iodoquinoline) *[130-26-7]* **M 305.5, m 181°, pK_1^{25} 2.7, pK_2^{25} 7.9.** It crystallises from AcOH or xylene, and dry it at 70° *in vacuo*. [*Beilstein* **21** III/IV 1190**.]**

Conessine *[546-06-5]* **$C_{24}H_{40}N_2$, M 356.6, m 125°, 127-128.5°, $[\alpha]_D^{20}$ -1.9 (in $CHCl_3$) and +26 (c 3, EtOH), $pK_{Est(1)}$~10.4 , $pK_{Est(2)}$~10.7.** It crystallises from acetone, sublimes at 95°/0.01mm and boils at 0.1mm with bath temperature at 220°. The ***dihydrochloride*** has **m >340°** (browns at 235° and decomposes at 338-240°) and has $[\alpha]_D^{20}$ +9.3 (c 2, H_2O). The **(+)-*dihydrobromide*** *[5913-82-6]*, **m ~340°**, crystallises from EtOH/Et_2O. [Marshall & Johnson *J Am Chem Soc* **84** 1485 *1962*, DOI: 10.1021/ja00867a026; *Beilstein* **22** III/IV 4382.]

Coproporphyrin I *[531-14-6]* **$C_{36}H_{38}N_4O_8$, M 654.7, λ_{max} 591, 548, 401nm in 10% HCl.** It crystallises from pyridine/glacial acetic acid. The ***dihydrochloride*** *[69477-27-6]* has M 727.6 and λ_{max} at 395nm in water. [*Beilstein* **26** III/IV 3094.]

Coumalic acid (2-pyrone-5-carboxylic acid) *[500-05-0]* **$C_6H_4O_4$, M 140.1, m 203-205°(dec), 205-210°(dec), 218°/120mm, pK_{Est} ~0.** The acid crystallises from MeOH. The ***methyl ester*** has **m 73-74°** (from petroleum ether) and **b 178-180°/60 mm**. [*Beilstein* **18/8** V 120.]

Coumarin *[91-64-5]* **$C_9H_6O_2$, M 146.2, m 68-69°, 68-70°, 68-73°, b 68-73°, 139°/5mm, pK^{25} -4.97 (aqueous H_2SO_4).** Coumarin crystallises from ethanol or water (solubility is 0.25w/v% at ~20°, and 2.0w/v% ~100°), and is soluble in organic solvents and alkaline solutions. It sublimes *in vacuo* at 43° [Srinivasan & De Levie *J Phys Chem* **91** 2904 *1987*, DOI: 10.1021/j100295a050]. [*Beilstein* **17/10** V 143.] It is a flavouring (vanilla) agent. ***Coumarin-3-carboxylic acid*** *[531-81-7]* **$C_{10}H_6O_4$, M 190.2,** has **m 188°(dec), 189-192°(dec), pK_{Est} ~1.5**, and crystallises from water. [*Beilstein* **18/8** V 323.]

γ-Crotonolactone [2(5*H*)-furanone] *[497-23-4]* **$C_4H_4O_2$, M 84.1, m 3-4°, 76-77°/3.5mm, 90.5-91°/11.5mm, 92-93°/14mm, 107-109°/24mm, 212-214°/760mm, d_4^{20} 1.197, n_D^{20} 1.470.** Fractionally distil the lactone under reduced pressure. Its IR(CCl_4) has 1784 and 1742 cm^{-1}, UV no max above 205nm (ε 1160 cm^{-1} M^{-1}) and ^{1}HNMR (CCl_3) has τ at 2.15 (pair of triplets 1H), 3.85 (pair of triplets 1H) and 5.03 (triplet 2H). [Price & Judge *Org Synth* Coll Vol **5** 255 *1973*, DOI: 10.15227/orgsyn.045.0022; Jones et al. *Can J Chem* **37** 2007, DOI: 10.1139/v59-293; 2092 *1959*, Smith & Jones *Can J Chem* **37** 2092 *1959*, DOI: 10.1139/v59-306; *Beilstein* **17/9** V 112.]

15-Crown-5 *[33100-27-5]* **$C_{10}H_{20}O_5$, M 220.3, b 93-96°/0.1mm, d_4^{20} 1.113, n_D^{20} 1.465.** Dry it over 3A molecular sieves and distil it in a high vacuum. [*Beilstein* **19/12** V 252.]
18-Crown-6 *[17455-13-9]* **$C_{12}H_{24}O_6$, M 264.3,** has **m 37-39°, 42-45°.** Recrystallise it from acetonitrile and dry it in a vacuum. Purify it also by precipitating the 18-crown-6/nitromethane 1:2 complex with Et_2O/nitromethane (10:1 mixture). The complex is decomposed in vacuum whereby 18-crown-6 distils off under the reduced pressure. [*Beilstein* **19/12** V 601.] It is a complexing agent with cations which solubilises them in non-polar solvents, and is useful as a phase-transfer catalyst in aqueous-organic mixed solvents [Gokel *Crown Ethers and Cryptands* The Royal Society of Chemistry (Cambridge, England *1991*), Gokel et al. *Org Synth* Coll Vol **6** 301 *1988*, DOI: 10.15227/orgsyn.057.0030; cf. Kotha & Kashinath *Synthesis* 971 *2005(6)*, DOI: 10.1055/s-2005-861840].

Cryptopine *[482-74-6]* **$C_{21}H_{23}NO_5$, M 369.4, m 220-221°, 220-223°, pK^{25} 8.09.** It crystallises from *benzene, hot EtOH (0.25% cold, 1.2% at boiling), petroleum ether or methyl ethyl ketone. It is a relatively strong organic base — store in the absence of CO_2 in the dark. The ***perchlorate*** crystallises from aqueous MeOH with **m 226-228°(dec)**. [Thomas et al. *Can J Chem* **33** 570 *1955*, DOI: 10.1139/v55-067; Haworth & Perkin *J Chem Soc* 1769 *1926*, DOI: 10.1039/JR9262901769; *Beilstein* **27** III/IV 6652.]

Cupreine (6'-hydroxycinchonidine) *[524-63-0]* **$C_{19}H_{22}N_2O_2$, M 310.4, m 202°(anhydrous), $[\alpha]_D^{17}$ -176 (c 0.5, MeOH), pK^{15} 7.63 (6.57).** Cupreine crystallises from EtOH (***anhydrous*** crystals) and wet Et_2O (as ***dihydrate*** crystals). It has K_b $2.7x10^{-7}$ [Kolthoff *Biochem Z* **162** 323]. The ***sulfate*** forms needles, **m 257°(dec)**, from MeOH, amyl alcohol or H_2O, with $[\alpha]_D^{20}$ -197.9 (c 1.2, H_2O). [*Beilstein* **22** I 165, **22** II 416.]

5-Cyanoindole *[15861-24-2]* **$C_9H_6N_2$, M 142.2, m 106-108°, 107-108°, pK^{25} <0.** Dissolve the nitrile in 95% EtOH, boil it in the presence of charcoal, filter, evaporate to a small volume and add enough H_2O to cause crystallisation and cool. Recrystallise it directly from aqueous EtOH and dry it in a vacuum. Its UV has λ_{max} at 276 nm (log ε 3.6) in MeOH. [Lindwall & Mantell *J Org Chem* **18** 345 *1953*, DOI: 10.1021/jo01132a001; Singer & Shive *J Org Chem* 1458 *1955*, DOI: 10.1021/jo01127a027; Thesing at al. *Chem Ber* **95** 2205 *1962*, DOI: 10.1002/cber.19620950917; NMR: Lallemend & Bernath *Bull Soc Chim Fr* 4091 *1970*, *Beilstein* **22/3** V 45.]

2-Cyanopyridine *[100-70-9]* **$C_6H_4N_2$, M 104.1, m 24-27°, 27°, 29°, b 212-215°/atm, pK^{25} 0.26.** Purify the 2-nitrile by distillation followed by recrystallisation to constant melting point from cyclohexane, or *o*-xylene/hexane. The UV has λ_{max}, ε_{max} (solvent): $\pi\rightarrow\pi$ bands at 265nm, 2730; $n\rightarrow\pi$ infl at *278nm*, *340* (cyclohexane). [Mason *J Chem Soc* 1247 *1959*, DOI: 10.1039/JR9590001247, *Beilstein* **22/2** V 19.]
3-Cyanopyridine *[100-54-9]* has **m 48-52°, 50°, b 201°/atm, pK^{25} 1.26.** Purify the 3-nitrile by distillation followed by recrystallisation to constant melting point from cyclohexane or *o*-xylene/hexane. The UV has λ_{max}, ε_{max} (solvent): $\pi\rightarrow\pi$ bands at 265nm, 2230; $n\rightarrow\pi$ infl at *279nm*, *430* (cyclohexane). [Mason *J Chem Soc* 1247 *1959*, DOI: 10.1039/JR9590001247, *Beilstein* **22/2** V 115.]
4-Cyanopyridine *[100-48-1]* has **m 76-79°, 79°, 80°, b 194-196°/atm, pK^{25} 1.90.** Purify the 4-nitrile by distillation followed by recrystallisation to constant melting point from cyclohexane or dichloromethane/diethyl ether mixture. The UV has λ_{max}, ε_{max} (solvent): $\pi\rightarrow\pi$ bands at 271nm, 2840; $n\rightarrow\pi$ infl at *290nm*, *500* (cyclohexane). [Mason *J Chem Soc* 1247 *1959*, DOI: 10.1039/JR9590001247, *Beilstein* **22/2** V 214.]

Cyanuric acid (2,4,6-trihydroxy-1,3,5-triazine) *[108-80-5]* **$C_3H_3N_3O_3$, M 129.1, m >300°, pK^{25} 6.78.** It crystallises from water. Dry it at room temperature in a desiccator in a vacuum. [*Beilstein* **26** III/IV 632] It is a disinfectant.
Cyanuric chloride **(TCT, 2,4,6-trichloro-1,3,5-triazine)** *[108-77-0]* **$C_3Cl_3N_3$, M 184.4,** has **m 146-149°, 154°, b 190°.** TCT crystallises from CCl_4 or petroleum ether (b 90-100°) and is dried under vacuum. It has also been recrystallised twice from anhydrous *benzene immediately before use [Abuchowski et al. *J Biol Chem* **252** 3582 *1977*, http://www.jbc.org/content/254/11/4856]. [*Beilstein* **26** III/IV 66.]

Cyclohexene oxide (7-oxabicyclo[4.1.0]heptane) *[286-20-4]* **$C_6H_{10}O$, M 98.1, b 131-133°/atm, d_4^{20} 0.971, n_D^{20} 1.452.** Fractionate the oxide through an efficient column. The main impurity is probably H_2O. Dry the oxide over $MgSO_4$, filter it, and redistil it several times (**b 129-134°/760mm**). The residue can be hard to remove from the distilling flask. To avoid this difficulty, add a small amount of a mixture of ground NaCl

and Celite (1:1) to help break up the residue particularly if hot H_2O is added. [Osterberg *Org Synth* Coll Vol **I** 185 *1948*, DOI: 10.15227/orgsyn.005.0035; *Beilstein* **17** H 21, **17/1** V 203.]

Cyclohexene sulfide [7-thiabicyclo[4.1.0]heptane] *[286-28-2]* **$C_6H_{10}S$, M 114.2, b 55-58°/12mm, 67-68°/16mm, 69-71°/19mm, 71.5-73.5°/21mm, 73-74.5°/22mm, 80°/40mm, 83-87°/46mm, d_4^{20} 0.971, n_D^{20} 1.5292.** Prepared by reaction of cyclohexeneoxide with thiourea, KCNS or NH_2CNS in EtOH at 60° for 1 to 3hrs, poured into H_2O extracted with $CHCl_3$, then evaporated and the residual oil distilled (short Vigreux column) to give 41 to 73% yields of the sulfide. It can be stored at 5° in a closed container for at least 1 month without apparent decomposition. Its UV (iso-octane) has λ_{max} 262.5nm (ε_{max} 39.6 L.mole^{-1}.cm^{-1}) and λ_{min} 237nm (ε_{min} 19.7 L.mole^{-1}.cm^{-1}). [Synth: Van Tamelen *Org Synth* Coll Vol **4** 232 *1963*; DOI: 10.15227/orgsyn.032.0039; Synth and reactions: Culvenor et al. *J Chem Soc* 1050 *1946*, DOI: 10.1039/JR9460001050; UV: Davis *J Org Chem* **23** 216 *1958*, DOI: 10.1021/jo01096a017; synth and reactions: van Tamelen *J Am Chem Soc* **73** 3444 *1951*, DOI: 10.1021/ja01151a132; *Beilstein* **17** III 166, **17/1** V 204.]

Cycloheximide (actidione) *[68-81-9]* **$C_{15}H_{23}NO_4$, M 281.4, m 119.5-121°, $[\alpha]_{546}^{20}$ +9.5 (c 2, H_2O), pK 11.2.** Crystallise it from water/MeOH (4:1), amyl acetate, isopropyl acetate/isopropyl ether or water. The ***acetate*** has **m 150-152°** (from aqueous EtOH), the ***p-nitrobenzoate*** has **m 215-220°(dec)** (from aqueous dioxane) and the ***oxime*** has **m 203-204°** (from MeOH). [Kornfeld et al. *J Am Chem Soc* **71** 150 *1949*, DOI: 10.1021/ja01169a041; *Beilstein* **21** IV 6632, **21/13** V 434.]

1-Cyclohexyl-5-methyl-1*H*-tetrazole *[7707-57-5]* **M 166.2, m 124-124.5°.** Crystallise it from absolute EtOH or H_2O (heavy needles), then sublime it at 115°/3mm. [Harvill et al. *J Org Chem* **15** 662, 668 *1950*, DOI: 10.1021/jo01149a035; Billuber Inc USP 2507337 *1946*, *Beilstein* **26** III/IV 1661.]

cis*-Cyclooctene oxide {(1r, 8c)-9-oxabicyclo[6.1.0]nonane}** *[286-62-4]* **$C_8H_{14}O$, M 126.2, m 53-57°, 56-57°, 57.5-57.8°, 50-60°, b 55°/5mm, 85-88°/17mm, 82.5°/22mm, 90-93°/37mm, 189-190°/atm.** It can be distilled in a vacuum, and the solidified distillate can be sublimed in a vacuum below 50°. It has a characteristic odour. [IR: Cope et al. *J Am Chem Soc* **74** 5884 *1952*, DOI: 10.1021/ja01143a018; cf. ***trans-isomer: Cope et al. *J Am Chem Soc* **79** 3905 *1957*, DOI: 10.1021/ja01571a075; Reppe et al. *Justus Liebigs Ann Chem* **560** 1 *1948*, DOI: 10.1002/jlac.19485600102; *Beilstein* **17** V/I 234.]

Cyclotrimethylenetrinitramine (RDX, Cyclonite, 1,3,5-trinitrohexahydro-1,3,5-triazine) *[121-82-4]* **$C_3H_6N_6O_6$, M 222.2, m 203.8°(dec), 205-206°(dec).** RDX crystallises from acetone (solubility at ~20° is ~4w/v%), but is less soluble in MeOH. [Bachmann & Sheehan *J Am Chem Soc* **71** 1842 *1949*, DOI: 10.1021/ja01173a092; *Beilstein* **26** II 5, **26** III/IV 22.] **EXPLOSIVE.**

Cytisine (7*R*,9*S*-7,9,10,11,12,13-hexahydro-7,9-methano-12*H*-pyrido[1,2-*a*][1,5]diazocin-8-one, Laburnine, Ulexine) *[485-35-8]* **$C_{11}H_{14}N_2O$, M 190.3, m 152-153°, 155°, b 218°/2mm, $[\alpha]_D^{17}$ -120 (H_2O), $[\alpha]_D^{25}$ -115 (c 1, H_2O), pK_1^{15} 1.20, pK_2^{15} 8.12 [also stated are pK_1 6.11, pK_2 13.08].** Crystallise cytisine from acetone and sublime it in a vacuum. Its solubilities are: 77% (H_2O), 7.7% (Me_2CO), 28.6% (EtOH), 3.3% (*C_6H_6), 50% ($CHCl_3$) but it is insoluble in petroleum ether. The ***tartrate*** has **m 206-207°** $[\alpha]_D^{24}$ +45.9, the ***N-tosylate*** has **m 206-207°**, and the ***N-acetate*** has **m 208°**. cis-Decahydroisoquinoline *[2744-08-3]* $C_9H_{17}N$, M 139.2, b 97-98°/15mm, 208-209°/730mm, pK^{20} 11.32.

The free base is treated with saturated aqueous picric acid, allowed to stand for 12 hours, filtered, washed with MeOH to remove the more soluble ***trans*** **isomer** and recrystallised from MeOH to give pure **cis-*picrate* m 149-150°**. The picrate (~5g) is shaken with 5M aqueous NaOH (50ml) and Et_2O (150ml) while H_2O is added to the aqueous phase to dissolve insoluble Na picrate. The Et_2O extract is dried over solid NaOH and then shaken with Al_2O_3 (Merck for chromatography) until the yellow color of traces of picric acid disappears (this color cannot be removed by repeated shaking with 5-10 M aqueous NaOH). The extract is

concentrated to 50ml and dry HCl is bubbled through until separation of the white crystals of the **cis-*HCl*** is complete. These are washed with Et_2O, dried at 100° and recrystallised from EtOH/EtOAc to yield pure ***cis-hydrochloride*** **m 182-183°** (dried in a vacuum desiccator over KOH) with IR (KBr) ν_{max} 2920, 2820, 1582, 1470, 1445, 1410, 1395, 1313, 1135, 1080, 990, 870 cm^{-1}. The pure ***free base*** is prepared by dissolving the ***hydrochloride*** in 10 M aqueous NaOH, extracted with Et_2O, dried over solid KOH, filtered and distilled in a vacuum. It has IR (film) ν_{max} 2920, 2820, 2720, 2560, 1584, 1470, 1445, 1415, 1395, 1315, 1300, 1135, 1080, 1020, 990, 873 cm^{-1}. The ^{1}HNMR in $CDCl_3$ is characteristically different from that of the ***trans*-isomer**. [Armarego *J Chem Soc (C)* 377 *1967*, DOI: 10.1039/J39670000377; Gray & Heitmeier *J Am Chem Soc* **80** 6274 *1958* DOI: 10.1021/ja01556a028; Witkop *J Am Chem Soc* **70** 2617 *1948*, DOI: 10.1021/ja01188a001; Skita *Chem Ber* **57** 1977 *1924*, DOI: 10.1002/cber.19240571103; Helfer *Helv Chim Acta* **6** 785 *1923*, DOI: 10.1002/hlca.19230060186; *Beilstein* **20** II 73, **20** III/IV 2026.]

trans*-Decahydroisoquinoline** *[2744-09-4]* **$C_9H_{17}N$, M 139.2, b 106°/15mm, pK^{20} 11.32.** This is purified as the ***cis*-isomer** above. The **trans-*picrate has **m 175-176°**, and the **trans-*hydrochloride*** has **m 221-222°** and has IR (KBr) has ν_{max} at 2930, 3800, 1589, 1450, 1400, 1070, 952, 837 cm^{-1}. The pure ***free base*** is prepared as above and had IR (film) with ν_{max} at 2920, 2820, 2720, 2560, 1584, 1470, 1445, 1415, 1395, 1315, 1300, 1135, 1080, 1020, 990, 873 cm^{-1}. The ^{1}HNMR in $CDCl_3$ is characteristically different from that of the ***cis*-isomer**. (references as above and Helfer *Helv Chim Acta* **9** 814 *1926*, DOI: 10.1002/hlca.192600901110). [*Beilstein* **20** II 73, **20** III/IV 2026.]

cis*-Decahydroquinoline** *[10343-99-4]* **$C_9H_{17}N$, M 139.2, b 207-208°/708mm, pK^{20} 11.29.** It is available as a ***cis-trans*-mixture** (**b** 70-73°/10mm, Aldrich, ~ 18% *cis*-isomer *[2051-28-7]*), but the isomers can be separated by fractionating in a spinning band column (1~1.5 metre, type E) at atmospheric pressure and collecting 2ml fractions with a distillation rate of 1 drop in 8-10 seconds. The lower boiling fraction solidifies and contains the ***trans*-isomer** (see below, **m 48°**). The higher boiling fraction **b** 207-208°/708mm remains liquid and is mostly pure ***cis*-isomer**. This is reacted with PhCOCl and M aqueous NaOH to yield the ***N-benzoyl derivative **m 96°** after recrystallisation from petroleum ether (b 80-100°). It is hydrolysed with 20% aqueous HCl by refluxing overnight. $PhCO_2H$ is filtered off, the filtrate is basified with 5M aqueous NaOH and extracted with Et_2O. The dried extract (Na_2SO_4) is saturated with dry HCl gas, and the ***cis-decahydroquinoline hydrochloride*** which separates has **m 222-224°** after washing with Et_2O and drying at 100°; and has IR (KBr) with ν_{max} at 2900, 2780, 2560, 1580, 1445, 1432, 1403, 1165, 1080, 1036, 990, 867 cm^{-1}. The ***free base*** is obtained by dissolving the ***hydrochloride*** salt in 5M aqueous NaOH, extracting with Et_2O and drying the extract (Na_2SO_4), evaporating and distilling the residue; it has IR (film) with ν_{max} at 2900, 2840, 2770, 1445, 1357, 1330, 1305, 1140, 1125, 1109, 1068, 844 cm^{-1}. The ^{1}H NMR in $CDCl_3$ is characteristically different from that of the ***trans*-isomer**. [Armarego *J Chem Soc (C)* 377 *1967*, DOI: 10.1039/J39670000377; Hückel & Stepf *Justus Liebigs Ann Chem* **453** 163 *1927*, DOI: 10.1002/jlac.19274530111; Bailey & McElvain *J Am Chem Soc* **52** 4013 *1930*, DOI: 10.1021/ja01373a037; *Beilstein* **20** H 157, **20** I 35, **20** II 72-73, **20** III/IV 2017.]

trans-Decahydroquinoline *[767-92-0]* has **m 48°**, **b 205-206°/708mm, pK^{20} 11.29.** The lower boiling fraction from the preceding spinning band column fractionation of the commercial *cis-trans-* mixture (~ 20:60; see the *cis*-isomer above) solidifies readily (**m** 48°), and the receiver has to be kept hot with warm water. It is further purified by conversion to the ***hydrochloride*** **m 285-286°** after recrystallisation from EtOH/AcOEt. This has IR (KBr) with ν_{max} at 2920, 2760, 2578, 2520, 1580, 1455, 1070, 1050, 975, 950, 833 cm^{-1}. The ***free base*** is prepared as for the ***cis*-isomer** above and distilled; and has IR (film, at ca 50°) with ν_{max} at 2905, 2840, 2780, 1447, 1335, 1305, 1240, 1177, 1125, 987, 900, 835 cm^{-1}. The ^{1}HNMR in $CDCl_3$ is characteristically different from that of the ***cis*-isomer**. [Armarego *J Chem Soc (C)* 377 *1967*, DOI: 10.1039/J39670000377; Hückel & Stepf *Justus Liebigs Ann Chem* **453** 163 *1927*, DOI: 10.1002/jlac.19274530111; Bailey & McElvain *J Am Chem Soc* **52** 4013 *1930*, DOI: 10.1021/ja01373a037; Prelog & Szpilfogel *Helv Chim Acta* **28** 1684 *1945*, DOI: 10.1002/hlca.6602801233; *Beilstein* **20** H 157, **20** I 35, **20** II 72-73, **20** III/IV 2017.]

Delphinine *[561-07-9]* **$C_{33}H_{45}NO_9$, M 559.7, m 197-199°, $[\alpha]_D^{20}$ +26 (c 1, EtOH).** It crystallises from EtOH with 198-200° uncorrected (187.5-188.5°) and from Et_2O or Me_2CO. Its solubility at ~25° in EtOH, $CHCl_3$ and Et_2O is 4%, 5% and 10% respectively. In c 1, EtOH, it has $[\alpha]_D^{20}$ +22 changing to +19 in 4 hours. [Markwood *J Am Pharm Assoc* **16** 928 *1927*.] The ***hydrochloride*** has **m 214°(dec)** from MeOH or MeOH/Et_2O. [Weisner et al. *Can J Chem* **50** 1925 *1972*, DOI: 10.1139/v72-308; Jacobs & Craig *J Biol Chem* **127** 361 *1939*, http://www.jbc.org/content/127/2/361; *Beilstein* **21** III/IV 2867.]

3,6-Diaminoacridine hydrochloride *[952-23-8]* **$C_{13}H_{11}N_3$.HCl, M 245.7, m 270°(dec), ε_{456} 4.3 x 10^4, pK_1^{20} 1.5, pK_2^{20} 9.60 (9.65 free base).** It is first purified by precipitation of the ***free base*** by adding aqueous NH_3 solution to an aqueous solution of the hydrochloride or hydrogen sulfate (see below), drying the precipitate and subliming at 0.01mm Hg [Müller & Crothers *Eur J Biochem,* **54** 267 *1975*]. The ***free base*** in EtOH is treated with ethanolic HCl, and Et_2O is added to crystallise out the hydrochloride which is filtered off washed with Et_2O and dried *in vacuo* over solid KOH. [*Beilstein* **22** H 487.]
3,6-Diaminoacridine sulfate **(proflavin sulfate)** *[1811-28-5]* **$C_{13}H_{11}N_3.0.5H_2SO_4.xH_2O$, M 516.6,** has **m >300°(dec), λ_{max} 456nm.** An aqueous solution, after treatment with charcoal, is concentrated, chilled overnight, filtered and the precipitate is rinsed with a little diethyl ether. The precipitate is dried in air, then overnight in a vacuum oven at 70°. [*Beilstein* **22** I 650, **22/11** V 323.]

4,5-Diamino-2,6-dihydroxypyrimidine (diamino uracil) sulfate *[32014-70-3]* **$C_4H_6N_4O_2.\ xH_2SO_4.yH_2O$, M 382.3, m >260°(dec), >300°(dec), pK_1^{20} 1.7, pK_2^{20} 3.20, pK_3^{25} 4.56.** The salt is quite insoluble in H_2O but can be converted to the ***free base*** which is recrystallised from H_2O and converted to the sulfate by addition of the required amount of H_2SO_4. The ***hydrochloride*** has **m 300-305°(dec)** and can be used to prepare the sulfate by addition of H_2SO_4; it is more soluble than the sulfate. The ***perchlorate*** has **m 252-254°**. The ***free base*** has λ_{max} at 260nm (log ε 4.24) in 0.1M HCl. [Bogert & Davidson *J Am Chem Soc* **55** 1667 *1933*, DOI: 10.1021/ja01331a059; Bredereck et al. *Chem Ber* **86** 850 *1953*, DOI: 10.1002/cber.19240571103; Sherman & Taylor *Org Synth* Coll Vol **4** 247 *1963*, DOI: 10.15227/orgsyn.037.0015; Barlin & Pfleiderer *J Chem Soc (B)* 1425 *1971*, DOI: 10.1039/J29710001425; *Beilstein* **25** II 382.]

5,6-Diamino-1,3-dimethyluracil hydrate (5,6-diamino-1,3-dimethyl-2-pyrimidine-2,4-dione hydrate) *[5440-00-6]* **$C_6H_{10}N_4O_2.\ xH_2O$, M 188.2, m 205-208°(dec), 209°(dec), 210°dec, pK_1 1.7, pK_2 4.6.** It recrystallises from EtOH. The ***hydrochloride*** has **m 310°** (from MeOH), and the ***perchlorate*** has **m 246-248°**. [UV: Bredereck et al. *Chem Ber* **92** 583 *1959*, DOI: 10.1002/cber.19590920310; Taylor et al. *J Am Chem Soc* **77** 2243 *1955*, DOI: 10.1021/ja01613a066; *Beilstein* **25** III/IV 4133.]

6,9-Diamino-2-ethoxyacridine (Ethacridine) *[442-16-0]* **$C_{15}H_{15}N_3O$, M 257.3, m 226°, pK^{20} 11.6.** It crystallises from 50% EtOH or EtOH (yellow-orange crystals). It also crystallises as a ***monohydrate*** **m 116-118°**. It has a pK^{20} of 11.04 in 50% aqueous EtOH. The ***methiodide*** is soluble in H_2O and has **m 332-334°** (dec) (from aqueous Me_2CO). It is an antiseptic and abortive agent. [Albert & Gledhill *J Soc Chem Ind* **61** 159 *1942*, Foye et al. *J Pharm Sci* **57** 1793 *1968*, DOI: 10.1002/jps.2600571040; Albert & Goldacre *J Chem Soc* 706 *1946*, DOI: 10.1039/JR9460000706; *Beilstein* **22** II 458, **22** III/IV 6679, **22/12** V 243.]
6,9-Diamino-2-ethoxyacridine dl-lactate moohydrate **(Rivanol, Acrinol)** *[6402-23-9]* **$C_{15}H_{15}N_3O.\ C_3H_6O_3.H_2O$, M 361.4,** has **m 235° (dark at ~200°), pK^{20} 11.6.** It forms yellow crystals from 90% EtOH/Et_2O. Its solubility in H_2O is ~15% at 25° and ~9% at 100°, and its solutions have a yellow fluorescence which is stable on boiling. It is an antiseptic and abortive agent. See ethacridine above, *Beilstein* **22** II 458, **22** III/IV 6680, **22/12** V 243.]

2,4-Diamino-6-hydroxypyrimidine *[56-06-4]* **$C_4H_6N_4O$. M 126.1, m 260-270°(dec), 285-286°(dec), pK_1^{25} 1.34, pK_2^{25} 3.27, pK_3^{25} 10.83.** It recrystallises from H_2O. [*Beilstein* **25** III/IV 3642.]
4,5-Diamino-6-hydroxypyrimidine hemisulfate *[102783-18-6]* **$C_4H_6N_4O.\ 0.5H_2SO_4$, M 350.3,** has **m 268°(dec), 270°(dec), pK_1^{25} 1.34, pK_2^{25} 3.57, pK_3^{25} 9.86**. It crystallises from H_2O. The ***free base***, obtained by basifying the salt with aqueous ammonia, also crystallises from H_2O (**m 239°**). [Mason *J Chem Soc* 2071 *1954*, DOI: 10.1039/JR9540002071; Elion et al. *J Am Chem Soc* **74** 411 *1952*, DOI: 10.1021/ja01122a037; *Beilstein* **25** III/IV 3645.]

2,4-Diamino-5-phenylthiazole (DAPT, Amiphenazole) *[490-55-1]* **$C_9H_9N_3S$, M 191.3, m 163-164°(dec).** The thiazole crystallises from aqueous EtOH or water. Store it in the dark under N_2. It is a barbiturate and narcotic antagonist. The ***hydrochloride*** has **m 273-274°(dec)** (from MeOH/EtOAc), and the ***picrate*** has **m 189-191°(dec)** (from H_2O). [Davies et al. *J Chem Soc* 3491 *1950*, DOI: 10.1039/JR9500003491; Dodson & Turner *J Am Chem Soc* **73** 4517 *1951*, DOI: 10.1021/ja01154a005; *Beilstein* **27** III/IV 5139.]

2,3-Diaminopyridine *[452-58-4]* **$C_5H_7N_3$, M 109.1, m 110-115°, 116°, pK_1^{25} -0.50, pK_2^{25} 6.92.** It crystallises from *benzene and sublimes *in vacuo*. It is a ligand for organometallic complexing. [cf. Fidalgo et

al. *J Organomet Chem* **447** 299 *1993*, DOI: 10.1016/0022-328X(93)80253-8; *Beilstein* **22/11** V 241.]
2,6-Diaminopyridine *[141-86-6]* has **m 117-122°, 121.5°, b 285°/atm, $pK_{Est(1)}$ <-6.0, $pK_{Est(2)}$ ~7.3.** It crystallises from *benzene and sublimes *in vacuo*. [*Beilstein* **22** III/IV 255.]
3,4-Diaminopyridine *[54-96-6]* has **m 216-218°, 218-219°, 220°, pK_1^{20} 0.49, pK_2^{20} 9.14.** It crystallises from *benzene and is stored under N_2 because it is ***deliquescent*** and absorbs CO_2. [*Beilstein* **22/11** V 266.]

3,5-Diamino-1,2,4-triazole (Guanazole) *[1455-77-2]* **$C_2H_5N_5$, M 99.1, m 202-205°, 206°, pK_1^{20} 4.43, pK_2^{20} 12.12.** The triazole crystallises from water or EtOH. It is a DNA synthesis inhibitor. [*Beilstein* **26** III/IV 1161.]

1,3-Diazaazulene (cycloheptimidazole) *[275-94-5]* **$C_8H_{12}N_2$, M 136.2, m 110-112°, 120°.** It is recrystallised repeatedly from de-aerated cyclohexane in the dark or from petroleum ether/*C_6H_6 and forms yellow needles. It is soluble in H_2O, EtOH and *C_6H_6, and forms a ***monohydrate*** which loses H_2O at 60°. The ***picrate*** has **m 207°(dec)**. [Nozoe et al. *J Am Chem Soc* **76** 3352 *1954*, DOI: 10.1021/ja01641a086; Nukai et al. *Bull Chem Soc Jpn* **40** 1967 *1967*, *Beilstein* **23** III/IV 1216.]

1,5-Diazabicyclo[4.3.0]non-5-ene (DBN, 2,3,4,,6,7,8-hexahydropyrrolo[1,2-*a*]-pyrimidine) *[3001-72-7]* **$C_7H_{12}N_2$, M 124.2, b 95-98°/7.5mm, 96-98°/11mm, 100-102°/12mm, 118-121°/32mm, d_4^{20} 1.040, n_D^{20} 1.520, pK^{25} >13.0.** Distil this ***strong base*** from BaO. It forms a ***hydroiodide*** on addition of 47% HI; dry it and dissolve it in MeCN, evaporate and repeat; recrystallise from EtOH, dry at 25°/1mm for 5 hours, then at 80°/0.03mm for 12 hours and store and dispense it in a dry box, **m 154-156°** [Jaeger et al. *J Am Chem Soc* **101** 717 *1979*, DOI: 10.1021/ja00497a039]. The ***methiodide*** is recrystallised from $CHCl_3/Et_2O$, **m 248-250°**, and the ***hydrogen fumarate*** has **m 159-160°** and is crystallised from *iso*-PrOH [Rokach et al. *J Med Chem* **22** 237 *1979*, DOI: 10.1021/jm00189a004; Oediger et al. *Chem Ber* **99** 2012 *1966*, DOI: 10.1002/cber.19660990633; Reppe et al. *Justus Liebigs Ann Chem* **596** 158 *1955*, DOI: 10.1002/jlac.19555960109]. [*Beilstein* **23/5** V 239.]

1,4-Diazabicyclo[2.2.2]octane (DABCO, triethylenediamine, TED) *[280-57-9]* **$C_6H_{12}N_2$, M 112.2, m 156-157° (sealed tube), pK_1^{25} 2.97, pK_2^{25} 8.82** DABCO crystallises from 95% EtOH, petroleum ether or MeOH/diethyl ether (1:1). Dry it under vacuum over $CaCl_2$ and BaO. It can be sublimed *in vacuo*, and readily at room temperature. It has also been purified by removal of water during azeotropic distillation of a *benzene solution. It is then recrystallised twice from anhydrous diethyl ether under argon, and stored under argon [Blackstock et al. *J Org Chem* **52** 1451 *1987*, DOI: 10.1021/jo00384a013]. [*Beilstein* **23/3** V 487.]

1,8-Diazabicyclo[5.4.0]undec-7-ene (DBU, 2,3,4,6,7,8,9,10-octahydropyrimidino[1,2-*a*]-azepine) *[6674-22-2]* **$C_9H_{16}N_2$, M 152.2, b 80-83°/06mm, 115°/11mm, d_4^{20} 1.023, n_D^{20} 1.522, pK_{Est} ~ >13.** Fractionally distil DBU under vacuum. Also purify it by chromatography on Kieselgel and eluting with $CHCl_3$/EtOH/25% aqueous NH_3 (15:5:2) and checking by IR and MS. [Oediger et al. *Chem Ber* **99** 2012 *1962*, DOI: 10.1002/cber.19660990633; *Angew Chem Int Ed* **6** 76 *1967*, DOI: 10.1002/anie.196700761; Guggisberg et al. *Helv Chim Acta* **61** 1050 *1978*, DOI: 10.1002/hlca.19780610315; *Beilstein* **23/5** V 271.] It is a very useful ***strong hindered base*** in organic syntheses [Bella et al. *Tetrahedron* **60** 4821 *2004*, DOI: 10.1016/j.tet.2004.04.007; Ghosh *Synlett* **3** *574 2004*, DOI: 10.1055/s-2004-815436].

1,8-Diazabiphenylene *[259-84-7]* **$C_{10}H_6N_2$, M 154.2, m 156-158.5°, pK_{Est} ~4.4.** Recrystallise it from cyclohexane, then sublime it in a vacuum. [Barton & Walker *Tetrahedron Lett* **16** 569 *1975*, DOI: 10.1016/S0040-4039(00)71923-X; Deroski et al *Can J Chem* **62** 2235 *1984*, DOI: 10.1139/v84-381.]
2,7-Diazabiphenylene *[31857-42-8]* **$C_{10}H_6N_2$,** has **m 192-192.5°, pK_{Est} ~4.5.** It forms yellow crystals from cyclohexane, and sublimes in a vacuum. [MacBride *JCS Chem Commun* 359 *1974*, DOI: 10.1039/C3974000359B; Kramer & Berry *J Am Chem Soc* **94** 8336 *1972*, DOI: 10.1021/ja00779a010.]

1,8-Diazafluoren-9-one (cyclopenta[1.2-*b*:4,3-*b*']dipyridin-9-one) *[54078-29-4]* **$C_{11}H_6N_2O$, M 182.2, m 205°, 229-231°, pK_{Est} ~ 2.6.** Recrystallise it from Me_2CO, and has λ_{ex} 470nm, λ_{em} 570nm. The ***oxime*** has **m 119-200°**. [Druey & Schmidt *Helv Chim Acta* **33** 1080 *1950*, DOI: 10.1002/hlca.19500330438; *Beilstein* **24** III/IV 622.]

5*H*-Dibenz[*b*,*f*]azepine (iminostilbene, 2,2-iminostilbene) *[256-96-2]* **$C_{14}H_{11}N$, M 193.2, m 196-199°, 204-206°, pK_{Est} ~12.3 (acidic NH).** The dibenzazepine has been synthesised in a variety of ways [Kricka &

Ledwith *Chem Rev* **74**101 *1974*, DOI: 10.1021/cr60287a006]. One in particular is from 2,2'diaminodihydrostibene (**m 86°** from Na/amyl alcohol reduction of the stilbene) by heating it and HCl at 265-275°/26-30hrs to give a dark brown product which is dissolved in warm EtOH, then treated with aqueous NaOH and steam distilled (6 hours). The distillate is filtered, and the solid is dissolved in Et_2O, washed with HCl (to remove aniline and starting amine), and then evaporated to give the colourless ***10,11-dihydro5H-dibenz[b,f]azepine (iminodibenzyl)*** *[494-19-9]* **$C_{14}H_{13}N$, M 195.3, m 110°** (from ligroin), **108°** (*C_6H_6), whose solubility (g/100ml at ~25°) is Et_2O (15.4), 96% EtOH (3.59) and petroleum ether (0.64) [the ***5-nitroso derivative*** has **m 108°** (Et_2O)] [Thiele & Häfliger *Justus Liebigs Ann Chem* **305** 96 *1899*, DOI: 10.1002/jlac.18993050108; cf. Jørgensen et al. *J Heterocycl Chem* **36** 57 *1999*, DOI: 10.1002/jhet.5570360110]. The ***5-acetyl-10,11-dihydrodibenz[b,f]azepine*** has **m 96-97°** (EtOH). Bromination of this acetyl-dihydro compound with N-bromosuccinimide in CCl_4 under UV light gave ***5-acetyl-10-bromo-10,11-dihydro dibenz[b,f]azepine*** with **m 118-119°** (EtOH)[UV has λ_{max} (MeOH) at 280nm (logε 3.20) and IR has 5.97μ (nujol, *tert*-amido gp), 6.24, 6.30, 6.33, 6.72 and 13.02μ (1,2-disubstit-phenyl)] which, when 31g are dissolved EtOH (68ml) and treated with 50% aqueous KOH (13g, exothermic reaction) followed by cooling (60°), allowing to stand for 1hr then diluting with H_2O (104ml), precipitated ***5-acetyldibenz[b,f]azepine*** (80% yield) with **m 121-122°** (after recrystallisation from Et_2O). Hydrolysis of this acetate (23.5g) with KOH (14g) in EtOH (70ml) by refluxing for 18 hours, and strong cooling precipitated yellow-orange needles, which were collected, washed with cold EtOH then H_2O until the filtrate pH was ~7, recrystallised first from EtOH then from 10 parts of Et_2O to give pure **5*H*-dibenz[*b,f*]azepine** (17.3g, 90% yield) with **m 204-206°** [Schindler & Plattner *Helv Chim Acta* **44** 753 *1961*, DOI: 10.1002/hlca.19610440319].

Dehydrogenation of ***10,11-dihydrodibenz[b,f]azepine*** to ***dibenz[b,f]azepine*** has also been achieved by (a) boiling in $PhNO_2$ for 8-10 hours, evaporate *in vacuo*, dissolve residue in *C_6H_6 and filter through Al_2O_3, and evaporate, (b) heating with stoichiometric amount of sulfur at 200°/2hrs the 230-240°/1hr, cool, dissolve in *C_6H_6 and filter through Al_2O_3, and evaporate, (c) treat a solution in *C_6H_6 with excess Pb(OAc) overnight, filter add *C_6H_6 and filter through Al_2O_3, and evaporate, and (d) reflux a toluene solution with chloranil (turns green) for 12hrs, filter off the dark solid and subject to chromatography [Teuber & Schmidtke *Chem Ber* **93** 1257 *1960*, DOI: 10.1002/cber.19600930602]. Dehydrogenation has also been achieved with sulfur as stated and also by boiling the dihydrodibenzepine (1.95g) in diethyl maleate (40ml) containing Pd (Mohr, 2g) under N_2 for 5hrs. The crystals that separated were treated with warm EtOH and the Pd was filtered off. After removal of EtOH and ester at 145-150° (bath temp)/0.001mm, the crude dibenzo-azepine, m192-194°, was obtained in 48-60% yield. ***5-Methyldibenz[b,f]azepine*** (**m 143-144.5°,** yellow needles from petroleum ether b 40-80°) was obtained by dehydrogenation of ***5-methyl-10,11-dihydrodibenz[b,f]azepine*** (**m 107-108°,** colourless needles from EtOH or MeOH) with S by the previous procedure, as well as by methylation of ***10,11-dihydrodibenz[b,f]azepine*** with dimethylsulfate/Na_2CO_3 at 100° (56% yield, **m 106-107°**), and with PhLi/Et_2O then MeI (63% yield, **m 107-108°**, colourless needles from MeOH) [Huisgen et al. *Chem Ber* **93** 392 *1960*, DOI: 10.1002/cber.19600930222].

10,11-Dihydrodibenz[b,f]azepine has UV with λ_{max} (EtOH) (nm, *logε*) at (206, *4.54*) and (287, *4.29*); the ^{1}H NMR (250MHz, $CDCl_3$, TMS) has δ at 3.06 (4H, s, H-10, H-11), 7.03 (2H, d, $J_{1,2}$ = 7.4Hz, H-1 and 9), 6.76 (2H, d, $J_{2,3}$ = 7.4Hz, H-2 and 8), 7.06 (2H, d, $J_{3,4}$ = 8.1Hz, H-3 an 7), 6.70 (2H, d, $J_{1,3}$ = 1.6Hz, H-4 and 6), and 5.94 (1H, br, N*H*); ***5-Me*** has δ at 3.00 (4H, s, H-10, H-11), 7.10-6.6 (8H, m, H-1,2,3,4,5,6,7,8) and 3.14 (1H, br, N*Me*); ^{13}C NMR (63MHz, $CDCl_3$, TMS) has δ at 130.51(C-1 and 9), 123.00 (C-2 and 8), 129.45 (C-3 and 7), 119.3 (C-4 and 6), 132.12 (C-10 and 11), 129.75 (C-9a and 11a) and 148.39 (C-4a abd 5a).

Dibenz[b,f]azepine has UV with λ_{max} (MeOH) (nm, *logε*) at (258, *4.62*), (292, *3.45*) and (355sh, *2.86*); (C_6H_{12}) (nm, *logε*) at (258, *4.65*), (293, *3.43*) and (365, *2.89*); ^{1}H NMR (250MHz, $CDCl_3$, TMS) has δ at 6.32 (2H, s, H-10, H-11), 6.85 (1H, d, $J_{1,2}$ = 7.3Hz, H-1 and 9), 6.81 (2H, d, $J_{2,3}$ = 6.6Hz, H-2 and 8), 7.02 (2H, d, $J_{3,4}$ = 7.7Hz, H-3 and 7), 6.47 (2H, d, $J_{1,3}$ = 2.3Hz, H-4 and 6), and 4.92 (1H, br, N*H*); ^{13}C NMR (63MHz, $CDCl_3$, TMS) has δ at 130.51(C-1 and 9), 123.00 (C-2 and 8), 129.45 (C-3 and 7), 119.3 (C-4 and 6), 132.12 (C-10 and 11), 129.75 (C-9a and 11a) and 148.39 (C-4a abd 5a). [for further NMR data see Hallberg et al. *J Heterocycl Chem* **21** 197 *1984*, DOI: 10.1002/jhet.5570210139.]

A series of ***5-(phenolic-anilino-3-propanoyl)-dibenz[b,f]azepines*** which may have possibilities as therapeutic antioxidants, were found to have antioxidant properties when evaluated using the following studies: DPPH (2,2-diphenyl-1-picrylhydrazine) free radical scavenging activity, inhibition of human LDL (low density lipoprotein) oxidation, reducing power assay and inhibition of lipid peroxidation in a β-carotene linoleate system, [Kumar & Naik *Eur Med Chem* **45** 2 *2010*, DOI: 10.1016/ j.ejmech.2009.09.016].

Dibenzo-18-crown-6 *[14187-32-7]* **$C_{20}H_{24}O_6$, M 360.4, m 162-164°, 163-164°.** Crystallise it from *benzene, *n*-heptane or toluene and dry it under vacuum at room temperature for several days. Useful phase-transfer catalyst and ion shield. [Szczygiel *J Phys Chem* **91** 1252 *1987*, DOI: 10.1021/j100289a042; Vögtle ed. *Top Corr Chem* (Host Guest Complex Chemistry) **98** *1981*, DOI: 10.1007/BFb0111244.]
Dibenzo-24-crown-8 *[14174-09-5]* **$C_{24}H_{32}O_8$, M 448.5,** has **m 103-105°, 103-106°.** Recrystallise it from EtOH, and dry in a vacuum at 60° over P_2O_5 for 16 hours. Useful phase-transfer catalyst and ion shield. [Delville et al. *J Am Chem Soc* **109** 7293 *1987*, DOI: 10.1021/ja00258a008; Vögtle ed. *Top Corr Chem* (Host Guest Complex Chemistry) **98** *1981*, DOI: 10.1007/BFb0111244.]

Dibenzofuran (Dipheylene oxide) *[132-64-9]* **$C_{12}H_8O$, M 168.2, m 80-82°, 82.4°, b 154-155°/20mm.** Dissolve dibenzofuran in diethyl ether, then shake it with two portions of aqueous NaOH (2M), wash it with water, separate and dry ($MgSO_4$) it. After evaporating the ether, dibenzofuran is crystallised from aqueous 80% EtOH and then dried under vacuum. [Cass et al. *J Chem Soc* 1406 *1958*, DOI: 10.1039/JR9580001406.] High purity material is obtained by zone refining. [*Beilstein* **17** V 234.]

Dibenzothiophene (Dipheylene sulfide) *[132-65-0]* **$C_{12}H_8S$, M 184.3, m 97-100°, 99°, b 332-333°/atm.** Purify dibenzothiophene by chromatography on alumina with petroleum ether, in a darkened room. Recrystallise it from water or EtOH (white crystals). [*Beilstein* **17/2** V 239.]

1,3-Dibromo-5,5-dimethylhydantoin *[77-48-5]* **$C_5H_6Br_2N_2O_2$, M 285.9, m 190-192°(dec), 190-193°(dec), 197-199°(dec).** Recrystallise it from H_2O. Its solubility in CCl_4 is 0.003 mol/L at 25° and 0.024 mol/L at 76.5°. It is a brominating agent. [Fieser **1** 208, **2** 108; *Beilstein* **24** III/IV 1101.]

4',5'-Dibromofluorescein *[596-03-2]* **$C_{20}H_{10}Br_2O_5$, M 490.1, m 285°.** Crystallise this fluorescent dye from aqueous 30% EtOH (red plates). It dissolves in concentrated H_2SO_4 to give an orange solution which becomes yellow-brown on dilution and precipitates an orange solid (of the sulfonate?). [*Beilstein* **19/6** V 462.]

5,7-Dibromo-8-hydroxyquinoline (Broxyquinoline) *[521-74-4]* **$C_9H_5Br_2NO$, M 303.0, m 196°, pK_1^{25} 5.84, pK_2^{25} 9.56.** Crystallise it from acetone/EtOH. It can be sublimed. It complexes with Cu, Fe and Ti ions, is a disinfectant and an antiseptic. [*Beilstein* **21/3** V 290.]

2,6-Dibromopyridine *[626-05-1]* **$C_5H_3Br_2N$, M 236.9, m 117-119°, 118.5-119°, b 249°/757.5mm, pK_{Est} <0.** Purify 2,6-dibromopyridine by steam distillation, then recrystallise it twice from EtOH. It does not form an $HgCl_2$ salt. [den Hertog & Wibaut *Recl Trav Chim Pays-Bas* **51** 381 *1932*, DOI: 10.1002/recl.19320510412; *Beilstein* **20/5** V 435.]

3,4-Dibromothiophene *[3141-26-2]* **$C_4H_2Br_2S$, M 241.9, m 4-5°, b 94-95°/12mm, 212-213°/atm, 221-222°/atm, d_4^{25} 2.188, n_D^{20} 1.640.** Distil it in a vacuum, but if it is discoloured then dissolve it in Et_2O, wash it with 2M NaOH solution, separate the layers, filter, dry the Et_2O layer over $CaCl_2$, filter, evaporate, and distil the residual oil in a vacuum. Nitration with Ac_2O/HNO_3 at 60° yields ***3,4-dibromo-2-nitrothiophene*** **m 115-116°** (from EtOH). [Steinkopf et al. *Justus Liebigs Ann Chem* **512** 136 *1934*, DOI: 10.1002/jlac.19345120113; *Beilstein* **17** III/IV 248, **17/1** V 308.] It is a useful thiophene synthon [cf. He et al. *J Org Chem* **72** 442 *2007*, DOI: 10.1021/jo061853y].

2,6-Di-*tert*-butyl-4-methylpyridine *[38222-83-2]* **$C_{14}H_{23}N$, M 205.4, m 31-32°, 33-36°, b 148-153°/95mm, 223°/760mm, n_D^{20} 1.476, pK_{Est} ~5.7.** A possible impurity is 2,6-di-*tert*-butyl-4-neopentylpyridine. Attempts to remove coloured impurities directly by distillation, acid-base extraction or treatment with activated charcoal were unsuccessful. Pure material is obtained by dissolving 0.3mole of the alkylpyridine in pentane (150ml) and introducing it at the top of a cold water jacketed chromatographic column (40 x 4.5cm) (cooling is necessary because the base in pentane reacts exothermically with alumina) containing activated and acidic alumina (300g). The column is eluted with pentane using a 1L constant pressure funnel fitted at the top of the column to provide slight pressure. All the pyridine is obtained in the first two litres of eluent (the progress of elution is monitored by spotting a fluorescent TLC plate and examining under short wave UV light—a dark blue spot is evidence for the presence of the alkylpyridine). Elution is complete in 1 hour. Pentane is removed on a rotovap with 90-93% recovery yielding a liquid which solidifies on cooling, **m 31-32°**, and the ***free base*** can be distilled. The

H_2PtCl_6 salt has **m 213-314°(dec)**, and the ***CF_3SO_3H salt*** has **m 202.5-203.5°** (from CH_2Cl_2). [Anderson & Stang *Org Synth* Coll Vol **7** 144 *1981*, DOI: 10.15227/orgsyn.060.0034; *Beilstein* **20/6** V 190.]

2,6-Di-*tert*-butylpyridine *[585-48-8]* **$C_{13}H_{21}N$, M 191.3, b 100-101°/23mm, d_4^{25} 0.852, n_D^{20} 1.473, pK^{25} 5.02.** Redistil it from KOH pellets. Used for α-enolisation of aldehydes (in presence of ceric ammonium nitrate) [Jang et al. *J Am Chem Soc* **129** 7004 *2007*, DOI: 10.1021/ja0719428], and as a proton trap [cf. Gyor et al. *J Macromol Sci, Pure Appl Chem* **A29** 639 *1992*, DOI: 10.1080/10601329208052189]. [*Beilstein* **20** III/IV 2868.] § Polystyrene supported version is commercially available *[107054-29-5]* 200-400 mesh, crosslinked with 1% divinyllbenzene containing ~1.8mmol N/g polymer.

3,5-Dicarbethoxy-1,4-dihydro-2,4,6-collidine *[632-93-9]* **$C_{14}H_{21}NO_4$, M 267.3, m 130-132°, 131-132°.** Crystallise the ester from hot EtOH/water mixture. [*Beilstein* **22** H 147, **22** I 529, **22** II 100, **22** III/IV 1594.]

1*S*-(+)-(8,8-Dichlorocamphorsulfonyl)oxaziridine {(7*S*)-8,8-dichloro-10,10-dimethyl-5-thia-4-azatricyclo-[5.2.1.03,7]dec-3-ene-5,5-dioxide} *[127184-05-8]* **$C_{10}H_{13}Cl_2NO_3S$, M 298.2, m 178-180°, 181-186°, $[\alpha]_D^{20}$ +89.4 (c 1, $CHCl_3$).** This dichlorooxaziridine was prepared by Davis and Weismiller [*J Org Chem* **55** 3715 *1990*, DOI: 10.1021/jo00299a007; supporting data jo00299a007_si_001.pdf] from ***1S-(-)-Camphorsulfonylimine*** [see *60886-80-8* above] by treatment with ***sodium bis(trimethylsilyl)amide (NHMDS)*** at -78° in THF to form the azaenolate and then chlorinated with *N*-chlorosuccinimide (NCS, 2.5 equivalents) at -78° to form the ***1S-(+)-8,8-dichlorocamphorsulfonylimine*** (note inversion of rotation) which they purified by flash chromatography (silica gel, eluting with CH_2Cl_2/hexane 6:4) in 64% yield and had **m 174°, $[\alpha]_D^{20}$ +7.9 (c 1, $CHCl_3$)**, TLC R_F = 0.42 [silica gel plate (250μm thick), eluted with CH_2Cl_2 and developed with 10% molybdophosphoric acid in EtOH and heated for a few minutes in a 100° oven]; the ^1H NMR ($CDCl_3$) had δ at 1.19 (s, 3H, CH_3), 1.22 (s, 3H, CH_3), 1.85-2.45 (m, 4H), 2.80 (d, 1H, *J* = 3.6Hz), 3.28 (AB q, *J* = 13.5, 2H). Oxidation of the ***(+)-8,8-dichloroimine*** in CH_2Cl_2 was achieved by stirring vigorously with *m*-chloroperbenzoic acid (1.5equiv) in saturated K_2CO_3 for 18 hours to give ***(+)-(8,8-dichlorocamphorsulfonyl)oxaziridine*** in >90% yield after recrystallisation from EtOH which had **m 178-180°**, $[\alpha]_D^{20}$ +89.4 (c 1, $CHCl_3$), TLC R_F = 0.68 (same conditions as above) and the ^1H NMR ($CDCl_3$) had δ at 1.18 (s, 3H, CH_3), 1.49 (s, 3H, CH_3), 1.85-2.50 (m, 4H), 2.77 (d, 1H, *J* = 3.5Hz), 3.36 (AB q, *J* = 14.1, 2H).
1*R*-(-)-8,8-dichlorocamphorsulfonylimine was prepared from **1*R*-(+)-camphorsulfonylimine** by chlorination in the same manner (**NHMDS/NCS**), and oxidised to ***(-)-(8,8-dichlorocamphorsulfonyl)oxaziridine*** *[139628-16-3]* in similar yields, and their properties were similar to those of the enantiomers except for the optical rotations which were exactly of opposite sign.
1*S*-(+)-(8,8-Dimethoxycamphorsulfonyl)oxaziridine has **m 189°(dec)** after crystallisation from absolute EtOH, with **$[\alpha]_D^{20}$ +91.3 (c 3.39, $CHCl_3$)**; the IR (KBr) has ν_{max} at 1356 and 1165 cm^{-1}; the ^1H NMR ($CDCl_3$) δ at 3.35 (s, 3H), 3.28 (s, 3H), 3.20 (AB q, 2H *J* =12Hz), 2.30-1.75 (m, 5H), 1.32 (s, 3H), 1.05 (s, 3H); ^{13}C NMR ($CDCl_3$) δ at 102.7, 97.6, 54.6, 52.9, 50.8, 47.5, 45.2, 28.2, 21.7 and 20.6. It was prepared in three steps from **1*S*-(-)-*camphorsulfonylimine*** by oxidation with SeO_2/AcOH/reflux for 20 hours to **1*S*-(-)-3-oxocamphor-sulfonylimine** (72% yield), converted in 95% yield by boiling under reflux with $(MeO)_3CH/MeOH/H_2SO_4$(as catalyst)/Amberlist-15 ion-exchange resin (as catalyst) to **1*S*-(+)-8,8-dimethoxycamphorsulfonylimine** which has **m 186-187°** (after recrystallisation from absolute EtOH), **$[\alpha]_D^{20}$ +7.2 (c 3.6, $CHCl_3$)**; IR (KBr) with ν_{max} at 1620, 1340 and 1160 cm^{-1}; the ^1H NMR ($CDCl_3$) has δ at 3.46 (s, 3H), 3.38 (s, 3H), 3.09 (AB q, 2H *J* =12Hz), 2.38-1.80 (m, 5H), 1.10 (s, 3H), 1.00 (s, 3H); and the ^{13}C NMR ($CDCl_3$) has δ at 188.6, 102.9, 64.2, 52.0, 50.5, 48.8, 46.0, 29.2, 20.6, 20.5 and 20.4; followed by oxidation with *m*-chloroperbenzoic acid in CH_2Cl_2/saturated aqueous K_2CO_3 to the ***oxaziridine*** in 96% yield. [Davis et al. *J Org Chem* **56** 1143 *1991*, DOI: 10.1021/jo00003a042.]
1*R*-(-)-(8,8-Dimethoxycamphorsulfonyl)oxaziridine was prepared in similar yields from the respective enantiomeric intermediates and the products differed only in the signs of their optical rotations.
In very elegant work, Davis and coworkers have shown that the above three camphorsulfonyloxaziridines are highly stereospecific asymmetric enolate oxidants (**Davis oxidation**) to produce α-hydroxyketones from enolisable ketones in high to very high chemical yields and with high enantioselective hydroxylations of 90 to ≥95 %ee. The order of stereoselectivity increases with chiral *camphorsulfonyl)oxaziridine < 8,8-dichlorocamphor-sulfonyl)oxaziridine < 8,8-methoxycamphorsulfonyl)oxaziridine* **clearly the effects of going from 8,8-H,H to 8,8-Cl,Cl to 8,8-OMe,OMe**. They have used these stereospecific enolate hydroxylations successfully to prepare synthons for various anthracycline antibiotics among other compounds. [Davis &

Kumar *Tetrahedron Lett* **32** 7671 *1991*, DOI: 10.1016/0040-4039(91)80561-J; Davis & Chen *Tetrahedron Lett* **31** 6823 *1990*, DOI: 10.1016/S0040-4039(00)97181-8; Davis et al. *J Org Chem 56* 1143 *1991*, DOI: 10.1021/jo00003a042; Davis et al. *Tetrahedron Lett* **32** 867 *1991*, DOI: 10.1016/S0040-4039(00)92107-5.]

1,3-Dichloro-5,5'-dimethylhydantoin *[118-52-5]* **$C_5H_6Cl_2N_2O_2$, M 197.0, m 132-134°, 136°.** Purify it by dissolving in concentrated H_2SO_4 and diluting with ice H_2O, collect the solid, dry it in a vacuum and recrystallise it from $CHCl_3$. It sublimes at 100° in a vacuum. It exhibits time-dependent hydrolysis at pH 9. It is a chlorinating agent and a useful disinfectant. [Petterson & Grzeskowiak *J Org Chem* **24** 1414 *1959*, DOI: 10.1021/jo01092a006; *Beilstein* **24** III/IV 1100.]

4,5-Dichloro-3*H*-1,2-dithiol-3-one *[1192-52-5]* **M 187.1, m 52-56°, 61°, b 87°/0.5mm, 125°/11mm.** Dissolve it in CH_2Cl_2 (1g in 250ml), filter, wash it twice with H_2O, evaporate and distil the residue *in vacuo* and then recrystallise it from petroleum ether. Its IR has ν_{max} at 1650 cm^{-1}. [Boberg *Justus Liebigs Ann Chem* **679** 109 *1964*, DOI: 10.1002/jlac.19646790115; Boberg *Justus Liebigs Ann Chem* **693** 212 *1966*, DOI: 10.1002/jlac.19666930122; *Beilstein* **19/4** V 72.]

5,7-Dichloro-8-hydroxyquinoline *[773-76-2]* **$C_9H_5Cl_2NO$, M 214.1, m 178-180°, 180-181°, pK_1 1.89, pK_2 7.62.** Crystallise the dichloro-oxine from acetone/EtOH. It is a chelator that is useful in analytical chemistry, and is also used medicinally to clear sebaceous glands in the skin. [*Beilstein* **21** H 95.]

6,9-Dichloro-2-methoxyacridine (3,9-Dichloro-7-methoxyacridine) *[86-38-4]* **$C_{14}H_9Cl_2NO$, M 278.1, m 160-161°, 164°, 163-165°.** Crystallise it from *benzene or 1,2-dichloroethane (**m 162-163°**). [Hall & Turner *J Chem Soc* 694 *1945*, DOI: 10.1039/JR9450000694; *Beilstein* **21** III/IV 1553.]

5,7-Dichloro-2-methyl-8-hydroxyquinoline (5,7-dichloro-8-hydroxyquinaldine) *[72-80-0]* **M 228.1, m 114-115°, $pK_{Est(1)}$ ~2.0, $pK_{Est(2)}$ ~8.4.** Crystallise it from EtOH. [*Beilstein* **21** III/IV 1180, **21/3** V 346.]

4,6-Dichloro-5-nitropyrimidine *[4316-93-2]* **$C_4HCl_2N_3O_2$, M 194.0, m 100-103°, 101-102°, pK_{Est} <0**. If too impure, then dissolve it in Et_2O, wash it with H_2O, dry it over $MgSO_4$, evaporate it to dryness and recrystallise it from petroleum ether (b 85-105°) to give a light tan solid. It is soluble in *ca* 8 parts of MeOH [Boon et al. *J Chem Soc* 96 *1951*, DOI: 10.1039/JR9510000096; Montgomery et al. in *Synthetic Procedures in Nucleic Acid Chemistry* Zorbach & Tipson eds, Wiley & Sons, NY, p76 *1968*]. [*Beilstein* **23** III/IV 899.]

2,6-Dichloropurine *[5451-40-1]* **$C_5H_2Cl_2N_4$, M 189.0, m 180-181.5°, 181°, 185-195°(dec), 188-189°, pK_1^{20} 1.16 (aqueous H_2SO_4), pK_2^{20} 7.06.** It can be recrystallised from 150 parts of boiling H_2O and dried at 100° to constant weight. It is soluble in EtOAc. The ***$HgCl_2$ salt*** separates from EtOH solution. It has UV with λ_{max} at 275nm (ε 8.9K) at pH 1; and 280nm (ε 8.5K) at pH 11 [Elion & Hitchings *J Am Chem Soc* **78** 3508 *1956*, DOI: 10.1021/ja01595a065; Schaeffer & Thomas *J Am Chem Soc* **80** 3738 *1958*, DOI: 10.1021/ja01547a068; Beaman & Robins *J Appl Chem (London)* **12** 432 *1962*, Montgomery *J Am Chem Soc* **78** 1928 *1956*, DOI: 10.1021/ja01590a043]. [Lister *Purines Part II, Fused Pyrimidines* Brown Ed, Wiley-Interscience pp254-225 *1971*, ISBN 0-471-38205-1, *Beilstein* **26** III/IV 1747.] Substrate in Suzuki-Miyaura coupling with arylboronic acids [cf. *Synthesis* 3515 *2006*].

2,6-Dichloropyridine *[2402-78-0]* **$C_5H_3Cl_2N$, M 148.0, m 83-86°, 87-88°, pK^{25} -2.86 (aqueous H_2SO_4).** It crystallises from EtOH. [*Beilstein* **20/5** V 416.]
3,5-Dichloropyridine *[2457-47-8]* has **m 64-65°, 66-67°, b 178-178°/~760mm, pK^{25} 0.67.** Crystallise 3,5-dichloropyridine from EtOH, or distil it. [den Hertog et al. *Recl Trav Chim Pays-Bas* **69** 673 *1950*, DOI: 10.1002/recl.19500690604; *Beilstein* **20** H 231, **20** III/IV 2502, **20** V 417.]

2,6-Dichloropyridine-3-carboxylic acid (2,6-dichloronicotinic acid) *[38496-18-3]* **$C_6H_3Cl_2NO_2$, M 192.0, m 140-143°, 146-148°, 147°, $pK_{Est(1)}$ ~ -1.** Purify the acid by recrystallisation from H_2O or Et_2O/petroleum ether (colourless needles), and the IR(KBr) has ν_{max} at 1738 cm^{-1}, and λ_{max} (ε) at 228.5(4700) and 273.5(8300)nm. The ***acid chloride*** *[58584-83-1]* **M 210.4, b 72-74°/0.01mm, 117-118°/45mm, n_D^{20} 1.5944**, was obtained by treatment with $SOCl_2$/DMF/*C_6H_6 and converted into the ***amide*** *[70445-62-4]* **M 191.0, m 148-148.5°**, or the ***hydrazide*** **m 171-173°** which crystallised from a large volume of MeCN. [Mutterer & Weis

Helv Chim Acta **59** 222 *1976*, DOI: 10.1002/hlca.19760590124; Newkome et al. *J Org Chem* **44** 2693 *1979*, DOI: 10.1021/jo01329a020; *Beilstein* **22** H 44.] A pharmaceutical research building block acid of 90% grade is also available commercially.
2,6-Dichloropyridine-4-carboxylic acid **(2,6-dichloroisonicotinic acid)** *[5398-44-7]* has **m 210°, 209-212°, $pK_{Est(1)}$ ~ -1.** Purify the acid by crystallisation from H_2O, and it forms needles or platelets from EtOH. The ***methyl ester*** crystallises from aqueous MeOH with **m 82°**, the ***ethyl ester*** from aqueous EtOH has **m 66°**, and the ***amide*** from H_2O has **m 207-208°**. [Meyer et al. *Monatsh Chem* **36** 731 *1915*, DOI: 10.1007/BF01519430; Levelt & Wibaut *Recl Trav Chim Pays-Bas* **48** 466 *1929*, DOI: 10.1002/recl.19290480506.]
5,6-Dichloropyridine-3-carboxylic acid **(5,6-dichloronicotinic acid)** *[41667-95-2]* has **m 160-161°, 164-168°, 168°, $pK_{Est(1)}$ ~ 0.5.** Recrystallisation of the acid from H_2O provides the ***monohydrate*** which becomes ***anhydrous*** (**m 161-162°**) on heating at 100°. The ***acid chloride*** distils at **125°/~24mm**, solidifies on cooling, and crystallises from petroleum ether with **m 48-49°**. The ***methyl ester*** has **m 67-68°** (from aqueous MeOH), and the ***amide*** forms colourless plates from aqueous EtOH with **m 218-220°**. [Räth et al. *Justus Liebigs Ann Chem* **487** 127 *1931*, DOI: 10.1002/jlac.19314870109; Meyer & Graf *Chem Ber* **61** 2202 *1928*, DOI: 10.1002/cber.19280610925; *Beilstein* **22** H 44, **22** II 36, **22** III/IV 511, **22/2** V 80.]

4,7-Dichloroquinoline *[86-98-6]* **M 198.1, $C_9H_5Cl_2N$, m 81-83°, 86.4-87.4°, b 148°/10mm, pK^{25} 2.80.** Crystallise the dichloroquinoline from MeOH or 95% EtOH. [*Beilstein* **20/7** V 316.]
2,3-Dichloroquinoxaline *[2213-63-0]* **$C_8H_4Cl_2N_2$, M 199.0, m 152-153°, 152-154°, pK_{Est} <0.** Recrystallise it from $*C_6H_6$ and dry it in a vacuum [Cheeseman *J Chem Soc* 1804 *1955*, DOI: 10.1039/JR9550001804; *Beilstein* **23/7** V 144].

***cis*-Dicyclohexyl-18-crown-6** *[16069-36-6]* **M 372.5, m 47-50°.** Purify it by chromatography on neutral alumina and elute with an ether/hexane mixture [see Izatt et al. *Inorg Chem* **14** 3132 *1975*]. Dissolve it in ether at *ca* 40°, and spectroscopic grade MeCN is added to the solution, which is then chilled. The crown ether precipitates and is filtered off. It is dried *in vacuo* at room temperature [Wallace *J Phys Chem* **89** 1357 *1985*]. [Vögtle ed. *Top Corr Chem* (Host Guest Complex Chemistry) **98** *1981*.] **SKIN IRRITANT.**

1,1'-Diethyl-2,2'-cyanine iodide *[977-96-8]* **M 454.4, m 274°(dec).** It crystallises from EtOH and is dried in a vacuum oven at 80° for 4 hours. [*Beilstein* **23** II 267.]

5,5-Diethylbarbituric acid (Barbital) *[57-44-3]* **M 184.2, m 188-192°, pK_1^{25} 8.02, pK_2^{25} 12.7.** Crystallise barbital from water or EtOH and dry it in a vacuum over P_2O_5. [*Beilstein* **24** III/IV 1901.]

2,3-Dihydrobenzofuran (coumaran) *[496-16-2]* **C_8H_8O, M 120.2, m -21.5°, 72-73°/12mm, 84°/17mm, 188°/atm, d_4^{20} 1.065, n_D^{20} 1.5524.** Suspend coumaran in aqueous NaOH and steam distil, saturate distillate with NaCl, extract with Et_2O, dry extract ($MgSO_4$), filter, evaporate and distil residue. It gives a violet colour with $FeCl_3/H_2SO_4$. Its yellow ***picrate***, **m 76°** (from EtOH or $*C_6H_6$) loses coumaran *in vacuo* [Bennett & Hafez *J Chem Soc* 287 *1941*, DOI: 10.1039/JR9410000287; Baddeley et al. *J Chem Soc* 2455 *1956*, DOI: 10.1039/JR9560002455]. [*Beilstein* **17/1** V 581.]

Dihydropyran (3,4-dihydro-2*H*-pyran) *[110-87-2]* **C_5H_8O, M 84.1, m -70°, b 84.4°/742mm, 85.4-85.6°/760mm, d_4^{20} 0.9261, n_D^{20} 1.4423, pK_{Est} ~ 4.2.** Dry dihydropyran with Na_2CO_3, then fractionally distil it. Fraction **b** 84-85° is refluxed with Na until H_2 no longer evolves; add fresh Na then distil again through a 60 x 1.2cm column packed with glass rings [Brandon et al. *J Am Chem Soc* **72** 2120 *1950*, DOI: 10.1021/ja01161a069; UV: Eglinton et al. *J Chem Soc* 2873 *1952*, DOI: 10.1039/JR9520002873; NMR: Bushweller & O'Neil *Tetrahedron Lett* **10** 4713 *1969*, DOI: 10.1016/S0040-4039(01)88791-8]. Characterise it as the ***2-(3,5-dinitrobenzoyloxy)tetrahydropyrane*** derivative, **m 103°** [made by dissolving 3,4-dinitrobenzoic acid (3g) in 50% excess of dihydropyran with warming, cooling, adding Et_2O (5ml), when the derivative crystallises out quantitatively] which forms pale yellow crystals from 80% dihydropyran/Et_2O [Woods & Kramer *J Am Chem Soc* **69** 2246 *1947*, DOI: 10.1021/ja01201a520]. [*Beilstein* **17/1** V 181.] It is an OH protecting group [Greene & Wuts *Protecting Groups in Organic Synthesis* 2nd Edn, J. Wiley (NY) p 31 *1991*].

3,4-Dihydro-2*H*-pyrido[1,2*a*]-pyrimidin-2-one *[5439-14-5]* **M 148.2, m 185-187°, 187-188°, 191-191.5°.** Dissolve it in $CHCl_3$, filter, evaporate, then recrystallise the residue from EtOH/Me_2CO (needles) which can be

washed with Et_2O and dried. It can also be recrystallised from $CHCl_3$/petroleum ether or $CHCl_3$/hexane. The ***hydrochloride*** has **m 295-295°** (**dec**, from EtOH or MeOH/Et_2O), the ***hydrobromide*** has **m 299-300°**(**dec**) (from MeOH/Et_2O) and the ***picrate*** has **m 224-226°**(**corr**), **m 219-220°** from EtOH. [Adams & Pachter *J Am Chem Soc* **74** 4906 *1952*, DOI: 10.1021/ja01139a051; Lappin *J Org Chem* **23** 1358 *1958*, DOI: 10.1021/jo01103a034; Hurd & Hayao *J Am Chem Soc* **77** 117 *1955*, DOI: 10.1021/ja01606a037; *Beilstein* **24** III/IV 299.]

7,8-Dihydroxycoumarin (Daphnetin) *[486-35-1]* **$C_9H_6O_4$, M 178.2, m 256°(dec), $pK_{Est(1)}$ ~8.5, $pK_{Est(2)}$ ~12.3.** Crystallise it from aqueous EtOH. It can be sublimed. It inhibits protein kinases. [*Beilstein* **18/3** V 202.].

trans*-2,3-Dihydroxy-1,4-dioxane** *[4845-50-5]* **$C_4H_8O_4$, M 120.1, m 91-95°, 100°.** Recrystallise it from Me_2CO. With phenylhydrazine it gives ***glyoxal phenylhydrazone **m 175°** (from Me_2CO/petroleum ether). The ***diacetyl*** derivative has **m 105-106°** [Head *J Chem Soc* 1030 *1955*, DOI: 10.1039/JR9550001030; Raudnitz *Chem Ind (London)* 166 *1956*]. [*Beilstein* **1** IV 3627.]

2,5-Dihydroxy-1,4-dithiane *[40018-26-6]* **$C_4H_8O_2S_2$, M 152.2, m (130° dec, 142-147°) 150-152°, 151°**. Recrystallise the dithiane from EtOH. ***2,5-Diethoxy-dithiane*** has **m 91°** (**92-93°**); it crystallises from petroleum ether and can be sublimed at 60°/0.001mm [Hromatka & Haberl *Monatsh Chem* **85** 1088 *1954*, DOI: 10.1007/BF00899857; Thiel et al. *Justus Liebigs Ann Chem* **611** 121 *1958*, DOI: 10.1002/jlac.19586110113; Hesse & Jørder *Chem Be* **85** 924 *1952*, DOI: 10.1002/cber.19520850915]. [*Beilstein* **1** IV 3966.]

***S(-)*-4',7-Dihydroxyflavanone (3,4'-dihydroxyisoflavone, Liquiritigenin)** *[578-86-9]* **M 256.3, m 203-205° $[\alpha]_D^{20}$ -225 (c 0.95, 95%EtOH).** It crystallises from aqueous 50% EtOH. It inhibits rat monoamine oxidase *in vitro* [Pan et al. *Acta Pharmacolo Sinica* **21** 949 *2000*, PMID:11501051] [*Beilstein* **18** III/IV 1780, **18/4** V 82.]

5,7-Dihydroxy-4'-methoxyflavone (Acacetin) *[480-44-4]* **$C_{16}H_{12}O_5$, M 284.3, m 261°, 260-265°, 265°.** Acacetin crystallises from 95% EtOH or acetic acid as pale yellow needles (**m 263°**). It is an anti-inflammatory. [Zemplen & Bognar *Chem Ber* **76** 452 *1943*, DOI: 10.1002/cber.19430760503; Pillon *Bull Soc Chim* Fr 9 *1954*, UV: Gaydou & Bianchini *Bull Soc Chim Fr* II 43 *1978*, *Beilstein* **18** III/IV 2683, **18/4** V 575.]

(±)-7-(2,3-Dihydroxypropyl)theophylline (Diprophylline, Dyphylline) *[479-18-5]* **$C_{10}H_{14}N_4O_4$, M 254.3, m 158°, 160-164°, 161°, 161-162°, 161-164°, pK_{Est} ~ 8.7.** Recrystallise it from EtOH or H_2O. Its solubility in H_2O is 33% at 25°, in EtOH it is 2% and in $CHCl_3$ it is 1%. Its UV has λ_{max} (H_2O) at 273nm (ε 8,855). [Roth *Arch Pharm* **292** 234 *1959*, DOI: 10.1002/ardp.19592920504.] The ***4-nitrobenzoyl*** derivative has **m 178°** [Ishay *J Chem Soc* 3975 *1956*, DOI: 10.1039/JR9560003975]. [Lister *Purines Part II, Fused Pyrimidines* Brown Ed, Wiley-Interscience pp254-225 *1971*, ISBN 0-471-38205-1, *Beilstein* **26** III/IV 2370.]

1,3-Diiminoisoindoline *[3468-11-9]* **$C_8H_7N_3$, M 145.2, m 193-194°(dec), 196°(dec), pK^{25} 8.27.** It crystallises from H_2O, MeOH or MeOH/Et_2O (charcoal) in colourless prisms that become green on heating. [Elvidge & Linstead *J Chem Soc* 5000 *1952*, DOI: 10.1039/JR9520005000]. Its IR (nujol) has bands at 3150 and 690 cm^{-1}, and the UV has λ_{max} at 251nm (ε 12,500), 256nm (ε 12,5000) and 303nm (ε 4,600) [Elvidge & Golden *J Chem Soc* 700 *1957*, DOI: 10.1039/JR9570000700; Clark et al. *J Chem Soc* 3593 *1953*, DOI: 10.1039/JR9530003593]. The ***thiocyanate*** has **m 250-255°** (**dec**), the ***monohydrochloride*** has **m 300-301°** (turns green), and the ***dihydrochloride*** has **m 326-328°** (turns green) and the ***picrate*** crystallises from EtOH with **m 299°** (**dec**). [*Beilstein* **22/13** V 5.]

5,7-Diiodo-8-hydroxyquinoline *[83-73-8]* **C_9H_5INO, M 397.0, m >200°(dec), 214-215°(dec), $pK_{Est(1)}$~3.2, $pK_{Est(2)}$ ~8.2.** It crystallises from xylene and is dried at 70° in a vacuum. It is a metal chelating agent. [*Beilstein* **21** II 58.]

6-Dimethylaminopurine *[938-55-6]* **M 163.1, m 257.5-258.5°, 259-262°, 263-264°, pK_1^{25} 3.87, pK_2^{25} 10.5.** It is purified by recrystallisation from H_2O, EtOH (0.32g in 10ml) or $CHCl_3$. [Albert & Brown *J Chem Soc* 2060 *1954*, DOI: 10.1039/JR9540002060; UV: Mason *J Chem Soc* 2071 *1954*, DOI: 10.1039/JR9540002071.] The ***monohydrochloride*** crystallises from EtOH/Et_2O, **m 253°**(**dec**) [Elion et al. *J Am Chem Soc* **74** 411 *1952*,

DOI: 10.1021/ja01122a037], the ***dihydrochloride*** has **m 225°(dec)** and the ***picrate*** has **m 245°** (**235-236.5°**) [Fryth et al. *J Am Chem Soc* **80** 2736 *1958*, DOI: 10.1021/ja01544a039]. [*Beilstein* **26** III/IV 3566.]

1,3-Dimethylbarbituric acid *[769-42-6]* **$C_6H_8N_2O_3$, M 156.1, m 121-123°, 123°, pK^{25} 4.56.** Crystallise the acid from water and sublime it in a vacuum. Also purify it by dissolving 10g in 100ml of boiling CCl_4/$CHCl_3$ (8:2) (1g charcoal), filtering and cooling to 25°. Dry it *in vacuo* [Kohn et al. *Anal Chem* **58** 3184 *1986*, DOI: 10.1021/ac00127a058]. [*Beilstein* **24** III/IV 1875.]

5,6-Dimethylbenzimidazole *[582-60-5]* **$C_9H_{10}N_2$, M 146.2, m 202-205°, 205-206°, pK_1^{25} 5.96, pK_2^{25} 12.52.** Crystallise 5,6-dimethylbenzimidazole from diethyl ether. It sublimes at 140°/3mm. [*Beilstein* **23/6** V 454.]

2,3-Dimethylbenzothiophene *[31317-17-6]* **M 212.3, m 69-70°, b 123-124°/10mm, n_D^{19} 1.6171.** Fractionate it through a 90cm Monel spiral column, or other efficient fractionating or spinning band column and collect the middle fraction. It has also been purified by chromatography on basic alumina using pentane as eluent. [Tedjamulia et al. *J Heterocycl Chem* **20** 1485 *1983*, DOI: 10.1002/jhet.5570200610; *Beilstein* **17** III/IV 161.]

4,4'-Dimethyl-2,2'-bipyridine *[1134-35-6]* **$C_{12}H_{12}N_2$, M 184.2, m 169-174°, 175-176°, $pK_{Est(1)}$ ~0.2, $pK_{Est(2)}$ ~4.9.** Crystallise it from ethyl acetate. [Elliott et al. *J Am Chem Soc* **107** 4647 *1985*, DOI: 10.1021/ja00302a009; *Beilstein* **23/8** V 79.]

1,1'-Dimethyl-4,4'-bipyridylium dichloride ($3H_2O$; Methyl Viologen Dichloride, paraquat dichloride) *[1910-42-5]* **$C_{12}H_{14}Cl_2N_2$. xH_2O, M 311.2, m >300°(dec).** Recrystallise the dichloride from MeOH/acetone mixture. It has also been recrystallised three times from absolute EtOH [Bancroft et al. *Anal Chem* **53** 1390 *1981*, DOI: 10.1021/ac00232a021]. Dry it at 80° in a vacuum. It is an electron acceptor [cf. Kelly & Rodgers *J Phys Chem* **98** 6377 *1994*, DOI: 10.1021/j100076a023], and a transfer catalyst in redox reactions[cf. Koshechko et al. *Tetrahedron Lett* **33** 6677 *1993*, DOI: 10.1016/S0040-4039(00)61016-X]. [*Beilstein* **23/8** V 30.]

1,3-Dimethylbutadiene sulfone (1,3-dimethylsulfolene, 2,5-dihydro-2,4-dimethylthiophene) *[10033-92-8]* **M 145.2, m 40.4-41.0°.** Crystallise it from Et_2O, Et_2O/pentane or CCl_4. [Grummitt et al. *J Am Chem Soc* **72** 5167 *1950*, DOI: 10.1021/ja01167a103; Bartlett et al. *J Org Chem* **32** 1290 *1967*, DOI: 10.1021/jo01280a601; *Beilstein* **17** III/IV 161.]

2,2-Dimethyl-1,3-dioxan-4,6-dione (Meldrum's Acid) *[2033-24-1]* **$C_6H_8O_4$, M 144.1, m 92-96°, 94-95°, pK^{25} 5.1, 7.32.** Crystallise the dione from Me_2CO/H_2O. It is a useful synthon for the C3 malonic acid moiety. [Arnett et al. *J Am Chem Soc* **106** 6759 *1984*, DOI: 10.1021/ja00334a049; Bihlmayer et al. *Monatsh Chem* **98** 564 *1967*, DOI: 10.1007/BF00901364; Review: McNab *Chem Soc, Rev* **7** 345 *1978*, Chan & Huang *Synthesis* 452 *1982*, DOI: 10.1055/s-1982-29829; *Beilstein* **19/5** V 8.] It is synthesised by a modified procedure in which concentrated H_2SO_4 (1.5ml) is added to a stirred suspension of powdered malonic acid (52g, 0.5 mole) in acetic anhydride (60ml, 0.6 mole), whereby the malonic acid dissolves with spontaneous cooling. Acetone (40ml, 0.55 mole) is added to the mixture while keeping the temperature at 20-25°, then cooled in a refrigerator overnight, the crystals are filtered off, washed three times with ice-water (enough to cover the crystals) and air dried. The crude product (35g, 49%) is recrystallised without heating by dissolving it (10g) in Me_2CO (20ml), filtering, and adding H_2O (40ml), with ~70% recovery of material **m 94-95°**. [Pihlaja & Seilo *Acta Chem Scand* **22** 3053 *1968*, DOI: 10.3891/acta.chem.scand.22-3053.] ***Alternatively***, concentrated H_2SO_4 (0.5ml) is added dropwise to a stirred suspension of powdered malonic acid (52g, 0.5 mole) in redistilled isoprenyl acetate (62ml, 55g, [108-22-5]), when the temperature rose from 23° to 31° in 45 minutes and all the solid dissolved within 1 hour. Treatment of the reaction as above gave Meldrum's acid (37g, 50%). [Davidson & Bernhard *J Am Chem Soc* **70** 3426 *1948*, DOI: 10.1021/ja01190a060]. Its ^{1}H NMR ($CDCl_3$, TMS) has δ at 1.73 (s, 2-Me_2) and 3.60 (s, 5-H) [Schuster & Schuster *Tetrahedron* **25** 199 *1969*, DOI: 10.1016/S0040-4020(01)99472-4]. A similar synthesis can be used with substituted malonic acids.

3,6-Dimethyl-1,4-dioxan-2,5-dione (Lactide) *[cis-RS,RS-(±) 615-95-2, cis-R,R-(+) 95-96-5, cis-S,S-(-) 4511-42-6]* **$C_6H_8O_4$, M 144.1.** This is the cyclic dilactone of lactic acid. The **(±)-*cis-racemate*** has been distilled with **b 142°/8mm**; the distillate which solidifies gives yellow needles on recrystallisation from EtOH with **m 128°**, from Et_2O with **m 129°**, or $CHCl_3$ with **m 126°**, with IR ν_{max} at 1720-1740 cm^{-1}. It hydrolyses in cold

H_2O. [Carothers et al. *J Am Chem Soc* **54** 761 *1932*, DOI: 10.1021/ja01341a046]. A ***trans-form*** (probably *RS,SR*) has been reported which crystallises from Et_2O with **m 42-43°** [Hummel et al. *Acta Cryst (Sect B)* **38** 1679 *1982*, DOI: 10.1107/S0567740882006840]. The ***R,R-(+)-lactide*** has **b 150°/2mm** and crystallises from Et_2O with **m 95°**, or **m 96.5-97.5°** (from $CHCl_3$) or **m 97.7°** (from EtOAc) and **$[\alpha]_D^{22}$ +297 (c 1.2, *C_6H_6)**. The ***S,S-(-)-lactide*** has **b 150°/2.5mm** and crystallises from EtOAc with **m 98.7°**, or **m 95°** (from $CHCl_3$) or **m 96.5-97.5°** (from CCl_4) and **$[\alpha]_D^{22}$ -297 (c 1.2, *C_6H_6)**. [Toniolo et al. *J Org Chem* **35** 6 *1970*, DOI: 10.1021/jo00826a002; *Beilstein* **19** H 154, **19** I 179, **19** II 176, **19** IV 1927, **19/5** V 10.]

2,9-Dimethyl-4,7-diphenyl-1,10-phenanthroline (BCP, Bathocuproine) *[4733-39-5]* **$C_{26}H_{20}N_2$, M 360.5, m 279-283°, >280°, pK_{Est} ~5.6.** Purify it by recrystallisation from *benzene. It complexes with Cu. [Smith & Wilkins *Anal Chem* **25** 510 *1953*, DOI: 10.1021/ac60075a037; *Beilstein* **23** III/IV 2160.] For the ***disulfonic acid disodium salt*** and its analytical applications see 'Miscellaneous As, B, P, Si, S, Se and Te Compounds' in this Chapter.

2,2-Dimethylethyleneimine (2,2-dimethylaziridine) *[2658-24-4]* **M 71.1, b 70.5-71.0°, 72°, n_D^{20} 1.405, pK^{25} 8.64.** Dry the 2,2-dimethylaziridine over solid KOH, filter and freshly distil from sodium before use, and store it under dry nitrogen. The ***N-phenylthiocarbamoyl*** derivative crystallises from petroleum ether containing a trace of Me_2CO with **m 92.5-93.5°**. [Hassner et al. *J Am Chem Soc* **91** 5046 *1969*, DOI: 10.1021/ja01046a019; Cairns *J Am Chem Soc* **63** 871 *1941*, DOI: 10.1021/ja01848a504; Lamaty et al. *Justus Liebigs Ann Chem* **726** 77 *1969*, DOI: 10.1002/jlac.19697260112; *Beilstein* **20** III/IV 280.]

5,5-Dimethylhydantoin *[77-71-4]* **$C_5H_8N_2O_2$, M 128.1, m 174-177°, 177-178°, pK^{24} 9.19.** Crystallise the hydantoin from EtOH and sublime it *in vacuo*. [*Beilstein* **24** III/IV 1097.]

4,6-Dimethyl-2-hydroxypyrimidine *[108-79-2]* **M 124.1, m 198-199°, 202-205°, pK_1^{20} 3.77, pK_2^{20} 10.50.** Crystallise the pyrimidine from absolute EtOH (charcoal). [*Beilstein* **24/2** V 138.]

1,2-Dimethyl-1*H*-imidazole *[1739-84-0]* **$C_5H_8N_2$, M 96.1, m 37-39°, 38-40°, b 204°/atm, 206°/760mm, d_4^{20} 1.084, pK_{Est} ~8.1.** Crystallise the imidazole from *benzene, dry and store it at 0-4°. The ***picrate*** crystallises from H_2O or EtOH with **m 181°**. [Balaban & Pymann *J Chem Soc* **125** 1564 *1924*, DOI: 10.1039/CT9242501564; Gorun et al. *J Am Chem Soc* **109** 4244 *1987*, DOI: 10.1021/ja00248a019; *Beilstein* **23** H 66, **23** II 56, **23** III/IV 594.]

1,3-Dimethyl-2-imidazolinone (DMI, *N,N'*-dimethylethyleneurea, DMEU) *[80-73-9]* **$C_5H_{10}N_2O$, M 114.2, m 8.2°, b 67-68°/2mm, 104°/5mm, 106-107°/17mm, 224-226°/atm, d_4^{25} 1.056, n_D^{20} 1.472**. After preparation by reaction of *N,N'*-dimethylethylenediamine in toluene with phosgene in toluene below 15°, excess phosgene is removed by blowing air through the mixture. The hydrochloride salt that separates is removed by filtration, and washed with $CHCl_3$. The combined filtrate and washings are evaporated off, and the residue is distilled (b 129°/39mm). The crude distillate is treated with H_2O; K_2CO_3 is added to saturate the solution, and extracted with $CHCl_3$, the extract is dried (K_2CO_3), filtered, and pure ***1,3-dimethylimidazolin-2-one*** distils at **b 104°/5mm**. It has been used as an alternative to HMPA [see *680-31-9*] as a high dielectric solvent for reactions. [Boon *J Chem Soc* 307 *1947*, DOI: 10.1039/JR9470000307; Lien & Kumler *J Med Chem* **11** 214 *1968*, DOI: 10.1021/jm00308a005; Kohn et al. *J Org Chem* **42** 941 *1977*, DOI: 10.1021/jo00426a003; *Beilstein* **24** III/IV 9.]

***Cis*-2,3-dimethyloxirane (*cis*-epoxybutane)** *[1758-33-4]* **C_4H_8O, M 72.1, m -84 to -83°, b 59.7°/742mm, 61°/atm, 59-61°/atm, d^{25} 0.8226, n_D^{20} 1.3830.** Dry the oxirane over $CaCl_2$ and redistil slowly through a short Vigreux column [Cornforth & Green *J Chem Soc C* 846 *1970*, DOI: 10.1039/J39700000846]. Its IR spectrum is described by H. van Risseghem [*Bull Soc Chim Fr* 1661 *1959*]. Crude *cis*-2,3-dimethyloxirane, obtained from the *m*-chloroperbenzoic acid oxidation of *cis*-2-butene, is distilled off and the fraction boiling up to 100° is collected and fractionated through a 2 ft helices-packed column to give a 52-60% yield of pure *cis*-dimethyloxirane **b 58-59°/748mm**. The stereochemical purity of the oxirane was shown to be greater that 99.5% by gas chromatography on a 30-ft, 20% Carbowax 20M on Chromosorb P column at 150°, with retention time 10.0 minutes (compare with 8.7 minutes for *trans*-oxirane). [Pasto & Cumbo *J Org Chem* **30** 1271 *1965*, DOI: 10.1021/jo01015a523.] [*Beilstein* **17** III/IV 45, 48, **17** V/1 61.]

It is prepared under argon (Schlenk equipment) by adding Me_3Al solution (2.0M in toluene, 320ml, 0.64mmol), *via* a septum over 50 minutes, to an ice-water cooled stirred suspension of 9-xanthone (50.0g, 0.255mol) in toluene (300ml) (exothermic reaction, no gas evolved). The

dark red solution is allowed to warm to ~25° over 3 hours, and stirred for a further 14 hours. (*Alternatively*, it can be heated to 60° for ~0.5 hours.) The mixture is transferred (*via* a cannula under argon pressure) to a stirred mixture of concentrated HCl (250ml) and ice (4 L). The organic phase is separated, dried ($MgSO_4$), filtered, the solvent is evaporated *in vacuo* to give a yellow oil (51.5g, 96%) which distils at 114-115°/0.6mm, and solidifies on cooling. The ^1H NMR ($CDCl_3$, TMS) has δ at 1.63 (s, 6H, CH_3), 7.0-7.6 (m, 8H, aromatic-H); MS has *m/z* at 210 (M^+), 195 (base peak, M^+-CH_3). [Nowick et al. *J Am Chem Soc* **112** 8902 *1990*, DOI: 10.1021/ja00180a038; Meisters & Mole *Aust J Chem* **27** 1655 *1974*, DOI: 10.1071/CH9741655; *Beilstein* **17** II 287.]

1,3-Dioxolan-2-one (ethylene carbonate) *[96-49-1]* **$C_3H_4O_3$, M 88.1, m 35-38°, 37°, 39°, 40°, b 65-67°/1mm, 126°/17mm, 238°/760mm, 243-244°/atm, d_4^{20} 1.321, n^{40} 1.4199.** Dry 1,3-dioxolan-2-one over P_2O_5, then fractionally distil it at low or atmospheric pressure. Recrystallise it from dry Et_2O (plates, **m** 36.5°, 38.5-40° was also reported). It is soluble in H_2O. [*Beilstein* 19 II 135,**19** III/IV 1556, **19/4** V 6.]

1,3-Dioxane (formaldehyde trimethylene acetal) *[505-22-6]* **$C_4H_8O_2$, M 88.1, m -45°, b 104.5°/751mm, 105-106°/atm, d_4^{20} 1.040, n_D^{20} 1.417.** Dry the dioxane with Na and fractionally distil it. [*Beilstein* **19/1** V 11.]
1,4-Dioxane **(Dioxane, diethylene oxide)** *[123-91-1]* has **m 10-12°, 11.8°, b 12°/20mm, 34°/60mm, 45°/100mm, 82°/400mm, 101.1°/760mm, 100-102°/atm, 101.3°/atm, d_4^{25} 1.0292, n_D^{15} 1.4236, n_D^{25} 1.42025.** It is prepared commercially either by dehydration of ethylene glycol with H_2SO_4 and heating ethylene oxide or bis(ß-chloroethyl)ether with NaOH. The usual impurities are acetaldehyde, ethylene acetal, acetic acid, water and peroxides. Peroxides can be removed (and the aldehyde content decreased) by percolation through a column of activated alumina (80g per 100-200ml solvent), by refluxing with $NaBH_4$ or anhydrous stannous chloride and distilling, or by acidification with concentrated HCl, shaking with ferrous sulfate and leaving in contact with it for 24 hours before filtering and purifying further. Hess and Frahm [*Chem Ber* **71** 2627 *1938*, DOI: 10.1002/cber.19380711234] refluxed 2L of dioxane with 27ml concentrated HCl and 200ml water for 12 hours with slow passage of nitrogen to remove acetaldehyde. After cooling the solution, KOH pellets were added slowly and with shaking until no more would dissolve and a second layer had separated. The dioxane was decanted, treated with fresh KOH pellets to remove any aqueous phase, then transferred to a clean flask where it was refluxed for 6-12 hours with sodium, then distilled from it. *Alternatively*, Kraus and Vingee [*J Am Chem Soc* **56** 511 *1934*, DOI: 10.1021/ja01318a004] heated it on a steam bath with solid KOH until fresh addition of KOH gave no more resin (due to acetaldehyde). After filtering through paper, the dioxane was refluxed over sodium until the surface of the metal was not further discoloured during several hours. It was then distilled from sodium.
The acetal (**b 82.5°**) is removed during fractional distillation. Traces of *benzene, if present, can be removed as the *benzene/MeOH azeotrope by distillation in the presence of MeOH. Distillation from $LiAlH_4$ removes aldehydes, peroxides and water. Dioxane can be dried using Linde type 4X molecular sieves. Other purification procedures include distillation from excess C_2H_5MgBr, refluxing with PbO_2 to remove peroxides, fractional crystallisation by partial freezing and the addition of KI to dioxane acidified with aqueous HCl. Dioxane should be stored out of contact with air, preferably under N_2.
A detailed purification procedure is as follows: Dioxane is stood over ferrous sulfate for at least 2 days, under nitrogen. Then water (100ml) and conc HCl (14ml)/ litre of dioxane are added (giving a pale yellow colour). After refluxing for 8-12 hours with vigorous N_2 bubbling, pellets of KOH are added to the warm solution to form two layers and to discharge the colour. The solution is cooled rapidly with more KOH pellets being added (magnetic stirring) until no more dissolved in the cooled solution. After 4-12 hours, if the lower phase is not black, the upper phase is decanted rapidly into a clean flask containing sodium, and refluxed over sodium (until freshly added sodium remained bright) for 1 hour. The middle fraction is collected (and checked for minimum absorbency below 250nm). The distillate is fractionally frozen three times by cooling in a refrigerator, with occasional shaking or stirring. This material is stored in a refrigerator. Before use it is thawed, refluxed over sodium for 48 hours, and distilled into a container. All joints are clad with Teflon tape.
Coetzee and Chang [*Pure Appl Chem* **57** 633 *1985*, DOI: org/10.1351/pac198557040633] dried the solvent by passing it slowly through a column (20g/L) of 3A molecular sieves activated by heating at 250° for 24 hours. Impurities (including peroxides) are removed by passing the effluent slowly through a column packed with type NaX zeolite (pellets ground to 0.1mm size) activated by heating at 400° for 24 hours or chromatographic grade basic Al_2O_3 activated by heating at 250° for 24 hours. After removal of peroxides the

effluent is refluxed for several hours over sodium wire, excluding moisture, distilled under nitrogen or argon and stored in the dark. One of the best tests of purity of dioxane is the formation of the purple ***disodium benzophenone complex*** during reflux and its persistence on cooling. (Benzophenone is better than fluorenone for this purpose and for storing the solvent.) [Carter et al. *Trans Faraday Soc* **56** 343 *1960*, DOI: 10.1039/TF9605600343; *Beilstein* **19** V 16.] **TOXIC — do not inhale vapour.**
Rapid purification: Check for peroxides (see Chapter 1 and Chapter 2 for test under ethers). Pre-dry with $CaCl_2$ or better over Na wire. Then reflux the pre-dried solvent over Na (1% w/v) and benzophenone (0.2% w/v) under an inert atmosphere until the blue colour of the benzophenone ketyl radical anion persists. Distil, and store it over 4A molecular sieves in the dark.

1,3-Dioxolane (formaldehyde ethylene acetal) *[646-06-0]* **$C_3H_6O_2$, M 74.1, m -95°, b 74-75°/atm 75.0-75.2°/atm d_D^{20} 1.0600, n^{21} 1.3997.** Dry it with solid NaOH, KOH or $CaSO_4$, and distil it from sodium or sodium amalgam. Barker et al. [*J Chem Soc* 802 *1959*, DOI: 10.1039/JR9590000802] heated 34ml of dioxalane under reflux with 3g of PbO_2 for 2 hours, then cooled and filtered. After adding xylene (40ml) and PbO_2 (2g) to the filtrate, the mixture is fractionally distilled. Addition of xylene (20ml) and sodium wire to the main fraction (**b** 70-71°) led to a vigorous reaction, following which the mixture was again fractionally distilled. Xylene and sodium additions are made to the main fraction (**b** 73-74°) before it is finally distilled. [*Beilstein* **19/1** V 6.]

1,3-Diphenylisobenzofuran *[5471-63-6]* **$C_{20}H_{14}O$, M 270.3, m 128-130°, 129-130°.** Recrystallise it from EtOH or EtOH/$CHCl_3$ (1:1) under red light (as in photographic dark rooms) or from *benzene in the dark. [*Beilstein* **17/2** V 503.]

2,5-Diphenyl-1,3,4-oxadiazole (PPD) *[725-12-2]* **M 222.3, m 70° (hydrate), 139-140° (anhydrous), b 231°/13mm, 248°/16mm.** Its solubility in $CHCl_3$ is 10%. Crystallise it from EtOH and sublime it *in vacuo*. [*Beilstein* **27** III/IV 2712.]

2,5-Diphenyloxazole (PPO) *[92-71-7]* **$C_{15}H_{11}NO$, M 221.3, m 72-74°, 74°, b 360°/atm.** Distil it in steam and crystallise it from ligroin. Scintillation material for radioactive counting. [*Beilstein* **27** III/IV 1437.]

2*RS*,5*RS*-(±)-2,5-Diphenylpyrrolidine (± *trans* isomer) *[22147-84-8]* **$C_{16}H_{17}N$, M 223.3, b 136°/0.3mm, n_D^{25} 1.5866, pK_{Est} ~ 8.0.** A mixture of *cis-(meso)* and *trans*-(±) pyrrolidines (b ~130-145°/0.15-0.2mm, ~138g, 0.6mol) in EtOH (210ml) and concentrated HCl (100ml) was treated dropwise, during ~2 hours, with a solution of $NaNO_2$ (61.5g, 0.9mol) in H_2O (100ml) at ~0° (ice-bath cooling). The mixture was poured into H_2O (1 L) and the precipitate (~160g) was collected, washed with H_2O and fractionally recrystallised from Me_2CO to give the ***trans-nitroso*** derivative (**m 140-140.9°**, 51%) *[22147-82-6]*, and the ***cis-nitroso*** derivative (**m 97-98°**, 20%) *[22147-81-5]*. This *trans*-nitroso-pyrrolidine was de-nitrosated (HCl gas in Et_2O) to the ***trans-hydrochloride*** **m 196.5-180°** which was recrystallised from EtOH/Et_2O. The ***trans-free base*** was obtained by basifying an aqueous solution to pH 9-10 and extracting with Et_2O (3 x 50ml), drying the extract (Mg_2SO_4), filtering, evaporating and distilling the residual oil (**b 136°/0.3mm**). The IR (film) has ν_{max} at 1110-1025 (three peaks, one is for C-N) and 3330 (N-H) cm^{-1}. Similarly the ***cis (meso) N-nitroso derivative*** gave the *2RS,5SR-**diphenylpyrrolidine meso-hydrochloride*** which had **m 224.7-225.5°**, and the ***meso-free base*** *[22147-83-7]* had **b 121-123.4°/0.2mm, n_D^{25} 1.5850**. Emetine hydrochloride *[316-42-7]* **$C_{29}H_{40}N_2O_4$. 2HCl, M 553.6 + aq, m 235-240°, 235-250°, 240-250°, 248-250° (depending on H_2O content), $[\alpha]_D^{20}$ -49.2 (free base, c 4, $CHCl_3$), +18 (c 6, H_2O, dry salt), pK_1 5.77, pK_2 6.64.** It crystallises from MeOH/Et_2O, MeOH or Et_2O/EtOAc. The ***free base*** *[483-18-1]* has **m 104-105°**, and the ***(-)-phenylthiourea derivative*** has **m 220-221°** (from EtOAc/petroleum ether, $[\alpha]_D^{25}$ - 29.3 ($CHCl_3$)). Its IR has ν_{max} at 3413 (OH) and 2611 (NH^+) cm^{-1}; and UV λ_{max} at 230nm (ε 16 200) and 282nm (ε 6 890) [Brossi et al. *Helv Chim Acta* **42** 1515 *1959*, DOI: 10.1002/hlca.19590420513; Barash et al. *J Chem Soc* 3530 *1959*, DOI: 10.1039/JR9590003530]. This alkaloid is antiamebic. [*Beilstein* **23** III/IV 3419.]

(±)-Epichlorohydrin (chloromethyloxirane, γ-chloromethylpropyleneoxide) *[106-89-8]* **C_3H_5ClO, M 92.5, m -57°, b 16.5°/10mm, 42°/40mm, 115.5°/760mm, d_4^{25} 1.183, n_D^{20} 1.438.** Distil epichlorohydrin at 760mm, heat it on a steam bath with one-quarter its weight of CaO, then decant and fractionally distil it. [Clarke & Hartman *Org Synth* Coll Vol **1** 233 *1941*, DOI: 10.15227/orgsyn.003.0047; Braun *Org Synth* Coll Vol **2** 256 *1943*, DOI: 10.15227/orgsyn.016.0030; *Beilstein* **17** H 6, **17** III/IV 20, **17** V/1 20.]

Ergocornine *[564-36-3]* **$C_{31}H_{39}N_5O_5$, M 561.7, m 181°(dec), 182-184°, $[\alpha]_D^{20}$ -176 (c 0.5, $CHCl_3$).** It crystallises with solvent of crystallisation from MeOH. [Stadler et al. *Helv Chim Acta* **52** 1549 *1969*, DOI: 10.1002/hlca.19690520616; *Beilstein* **25** III/IV 963, **27** II 860.]

Ergocristine *[511-08-0]* **$C_{35}H_{39}N_5O_5$, M 609.7, m 155-157°, $[\alpha]_D^{20}$ -183 (c 0.5, $CHCl_3$).** It crystallises with 2 molecules of solvent of crystallisation from *benzene. [Stadler et al. *Helv Chim Acta* **52** 1549 *1969*, DOI: 10.1002/hlca.19690520616; *Beilstein* **25** III/IV 966, **27** II 860.]

α-Ergocryptine *[511-09-1]* **$C_{32}H_{41}N_5O_5$, M 575.7, m 212-214°, $[\alpha]_D^{20}$ -180 (c 0.5, $CHCl_3$).** It crystallises with solvent of crystallisation, from acetone, *benzene or methanol. [Stadler et al. *Helv Chim Acta* **52** 1549 *1969*, DOI: 10.1002/hlca.19690520616; *Beilstein* **25** III/IV 964, **27** II 860.]

Ergotamine *[113-15-5]* **$C_{33}H_{35}N_5O_5$, M 581.6, m 212-214°(dec), $[\alpha]_D^{20}$ -160 (c 0.5, $CHCl_3$), pK^{25} 6.40.** Crystallise it from *benzene, then dry it by prolonged heating in high vacuum. It is very ***hygroscopic***. [*Beilstein* **25** III/IV 964.] ***Ergotamine tartrate*** *[379-79-3]* **$C_{33}H_{35}N_5O_5$. 0.5 $C_4H_6O_6$, M 657.1,** has **m ~195°(dec), 203°(dec).** It crystallises from MeOH. [*Beilstein* **25** III/IV 964.]

Ergotaminine *[639-81-6]* **$C_{33}H_{35}N_5O_5$, M 581.7, m 241-243°, $[\alpha]_D^{20}$ +369° (c 0.5, $CHCl_3$).** It forms rhombic plates from MeOH which retain solvent unlike its isomer ergotamine (previous entry). It is less soluble than ergotamine, and its solubility is 0.1% in boiling ethanol and 0.07% in methanol. [Stoll *Helv Chim Acta* **28** 1283 *1945*, DOI: 10.1002/hlca.6602801182; *Beilstein* **25** II 860, 862, **25** III/IV 966.]

D-Erythronic acid γ-lactone (3*R*-3,4-dihydroxyfuran-2-one) *[15667-21-7]* **$C_4H_6O_4$, M 118.1, m 98-100°, 100-102°, 103-104°, 104-105°, 105°, $[\alpha]_D^{20}$ -73.2 (c 0.5, H_2O), $[\alpha]_{546}^{20}$ -87.6 (c 4, H_2O).** Recrystallise it from EtOAc (20 parts) or isoPrOH (3 parts). [Baker & MacDonald *J Am Chem Soc* **82** 2301 *1960*, DOI: 10.1021/ja01494a049; Glattfeld & Forbrich *J Am Chem Soc* **56** 1209 *1934*, DOI: 10.1021/ja01320a066; Weidenhagen & Wegner *Chem Ber* **72** 2010 *1939*, DOI: 10.1002/cber.19390721122; Musich & Rapoport *J Am Chem Soc* **100** 4865 *1978*, DOI: 10.1021/ja00483a037; *Beilstein* **18/2** V 457.]

Esculetin (cichorigenin, 6,7-dihydroxycoumarin) *[305-01-1]* **$C_9H_6O_4$, M 178.2, m 271-273°, 272-275° (dec), 274° (dec), pK^{25} 8.60 (70% aqueous EtOH), $pK_{Est(1)}$ ~8.7, $pK_{Est(2)}$ ~12.4.** It forms prisms from AcOH, aqueous EtOH or aqueous MeOH, and provides leaflets on sublimation in a vacuum. [Kagan *J Am Chem Soc* **88** 2617 *1966*, DOI: 10.1021/ja00963a064; Mabry et al. *Phytochemistry* **4** 487 *1965*, DOI: 10.1016/S0031-

9422(00)86201-9.] ***Esculin (the 6-glucoside)*** has **m 215°(dec)**, $[\alpha]_D^{20}$ -41 (c 5, pyridine). [*Beilstein* **18** III/IV 1322, **18/3** V 202.]

Eserine (Physostigmine, Physostol, [(3aS-*cis*)-1,2,3,3a,8,8a-hexahydro-1,3a,8-trimethyl-pyrrolo[2,3-b]indol-5-ol methylcarbamate ester] *[57-47-6]* **$C_{15}H_{21}N_3O_2$, M 275.4, m 102-104°, 105-106°, $[\alpha]_D^{17}$ -67 (c 1.3, $CHCl_3$), $[\alpha]_D^{25}$ -120 (*C_6H_6), pK_1^{25} 1.96, pK_2^{25} 8.08.** Eserine crystallises from Et_2O or *C_6H_6 and forms an unstable low melting form **m 86-87°** [Harley-Mason & Jackson *J Chem Soc* 3651 *1954*, DOI: 10.1039/JR9540003651; Wijberg & Speckamp *Tetrahedron* **34** 2399 *1978I,* DOI: 10.1016/0040-4020(78)89058-9]. It is an acetylcholinesterase inhibitor which can cross the blood-brain barrier. [*Beilstein* **23/11** V 401.]

2-Ethoxy-1-ethoxycarbonyl-1,2-dihydroquinoline (EEDQ) *[16357-59-8]* **$C_{14}H_{17}NO_3$, M 247.3, m 62-67°, 63.5-65°, 66-67°.** Dissolve EEDQ (~180g) in $CHCl_3$, evaporate to dryness in a vacuum. Add dry Et_2O (20ml) and a white solid separates on standing. Set aside for a few hours, collect the solid, wash it thoroughly with cold Et_2O and dry it in a vacuum (~140g, **m 63.5-65°**). A further crop of solid (~25g) is obtained from the filtrate on standing overnight. [Fieser **2** 191, Belleau et al. *J Am Chem Soc* **90** 823 *1968*, DOI: 10.1021/ja01005a067; and **90** 1651 *1968*, DOI: 10.1021/ja01008a045; *Beilstein* **21/3** V 28.] It is an irreversible membrane-bound receptor antagonist [Gozlan et al. *Neuropharmacology* **33** 423 *1994*].

Ethoxyquin (1,2-dihydro-6-ethoxy-2,2,4-trimethylquinoline) *[91-53-2]* **$C_{14}H_{19}NO$, M 217.3, b 123-125°/0.5mm, 169°/12-13mm, d_4^{20} 1.000, pK_{Est} ~ 5.8.** Purify Ethoxyquin by fractional distillation *in vacuo* whereby the distillate solidifies to a glass. [Knoevenagel **54** 1722, 1730 *1921*, DOI: 10.1002/cber.19210540807.] The ***methiodide*** has **m 179°** (from EtOH), and the ***1-phenylcarbamoyl*** derivative has **m 146-147°** (from EtOH). Used as a food antioxidant. [Beaver et al. *J Am Chem Soc* **79** 1236 *1957*, DOI: 10.1021/ja01562a053; *Beilstein* **21** III/IV 95.]

2-Ethyl-1,2-benzisoxazolium tetrafluoroborate *[4611-62-5]* **M 235.0, m 107-109°, 109.5-110.2°.** Recrystallise it from MeCN/EtOAc to give magnificent crystals. It is not hygroscopic but on long exposure to moisture it etches glass. It is light-sensitive and should be stored in brown glass bottles and free from moisture. The UV (H_2O), has λ_{max} at 258nm (ε 13 100) and λ_{max} 297nm (ε 2 900); the IR (CH_2Cl_2) has ν_{max} at 1613 (C=N) and 1111-1000 (BF_4^+) [UV, IR, NMR: Kemp & Woodward *Tetrahedron* **21** 3019 *1965*, DOI: 10.1016/S0040-4020(01)96921-2].

***N*-Ethylcarbazole** *[86-28-2]* **$C_{14}H_{13}N$, M 195.3, m 68-70°, 69-70°, 69-71°, b 199-200°/15mm.** Recrystallise it from MeOH, EtOH, EtOH/water or isopropanol and dry it below 55°. [*Beilstein* **20** H 436, **20** II 282, **20** III/IV 3829.]

Ethyl 1,3-dithiane-2-carboxylate *[20462-00-4]* **$C_7H_{12}O_2S_2$, M 192.3, b 75-77°/0.2mm, 96°/0.4mm, d_4^{20} 1.220, n_D^{25} 1.5379.** Dissolve the ester in $CHCl_3$, wash with aqueous K_2CO_3, twice with H_2O, dry over $MgSO_4$, filter, evaporate and distil the residue. [Eliel & Hartmann *J Org Chem* **37** 505 *1972*, DOI: 10.1021/jo00968a043; Seebach *Synthesis* **1** 17 *1969*, DOI: 10.1055/s-1969-34190; *Beilstein* **19/7** V 227.]

[Hermann et al *Tetrahedron Lett* **14** 2599 *1973*, DOI: 10.1016/S0040-4039(01)96155-6; Corey & Erickson *J Org Chem* **36** 3553 *1971*, DOI: 10.1021/jo00822a019]. [*Beilstein* **19/7** V 225.]

Ethylene oxide (oxirane) *[75-21-8]* **C_2H_4O, M 44.0, m -111°, b 10.7°/atm, 13.5°/746mm, d_4^{10} 0.882, n_D^7 1.3597.** Dry oxirane with $CaSO_4$, then distil it from crushed NaOH. It has also been purified by passage, as a gas, through towers containing solid NaOH. [*Beilstein* **17/1** V 3.]

Ethylene thiourea (2-imidazolidinethione) *[96-45-7]* **$C_3H_6N_2S$, M 102.2, m 196-200°, 203-204°.** Crystallise it from EtOH, amyl alcohol or H_2O in which the solubility is ~1.5w/v% at ~20° and ~50w/v% at ~100°.

[*Beilstein* **24** III/IV 22.]

Ethylene urea (2-imidazolidone) *[120-93-4]* **$C_3H_6N_2O$, M 86.1, m 129-132°, 131°.** Crystallise it from MeOH (charcoal). [*Beilstein* **24** III/IV 6.]

(±)-2-Ethylethylenimine (2-ethylaziridine) *[2549-67-9]* **C_4H_9N, M 71.1, b 88.5-89°, pK^{25} 8.31 (K_b 5.70 x 10^{-7}).** Freshly distil the aziridine from sodium before use. The ***picrate*** has **m 103-104°**. **TOXIC.** [O'Rourke et al. *J Am Chem Soc* **78** 2159 *1956*, DOI: 10.1021/ja01591a035; *Beilstein* **20** III/IV 280.]

Ethyl hydrocupreine hydrochloride (Optochin) *[3413-58-9]* **M 376.9, m 249-251°, pK_1^{25} 5.50, pK_2^{25} 9.95.** Recrystallise it from H_2O [UV: Heidt & Forbes *J Am Chem Soc* **55** 2701 *1933*, DOI: 10.1021/ja01334a012]. [*Beilstein* **24** H 385, **24** III/IV 1446.]

2-Ethyl-isothionicotinamide (ethionamide, 3-ethyl 4-pyrdinecarbothioamide) *[536-33-4]* **$C_8H_{10}N_2S$, M 166.2, m 163-164°, 164-166°(dec).** It crystallises from EtOH as lemon yellow needles. The ***hydrochloride*** crystallises from EtOH (+ few drops of HCl) as orange yellow needles with **m 212-214°**. [Kutscherowa et al. *J Gen Chem USSR* (English transl) **29** 915 *1959*, *Beilstein* **22** III/IV 737.] It causes peripheral and occular **neuropathy,** and is **carcinogenic** and **teratogenic**, but also has antibacterial properties.

Ethyloxirane (1,2-epoxybutane) *[RS 106-88-7; 2R(+) 3760-95-0; 2S(-) 30608-62-9]* **C_4H_8O, M 72.1, b 63-65°/atm and n_D^{20} 1.3829 for (±)-oxirane; b 61-63°/atm, n_D^{20} 1.3865 and $[\alpha]_D^{20}$ +13.6 (c 1.14,** Et_2O**) for *R(+)-enantiomer*,** and **b 62-63°/atm, n_D^{20} 1.3822 and $[\alpha]_D^{20}$ -13.7 (c 1.48,** Et_2O**) for *S(-)-enantiomer* 66.4-66.6°,** also with **d_4^{20} 0.837, $[\alpha]_D^{20}$ +10 and $[\alpha]_D^{20}$ -10 respectively neat.** All epoxides were prepared by adding the respective 1-bromo-2-acetoxybutanes dropwise to a solution of KOH in H_2O (60%w/v) at 100° during 15 minutes, then steam distilling the oxirane out, drying the distillate over solid KOH and distilling the oxirane (30-50% yield) at atmospheric pressure. [Mori et al. *Tetrahedron* **35** 1601 *1979*, DOI: 10.1016/0040-4020(79)80022-8.] *Alternatively*, dry with $CaSO_4$, and fractionally distil through a long (126cm) glass helices-packed column. The first fraction contains a water azeotrope where the water can be removed with solid KOH. The oxiranes have similar IR (film), ν_{max} 3080m, 2980s, 2940s, 2830m, 1470m, 1280m, 900s, 830s and 800m cm^{-1}; ^1H NMR (60MHz, TMS): δ 0.98 (3H, t, *J* 7 Hz), ~1.25 to ~1.80 (3H, m, 1.22, 1.42,1.51,1.58, 1.66), 2.20 to ~2.40 (3H, m); and MS: m/e 72 ($M^+ = C_4H_8O$). [*Beilstein* **17** II 17, **17** III/IV 45, **17** V/1 56.]

(±)-3-Ethyl-5-phenylhydantoin (Ethotoin) *[86-35-1]* **$C_{11}H_{12}N_2O_2$, M 204.2, m 94°.** Crystallise it from water. It is an anticonvulsant and is used in epilepsy. [Dudley & Bius *J Heterocycl Chem* **10** 173 *1973*, DOI: 10.1002/jhet.5570100208; Pinner *Chem Ber* **21** 2320 *1888*, DOI: 10.1002/cber.18880210226; *Beilstein* **25** III/IV 963, **27** II 860.]

***N*-Ethyl-5-phenylisoxazolinium-3'-sulfonate (Woodward's reagent K)** *[4156-16-5]* **$C_{11}H_{11}NO_4S$, M 253.3, m 220°(dec).** Crystallise the reagent from diethyl ether or ethyl acetate/petroleum ether. [Llamas et al. *J Am Chem Soc* **108** 5543 *1986*, DOI: 10.1021/ja00278a030.] It is best purified by dissolving in excess of aqueous N HCl and precipitating with Me_2CO to give a white fluffy solid. [Woodward et al. *Tetrahedron* **22** *Suppl* **8** 321 *1966*, DOI: 10.1016/S0040-4020(01)82192-X; Fieser **1** 385, **2** 198.]

(±)-3-Ethyl-3-phenyl-2,6-piperidinedione (Glutethimide) *[77-21-4]* **$C_{13}H_{15}NO_2$, M 217.3, m 84°.** Crystallise glutethimide from diethyl ether or ethyl acetate/petroleum ether. It has **m 91-92°** (from aqueous EtOH), 87-87.5° (from Et_2O/petroleum ether), 84-87° (from isopropanol), and 83-84° (from Et_2O). [Penprase & Biles *J Am Pharm Assoc* **47** 523 *1958*, Hoffmann et al. *Helv Chim Acta* **40** 387, 393 *1957*, DOI: 10.1002/hlca.19570400217; *Beilstein* **21** III/IV 5493.] The ***R(+)-enantomer*** crystallises from EtOAc/petroleum ether with **m 103-104°**, and $[\alpha]_D^{20}$+184 (c 1, EtOH). The ***S(-)-enantiomer*** has similar properties except it has $[\alpha]_D^{20}$ -181 (c 1, EtOH). [Branchini *Ricerche Scientifiche* **29** 2435 *1959*, Finch et al. *Experientia* **31** 1002 *1975*.]

2-Ethylpyridine *[100-71-0]* **C_7H_9N, M 107.2, b 148.6°/atm, d_4^{25} 0.942, pK^{25} 5.89.** Dry 2-ethylpyridine with BaO, and fractionally distil it. Purify it further by conversion to the ***picrate***, recrystallisation of the picrate and

regeneration of the free base followed by distillation. [*Beilstein* **20/6** V 3.]
4-Ethylpyridine *[536-75-4]* has **b 168.2-168.3°/atm, d_4^{25} 0.942, pK^{25} 6.02.** Dry 4-ethylpyridine with BaO, and fractionally distil it. Also purified by converting to the ***picrate***, recrystallising and the free base is regenerated and distilled. [*Beilstein* **20/6** V 10.] ***4-Ethylpyridine-1-oxide*** *[14906-55-9]* has **m 109-110°, pK_{Est}~1.1.** Crystallise the oxide from acetone/ether. [*Beilstein* **20/6** V 10.]

Flavone (2-phenyl-4*H*-1-benzopyran-4-one) *[525-82-6]* **$C_{15}H_{10}O_2$, M 222.3, m 94-97°, 99-100°, 100°.** Crystallise flavone from petroleum ether. [Wheeler *Org Synth* Coll Vol **4** 478 *1963*, DOI: 10.15227/orgsyn.032.007; *Beilstein* **17/10** V 552.]

Fluorescein [9-(*o*-carboxyphenyl)-6-hydroxy-3*H*-xanthene-3-one] *[2321-07-5]* **$C_{20}H_{12}O_5$, M 332.3, m 320°, ε_{495nm} 7.84 x 10^4 (in 10^{-3}M NaOH), pK_1 2.2, pK_2 4.4, pK_3 6.7.** Dissolve it in dilute aqueous NaOH, filter and precipitate it by adding dilute (1:1) HCl. The process is repeated twice more, and the fluorescein is dried at 100°. *Alternatively*, it has been crystallised from acetone by allowing the solution to evaporate at 37° in an open beaker. It has also been recrystallised from EtOH and dried in a vacuum oven. [*Beilstein* **19** I 721, **19** II 248, **19** III/IV 2904, **19/8** V 456.]

Fluoresceinamine (mixture of 5- and 6-aminofluorescein) *[27599-63-9]* **$C_{20}H_{13}NO_5$, M 347.3, m 215-220°(dec) and 223°(dec), (for 5-amino) and m 314-316°(dec, for 6-amino).** Dissolve it in EtOH, treat with charcoal, filter, evaporate and dry the residue in a vacuum at 100° overnight. Also recrystallise it from 6% HCl, then dissolve it in 0.5% aqueous NaOH and precipitate it by acidifying with acetic acid. The separate amines are made from the respective nitro compounds, which are best separated *via* their ***acetate salts***. They have similar R_F of 0.26 on Silica Gel Merck F_{254} in 5 ml MeOH + 150 ml Et_2O saturated with H_2O. The IR (Me_2SO) has a band at ν_{max} 1690 cm^{-1} (CO_2^-) and sometimes a weak band at ν_{max} 1750 cm^{-1} due to the lactone. The UV (EtOH) of the 6-isomer has λ_{max} at 222nm (ε 60 000) and the 5-isomer at λ_{max} 222nm (ε 60 000) and 285nm (ε 20.600). [IR: McKinney & Churchill *J Chem Soc (C)* 654 *1970*, DOI: 10.1039/J39700000654; McKinney et al. *J Org Chem* **27** 3986 *1962*, DOI: 10.1021/jo01058a055; UV: Verbiscar *J Org Chem* **29** 490 *1964*, DOI: 10.1021/jo01025a508; *Beilstein* **19** III/IV 4337, **19/8** V 713.]

Fluorescein isothiocyanate isomer I (FTIC, 5-isothiocyanato isomer) *[3326-32-7*; *27072-45-3 **mixture of 5- and 6-isomers**]* **$C_{21}H_{11}NO_5S$, M 389.4, m >160°(slow dec).** It is made from the pure 5-amino isomer. Purify it by dissolving it in boiling Me_2CO, filtering and adding petroleum ether (b 60-70°) until it becomes turbid. If an oil separates, then decant it and add more petroleum ether to the supernatant and cool. Orange-yellow crystals separate, collect and dry them *in vacuo*. It should give one spot on TLC (silica gel) in EtOAc/pyridine/AcOH (50:1:1) and in $Me_2NCHO/CHCl_3$/28% NH_4OH (10:5:4). Its IR (Me_2SO) has ν_{max} at 2110 (NCS) and 1760 (C=O) cm^{-1}. The ^{1}HNMR spectra in Me_2CO-d_6 of the 5- and 6-isomers are distinctly different for the protons in the *benzene ring; the UV in phosphate buffer pH 8.0 shows a λ_{max} at ~490nm. [Sinsheimer et al. *Anal Biochem* **57** 227 *1974*, DOI:10.1016/0003-2697(74)90068-2; McKinney et al. *Anal Biochem* **7** 74 *1964*, DOI:10.1016/0003-2697(64)90121-6; *Beilstein* **19** III/IV 4337.] Used for the FTIC labeling of proteins and microsequencing of peptides and proteins (by HPLC).

3-Fluoro-4-iodopyridine *[22282-75-3]* **C_5H_3FIN, M 223.0, m 80-81°, 85-89°, pK_{Est} ~1.7,** Crystallise it from petroleum ether and/or sublime it *in vacuo* (**m 87°**). The ***picrate*** *[22282-76-4]* has **m 140°** (from EtOH). [Gribble & Saulnier *Tetrahedron Lett* **21** 4137 *1980*, DOI: 10.1016/S0040-4020(01)82192-X.]

4-Fluoro-7-nitrobenzofurazan (4-fluoro-7-nitrobenzo-2-oxa-1,3-diazole) *[29270-56-2]* **$C_6H_2FN_3O_3$, M 183.1, m 52-54°, 52.5-53.5°, 53-56°, 53.5-54.5°.** Purify it by repeated recrystallisation from petroleum ether (b 40-60°). On treatment with MeONa in MeOH it gives ***4-methoxy-7-nitrobenzo-2-oxa-1,3-diazole*** **m 115-116°**. [Nunno et al. *J Chem Soc (C)* 1433 *1970*, DOI: 10.1039/J39700001433.] It is a very good fluorophore for amino acids [Imai & Watanabe *Analyt Chim Acta* **130** 377 *1981*, DOI: 10.1016/S0003-2670(01)93016-8], as it reacts with primary and secondary amines to form fluorescent adducts with λ_{ex} 470nm and λ_{em} 530nm. It gives a ***glycine*** derivative with **m 185-187°** [Miyano et al. *Anal Chim Acta* **170** 81 *1985*, DOI:10.1016/S0003-2670(98)00125-1]. Useful for the fluorescent labeling of amines and amino acids for HPLC analysis.

5-Fluorouracil (5-fluoropyrimidinedi-2,4-[1*H*,3*H*]-one, 5-FU) *[51-21-8]* **$C_4H_3FN_2O_2$, M 130.1, m 282-283° (dec), 282-286°(dec), pK_1^{25} 8.04, pK_2^{25} 13.0.** Recrystallise it from H_2O or MeOH/Et_2O and sublime it at 190-200°/0.1mm or 210-230°/0.5mm. UV: λ_{max} at 265-266nm (ε 7070). [Hesse et al. *J Org Chem* **37** 329 *1972*, DOI: 10.1021/jo00967a037; Duschinsky & Pleven *J Am Chem Soc* **79** 4559 *1957*, DOI: 10.1021/ja01573a087; *Beilstein* **24** III/IV 1229.] A potent antitumour agent which inhibits thymidilate synthase and the consequent depletion of d-TTP resulting in hindering cell division.

Fluram (Fluorescamine, 4-phenyl-spiro[furan-2(3*H*)-1-phthalan]-3,3'-dione) *[38183-12-9]* **$C_{17}H_{10}O_4$, M 278.3, m 153-155°, 153-157°, 154-155°.** Fluram is a non-fluorescent reagent that reacts with primary amines to form highly fluorescent compounds. Purify it by dissolving (~1g) in Et_2O/*C_6H_6 (1:1, 180 ml), washing with 1% aqueous $NaHCO_3$ (50ml), drying (Na_2SO_4), and evaporating in a vacuum. Dissolve the residue in warm CH_2Cl_2 (5ml), dilute with Et_2O (12ml) and refrigerate. Collect the solid and dry it in a vacuum. Its IR ($CHCl_3$) has ν_{max} at 1810, 1745, 1722, 1625 and 1600 cm^{-1}, and ^{1}HNMR ($CDCl_3$) with δ at 8.71 (s, -O**H**C=). [Weigele et al. *J Am Chem Soc* **94** 5927 *1972*, DOI: 10.1021/ja00771a084; Weigele et al. *J Org Chem* **41** 388 *1976*, DOI: 10.1021/jo00864a051; Lai *Methods Enzymol* **47** 236 *1977*, DOI: 10.1016/0076-6879(77)47028-9.]

Forskolin (Colforsin, Coleonol, 5-[acetyloxy]-3-ethenyldodecahydro-6,10,10b-trihydroxy-3,4a,7,7, 10a-penta-methyl-[3*R*-{3α-4aβ, 5β, 6β, 6aα, 10α, 10 aβ, 10bα}-1*H*-naphtho[2,1-b]pyran-1-one) *[66575-29-9]* **$C_{22}H_{34}O_7$, M 410.5, m 230-232°, 228-233°, $[\alpha]_D^{25}$ -26.2 (c 1.7, $CHCl_3$).** Recrystallise this diterpene from *C_6H_6/petroleum ether, EtOAc/petroleum ether. It is an antihypertensive, a positive ionotropic agent, a platelet aggregation inhibitor, and it has adenylate cyclase activating properties [*Chem Abstr* **89** 244150 *1978*, de Souza et al. *Med Res Rev* **3** 201 *1983*, DOI: 10.1002/med.2610030205; X-ray: Tandon et al. *Indian J Chem* **15B** 880 *1977*]. [*Beilstein* **18/5** V 55.]

Fumagillin {2,4,6,8-decatetraene-1,10-dioic acid mono[4-(1,2-epoxy-1,5-dimethyl-4-hexenyl)-5-methoxy-1-oxaspiro[2.5]oct-6-yl] ester} *[23110-15-8]* **$C_{26}H_{34}O_7$, M 458.5, m 194-195°, $[\alpha]_D^{20}$ -26.2 (in 95% EtOH), pK_{Est} ~4.5.** Forty grams of a commercial sample containing 42% fumagillin, 45% sucrose, 10% antifoam agent and 3% of other impurities are digested with 150ml of $CHCl_3$. The insoluble sucrose is filtered off and washed with $CHCl_3$. The combined $CHCl_3$ extracts are evaporated almost to dryness at room temperature under reduced pressure. The residue is triturated with 20ml of MeOH, and the fumagillin is filtered off by suction. It is crystallised twice from 500ml of hot MeOH by standing overnight in a refrigerator (yellow needles). (The long-chain fatty ester used as anti-foam agent is still present, but is then removed by repeated digestion, on a steam bath, with 100ml of diethyl ether.) For further purification, the fumagillin (10g) is dissolved in 150ml of 0.2M ammonia, and the insoluble residue is filtered off. The ammonia solution (cooled in running cold water) is then brought to pH 4 by careful addition of M HCl with constant shaking in the presence of 150ml of $CHCl_3$. (Fumagillin is acid-labile and must be removed rapidly from the aqueous acid solution.) The $CHCl_3$ extract is washed several times with distilled water, dried (Na_2SO_4) and evaporated under reduced pressure. The solid residue is washed with 20ml of MeOH. The fumagillin is filtered off by suction, then crystallised from 200ml of hot MeOH. [Tarbell et al. *J Am Chem Soc* **77** 5610 *1955*, DOI: 10.1021/ja01626a045.] ***Alternatively***, 10g of fumagillin in 100ml $CHCl_3$ is passed through a silica gel (5g) column to remove tarry material, and the $CHCl_3$ is evaporated to leave an oil which gives fumagillin on crystallisation from amyl acetate. It recrystallises from MeOH (charcoal) or Me_2CO/MeOH. The fumagillin is stored in dark bottles in the absence of oxygen and at low temperatures. [Schenck et al. *J Am Chem Soc* **77** 5606 *1955*, DOI: 10.1021/ja01626a044; *Beilstein* **19** III/IV 1012.] It is used as an antiprotozoal agent.

Furan *[110-00-9]* **C_4H_4O, M 68.1, b 31.3°/atm, 32°/758mm, d_4^{20} 1.42, n_D^{20} 1.4214.** Shake it with aqueous 5% KOH, dry it with $CaSO_4$ or Na_2SO_4, then distil it under nitrogen, from KOH or sodium, immediately before use. A trace of hydroquinone could be added as an inhibitor of oxidation. [*Beilstein* **17** H 27, **17** I 16, **17** II 34, **17/1** V 291.]

Furan-2-carboxylic (2-furoic) acid *[88-14-2]* **$C_5H_4O_3$, M 112.1, m 128-132°, 133-134°, b 141-144°/20mm, 230-232°/760mm, pK_1^{25} -7.3 (O-protonation), pK_2^{25} 3.32.** Crystallise the acid from hot water (charcoal), dry it at 120° for 2 hours, then recrystallise it from $CHCl_3$, and again dry it at 120° for 2 hours. For use as a standard in volumetric analysis, good quality commercial acid should be crystallised from $CHCl_3$ and dried as above or sublimed at 130-140°/50-60mm or less. [*Beilstein* **18** I 438, **18** II 265, **18** III/IV 3914, **18/6** V 102.]

Furan-3-carboxylic (3-furoic) acid *[488-93-7]* **$C_5H_4O_3$, M 112.1, m 120-122°, 122-123°, 123°.5, pK^{25} 4.03** Crystallise the acid from water or aqueous EtOH, and sublime it in a vacuum. [*Beilstein* **18** I 439, **18** III/IV 4052, **18/6** V 196.]

Furan-3,4-dicarboxylic acid *[3387-26-6]* **$C_6H_4O_5$, M 156.1, m 217-218°, 221.5-222.5°, pK_1^{25} 1.44, pK_2^{25} 7.84.** Crystallise it from water or Et_2O/petroleum ether, and sublime it in a vacuum. [*Beilstein* **18** III/IV 4497.]

Furan-2,5-dione (maleic anhydride) *[108-31-6]* **$C_4H_2O_3$, M 98.1, m 51-56°, 54°, b 94-96°/20mm, 199°/760mm.** Crystallise it from *benzene, $CHCl_3$, CH_2Cl_2 or CCl_4. Sublime it under reduced pressure. [Skell et al. *J Am Chem Soc* **108** 6300 *1986*, DOI: 10.1021/ja00280a030; *Beilstein* **17** III/IV 5897, **17/11** V 55.]

3-(2-Furanyl)acrylic acid *[539-47-9]* **$C_7H_6O_3$, M 138.1, (*cis*-isomer) m 106-108°, pK^{25} 3.5; (*trans*-isomer) m 141°, 143-144°, b 285°/atm, pK^{25} 4.5 (H_2O), 5.76 (50% aqueous EtOH), 6.65 (ethoxyethanol/H_2O— 80:20).** Recrystallise the ***cis*-isomer** from *C_6H_6 and the ***trans*-isomer** from H_2O, *C_6H_6 or petroleum ether (b 80-100°)(charcoal). [*Beilstein* **18** H 301, **18** III/IV 4143, **18/6** V 306.]

Furfural (2-furfuraldehyde) *[98-01-1]* **$C_5H_4O_2$, M 96.1, m -36°, b 54-56°/11mm, 59-60°/15mm, 67.8°/20mm, 90°/65mm, 161°/760mm, d_4^{20} 1.159, n_D^{20} 1.52608, pK^{25} -6.5 (O-protonation).** Furfural is unstable to air, light and acids. Impurities include formic acid, ß-formylacrylic acid and furan-2-carboxylic acid. Distil it in an oil bath from 7% (w/w) Na_2CO_3 (added to neutralise acids, especially pyromucic acid). Redistil it from 2% (w/w) Na_2CO_3, and then, finally fractionally distil it under vacuum. It is stored in the dark. [Evans & Aylesworth *Ind Eng Chem (Anal ed)* **18** 24 *1926*, DOI: 10.1021/ie50193a013.]
Impurities resulting from storage can be removed by passage through chromatographic grade alumina. Furfural can be separated from impurities other than carbonyl compounds by the bisulfite addition compound. The aldehyde is steam volatile. It has been purified by distillation (using a Claisen head) under reduced pressure. This is essential as is the use of an oil bath with temperatures of no higher than 130° which is highly recommended. When furfural is distilled at atmospheric pressure (in a stream of N_2), or under reduced pressure with a free flame (caution: because the aldehyde is flammable), an almost colourless oil is obtained. After a few days and sometimes a few hours, the oil gradually darkens and finally becomes black. This change is accelerated by light and occurs more slowly when it is kept in a brown bottle. However, when the aldehyde is distilled under vacuum and the bath temperature kept below 130° during the distillation, the oil develops only a slight colour when exposed to direct sunlight during several days. The distillation of very impure material should **NOT** be attempted at atmospheric pressure; otherwise the product darkens very rapidly. After one distillation under vacuum, a distillation at atmospheric pressure can be carried out without too much decomposition and darkening. The liquid **irritates mucous membranes.** Store it in dark containers under N_2, preferably in sealed ampoules. [Adams & Voorhees *Org Synth* Coll Vol **1** 280 *1941*, DOI: 10.15227/orgsyn.001.0049; *Beilstein* **17/9** V 292.]

Furfuryl alcohol (2-furylmethanol) *[98-00-0]* **$C_5H_6O_2$, M 98.1, m -29°, b 68-69°/20mm, 170.0°/750mm, d_4^{20} 1.132, n_D^{20} 1.4873, n_D^{30} 1.4801, pK^{25} 2.61.** Distil it under reduced pressure to remove tarry material, shake with aqueous $NaHCO_3$, dry it with Na_2SO_4 and fractionally distil it under reduced pressure from Na_2CO_3. It can be further dried by shaking with Linde 5A molecular sieves. [*Beilstein* **17/3** V 338.]

Furfurylamine (2-aminomethylfuran) *[617-89-0]* **$C_5H_6O_2$, M 97.1, m -70°, b 54-56°/17mm, 142.5-143°/735mm, 145-146°/atm, d_4^{20} 1.059, n_D^{20} 1.489, pK^{30} 8.89.** Distil it under nitrogen from KOH through a column packed with glass helices, preferably under vacuum. Store it away from CO_2, or better as a salt. The ***picrate*** has **m 184-184°(dec)**, the ***hydrochloride*** has **m 147-149°**, and the ***oxalate salt*** has **m 145-147°**. It has UV in MeOH with λ_{max} at 218, 260 and 376nm (log ε 4.27, 3.90 and 4.02, respectively); IR (Nujol) with ν_{max} at 1620, 1600, 1570 and 1535cm^{-1} and in $CHCl_3$ ν_{max} at 1470 and 1629cm^{-1}. [Spenser *Can J Chem* **37** 1851 *1959*, DOI: 10.1139/v59-272; Marion et al. *J Am Chem Soc* **73** 305 *1951*, DOI: 10.1021/ja01145a100; UV Pruckner & Witkop *Justus Liebigs Ann Chem* **554** 127 *1943*, DOI: 10.1002/jlac.19435540109.] The ***hydro-***

chloride dihydrate has **m 234-236°(dec)**, the ***picrate*** has **m 228-229°** (sinters at 215°) from aqueous EtOH, and the ***N-acetate*** forms needles **m 204-205°**. [*Beilstein* **23** H 396, **23** I 119, **23** II 345, **23** III/IV 2666, **23/12** V 148.] Harmaline is a CNS stimulant.

Harmane (2-methyl-β-carboline, 1-methyl-9*H*-pyrido[3,4-*b*]indole, Aribine) *[486-84-0]* **$C_{12}H_{10}N_2$, M 182.2, m 235-238°, 237-238°, pK_1 7.37 (basic, Pry N), pK_2 14.7 (acidic, NH).** Crystallise it from heptane/cyclohexane. It is insoluble in H_2O, but soluble in dilute HCl or H_2SO_4. Solutions show a blue fluorescence. Its UV (MeOH) has λ_{max} nm (log ε) at 234 (4.57), 287 (4.21) and 347 (3.66). The ***hydrochloride*** forms needles from EtOH/dil HCl which sublimes at **m 120-130°**. It is an imidazoline binding site agonist. [Wolfbeis et al. *Monatsh Chem* **113** 509 *1982*, DOI: 10.1007/BF00799926; *Beilstein* **23/12** 237.] Harmane is an I_1 imidazoline binding site agonist.

Harmine (7-methoxy-1-methyl-9*H*-pyrido[3,4-*b*]indole) *[442-51-3]* **$C_{13}H_{12}N_2O$, M 212.3, m 261°(dec), 262-264°, 265°, pK^{20} 7.61.** Crystallise harmine from MeOH and sublime it in a vacuum. Its UV (MeOH) has λ_{max} nm (log ε) at 241 (4.61), 301 (4.21) and 336 (3.69). [*Beilstein* **23** II 348, **23** III/IV 2702, **23/12** V 237.] ***Harmine hydrochloride (hydrate)*** *[343-27-1]* has **M 248.7, m 262°(dec, hydrate), 280°(dec).** The ***hydrate*** crystallises as fluorescent crystals from water. Freely soluble in hot water, but only 2.5% in cold water. The ***anhydrous*** salt has **m 319°**. [*Beilstein* **23/12** V 237.] It is a CNS stimulant.

Hesperetin (3',5,7-trihydroxy-4'-methoxyflavanone) *[520-33-2]* **$C_{16}H_{14}O_6$, M 302.3, (*R*,S) m 226-228°, 227-228°, pK_{Est} ~8.5-10.5 (phenolic).** Crystallise it from EtOAc or ethanol. The natural ***S*(-) form** crystallises from EtOH and has **m 216-218°** and $[\alpha]_D^{20}$ -37.6 (c 2, EtOH). ***Note*** that C2 is chiral. It is a weak phenolic acid which precipitates at pH 5-7 from alkaline solutions (see pKa values). [*Beilstein* **18** III/IV 3215, **18/5** V 214.]

Hesperidin (hesperetin 7-rhamnoside) *[520-26-3]* **$C_{28}H_{34}O_{15}$, M 610.6, m 258-262° (soft at ~250°), 261-263°(dec), $[\alpha]_{546}^{20}$ -82 (c 2, pyridine).** Dissolve hesperidine [the natural glycoside of hesperetin (above) from lemons and sweet oranges] in dilute aqueous alkali and crystallises out as fine needles on adjusting the pH to 6-7. [*Beilstein* **18** III/IV 3219, **18/5** V 218.]

Hexahydro-1*H*-azepine (hexamethyleneimine, Azepane) *[111-49-9]* **$C_6H_{13}N$, M 99.2, b 70-72°/30mm, 135-138°/atm, 138°/749mm, d_4^{20} 0.879, n_D^{20} 1.466, pK^{25} 11.10 (pK^0 9.71, pK^{75} 9.71).** Purify azepane by dissolving in Et_2O and adding ethanolic HCl until all the base separates as the white ***hydrochloride***, filter, wash with Et_2O and dry it (**m 236°**). The salt is dissolved in the minimum volume of H_2O and basified to pH ~ 14 with 10N KOH. The solution is extracted with Et_2O, the extract is dried over KOH, evaporated and distilled. The ***free base*** is a **FLAMMABLE** and **TOXIC** liquid, and best kept as the salt. The ***nitrate*** has **m 120-123°**, the ***picrate*** has **m 145-147°**, and the ***tosylate salt*** has **m 76.5°** (ligroin). [Müller & Sauerwald *Monatsh Chem* **48** 727 *1927*, DOI: 10.1007/BF01526517; Hjelte & Agback *Acta Chem Scand* **18** 191 *1964*, DOI: 10.3891/acta.chem.scand.18-0191; *Beilstein* **20** II 1406, **20** III/IV 1406, **20/4** V 3.]

Hexamethylenetetramine (Urotropine, hexamine, HMTA) *[100-97-0]* **$C_6H_{12}N_4$, M 140.1, m 280° (subl), 290-292° (sealed tube, CARE), d_4^{20} 1.331, pK^{25} 4.85 (6.30).** It is soluble in H_2O (67%), $CHCl_3$ (10%), EtOH (8%) and Et_2O (0.3%), and a 0.2M solution has a pH of 8.4. Dissolve it in hot absolute EtOH (reflux, Norit), filter using a heated funnel, cool at room temperature first, then in ice. Wash the crystals with cold Et_2O, dry them in air or under a vacuum. A further crop can be obtained by adding Et_2O to the filtrate. It sublimes above 260° without melting. It forms salts readily with organic and inorganic acids. The ***hydrobromide perbromide*** [149261-40-5] $C_6H_{12}N_4.HBr.Br_2$, M 380.9, has **m 220°(dec),** and the ***picrate*** has **m 179°(dec)**. [pK^{20} 4.85: Reilley & Schmid *Anal Chem* **30** 947 *1958*, DOI: 10.1021/ac60137a021; pK^{20} 6.30: Pummerer & Hofmann *Chem Ber* **56** 1255 *1923*, DOI: 10.1002/cber.19230560603.] [*Beilstein* **26** I 306, **26** II 200, **26** III/IV 1680.] It is a urinary antibacterial and an antimicrobial food additive.

***R*-(+)-2-Hexyloxirane [*R*-(+)-1,2-epoxyoctane, *R*-(+)-octene oxide)** *[77495-66-0]* **$C_8H_{16}O$, M 128.2, b 51-54°/10mm, 60-62°/15mm, 157°/atm, d_4^{25} 0.839, n_D^{20} 1.418, $[\alpha]_D^{20}$ +14 (neat), the *S*-(-)- enantiomer has** *[50418-68-3]* **$[\alpha]_D^{20}$ -14.5 (c 2.5, EtOH), n_D^{20} 1.412.** The enantiomeric oxiranes have been purified by passage through a silica gel column in pentane and eluted with pentane/Et_2O. The eluate is evaporated and subjected to bulb-to-bulb distillation in a vacuum. The enantiomeric purity is checked by HPLC. [White & Emmons *Tetra-*

hedron **17** 31 *1962*, DOI:10.1016/S0040-4020(01)99002-7; Johnson & Rogers *J Org Chem* **38** 1793 *1973*, DOI: 10.1021/jo00950a005; *Beilstein* **17** H 17, **17** I 11, **17** III/IV 111, **17/1** V 138.]

Histamine [4-(2-aminoethyl)imidazole, β-aminoethylglyoxaline, 1*H*-imidazole-4-ethanamine] *[51-45-6]* **$C_5H_9N_3$, M 111.2, m 83-84°, 86° (sealed tube), b 167°/0.8mm, 209°/18mm, pK_1^{25} 6.02, pK_2^{25} 9.70.** It was prepared by decarboxylation of histidine monohydrochloride with concentrated HCl at 265-270° in a sealed tube for 3 hours, cooled, evaporated, neutralised and treated with picric acid to isolate ***histamine dipicrate*** **m 233-235°** which crystallised from H_2O. Repeated recrystallisation from H_2O gave the ***monopicrate*** which also had **m 233-234°**. Similar treatment of ***histidine monohydrochloride*** with 20% aqueous H_2SO_4 at 265-270°/sealed tube/3hrs, cooled, basified with Na_2CO_3 until no further precipitation (Na_2SO_4), filtered, and the filtrate evaporated to a small volume and mixed with saturated picric acid to isolate histamine as its picrate. *Alternatively*, *N*-benzoylhistidine (prepared by the Schtotten-Baumann method) was heated in a vacuum at 240° until frothing ceased, the dark tarry mass was dissolved in concentrated HCl and hydrolysed at 180°, cooled, treated with H_2O, benzoic acid was filtered off. The filtrate was extracted with Et_2O (to remove all the benzoic acid), neutralised, treated with aqueous picrolonic acid and ***histamine picrolonate*** was isolated after recrystallising from EtOH (bunched yellow needles) **m 262-264°** (**m 233-234°, 266°** also reported). The yield of histamine, as calculated from the isolated picrates and picrolonate, from the three procedures were ~20% to 25%. [Ewins & Pyman *J Chem Soc* 339 *1911*, DOI: 10.1039/CT9119900339.]
In an alternative procedure Windaus & Vogt [*Chem Ber* **40** 3691 *1907*, DOI: 10.1002/cber.190704003164] converted ***ethyl 3-(imidazol-4-yl)propionate*** into its ***hydrazide*** (**m 142°**) (3.08g) which on treatment with amylnitrite (2.34g) in EtOH (15ml) followed by ethanolic HCl (0.73g), allowing to stand for 1 hour at ~25°, then heating until evolution of N_2 ceased, and heating in a boiling water-bath for 8 hours, was evaporated to dryness. The resulting urethane was hydrolysed with boiling concentrated HCl. Evaporation to dryness provided ***histamine dihydrochloride*** (see below) in 55% yield which crystallised in prisms from EtOH.
Pyman [*J Chem Soc* 530 *1912*, DOI: 10.1039/CT9120100530] isolated the ***free base*** by mixing an aqueous solution of a pure salt (***dihydrobromide*** or ***diphosphate***, and presumably ***dihydrochloride*** see below) with excess Na_2CO_3, evaporating completely dry in a vacuum, and extracting with cold $CHCl_3$. The extract was dried with NaOH, evaporated to a small volume and on keeping, the base crystallised in clear, colourless, wedge-shaped plates which melted at **83-84° (corr),** after softening a few degrees earlier. An analytical sample was obtained by drying in a vacuum over H_2SO_4. The ***free base*** is soluble in H_2O or EtOH, readily soluble in hot $CHCl_3$, but sparingly so in cold $CHCl_3$, and practically insoluble in Et_2O. It distils at **209-210°/18mm**, into a very viscous colourless oil which solidifies on seeding into a colourless crystalline mass. It also crystallises from *benzene. It is best stored as the dihydrochloride or preferably as the diphosphate (see below) because the ***free base*** is strongly basic (see pKa values above) and likely to absorb CO_2 from the atmosphere to form carbonate-carbamate salts. It forms an anhydrous ***monohydrobromide*** **m 182-183°** (from absolute EtOH in prismatic rods) which is soluble in H_2O forming a strongly alkaline solution, but is sparingly soluble in cold EtOH. It is a potent endogenous vasodilator as it is a histamine receptor agonist and activates nitric oxide synthase. [*Beilstein* **25** I 628, **25** II 302, **25** III/IV 2049.]
Histamine dihydrochloride **(Maxamine)** *[56-92-8]* **$C_5H_9N_3$. 2HCl, M 184.1,** has **m 249-252°(244-245°).** The dihydrochloride crystallises from aqueous EtOH, Et_2O-Me_2CO (plates) or H_2O (prisms). It is freely soluble in excess H_2O and MeOH. [*Beilstein* **25** III/IV 2049.] See previous entry for biological activity.
Histamine diphosphate *[51-74-1]* **$C_5H_9N_3$. 2 H_3PO_4, M 307.2,** has **m 132-133°(corr).** The phosphate is particularly suitable for characterising and purifying histamine on account of its crystalline form, sparing solubility in H_2O, and in almost trebleling the weight of the free base. It is soluble in only four parts of H_2O, but freely soluble in hot H_2O from which it separates in magnificent ***anhydrous***, clear, colourless, quadrihedral prisms, belonging to the monoclinic system. The crystals are almost completely capped by a pair of pyramid faces, with a diminutive second pair present and usually with a basal plane. Crystals resembling **augite**, with half inch lengths and quarter inch breadth can be deposited from only a few grams of phosphate. [Isolation: Pyman *J Chem Soc* 530 *1912*, DOI: 10.1039/CT9120100530; *Beilstein* **25** I 630.] See above for biological activity.

Homopiperazine (1,4-diazepane) *[505-66-8]* **$C_5H_{12}N_2$, M 100.2, m 38-40°, 43°, b 60°/10mm, 92°/50mm, 169°/atm, pK_1^{20} 6.70, pK_2^{20} 10.41.** Purify it by fractionation through a column of 10 theoretical plates with a reflux ratio of 3:1. It boils at 169°, and the cool distillate crystallises in plates **m 43°**. [Poppelsdorf and Myerly *J Org Chem* **26** 131 *1961*, DOI: 10.1021/jo01060a031] Its pKa values are 6.67 and 10.09 at 29.7°, and 6.28 and

9.86 at 40° [Pagano et al. *J Phys Chem* **65** 1062 *1961*, DOI: 10.1021/j100824a513]. The ***1,4-bis(4-bromobenzoyl) derivative*** has **m 194-198°** (from EtOH); the ***hydrochloride*** has **m 270-290°** (from EtOH) and the ***picrate*** has **m 265°(dec)** [Lloyd et al. *J Chem Soc (C)* 780 *1966*, DOI: 10.1039/J39660000780]. [*Beilstein* **23** III/IV 388, **23/3** V 240.] It is an antihypertensive.

1-Hydrazinophthalazine (hydralazine, Alphapress) *[86-54-4]* **$C_8H_8N_4$, M 160.1, m 172-173°(dec), pK_1^{25} 2.90, pK_2^{25} 7.25 (NNH_2).** It crystallises from MeOH. Its UV has λ_{max} at 656nm at pH ~11. It complexes with Bi^{3+}, Zn^{2+}, Fe^{2+} and Co^{2+}. The ***hydrochloride (hydralazine hydrochloride)*** *[304-20-1]* $C_8H_8N_4$. HCl, **M 196.6,** also crystallises from MeOH and has **m 172-173°(dec).** [Druey & Ringier *Helv Chim Acta* **34** 195 *1951*, DOI: 10.1002/hlca.19510340122; *Beilstein* **25** III/IV 4552.] It is an antihypertensive.

2-Hydrazinopyridine *[4930-98-7]* **$C_5H_7N_3$, M 109.1, m 41-44°, 46-47°, 49-50°, b 90-92°/1mm, 105°/5mm, 128-135°/13mm.** Purify it by distillation under a vacuum and by recrystallisation from Et_2O/hexane. [Kauffmann et al. *Justus Liebigs Ann Chem* **656** 103 *1962*, DOI: 10.1002/jlac.19626560116; Potts & Burton *J Org Chem* **31** 251 *1966*, DOI: 10.1021/jo01339a057.] The ***mono-hydrochloride*** has **m 183°(dec)** from aqueous HCl, and the ***di-hydrochloride*** *[62437-99-4]* $C_5H_7N_3$. 2HCl, M 182.1, has **m 214-215°**. [*Beilstein* **22** II 487, **22** III/IV 7025, **22/14** V 486.]

4-Hydroxyacridine (4-acridinol, neo-oxine) *[18123-20-1]* **$C_{13}H_9NO$, M 195.2, m 116.5°, 122-123°, pK_1^{15} 5.28, pK_2^{15} 9.75.** Crystallise neo-oxine from EtOH or aqueous EtOH. It complexes with Zn^{2+}, Cd^{2+}, Ga^{2+}, Pb^{2+}, Cr^{2+}, Mn^{2+}, Fe^{2+}, Co^{2+} and Ni^{2+}. The ***hydrochloride*** crystallises from EtOH with **m 242°**. [*Beilstein* **21** II 78, **21** III/IV 1562, **21/4** V 90.]

1-Hydroxy-1,2-benziodoxol-3(1*H*)-one (IBX, 2-iodoxybenzoic acid) *[61717-82-6]* **$C_7H_5IO_4$, M 280.0, m 224-225°, 226-234°, 232-233°(dec), 233°(dec), pK <4.** IBX prepared by the Dess-Martin procedure ($KBrO_3/H_2SO_4$) [Dess & Martin *J Am Chem Soc* **113** 7277 *1991*, DOI: 10.1021/ja00019a027] has been reported as being explosive and comparable to TNT [Hartmann & Meyer *Chem Ber* **26** 1727 *1893*, DOI: 10.1002/cber.189302602109; Plumb & Harper *Chem Eng News* (July 16) 3 *1990*] when apparently the iodine content was below 43.5% (theoretical value is 45.32%). In an attempt to avoid this, **IBX** has been washed with H_2O and EtOH to render it non-explosive. Although deliberate attempts to detonate it on several occasions have been unsuccessful; operators should exercise CAUTION however when working with **IBX** particularly with large scale preparations. This is among the substances for which it may be difficult to obtain permission to transport it, so detailed preparations are described here.

Dess-Martin method: To a vigorously stirred mixture of 2-iodobenzoic acid (85.2g, 340mmol, see *[88-67-5]*) and 0.73 M H_2SO_4 (730ml) in a bath at 55° is added $KBrO_3$ (76.0g, 450mmol) over 1 hour. The mixture is stirred further for 3.6 hours at 65°, cooled in an ice bath, and the solid is filtered off, washed with H_2O (1000ml) then EtOH (2 x 50ml) and dried *in vacuo* to give BTX (89.1g, 320mmol, 93%) of analytical purity. [Dess & Martin *J Am Chem Soc* **113** 7277 *1991*, DOI: 10.1021/ja00019a027]

Santagostino et al.'s method: To ***oxone*** (181.0g, 290mmol, see *[70693-62-8]* $2KHSO_5—KHSO_4—K_2SO_4$ triple salt) in deionised H_2O (650ml, 450mmol) is added rapidly 2-iodobenzoic acid (50.0g, 200mmol), and kept at 70-73° for 20 minutes then stirred mechanically at 70-73° for 3 hours. Initially a thick slurry coating along the walls of the container is formed which gradually becomes finely dispersed and the now easily stirred suspension readily sediments if stirring is interrupted. The mixture is then stirred slowly at 5° for 1.5 hours, the white crystalline solid is collected onto a medium porosity sintered-glass funnel, washed with H_2O (6 x 100ml) and Me_2CO (2 x 100ml) then Et_2O, and left in dry air for 16 hours to give IBX (44.8 to 45.7g, ~80%). The filtrates are disposed of by treating with solid Na_2SO_3 (70g, 55mmol) and neutralising with M aqueous NaOH. Analysis indicated that the purity was ≥95% (judging by the ^1H NMR integrals of the triplets at 7.84 and 7.47 ppm, and elemental analysis), and it contained 2-iodosobenzoic acid (~4%) and 2-iodobenzoic acid (~0.5%). **IBX** of analytical purity (≥99%) is similarly obtained on a small scale by adding 2-iodobenzoic acid (5.0g, 20mmol) to a solution of oxone in deionised H_2O (37.2g, 61mmol, in 200ml), and the suspension is kept at 70° for 1 hour when it becomes clear. After 0.5 hours at 0-5° the white crystals that separate are collected, washed and dried as before to give analytically pure **IBX** (4.4g, 77%), m 233° (dec). This procedure is more environmentally friendly than the Dess-Martin procedure. [Frigerio et al. *J Org Chem* **64** 4537 *1999*, DOI: 10.1021/jo9824596.] It has IR (film) with a ν_{max} at 1640 cm^{-1}; the ^1H NMR (DMSOd_6, TMS) has δ at 8.15 (d,

1H), 8.01 (d, 1H), 7.89 (t, 1H), and 7.84 (t, 1H); and for ^{13}C NMR see reference see Frigerio and Santagostino [*Tetrahedron Lett* **35** 8019 *1994*, DOI: 10.1016/0040-4039(94)80038-3].
SIBX is an even more stabilised, non-explosive formulation that has all the oxidative characteristics of **IBX**. It is prepared as follows: 2-iodobenzoic acid (200g) and isophthalic acid (133g, see *[121-91-5]*) are added into a solution of oxone (625g) in H_2O (2000ml) and kept at 70° for 3 hours, then sodium benzoate (128g) in H_2O (500ml) is added at 40°. The precipitate that is formed on cooling to 20° is filtered off, washed with H_2O (700ml) and dried in a ventilated oven at 60° to give **SBTX** (420g, 90%) containing 49% w/w of active **IBX**. [Ozanne et al. *Org Lett* **5** 2903 *2003*, DOI: 10.1021/ol0349965.]
SIBX and/or **IBX** are water tolerant, inexpensive to prepare and easy to use. They oxidise primary and secondary alcohols smoothly to aldehydes and ketones, and vicinal diols are oxidised to mono and/or dicarbonyl compounds without C-C cleavage [Frigerio & Santagostino *Tetrahedron Lett* **35** 8019 *1994*, DOI: 10.1016/0040-4039(94)80038-3], as well as allylic and benzylic alcohols to respective aldehydes [Ozanne et al. *Org Lett* **5** 2903 *2003*, DOI: 10.1021/ol0349965], amino alcohols to amino carbonyls without amino protection [Chen & Aduda *Synth Commun* **37** 3493 *2007*, DOI: 10.1080/00397910701555469], and sensitive heterocyclic substituents are not affected [Frigeio et al. *J Org Chem* **60** 7272 *1995*, DOI: 10.1021/ jo00127a036]. The structure and kinetics of the reactive intermediates in the oxidation have been studied in detail [Munari et al. *J Org Chem* **61** 9272 *1961*, DOI: 10.1021/jo961044m]. The reagents are generally sparingly soluble in organic solvents such as EtOAc, THF, Me_2CO, MeCN, toluene, DMSO and *N*-methylpyrrolidine, but the reactions usually proceed in these solvents, or mixtures of them, with ease and in good to excellent yields either at room temperature or at as high as reflux temperatures.

2-Hydroxybenzothiazole (benzothiazol-2(3*H*)-one) *[934-34-9]* **C_7H_5NOS, M 151.1, m 140-141°,** Crystallise it from aqueous EtOH or water. [Hoggarth *J Chem Soc* 3311 *1949*, DOI: 10.1039/JR9490003311; Hunter *J Chem Soc* 125 1930, DOI: 10.1039/JR9300000125; *Beilstein* **27** H 182, **27** I 270, **27** II 225, **27** III/IV 2693.]

1-Hydroxybenzotriazole hydrate (HOBt) *[2592-95-2; 123333-53-9 (H_2O)]* **$C_6H_5N_3O.xH_2O$, M 135.1, m 155-158°, 157°, 159-160°, pK^{20} 7.88.** Crystallise HOBt from hot aqueous EtOH or water (charcoal). It is prepared from *o*-nitrophenylhydrazine or its hydrochloride dissolved in a small volume of H_2O by treating with 25% of aqueous KOH or aqueous ammonia whereby the mixture warms up immediately and discolours. After the mixture cools to room temperature it is acidified with hydrochloric acid and the ***hydroxybenzotriazole*** separates as colourless needles. It is soluble in hot H_2O, EtOH and AcOH, but much less soluble in Et_2O, petroleum ether, $*C_6H_6$ and $CHCl_3$. It is an acid and forms metal salts such the ***Pb salt*** which crystallises from hot H_2O in glistening leaflets with **m 270°**. In aqueous solution it exists mainly as the zwitterionic N-oxide tautomer with H^+ on N-2. [Nietzki & Braunschweig *Chem Ber* **27** 3381 *1894*, DOI: 10.1002/cber.189402703148; Zincke & Schwartz *Justus Liebigs Ann Chem* **311** 329 *1900*, DOI: 10.1002/jlac.19003110304; Boyle & Jones *JCS Perkin Trans II* 160 *1973*, DOI: 10.1039/P29730000160; Tomita & Ikawa *J Pharm Soc Jpn* **75** 449 *1955*, *Beilstein* **26** III/IV 95.] It is a useful reagent for peptide synthesis [Heusel et al. *Angew Chem Int Ed* **16** 642 *1977*, DOI: 10.1002/anie.197706421].
§ A polystyrene supported version is commercially available. For use in solid phase peptide synthesis, see Dryland & Sheppard *JCS Perkin Trans 1* 125 *1986*, DOI: 10.1039/P19860000125.

4-Hydroxycoumarin (4-hydroxy-1-benzopyran-2-one) *[1076-38-6]* **$C_9H_6O_3$, M 162.1, m 206°, 211-213°, pK_{Est} ~9.0.** Crystallise 4-hydroxycoumarin from water and dry it in a vacuum desiccator over Sicapent. [*Beilstein* **18/1** V 378.]

N*-2-Hydroxyethylpiperazine-*N*'-2-ethanesulfonic acid (HEPES)** *[7365-45-9]* **$C_8H_{18}N_2O_4S$, M 238.3, pK^{20} 7.55.** Crystallise the acid from hot EtOH and water. The ***disodium salt *[75277-39-3]* $C_8H_{17}N_2NaO_4S$, M 260.3, is purified by dissolving in the minimum volume of H_2O and adding EtOH, then drying *in vacuo*. They are useful buffers in the pH range 6.8—8.2. [*Beilstein* **23** V 376.]

3-Hydroxyflavone (Flavanol) *[577-85-5]* **$C_{15}H_{10}O_3$, M 238.2, m 169-170°, 171-172°.** Recrystallise it from MeOH (**m 169.5-170°**), EtOH, aqueous EtOH (**m 167°**) or hexane. It has also been purified by repeated sublimation under high vacuum, and dried at high vacuum pumping for at least one hour [Brucker & Kelley *J Phys Chem* **91** 2856 *1987*, DOI: 10.1021/j100295a040]. [*Beilstein* **17** H 527, **17** I 268, **17** II 498, **17** III/IV 6428.]

7-Hydroxy-4-methylcoumarin (4-methylumbelliferone(β) hydrate) *[90-33-5]* **$C_{10}H_8O_3.H_2O$, M 194.2, m 185-186°, 188-188.5°, 194-195°, pK^{25} 7.80 (phenolic OH).** Purify it by recrystallisation from EtOH. It is very slightly soluble in cold H_2O (solubility at 37° is 0.22%), slightly soluble in Et_2O and $CHCl_3$, but soluble in MeOH and AcOH. It has a blue fluorescence in aqueous EtOH and has UV with λ_{max} at 221, 251 and 322.5nm (MeOH). The IR has ν_{max} at 3077 br, 1667, 1592, 1385, 1267, 1156, 1130 and 1066 cm^{-1}. The ***acetate*** has **m 153-154°**. It is highly fluorescent in alkaline solution. [Woods & Sapp *J Org Chem* **27** 3703 *1962*, DOI: 10.1021/jo01057a519; *Beilstein* **18** III/IV 332, **18/1** V 439.]

2-Hydroxymethyl-12-crown-4 *[75507-26-5]* **$C_9H_{18}O_5$, M 206.2, b 115°/0.04mm, d_4^{20} 1.186, n_D^{20} 1.480.** Purify it by chromatography on Al_2O_3 with EtOAc as eluent to give a ***hygroscopic*** colourless oil, which is distilled under high vacuum and is distilled *in vacuo*. It has IR with ν_{max} at 3418 (OH) and 1103 (COC) cm^{-1}, and NMR: δ 3.70s. [Kimura et al. *JCS Chem Commun* 492 *1983*, DOI: 10.1039/C39830000492; Pugia et al. *J Org Chem* **52** 2617 *1987*, DOI: 10.1021/jo00388a057.]

***S*-(-)-5-Hydroxymethyl-2(5*H*)-furanone** *[78508-96-0]* **$C_5H_6O_3$, M 114.1, 39-42°, 41-43°, 40-44°, b 130°/0.3mm, $[\alpha]_{546}^{20}$ -180, $[\alpha]_D^{20}$ -148 (c 1.4, H_2O).** It is purified by chromatography on Silica gel using hexane/EtOAc (1:1) to give a colourless oil which is distilled using a Kügelrohr apparatus, and the distillate crystallises on cooling. It has R_F 0.51 on Whatman No 1 paper using pentan-1-ol and 85% formic acid (1:1) and developing with ammoniacal $AgNO_3$. [Boll *Acta Chem Scand* **22** 3245 *1968*, DOI: 10.3891/acta.chem.scand.22-3245; NMR: Oppolzer et al. *Helv Chim Acta* **68** 2100 *1985*, DOI: 10.1002/hlca.19850680803; *Beilstein* **18** III/IV 56, **18/1** V 54.]

5-(Hydroxymethyl)furfural *[67-47-0]* **$C_6H_6O_3$, M 126.1, m 28-34°, 33.5°, b 114-116°/1mm, d_{25}^{25} 1.2620, n_D^{25} 1.5533.** Crystallise it from diethyl ether/petroleum ether. [*Beilstein* **18** III/IV 100, **18/1** V 130.]

***dl*-3-Hydroxy-*N*-methylmorphinan (Racemorphan)**, see entry in 'Physiologically Active……', in Chapter 6.

8-Hydroxy-2-methylquinoline *[826-81-3]* **$C_{10}H_9NO$, M 159.2, m 71-73°, 74-75°, b 266-267°/atm, pK_1^{25} 5.61, pK_2^{25} 10.16.** Crystallise the quinoline from EtOH or aqueous EtOH. Its solubility at 20° in H_2O is 0.366g/L, and in $CHCl_3$ it is 466g/L. It complexes with many metals. [*Beilstein* **21** H 106, **21** III/IV 2132, **21/3** V 341.]

4-Hydroxy-2-*n*-nonylquinoline *N*-oxide *[316-66-5]* **M 287.4, m 148-149°, pK_{Est} ~6.0.** Crystallise the *N*-oxide from EtOH. Its UV has λ_{max} at 220-230nm in 0.001N NaOH. [Cornforth & James *Biochem J* **63** 124 *1956*, DOI: 10.1042/bj0630124; *Beilstein* **21** III/IV 3834.]

1-Hydroxyphenazine (Hemipyocyanine) *[528-71-2]* **$C_{12}H_8N_2O$, M 196.2, m 156-160°, 157-158°, 165-166°, pK_1^{15} 1.61, pK_2^{15} 8.33 (10% aqueous MeOH)** Purify the hydroxyphenazine by chromatography on acidic alumina with *benzene/ether, and recrystallise it from aqueous EtOH, *benzene/heptane, then sublime it at 140°/1.5mm. It forms a red ***chloride*** or ***sulfate salt***. When dissolved in alkaline solution it gives a purple-red colour which turns yellow on dilution. [UV, IR: Badger et al. *J Chem Soc* 3204 *1951*, DOI: 10.1039/JR9510003204; Hegedüs *Helv Chim Acta* **33** 766 *1950*, DOI: 10.1002/hlca.19500330340; *Beilstein* **23** II 360, **23** III/IV 2753.]

2-(2-Hydroxyphenyl)benzothiazole *[3411-95-8]* **$C_{13}H_9NOS$, M 227.2, m 128-132°, 132-133°, b 173-179°/3mm.** Recrystallise it several times from aqueous EtOH or dilute AcOH and sublime it. [Itoh & Fujiwara *J Am Chem Soc* **107** 1561 *1985*, DOI: 10.1021/ja00292a018; Bogert & Corbitt *J Am Chem Soc* **48** 783 *1926*, DOI: 10.1021/ja01414a040; *Beilstein* **27** H 118, **27** II 91.]

2-(2-Hydroxyphenyl)benzoxazole *[835-64-3]* **$C_{13}H_9NO_2$, M 211.2, m 122-124°, 127°, b 338°/760mm.** Recrystallise it several times from aqueous EtOH or dilute AcOH and sublime it. An aqueous alkaline solution containing EtOH has a blue fluorescence. [Itoh & Fujiwara *J Am Chem Soc* **107** 1561 *1985*, DOI: 10.1021/ja00292a018; *Beilstein* **27** II 91.]

3-Hydroxy-2-phenylcinchoninic acid (Oxycincophen) *[485-89-2]* **$C_{16}H_{11}NO_3$, M 265.3, m 206-207°(dec).** It is precipitated from alkaline solution on acidification, and crystallises from EtOH or AcOH in yellow prisms. It has antidiuretic properties. [Marshall & Blanchard *J Pharmacol Exp Ther* **95** 186 *1949*, PMID: 18124061; *Beilstein* **22** H 245, **22** II 183, **22** III/IV 2383.]

(±)-2-(α-Hydroxypropyl)piperidine [2-piperidinepropanol, *RS*-1-(*SR*-2-piperidyl)propan-1-ol, (±)-α-conhydrine] *[8338-62-8, 63401-12-7, 24448-89-3]* **$C_8H_{17}NO$, M 143.2, m 99-100°, pK_{Est} ~10.2.** Crystallise it from ether. The **[*RS-1-(SR-2)*-isomer** also crystallises from ether and has **m** 98-98.5°. The ***methiodide*** crystallises from Me_2CO/MeOH with **m 127-130.5°**. **POISONOUS** [Synth: Shono et al. *Tetrahedron Lett* **24** 4457 *1983*, DOI: 10.1016/S0040-4039(00)85960-2; Sicher & Tichy *Coll Czech Chem Commun* **23** 2081 *1958*, DOI: 10.1135/cccc19582081; Govindachari & Rajappa *J Chem Soc* 1297, 1306 *1958*, DOI: 10.1039/JR9580001297; Stereochemistry: Hill *J Am Chem Soc* **80** 1609 *1958*, DOI: 10.1021/ja01540a025; *Beilstein* **21** II 21, **21** III/IV 122.]
(+)-2-(α-Hydroxypropyl)piperidine **[2-piperidinepropanol, *R*-1-(*S*-2-piperidyl)propan-1-ol, (+)-α-conhydrine]** *[495-20-5]* has **m 121°, b 224-5°/720mm, 226°/atm, $[\alpha]_D^{20}$ +9.8 (c 4, EtOH), +10 (c 10, EtOH), pK_{Est} ~10.2.** This very **POISONOUS** alkaloid from hemlock crystallises in leaflets from ether, or from H_2O. The ***O,N-dibenzoyl derivative*** has **m 133-134°** and $[\alpha]_D^{24}$ -13 (c 3, $CHCl_3$). The ***acetate*** has **b 133-135°/3mm**. (±)-7-(2-Hydroxypropyl)theophylline (Proxyphylline, 1,3-dimethyl-3*H*,7*H*-purine-2,6-dione) *[603-00-9]* **$C_{10}H_{14}N_4O_3$, M 238.2, m 135-136°.** Crystallise it from EtOH, aqueous MeOH or EtOAc. It is a vaso(broncho) dilator. [Roth *Archiv Pharmazie* **292** 234 *1959*, DOI: 10.1002/ardp.19592920504; Zelnik et al. *Bull Soc Chim Fr* 1733 *1956*, *Beilstein* **26** III/IV 2366.]

6-Hydroxypurine (hypoxanthine) *[68-94-0]* **$C_5H_4N_4O$, M 136.1, m 150°(dec), >300°(dec), pK_1^{20} 1.98, pK_2^{20} 8.96, pK_3^{20} 12.18.** Crystallise it from hot water (solubility (w/v) is 0.07%at ~20° and 1.42% at ~100°) and dry it at 105°. [Lister *Purines Part II, Fused Pyrimidines* Brown Ed, Wiley-Interscience pp254-225 *1971*, ISBN 0-471-38205-1, *Beilstein* **26** II 252, **26** III/IV 2081.]

2-Hydroxypyridine (2-pyridone) *[142-08-5]* **C_5H_5NO, M 95.1, m 105-107°, 107.8°, b 181-185°/24mm, 280-281°/atm, d^{20} 3.1g/cm^3, ε_{293nm} 5900 (H_2O) pK_1^{25} 1.25 (0.75), pK_2^{25} 11.99 (11.62).** It has been prepared from 2-aminopyrdine and nitrous acid [Adams & Jones *J Am Chem Soc* **69** 1803 *1947*, DOI: 10.1021/ja01199a067], from pyridine N-oxide and Ac_2O, pyridine and KOH at 300°, or 2-chloropyridine and dilute miniral acid. X-ray analysis by Penfold [*Acta Cryst* **6** 591 *1953* DOI: 10.1107/S0365110X5300168X, **6** 707 *1953*, DOI: 10.1107/S0365110X5300199X] who showed that it has the ***pyridone*** structure in the solid state, and UV spectral comparisons support this structure in solution, rather than the 2-hydroxypyridine structure since the UV spectra are similar to those of 1-methyl-2-pyridone and not to those of 2-methoxypyridine. [Mason *J Chem Soc* 5010 *1957*, DOI: 10.1039/JR9570005010; Mason *J Chem Soc* 1253 *1959*, DOI: 10.1039/JR9590001253; UV: Armarego in *Physical Methods in Heterocyclic Chemistry* (Ed Katritzky, Academic Press, LCCC No 62-12037, Internet Public Domain) **Vol III** 79 *1971*]. Distil 2-pyridone under vacuum to remove coloured impurity, then recrystallise from *benzene, CCl_4, Me_2CO or EtOH. It can be sublimed under high vacuum then recrystallised from $CHCl_3$/diethyl ether. [DePue et al. *J Am Chem Soc* **107** 2131 *1985*, DOI: 10.1021/ja00293a050; *Beilstein* **21/7** V 106.]
1-Methyl-2-pyridone *[694-85-9, 94071-56-4]* **C_6H_7NO, M 109.1, m 30-32°, b 250°/740mm, d^{20} 1.11g/cm^3, pK^{20} 0.32.** It has been prepared in 65-70% yield by converting pyridine to ***1-methylpyridnium methosulfate*** with dimethyl sulfate followed by oxidation with $K_3Fe(CN)_6$/NaOH/H_2O, salting out with Na_2CO_3, extracting with isoamyl alcohol and distilling under vacuum. It distils at **b 121°/10mm, 126°/12.5mm** and **130°/14.5mm.**

[Prill & McElvain *Org Synth* Coll Vol **2** 418 *1943*, *Org Synth* **15** 41 *1935*, DOI: 10.15227/orgsyn.015.0041.]
2-Methoxypyridine *[1628-89-3]* **C_6H_7NO, M 109.1, b 142°/760mm, d ^{25} 1.038g/ml, n $^{20}_{D}$ 1.503, pK^{20} 3.28,** is obtained by reaction of 2-chloropyridine with MeOH and is purified by distillation after washing with H_2O (at pH slightly higher than 7).
2-Pyridyl acetate (2-acetoxypyridine) *[3847-19-6]* **$C_7H_7NO_7$, M 137.1,** prepared by treating the sodium salt of 2-pyridone with acetyl chloride and purified by vacuum distillation, has **b 110-112°/10mm.** This ***acetate*** is a useful acetylating agent and in THF, xylene or neat, it will acetylate a variety of alcohols, phenols and amines in yields generally above 80%. It is more reactive than 3-pyridyl acetate (see below) in Friedel-Crafts reactions (in the presence of $AlCl_3$, or better BF_3) as in the acylation of $*C_6H_6$, toluene (mostly *p*-) and anisole (mostly *p*-) [Ueno et al. *Bull Chem Soc Jpn* **37** 864 *1964*, DOI: 10.1246/bcsj.37.864].
3-Hydroxypyridine *[109-00-2]* **C_5H_5NO, M 95.1,** has **m 125-128°, 129°, 130°, pK $^{25}_{1}$ 5.10 (4.88), pK $^{25}_{2}$ 8.60 (8.72).** 3-Hydroxypyridine was obtained by fusing pyridine-3-sulfonic acid with KOH, or by decomposing pyridine-3-diazonium salts with H_2O and purified by recrystallisation from $*C_6H_6$, water or EtOH. Unlike the 2- and 4- isomers it cannot tautomerises to an amide-like pyridine, and displays properties not unlike phenols, e.g. gives a colour with $FeCl_3$. It has zwitterionic properties and when alkylated, e.g. with MeI/*n*-PrOH, it forms the *N*-methyl zwitterion which can be converted into ***N-methyl-3-hydroxypyridinium iodide*** **m 109-111°** and the ***picrate*** **m 201-202°**. [Shapiro et al. *J Am Chem Soc* **81** 5140 *1959*, DOI: 10.1021/ja01528a030; Albert & Phillips *J Chem Soc* 1294 *1956*, DOI: 10.1039/JR9560001294; Metzler & Snell *J Am Chem Soc* **77** 2431 *1955*, DOI: 10.1021/ja01614a022; and for UV see Mason *J Chem Soc* 1253 *1959*, DOI: 10.1039/JR9590001253; and Armarego in *Physical Methods in Heterocyclic Chemistry* (Ed Katritzky, Academic Press, LCCC No 62-12037, Internet Public Domain) **Vol III** 79 *1971*.] Methylation of 3-hydroxy-pyridine with diazomethane normally provides the *N*-methyl compound, however diazomethane in *tert*-BuOH at -15° gives ***3-methoxypyridine*** *[7295-76-3]* **C_6H_7NO, M 109.1, b 65°/15mm, d ^{25} 1.083g/ml, n $^{20}_{D}$ 1.518, pK^{20} 4.88,** in 70% yield and is purified by vacuum distillation [Prins *Recl Trav Chim Pays-Bas* **76** 58 *1957*, DOI: 10.1002/recl.19570760107]. **3-Pyridyl acetate (3-acetoxypyridine)** *[17747-43-2]* **$C_7H_7NO_7$, M 137.1, b 92 °/9mm, d ^{25} 3.1g/ml, n $^{20}_{D}$ 1.503,** is obtained by acetylation with acetic anhydride, as with phenols and unlike the 2-pyridone (see above), is purified by vacuum distillation with **b 92 °/9mm**. Like the ***2-isomer*** (see above) it is an acetylating agent and undergoes the Friedel-Crafts reaction but is marginally less active [Ueno et al. *Bull Chem Soc Jpn* **37** 864 *1964*, DOI: 10.1246/bcsj.37.864]. [*Beilstein* **21** III/IV 402, **21/2** V 68.] 3-Hydroxypyridine forms esters with the terminal carboxy groups of N-protected peptides, using dicyclohexylcarbodiimide in EtOAc, whereby the carboxy groups is activated to form a peptide bond with an unprotected terminal NH_2 [Taschner et al. *Angew Chem Int Ed* **4** 594 *1965*, DOI: 10.1002/anie.196505941].
4-Hydroxypyridine **(4-pyridone)** *[626-64-2]* has **m 65°, 68° (hydrate), 148.5°, 150-151°, 151-152° (anhydr), b 230-235°/12mm, >350°/760mm, pK $^{20}_{1}$ 3.20, pK $^{20}_{2}$ 11.12.** It has been prepared from pyridine by treatment with $SOCl_2$ which forms 4-chloropyridine that reacts with pyridine to give N(4-pyridyl)-pyridinium chloride followed by hydrolysis with H_2O at 15°. Crystallise 4-pyridone from H_2O or wet $CHCl_3$ as the ***monohydrate***. It loses H_2O on drying *in vacuo* over H_2SO_4. Store it over KOH because it is ***hygroscopic***. Like 2-pyridone (see above) it exists in the keto ***4-one tautomer*** as evidenced by IR and Raman spectra [Spinner *J Chem Soc* 1226, 1232 *1960*,], and pKa and UV spectral comparison with 4-methoxypyridine and 1-methyl-4-pyridone [Mason *J Chem Soc* 5010 *1957*, DOI: 10.1039/JR9570005010; Mason *J Chem Soc* 1253 *1959*, DOI: 10.1039/JR9590001253; UV: Armarego in *Physical Methods in Heterocyclic Chemistry* (Ed Katritzky, Academic Press, LCCC No 62-12037, Internet Public Domain) **Vol III** 79 *1971*]. For protonated species see Katritzky and Jones [*Proc Chem Soc* 297 *1960*, DOI: 10.1039/PS9600000297]. [*Beilstein* **21** III/IV 446, **21/7** V 152.] ***4-Methoxypyridine*** *[620-08-6]* **C_6H_7NO, M 109.1, b 95°/45mm, 108-111°/65mm, 191°/738mm, d ^{25} 1.075g/ml, n $^{20}_{D}$ 1.516, pK^{20} 6.62,** like the ***2-isomer***, can be prepared from 4-chloropyridine and MeOH, washing the extracted product with aqueous bicarbonate before drying and distilling preferably under vacuum. Care should be taken that it should be free of traces of acid as this causes serious deterioration by polymerisation. ***1-Methyl-4-pyridone*** *[695-19-2]* **C_6H_7NO, M 109.1,** has **m 94.5-95.5°, b 188-192°/2.4mm, d ^{20} 1.11g/cm^3, pK^{20} 3.33.** Prepared from 4-pyridone and MeI, then washed with H_2O and recrystallised from MeOH. The ***hydrochloride*** crystallises from isoPrOH with **m 186-187°**.

2(6)-Hydroxypyridine-5(3)-carboxylic acid (6-hydroxynicotinic acid) *[5006-66-6]* **$C_6H_5NO_3$, M 139.1, m 304°(dec), pK $^{20}_{1}$ 3.82 (proton gain) and pK $^{20}_{2}$ 9.92 (proton loss).** It crystallises from water (400 parts and dried at 110°) with **m 303.4-303.7°(dec)**, or with **m 325°(dec)** from aqueous EtOH. The ***methyl ester*** crystallises from Me_2CO with **m 166°** and pK^{20} 9.92 (proton loss). Used in the synthesis of retinoids [Torrado

et al. *Synthesis* 285 *1995*, DOI: 10.1055/s-1995-3905]. [Synthesis, pKa and UV spectra: Albert *J Chem Soc* 1020 *1960*, DOI: 10.1039/JR9600001020, *Beilstein* **22** III/IV 2147, **22/6** V 119.]

4-Hydroxypyridine-2,6-dicarboxylic acid (chelidamic acid) *[138-60-3]* **$C_7H_5NO_5$. xH_2O, M 183.1, m 248°(dec, 1 H_2O), 254°(dec), 263°(dec), 268°(dec), pK_1^{22} 1.9, pK_2^{22} 3.18, pK_3^{22} 10.85; pK_1 3.62, pK_2 4.82 (80% aqueous methoxyethanol).** It crystallises from water. The ***dimethyl ester*** crystallises from MeOH with **m 167°**(***monohydrate***, from H_2O), **m 170-171°**(***anhydrous***, from MeOH), and has pK^{25} 6.25. [Bensaude et al. *J Am Chem Soc* **99** 4438 *1972*, DOI: 10.1021/ja00455a037; *Beilstein* **22** III/IV 2583, **22/7** V 164.]

2-Hydroxypyrimidine *[557-01-7]* **$C_4H_4N_2O$, M 96.1, m 179-180°, pK_1^{20} 2.24, pK_2^{20} 9.17.** It crystallises from EtOH or ethyl acetate. Its solubility in H_2O at 20° is 1g/2.2ml. [Albert *J Chem Soc* 4219 1952, DOI: 10.1039/JR9600001020; *Beilstein* **24** III/IV 194.]. ***2-Hydroxypyrimidine hydrochloride*** *[38353-09-2]* M 132.5, has **m 203-205.5°(dec)** and crystallises from EtOH. [*Beilstein* **24** III/IV 173.] The ***picrate*** has **m 199°** and crystallises from EtOH. [Brown et al. *J Chem Soc* 211 1955, DOI: 10.1039/JR9550000211.]
4-Hydroxypyrimidine *[4562-27-0, 51953-17-4]* has **m 163-167°, 164-165°, 166-169°, pK_1^{20} 1.66, pK_2^{20} 8.63.** It crystallises from *benzene or ethyl acetate. The ***picrate*** has **m 164-166°** and crystallises from EtOH [Brown et al. *J Chem Soc* 4035 *1955*, DOI: 10.1039/JR9550004035; *Beilstein* **24** III/IV 171.]

R*-(+)-3-Hydroxypyrrolidine** *[R(+) 2799-21-5, (±) 40499-83-0, S(-) 100243-39-8]* **C_4H_9NO, M 87.1, b 215-216°/atm, d_4^{20} 1.078, n_D^{20} 1.490, $[\alpha]_D^{20}$ +6.5 and -6.5 (c 1.5, MeOH), pK_{Est} ~10.1.** The ***(±)-base is purified by repeated distillation (**b 102-104°/12mm, 108-110°/18mm**), and the ***(±)-picrate*** crystallises from EtOH with **m 140-141°**. The ***R(+)-enantiomer*** has **b 70°/0.6mm** and $[\alpha]_D^{20}$ +5.6 (c 3.63, MeOH). Its ***hydrochloride*** *[104706-47-0]* M 123.6, **m 104-107°**, has a negative rotation $[\alpha]_D^{20}$ -7.6 (c 3.5, MeOH), and its ***dimethiodide*** has **m 230°** and $[\alpha]_D^{24}$ -8.02°. [Uno et al. *J Heterocycl Chem* **24** 1025 *1987*, DOI: 10.1002/jhet.5570240423; Flanagan & Joullie *Heterocycles* **26** 2247 *1987,* DOI: 10.3987/R-1987-08-2247; *Beilstein* **21** III/IV 44.]

2-Hydroxyquinoline (carbostyril) *[59-31-4]* **C_9H_7NO, M 145.2, m 198-199°, 199-200°, pK_1^{20} -0.31, pK_2^{20} 11.76.** Crystallise it from MeOH. It has **m 200-201°** after sublimation in a vacuum. The ***picrate*** has **m 132°** after crystallisation from Et_2O. [Gibson et al. *J Chem Soc* 4340 *1955*, DOI: 10.1039/JR9550004340; *Beilstein* **21** III/IV 1057, **21/8** V 217.]
8-Hydroxyquinoline **(oxine, 8-quinolinol)** *[148-24-3]* has **m 70-73°, 71-73°, 75-76°, 76°, b 122°/0.1mm, ~267°/752m, pK_1^{25} 4.91, pK_2^{25} 9.81.** Crystallise oxine from hot EtOH, acetone, petroleum ether (b 60-80°) or water. Crude oxine can be purified by precipitation of ***CuII oxinate*** *[13014-03-4]* $Cu(C_9H_7NO)_2$, **m** 240°(dec), followed by liberation of ***free oxine*** with H_2S or by steam distillation after acidification with H_2SO_4. Store it in the dark. It forms complexes with many metals or metal oxides on fusing or in solution. [Feigl & Heisig *Anal Chim Acta* **3** 561 *1949*, DOI: 10.1016/S0003-2670(00)87382-1]. The ***hemisulfate hemi-hydrate*** *[207386-91-2]* C_9H_7NO. $0.5H_2SO_4$. 0.5 H_2O, M 203.2 has **m 176-179°**. [Manske et al. *Can J Research* **27F** 359 *1949*, DOI:10.1139/cjr49f-038; Phillips *Chem Rev* **56** 271 *1956*, DOI: 10.1021/ cr50008a003; *Beilstein* **21** III/IV 1135, **21/3** V 252.]
8-Hydroxyquinoline-5-sulfonic acid **(H_2O)** *[84-88-8, 20946-17-2]* **$C_9H_7NO_4S$. H_2O, M 243.3,** has **m 322-323°(sintering at ~305°), >310°, pK_1^{25} 4.09, pK_2^{25} 8.66.** Crystallise the acid from water (as the ***1.5 hydrate***, **m 316-317°**) or dilute HCl (*ca* 2% by weight). It is a water-soluble metal complexing agent. [*Beilstein* **22** I 620, **22** II 313, **22** III/IV 3493.]

4-Hydroxy-2,2,6,6-tetramethylpiperidine *[2403-88-5]* **$C_9H_{19}NO$, M 157.3, m 129-131°, 130-131°, b 212-215°/atm, pK^{20} 10.05.** The piperidine crystallises from water as a ***hydrate***, and crystallises from dry ether or *C_6H_6 as the ***anhydrous*** base. The ***hydrochloride*** has **m 282-284°** (from EtOH/H_2O), and the ***formate*** has **m 207°(dec**, from EtOH/EtOAc). [Mailey & Day *J Org Chem* **22** 1061 *1957*, DOI: 10.1021/jo01360a017; *Beilstein* **21** I 195, **21** III/IV 146, **21/1** V 159.]

4(6)-Hydroxy-2,5,6(2,4,5)-triaminopyrimidine sulfate *[35011-47-3]* **$C_4H_7N_5O$. H_2SO_4, M 239.2, m >~300°, >340°, pK_1 2.0, pK_2 5.1, pK_3 10.1**. This salt has very low solubility in H_2O. It is best purified by conversion into the dihydrochloride salt, which is then re-converted to the insoluble sulfate salt. The sulfate salt (2.57g, 10mmoles) is suspended in H_2O (20ml) containing $BaCl_2$ (10mmoles) and stirred in a boiling water bath for 15 minutes. After cooling, the insoluble $BaSO_4$ is filtered off and washed with boiling H_2O (10ml). The

combined filtrate and washings are made acidic with HCl and evaporated to dryness. The residual hydrochloride salt is recrystallised from H_2O by adding concentrated HCl whereby the ***dihydrochloride salt*** separates as clusters which darken at 260° and dec > 300°[darkening > 360°]. [Baugh & Shaw *J Org Chem* **29** 3610 *1964*, DOI: 10.1021/jo01035a042; King & Spengley *J Chem Soc* 2144 *1952*, DOI: 10.1039/JR9520002144]. The ***hydrochloride*** is then dissolved in H_2O, and while hot an equivalent of H_2SO_4 is added when the ***sulfate*** separates as a white microcrystalline solid which is filtered off washed liberally with H_2O and dried in vacuum over P_2O_5. [Albert & Wood *J Appl Chem London* **3** 521 *1953*, UV: Cavalieri et al. *J Am Chem Soc* **70** 3875 *1948*, DOI: 10.1021/ja01191a102; see also Pfleiderer *Chem Ber* **90** 2272 *1957*, DOI: 10.1002/ cber.19570901022; Traube *Chem Ber* **33** 1371 *1900*, DOI: 10.1002/cber.190003301236.] The ***hydrochloride*** has **m > 300°**. [*Beilstein* **25** III/IV 3648.] It is a useful synthon for purines and pteridines.

3-Hydroxyxanthone (3-hydroxy-9*H*-9-xanthenone) *[3722-51-8]* **$C_{13}H_8O_3$, M 212.2, m 243°, 246°, 249-250°.** Purify the xanthone by chromatography on SiO_2 gel with petroleum ether/*C_6H_6. as eluent. Recrystallise it from *C_6H_6, EtOH or aqueous EtOH (white needles). It exhibits interesting two-step laser-excitation fluorescence spectra. The 9 C=O and 3-OH form a tautomeric couple, and it forms a resonance-stabilised anion and radical anion. An alkaline solution has a blue fluorescence. The ***acetate*** has **m 157-158°**, and the ***methyl ether*** *[3722-52-9]* $C_{14}H_{10}O_3$, M 226.2, forms plates with **m 129°** from aqueous EtOH. [Davies et al. *J Org Chem* **23** 307 *1958*, DOI: 10.1021/jo01096a610; Itoh et al. *J Am Chem Soc* **107** 4819 *1985*, DOI: 10.1021/ja00303a003; Atkinson & Heilbron *J Chem Soc* 2688 1926, DOI: 10.1039/JR9262902688; for spectroscopic and theoretical studies of protonation see Mizutani et al. *Bull Chem Soc Jpn*, DOI: org/10.1246/bcsj.47.1596]. Ibogaine (12-methoxybogamine) *[83-74-9]* **$C_{20}H_{26}N_2O$, M 310.4, m 152-153°, $[\alpha]_D^{20}$ -54° (EtOH), pK^{25} 8.1 (80% aqueous $MeOCH_2CH_2OH$).** Crystallise this akaloid from EtOH or aqueous EtOH and sublime it at 150°/0.01mm. It is soluble in organic solvents but insoluble in H_2O. The ***hydrochloride***, **m 299-300°(dec)**, $[\alpha]_D^{25}$ -63 (EtOH), is soluble in H_2O and alcohols. [Büchi et al. *J Am Chem Soc* **88** 3099 *1866*, DOI: 10.1021/ja00965a039; Rosenmund et al. *Chem Ber* **108** 1871 *1975*, DOI: 10.1002/cber.19751080611; *Beilstein* **23** III/IV 2742.]

Imidazole (glyoxaline) *[288-32-4]* **$C_3H_4N_2$, M 68.1, m 89.5-91°, 89-90°, b 140-145°/15mm, 256°/atm, 262-264°/atm, pK_1^{25} 6.99, pK_2^{25} 14.44**. Crystallise imidazole from *benzene, CCl_4, CH_2Cl_2, EtOH, petroleum ether, acetone/petroleum ether and distilled de-ionized water. Dry it at 40° under vacuum over P_2O_5. Distil it at low pressure. It is also purified by sublimation or by zone melting. [Snyder et al. *Org Synth* Coll Vol **3** 471 *1955*, DOI: 10.15227/orgsyn.022.0065; Bredereck et al. *Chem Ber* **97** 827 *1964*, DOI: 10.1002/cber.19640970326; Caswell & Spiro *J Am Chem Soc* **108** 6470 *1986*, DOI: 10.1021/ja00281a004.] ***^{15}N-imidazole*** crystallises from *benzene [Scholes et al. *J Am Chem Soc* **108** 1660 *1986*, DOI: 10.1021/ ja00267a041]. [*Beilstein* **23** II 34, **23** III/IV 564, **23/4** V 191.] The ***hydrochloride*** *[1467-16-9]* $C_3H_4N_2$. HCl, M 104.5, has **m 158-161°** on crystallisation from EtOH/HCl/Et_2O, and the ***sodium salt*** *[5587-42-8]* $C_3H_3N_2Na$, M 90.1, has **m 284°(dec)**. Imidazole is useful for buffers in the pH range 6.2—7.8.

1*H*-Indazole-3-carboxylic acid *[4498-67-3]* **$C_8H_6N_2O_2$, M 162.2, m 265-265.5°, 266-270°(dec), 268-268.5°, $pK_{Est(1)}$ ~4.5.** Purify the acid by recrystallisation from glacial acetic acid (charcoal), and dry the yellow crystals *in vacuo*. *Alternatively*, dissolve the acid in boiling H_2O, concentrate the solution to one third its volume, cool and collect the yellow powder. Its UV has λ_{max} (H_2O) at 295 (logε 3.88) nm. The ***ethyl ester*** (prepared *via* the acid chloride) has **m 139°** (from EtOH) and has λ_{max} (MeOH) at 393 nm; and the ***N-methylamide*** crystallises in tan needles from $MeNO_2$ with **m 191-191°** (**187-188.5°** was also reported). [Rousseau & Lindwall *J Am Chem Soc* **72** 3047 *1950*, DOI: 10.1021/ja01163a068; Snyder et al. *J Am Chem Soc* **74** 2009 *1952*, DOI: 10.1021/ja01128a042; *Beilstein* **25** H 129, **25** I 238, **25** II 128, **25** IV 808.]

1*H*, *2H*-Indazol-3-one (3-hydroxy-1*H*-indazole) $C_7H_6N_2O$, *[7364-25-2]* **M 134.1, m 250-252°, 253-254°, $pK_{Est(1)}$ ~6.0.** Purify indazol-3-one by recrystallisation from $MeNO_2$ or aqueous MeOH, and sublimation at 220°/0.1mm. In the UV it has λ_{max} in MeOH at 215 and 306 nm, and it is in the 3-OH form in ethanolic solution. There appears to be some controversy regarding the tautomeric form in the solid state, but the IR peak at ν_{max} 1627 cm^{-1} (KBr) supports the keto form. [Ainsworth *J Am Chem Soc* **79** 5242 *1957*, DOI: 10.1021/

ja01576a047; Elguero et al. *Adv Heterocycl Chem,* **Suppl 1** 354 *1976*, Chernokal'skii et al. *Khim Geterotsikl Soedin* 96 *1966*, *Beilstein* **24** H 111, **24** II 59, **24** III/IV 270.]

4'-(Imidazol-1-yl)acetophenone *[10041-06-2]* **$C_{11}H_{10}N_2O$, M 186.2, m 104-107°, 108-110°, pK^{25} 4.54.** Recrystallise it twice from CH_2Cl_2/hexane [Collman et al. *J Am Chem Soc* **108** 2588 *1986*, DOI: 10.1021/ja00270a016].

2-Iminothiolane hydrochloride (2-iminotetrahydrothiophene, Traut's reagent) *[4781-83-3]* **C_4H_7NS. HCl, M 137.6, m 187-192°, 190-195°, 192-193°, 193-194°, 190-201°, 202-203°, pK^{25} <2 (free base).** Recrystallise the hydrochloride from MeOH/Et_2O (**m 187-192°**) or (MeOH/Me_2CO), but after sublimation at ~180°/0.2mm the melting point rises to 202-203°. It has ^{1}HNMR with δ 2.27 (2H, t), 3.25 (2H, t) and 3.52 (2H, t) in $(CD_3)_2SO$. [King et al. *Biochemistry* **17** 1499 *1978*, DOI: 10.1021/bi00601a022.] The ***free base*** is purifed by vacuum distillation (**b 71-72°/6mm**), has IR (film) with ν_{max} at 1700 (C=N)cm^{-1} and ^{1}HNMR ($CDCl_3$) with δ at 3.58 (2H, t) and 2.10-2.8 (4H, m). The ***free base*** is stable on storage but slowly hydrolyses in aqueous solutions with half-lives at 25° of 390 hours at pH 9.1, 210 hours at pH 10 and 18 hours at pH 11. It is a useful reagent for thiolating primary amines. [Traut et al. *Biochemistry* **12** 3266 *1973*, DOI: 10.1021/bi00741a019; Jue et al. *Biochemistry* **17** 5399 *1978*, DOI: 10.1021/bi00618a013; Alagon & King *Biochemistry* **19** 4341 *1980*, DOI: 10.1021/bi00559a030; *Beilstein* **17/9** V 12.]

Indanthrene (*N,N'*-dihydro-1,2,1',2'-anthraquinonazine) *[81-77-6]* **$C_{28}H_{16}N_2O_4$, M 442.4, m 470-500°(dec).** Crystallise indanthrene repeatedly from 1,2,4-trichlorobenzene to give a blue powder. It is soluble in alkali and concentrated H_2SO_4. It as been used for dyeing cotton. [Weinstein & Merritt *J Am Chem Soc* **81** 3759 *1959*, DOI: 10.1021/ja01523a067; *Beilstein* **24** II 317, **24** III/IV 2193.]

Indazole (1,2-benzopyrazole, 1,2-benzodiazole) *[271-44-3]* **$C_7H_6N_2$, M 118.1, m 145-148°, 147°, 150°, b 270°/743mm, pK_1^{20} 1.32, p K_2^{20} 13.80 (acidic NH).** Crystallise indazole from water, sublime it *in vacuo*, then recrystallise it from petroleum ether (b 60-80°). The ***picrate*** crystallises from Et_2O with **m 136°**. [Ainsworth *Org Synth* Coll Vol **4** 536 *1963*, DOI: 10.15227/orgsyn.039.0027; *Beilstein* **23** III/IV 1055, **23/6** V 156.]

Indigo (indigo blue) *[482-89-3]* **$C_{16}H_{10}N_2O_2$, M 262.3, sublimes at ~300°, m 390°(dec), CI 73000, and halogen-substituted indigo dyes.** First reduce indigo in alkaline solution with sodium hydrosulfite, and filter. The filtrate is then oxidised by air, and the resulting precipitate is filtered off, dried at 65-70°, ground to a fine powder, and extracted with $CHCl_3$ in a Soxhlet extractor. Evaporation of the $CHCl_3$ extract gives the purified dye. It has λ_{max} at 602nm. [Brode et al. *J Am Chem Soc* **76** 1034 *1954*, DOI: 10.1021/ja01633a033; spectral characteristics are listed, *Beilstein* **24** II 233, **24** III/IV 1791.]

Indole *[120-72-9]* **C_8H_7NM 117.2, m 51-54°, 52°, 54.5°, b 124°/5mm, 253-254°/760mm, pK_1^{25} -2.47 (H_o scale), pK_2^{25} 16.97 (acidic NH).** Crystallise indole from *benzene, hexane, petroleum ether, water or EtOH/water (1:10). It can be further purified by sublimation in a vacuum or by zone melting. The ***picrate*** forms orange crystals from EtOH and has **m 175°**. [*Beilstein* **20** II 196, **20** III/IV 3176, **20/7** V 5.]

Indole-3-acetic acid (heteroauxin) *[87-51-4]* **$C_{10}H_9NO_2$, M 175.2, m 165-169°, 167-169°(dec), pK_1^{25} -6.13 (aqueous H_2SO_4), pK_2^{25} 4.54 (CO_2H).** Recrystallise heteroauxin from EtOH/water [James & Ware *J Phys Chem* **89** 5450 *1985*, DOI: 10.1021/j100271a028]. [*Beilstein* **22** III/IV 65.] *Alternatively*, recrystallise 30g of the acid with 10g of charcoal in 1L of hot water, filter and cool when 22g of colourless acid separate. Dry it and store it in a dark bottle away from direct sunlight [Johnson & Crosby *Org Synth* Coll Vol **5** 654 *1973,* DOI: 10.15227/orgsyn.044.0064]. The ***picrate*** has **m 178-180°**. [*Beilstein* **22** H 66, **22** I 508, **22** II 50, **22** III/IV 1088.] It is a plant growth substance.

3-Indoleacetonitrile *[771-51-7]* **$C_{10}H_8N_2$, M 156.2, m 33-36°, 36-38°, b 157°/0.2mm, 158-160°/0.1mm, viscous oil n_D^{20} 1.6097.** Distil the nitrile at very high vacuum, and the viscous distillate crystallises on standing after a few days; the ***picrate*** has **m 127-128°** (from EtOH) [Coker et al. *J Org Chem* **27** 850 *1962*, DOI: 10.1021/jo01050a038; Thesing & Schülde *Chem Ber* **85** 324 *1952*, DOI: 10.1002/cber.19520850409]. Store it away from light. The ***N-acetate*** has **m 118°** (from MeOH) and R_F = 0.8, on Silica Gel F_{254} in $CHCl_2$/MeOH

19:1 [Buzas et al. *Synthesis* 129 *1977*, DOI: 10.1055/s-1977-24296]. [*Beilstein* **22** III/IV 1097, **22/3** V 74.] It is a plant growth substance.

Indole-2-carboxaldehyde *[19005-93-7]* **C_9H_7NO, M 145.2, m 138°, 138-142°, 140-141°, 138-142°, pK_{Est} <1.** Recrystallise the indole from aqueous MeOH (**m** 141-142°), Et_2O (**m** 138°) or sublime it *in vacuo* (**m 138°**). The ***N,N-dimethylhydrazone*** *[127280-17-5]* has **m 105-106°** (from hexane/*C_6H_6). The ***thiosemicarbazone*** has **m 229°** (**dec**) (from 50% aqueous EtOH) [Doyle et al. *J Chem Soc* 2853 *1956*, DOI: 10.1039/JR9560002853]. The ***2,4-dinitrophenylhydrazone*** has **m 315-320°** (**dec**) (from pyridine/MeOH). [Suzuki et al. *Chem Pharm Bull Jpn* **39** 2170 *1991*, DOI :org/10.1248/cpb.39.2170; *Beilstein* **21** III/IV 3754.]

Indole-3-propionic acid (IPA) *[830-96-6]* **$C_{11}H_{11}NO_2$, M 189.2, m ~133°, 134-135°, pK^{25} 4.95.** Recrystallise it from EtOH/water [James & Ware *J Phys Chem* **89** 5450 *1985*, DOI: 10.1021/j100271a028]. The ***picrate*** has **m 143-144°**, and the ***methyl ester*** crystallises from *C_6H_6 or MeOH with **m 81-83°**. [*Beilstein* **22** III/IV 1113, **22/3** V 114.]

(±)-Indoline-2-carboxylic acid (2,3-dihydro-1*H*-indole-2-carboxylic acid) *[78348-24-0]* **$C_9H_9NO_2$, M 163.2, m 168°(dec), $pK_{Est(1)}$ ~2.1, $pK_{Est(2)}$ ~3.8.** Dissolve the acid in hot EtOH, add excess of dry Et_2O and cool to yield colourless plates that decompose in the range of 120-150°. The ***amide*** **(m 208-209°)** crystallises as colourless plates which sublime at 150°/1.0mm and has ν_{max} at 1625cm^{-1} (paraffin mull) [Hudson & Robertson *Aust J Chem* **20** 1935 *1967*, DOI: 10.1071/CH9671935]. [*Beilstein* **22/2** V 421.] See Chapter 5, Catalysts-Part 1 for optical isomers.

Indolizine [pyrrocoline, pyrrolo(1,2-*a*)pyridine] *[274-40-8]* **C_8H_7N, M 117.1, m 73-74°, 75°, pK^{20} 3.94 (C-1 and very little C-3 2protonation).** Purify indolizine through an alumina column in *C_6H_6 and elute with *C_6H_6 (toluene could be used instead). The eluate contained in the fluorescent band (using UV light λ 365mn) is collected, evaporated and the crystalline residue is sublimed twice at 40-50°/0.2-0.5mm. The colourless crystals have a '*naphthalene*' odour, darken on standing and should be stored in dark sealed containers. If the original sample is dark in colour then it should be covered with water and steam distilled. The colourless crystals in the distillate are collected and dried between filter paper and sublimed. It protonates mostly on C3 in aqueous acid. It should give one fluorescent spot on paper chromatography (Whatman 1) in 3% aqueous ammonia and in *n*-BuOH/AcOH/H_2O (4:1:1). The ***picrate*** has **m 101°** from EtOH. [Armarego *J Chem Soc* 4226 *1964*, DOI: 10.1039/JR9640004226; Armarego *J Chem Soc (B)* 191 *1966*, DOI: 10.1039/J29660000191; Scholtz *Chem Be* **45** 734 *1912*, DOI: 10.1002/cber.191204501108; *Beilstein* **20** II 200, **20** III/IV 3195.]

***trans*-Indol-3-ylacrylic acid** *[1204-06-4]* **$C_{11}H_9NO_2$, M 187.2, m 190-195°(dec), 195°(dec), 196°(dec), 195-196°(dec), pK_{Est} ~ 4.2.** Recrystallise the acid from AcOH, H_2O or EtOAc/cyclohexane. UV in MeOH has λ_{max} at 225, 274 and 325nm. [Shaw et al. *J Org Chem* **23** 1171 *1958*, DOI: 10.1021/jo01102a025; constitution: Rappe *Acta Chem Scand* **18** 818 *1964*, DOI: 10.3891/acta.chem.scand.18-0818a; Moffatt *J Chem Soc* 1432 1442 *1957*, DOI: 10.1039/JR9570001432; Kimming et al. *Hoppe Seyler's Z Physiol Chem* **371** 234 *1958*, *Beilstein* **22** V 249.]

3-Indolylbutyric acid (IBA) *[133-32-4]* **$C_{12}H_{13}NO_2$, M 203.2, m 120-123°, 123-125°, 124°, pK^{25} 4.84.** Recrystallise the acid from H_2O. It is soluble in EtOH, Et_2O and Me_2CO but insoluble in $CHCl_3$. [Bowman & Islip *Chem Ind London* 154 *1971*, Jackson & Manske *J Am Chem Soc* **52** 5029 *1930*, DOI: 10.1021/ja01375a056; Albaum & Kaiser *Am J Bot* **24** 420 *1937*, http://www.jstor.org.virtual.anu.edu.au/stable/2436425.] It has also been recrystallised from EtOH/water [James & Ware *J Phys Chem* **89** 5450 *1985*, DOI: 10.1021/j100271a028]. Its UV has λ_{max} at 278 and 320nm in isoPrOH [Elvidge *Quart J Pharm Pharmacol* **13** 219 *1940*]. The ***methyl ester*** has **m 73-74°** (from *C_6H_6/petroleum ether) and **b 230°/6mm** [Bullock & Hand *J Am Chem Soc* **78** 5854 *1951*, DOI: 10.1021/ja01603a040]. It stimulates root growth in plant clippings. [*Beilstein* **22** III/IV 1128, **22/3** V 140.]

3-Indolylpyruvic acid *[392-12-1]* **$C_{11}H_9NO_3$, M 203.2, m~210°(dec), 208-210°(dec), 215°(dec), 219°(dec), pK_{Est} ~2.4.** Recrystallise the acid from Me_2CO/*C_6H_6, EtOAc/$CHCl_3$, Me_2CO/AcOH (crystals have 1 molecule of AcOH) and dioxane/*C_6H_6 (with 0.5 molecule of dioxane) [Shaw et al. *J Org Chem* **23** 1171 *1958*,

DOI: 10.1021/jo01102a025; Kaper & Veldstra *Biochim Biophys Acta* **30** 401 *1958*, DOI:10.1016/0006-3002(58)90065-9]. The ***ethyl ester*** has **m 133°** (from Et_2O), and its ***2,4-dinitro-phenylhydrazone*** has **m 255°** (from Me_2CO). [Baker *J Chem Soc* 461 *1946*, DOI: 10.1039/JR9460000461.] The ***oxime*** has **m 157°(dec**, from EtOAc/Et_2O) and pK^{20} 3.40 [Ahmad & Spenser *Can J Chem* **39** 1340 *1961*, DOI: 10.1139/v61-169]. [*Beilstein* **22** II 250, **22** III/IV 3080, **22/6** V 324.]

7-Iodoindole *[89976-15-8]* **C_8H_6IN, M 243.0, m 52-56°, pK_{Est} <1.** Purify 7-iodoindole by chromatography through a silica gel column and eluting with CH_2Cl_2/hexane (1:3, v/v) followed by recrystallisation from hexane (colourless plates, **m 55-56°**). [Somei et al. *Chem Pharm Bull Jpn* **35** 3146 *1987*, DOI:org/10.1248/cpb.35.3146; Somei & Saida *Heterocycle* **23** 3113 *1985*, DOI: 10.3987/R-1985-12-3113.]

Iodinin (1,6-dihydroxyphenazine-5,10-dioxide) *[68-81-5]* **$C_{12}H_8N_2O_4$, M 244.1, m 236°(dec), pK^{25} 12.5.** Purify iodinin through a column of silica gel and elute with $Me_2CO/CHCl_3$, then recrystallise it from $CHCl_3$ to give purple crystals with a copper-coloured luster. Gives coloured solutions with acids and with alkali. [Clemo & Dalglish *J Chem Soc* 1481 *1950*, DOI: 10.1039/JR9500001481; Gerber & Lechevalier *Biochemistry* **3** 598 *1964*, DOI: 10.1021/bi00892a022; *Beilstein* **23** III/IV 3227,]

Iodonitrotetrazolium chloride (2[4-iodophenyl]-3-[4-nitrophenyl]-5-phenyl-2*H*-tetrazolium chloride) *[146-68-9]* **$C_{19}H_{13}ClIN_5O_2$, M 505.7, m 229°(dec), 240°(dec), ~245°(dec).** Recrystallise the chloride from H_2O, aqueous EtOH or EtOH/Et_2O. *Alternatively*, dissolve it in the minimum volume of EtOH and add Et_2O; or dissolve it in hot H_2O (charcoal), filter and precipitate it by adding conc HCl. Filter the solid off and dry it at 100°. Its solubility in H_2O at 25° is 0.5%, and in hot MeOH/H_2O (1:1) it is 5%. [Fox & Atkinson *J Am Chem Soc* **72** 3629 *1950*, DOI: 10.1021/ja01164a086; *Beilstein* **26** III/IV 1776.]

Iodonitrotetrazolium violet-Formazan *[7781-49-9]* **$C_{19}H_{14}IN_5O_2$, M 471.3, m 185-186°.** Dissolve it in boiling dioxane (20g in 300ml), add H_2O (100ml) slowly, cool, filter and dry it *in vacuo* at 100°. Its solubility in $CHCl_3$ is ~1%. [UV: Fox & Atkinson *J Am Chem Soc* **72** 3629 *1950*, DOI: 10.1021/ja01164a086; *Beilstein* **16** III/IV 1776, **26** III/IV 1776.]

Isatin (indole-2,3-dione) *[91-56-5]* **$C_8H_5NO_2$, M 147.1, m 193-195°, 201-203°, 205°, pK^{25} >12 (acidic NH).** Crystallise isatin from amyl alcohol and sublime it at 180°/1mm. In aqueous NaOH the ring opens to yield sodium *o*-aminobenzoylformate. Used as a chromatographic spray reagent for amino acids. [*Beilstein* **21** II327, 567, **21** IV 58, **21/10** V 221.]

Isatoic anhydride (3,1-benzoxazin-2,4[1-*H*]-dione) *[118-48-9]* **$C_8H_5NO_3$, M 163.1, m 235-240°, 240-243°, 243°, 243-245°.** Recrystallise it from EtOH or 95% EtOH (30ml/g) or dioxane (10ml/g) and dry it in a vacuum. [Wagner & Fegley *Org Synth* Coll Vol **3** 488 *1955*, DOI: 10.15227/orgsyn.027.0045; Ben-Ishai & Katchalski *J Am Chem Soc* **74** 3688 *1952*, DOI: 10.1021/ja01134a501; UV: Zentmyer & Wagner *J Org Chem* **14** 967 *1949*, DOI: 10.1021/jo01158a006; *Beilstein* **27** II 299, **27** III/IV 3330.]

3-Isobutyl-1-methylxanthine (3-isobutyl-1-methylpurine-2,6-dione) *[28822-58-4]* **$C_{10}H_{14}N_4O_2$, M 222.3, m 199-210°, 200-201°, 202-203°, pK_{Est} ~ 6.7 (acidic NH).** Recrystallise it from aqueous EtOH. It is a non-specific inhibitor of cAMP and cGMP phosphodiesterases. [*Beilstein* **26** III/IV 2350.]

Isonicotinic acid (pyridine-4-carboxylic acid) *[55-22-1]* **$C_6H_5NO_2$, M 123.1, m >300°, 320°, 323-325°(dec), pK_1^{25} 1.70, pK_2^{25} 4.89.** Crystallise the acid repeatedly from water and dry it under vacuum at 110° or sublime it at 260°/15mm (**m 319°**). [*Beilstein* **22** III/IV 518, **22/2** V 188.] ***Isonicotinamide*** **(pyridine-4-carboxylic acid amide)** *[1453-82-3]* **$C_6H_6N_2O$, M 122.1,** has **m 155-157°, 155.5-156°, pK_1^{20} -1.0 (protonation of $CONH_2$), pK_2^{25} 3.61, pK_3^{25} 11.47 (acidic $CONH_2$).** Recrystallise isonicotinamide from hot water or isopropanol (**158.5-159°**), and dry it in a vacuum at 100°. The ***picrate*** crystallises from aqueous EtOH or H_2O and has **m 217-218°** (**214-215°**). [*Beilstein* **22** III/IV 527, **22/2** V 195.] ***Isonicotinic acid hydrazide*** **(isoniazide)** *[54-85-3]* **$C_6H_7N_3O$, M 137.1,** has **m 171-173°, 172°, pK_1 1.75 ($NHNH_2$), pK_2 3.57 (=N-), pK_3 10.75 (-NH).** Crystallise isoniazide from 95% EtOH and dry it in a vacuum. [*Beilstein* **22** III/IV 545, **22/2** V 219.] It is an antimicrobial which inhibits mycolic acid biosynthesis.

1-Isonicotinyl-2-isopropylhydrazide (Iproniazid) *[54-92-2]* **$C_9H_{13}N_3O$, M 179.2, m 112.5-113.5°, 114-115°, pK_{Est} ~3.5.** Crystallise it from *benzene or *benzene /petroleum ether and dry it in a vacuum. It is soluble in H_2O and EtOH. [Fox & Gibas *J Org Chem* **18** 994 *1953*, DOI: 10.1021/jo50014a014.] The ***dihydrochloride*** has **m 227-228°** (from EtOH). [*Beilstein* **22** III/IV 551.] It is an antidepressant.
1-Isonicotinyl-2-isopropylhydrazide phosphate **(Iproniazid phosphate, Marsilide)** *[305-33-9]* **$C_9H_{13}N_3O.H_3PO_4$, M 277.2,** has **m 175-184°, 178-179°, 180-184°, pK_{Est} ~3.5 (free base).** Crystallise it from H_2O and Me_2CO. The ***free base*** (see above) has **m 113-114°** from *C_6H_6/petroleum ether and is soluble in H_2O and EtOH. [Fox & Gibas *J Org Chem* **18** 994 *1953*, DOI: 10.1021/jo50014a014; *Beilstein* **22** III/IV 551.] It is an antidepressant.
1-Isonicotinyl-2-salicylidenehydrazide **(Salinazide)** *[495-84-1]* **$C_{13}H_{11}N_3O_2$, M 241.2,** has **m 232-233° (also 251°).** Crystallise it from EtOH (**m 265-266°** or **244-245°**), aqueous EtOH or MeOH (252-253°) and dry it in a vacuum at 100°. [*Beilstein* **22** III/IV 584.] Tuberculostatic.

5-Isonitrosobarbituric acid (violuric acid) *[87-39-8, 1H_2O 26851-19-9]* **$C_4H_3N_3O_4$, M 175.1, m 221-223°, 240-241°(dec), 245-250°(dec, mono hydrate), pK_1 4.41, pK_2 9.66 (10.1).** Crystallise violuric acid from water or EtOH. ***1,1-Dimethylvioluric acid*****, m 144-147°** has pK^{25} 4.72 [Taylor & Robinson *Talanta* **8** 518 *1961,* DOI: 10.1016/0039-9140(63)80055-7]. [*Beilstein* **24** III/IV 2142.] It chelates with metals.

N*-Isopropylcarbazole** *[1484-09-9]* **$C_{15}H_{15}N$, M 209.3, m 120°.** Crystallise it from isopropanol. It sublimes under vacuum. It was also purified by zone refining. The ***picrate has **m 143°** after recrystallisation from EtOH. [*Beilstein* **20** I 164.]

Isoquinoline *[119-65-3]* **C_9H_7N, M 129.2, m 24°, 25.5-26°, b 120°/18mm, 242-243°/atm, 243.25°/760mm, d_4^{20} 1.0986, n_D^{20} 1.6148, pK^{25} 5.40.** Dry isoquinoline with Linde type 5A molecular sieves or Na_2SO_4 and fractionally distil at reduced pressure. ***Alternatively***, it can be refluxed with, and distilled from, BaO. It is also purified by fractional crystallisation from the melt and distilled from zinc dust. It forms a ***phosphate*** (**m 135°**) and a ***picrate*** (**m 223°**), which are purified by crystallisation, and the free base can be recovered and distilled. [Packer et al. *J Am Chem Soc* **80** 905 *1958*, DOI: 10.1021/ja01537a039.] The procedure for purification *via* the picrate comprises the addition of quinoline to picric acid dissolved in the minimum volume of 95% EtOH to yield yellow crystals which are washed with EtOH and air dried before recrystallising from acetonitrile. The crystals are dissolved in dimethyl sulfoxide (previously dried over 4A molecular sieves) and passed through a basic alumina column, on which picric acid is adsorbed. The ***free base*** in the effluent is extracted with *n*-pentane and distilled under vacuum. Traces of solvent from small quantities are removed by vapour phase chromatography. The ***hydrochloride*** crystallises from EtOH with **m 193°**. [Moomaw & Anton *J Phys Chem* **80** 2243 *1976*, DOI: 10.1021/j100561a022; *Beilstein* **20** II 236, **20** III/IV 3410, **20/7** V 333.]

Isoxanthopterin (2-amino-4,7-dihydroxypteridine) *[529-69-1]* **$C_6H_5N_5O_2$, M 179.1, m>300°, pK_1^{20} -0.5 (basic), pK_2^{20} 7.34 (acidic), pK_3^{20} 10.06 (acidic).** Purify it by repeated precipitation from alkaline solution with acid (preferably AcOH or formic acid), filter, wash well with H_2O, then EtOH and dry at 100°. The purity is checked by paper chromatography [R_F 0.15 (*n*-BuOH/AcOH/H_2O, 4:1:1); 0.33 (3% aqueous NH_4OH). [Goto et al. *Arch Biochem Biophys* **111** 8 *1965*, DOI: 10.1016/0003-9861(65)90316-4.] [For biochemistry see Blakley *Biochemistry of Folic Acid and Related Pteridines* North Holland Publ Co, Amsterdam 1969.] [*Beilstein* **26** III/IV 3999.]

Janus Green B **(3-dimethylamino-7-[4-dimethylaminoazo]-5-phenylphenazonium chloride)** *[2869-83-2]* **$C_{30}H_{31}ClN_6$, M 511.1, m >200°, CI 11050.** The dye dissolves in H_2O to give a bluish violet solution which becomes colourless when made 10M in NaOH. It dissolves in EtOH to give a blue-violet colour, filter from insoluble material, then add dry Et_2O whereby the dye separates out leaving a small amount of blue colour in solution. Filter off the solid and dry it in a vacuum. Store it in a dark bottle. [Colour Index Vol 4, 3rd edn, 4015 *1971*.] It is a biological stain.

Jervine (3β,23β-17,23-epoxy-2-hydroxyvertraman-11-one, a steroidal alkaloid) *[469-59-0]* **$C_{27}H_{39}NO_3$, M 425.6, m 243-245°, 247-248°, $[\alpha]_D^{20}$ -150 (in EtOH), pK_{Est}~9.4** Crystallise Jervine from MeOH/H_2O or Me_2O. The ***hydrochloride*** has **m 300-302°** (from MeOH/Et_2O), and the ***picrate*** has **m 262.5°** (from aqueous

MeOH). [Kutney et al. *Can J Chem* **53** 1796 *1975*, DOI: 10.1139/v75-252; *Beilstein* **27** III/IV 3590.] It is **teratogenic.**

Julolidine (2,3,6,7-tetrahydro-1*H*,5*H*-benzo[*ij*]quinolizidine) *[479-59-4]* **$C_{12}H_{15}N$, M 173.3, m 34-36°, 40°, b 105-110°/1mm, 155-156°/17mm, 280°(dec), pK_{Est} ~7.0.** Purify julolidine by dissolving it in dilute HCl, steam is bubbled through the solution and the residual acidic solution is basified with 10N NaOH, extracted with Et_2O, the extrtact is washed with H_2O, dried (NaOH pellets), filtered, evaporated and distilled *in vacuo*. The distillate crystallises on cooling (**m** 39-40°). It develops a red colour on standing in contact with air for several days. The colour can be removed by distilling or dissolving in 2-3 parts of hexane, adding charcoal, filtering and cooling in an Me_2CO/Dry-ice bath when ***julolidine*** crystallises out (85-90% yield **m 39-40°**). The ***hydrobromide*** *[83646-41-7]* has **m 218°** (**239-242°**), the ***picrate*** has **m 174°**(**165°**) and the ***methiodide*** crystallises from MeOH, with **m 186°** [Glass & Weissberger *Org Synth* Coll Vol **3** 504 *1955*, DOI: 10.15227/orgsyn.026.0040; Smith & Yu *J Org* Chem **17** 1281 *1952*, DOI: 10.1021/jo50009a015; *Beilstein* **20** H 332, **20** I 133, **20** II 214, **20** III/IV 3281.] **Highly TOXIC.**

Kainic acid H_2O (2*S*,3*S*,4*S*-2-carboxy-4-isoprenyl-3-pyrrolidine- acetic acid) *[487-79-6]* **$C_{10}H_{15}NO_4$, M 231.4, m 235-245°(dec), 251°(dec), $[\alpha]_D^{20}$ -14.6 (c 1.46, H_2O), pK_1 2.09, pK_2 4.58, pK_3 10.21.** Purify the acid by adsorbing on to a strongly acidic ion-exchange resin (Merck), elute the diacid with aqueous M NaOH, the eluate is evaporated, H_2O is added, and filtered through a weakly acidic ion-exchange resin (Merck). The filtrate is then evaporated and recrystallised from EtOH. Its solubility is 0.1g in 1ml of 0.5N HCl. ***(±)-α-Kainic acid*** is recrystallised from H_2O with **m** 230-260°. Its UV (MeOH) has λ_{max} at 219 (log ε 3.9); the ^{1}HNMR (CCl_4, 100MHz, Me_4Si standard) has δ at 1.64 (s 1H), 1.70 (s 3H), 3.24 (d *J* = 7.5, 2H), 3.3-4.2 (1H), 3.70 (s 3H), 3.83 (s 3H), 4.35 (dd *J* = 7.5, 14.5, 1H), 5.21 (t *J* = 7.5, 1H), 7.26 (*t J* = 7.5, 1H). [Oppolzer & Andres *Helv Chim Acta* **62** 2282 *1979*, DOI: 10.1002/hlca.19790620724; *Beilstein* **22** III/IV 1523.] It is a useful neurobiology tool, and has anthelmintic properties.

Ketanserin [3(4-*p*-fluorobenzoylpiperidinyl-*N*-ethyl)quinazolin-2,4-dione] *[74050-98-9]* **$C_{22}H_{22}FN_3O_3$, M 395.4, m 227-235°, pK^{25} 7.5.** Its solubility is 0.001% in H_2O, 0.038% in EtOH and 2.34% in Me_2NCHO. It has been purified by recrystallisation from 4-methyl-3-pentanone [Peeters et al. *Cryst Structure Commun* **11** 375 *1982*, Kacprowicz et al. *J Chromatogr* **272** 417 *1983*, Davies et al. *J Chromatogr* **275** 232 *1983*]. The ***Tartrate salt*** *[83846-83-7]* **$C_{22}H_{22}FN_3O_3.C_4H_6O_6$, M 545.5,** is the antihypertensive drug ***Serepress***.

Khellin (4,9-dimethoxy-7-methyl-5-oxofuro[3,2-g]-1,2-chromene) *[82-02-0]* **M 260.3, m 154-155°, b 180-200°/0.05mm.** Crystallise khellin from H_2O, MeOH, petroleum ether or Et_2O. The ***hydrochloride*** has **m 98°(dec)** (from EtOH/HCl). [*Beilstein* **19** II 236, **19** III/IV 2816, **19/6** V 320.]

Kojic acid [(5-hydroxy-2-hydroxymethyl)-4*H*-pyran-4-one] *[501-30-4]* **$C_6H_6O_4$,M 142.1, m 152°, 152-155°, 154-155°, pK_1^{25} -1.38, pK_2^{25} 7.66.** Crystallise the acid (yellow solid) from MeOH (charcoal) by adding Et_2O, or from H_2O (solubility is 0.9w/v% at boiling). It sublimes at 150-200°/0.1torr. It is a tyrosinase inhibitor. [*Beilstein* **18** II 57, **18** III/IV 1145, **18/2** V 516.]

Kynurenic acid (4-hydroxyquinoline-2-carboxylic acid) *[492-27-3]* **$C_{10}H_7NO_3$, M 189.1, m 282-283°, 285°, $pK_{Est(1)}$~2, $pK_{Est(2)}$~10.** Crystallise the acid from absolute EtOH. The ***methyl ester*** crystallises from MeOH with **m 224-226°**. [Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, **Vol 3** p2723 *1961*, *Beilstein* **22** II 174, **22** III/IV 2245, **22/6** V 280.]

L-Kynurenine [2-amino-3-(2-aminobenzoyl)-4-propionic acid] *[343-65-7]* **$C_{10}H_{12}N_2O_3$, M 208.2, m 190°(dec), 210°(dec), $[\alpha]_D^{20}$ -30 (c 0.4, H_2O), $pK_{Est(1)}$~2.3, $pK_{Est(2)}$~3.5, $pK_{Est(3)}$~9.2.** Crystallise it from H_2O or aqueous AcOH. The ***picrate*** has **m 188.5-189°(dec)** after crystallisation from H_2O. ***(±)-Kynurenine*** has **m 218° (~235° dec**, also reported). [Greenstein & Winitz *The Chemistry of the Amino Acids* J. Wiley, **Vol 3** p2726 *1961*, *Beilstein* **14** III 1657, **14** IV 2562.] **L-Kynurenine sulfate** *[16055-80-4]* **$C_{10}H_{12}N_2O_3.H_2SO_4.H_2O$, M 306.3,** has **m 194°, monohydrate m 178°, $[\alpha]_D^{25}$ +9.6 (H_2O)**, and crystallises from water by addition of EtOH. The ***(±)-sulfate*** has **m 173°** (darkening at 166° and decomposing at 194° is also reported). [*Beilstein* **14** IV 2562.]

dl- and l-*Laudanosine {1-[(3,4-dimethoxyphenyl)methyl]-1,2,3,4-tetrahydro-6,7-dimethoxy-2-methyl-isoquinoline}** *[(±) 1699-51-0, (-) 2688-77-9]* **M 357.4, m 114-115°, 118°.** Crystallise these from EtOH. The ***(±)-picrate crystallises from EtOH with **m 177-178°**. The *(-)*-isomer has **m 83-85°** and $[\alpha]_D^{24}$ -110° (c 0.3, EtOH). The *hydrobromide tetrahydrate* [303136-74-5] **M** 436.3 has **m 232-234°**. [Frydman et al. *Tetrahedron* **4** 342 *1958*, Elliott *J Heterocycl Chem* **9** 853 *1972*, *Beilstein* **21** II 183, **21** III/IV 2704.]

Luminol (5-aminophthalazin-1,4-dione) *[521-31-3]* **M 177.2, m 329-332°, pK_1 3.37, pK_2 6.35.** Dissolve luminol in KOH solution, treat with Norit (charcoal), filter and precipitate it with conc HCl. [Hardy et al. *Talanta* **24** 297 *1977*.] Store it in the dark in an inert atmosphere, because its structure changes during its luminescence. It has been recrystallised from 0.1M KOH [Merenyi et al. *J Am Chem Soc* **108** 7716 *1986*, DOI: 10.1021/ja00284a040]. [*Beilstein* **25** II 389, **25** III/IV 4192.]

dl*-Lupinine (1-hydroxymethyloctahydroquinolizine, 1-hydroxymethylquinolizidine)** *[10248-30-3]* **M 169.3, m 57-58°, 59°, 107°/1mm, pK_{Est} ~7.0.** It crystallises from Me_2CO, pentane and petroleum ether (b. 40-60°) and can be sublimed or distilled in high vacuum. The ***picrate has **m 127°**(from Et_2O), the ***picrolonate*** has **m 203-204°**, and the ***methiodide*** has **m 203°(dec**, from EtOH). [Clemo et al. *J Chem Soc* 965 *1937*, DOI: 10.1039/JR9370000965, Boekelheide & Lodge *J Am Chem Soc* **73** 3681 *1951*, DOI: 10.1021/ja01152a033; *Beilstein* **21** II 28, **21** III/IV 291.]

Lutidine (dimethylpyridine mixture). For the preparation of pure 2,3-, 2,4- and 2,5-lutidine from commercial '2,4- and 2,5-lutidine' see Coulson et al. *J Chem Soc* 1934 *1959*, DOI: 10.1039/JR9590001934; and Kyte et al. *J Chem Soc* 4454 *1960*, DOI: 10.1039/JR9600004454.

2,3-Lutidine* (2,3-dimethylpyridine)** *[583-61-9]* **C_7H_9N, M 107.2, m -14.8°, -15°, b 160.6°/760mm, 162-163°/atm, d_4^{20} 0.9464, n_D^{20} 1.50857, pK^{25} 6.57.** Steam distil it from a solution containing about 1.2 equivalents of 20% H_2SO_4, until *ca* 10% of the base has been carried over with the non-basic impurities. The acidic solution is then made alkaline, and the base is separated, dried over NaOH or BaO, and fractionally distilled. The distilled lutidine is converted to its ***urea complex by stirring 100g with 40g of urea in 75ml of H_2O, cooling to 5°, filtering at the pump, and washing with 75ml of H_2O. The complex, dissolved in 300ml of H_2O, is steam distilled until the distillate gives no turbidity with a little solid NaOH. The distillate is then treated with excess solid NaOH, and the upper layer is removed: the aqueous layer is then extracted with Et_2O. The combined organic solutions are dried (K_2CO_3), and distilled through a short column. Final purification is by fractional crystallisation using partial freezing. The ***picrate*** crystallises from EtOH with **m 187-188°**. [Kyte et al. *J Chem Soc* 4454 *1960*, DOI: 10.1039/JR9600004454; **20** H 243, **20** II 159, **20** III/IV 2765, **20/6** V 15.]

2,4-Lutidine* (2,4-dimethylpyridine)** *[108-47-4]* has **m -60°, b 157.8°/760mm, 159°/atm, d_4^{20} 0.9305, n_D^{20} 1.50087, n_D^{25} 1.4985, pK^{25} 6.77.** Purify as described in *Purification of Laboratory Chemicals* 7th edn, *2013*; ISBN: 978012382161-4. [see Kyte et al. *J Chem Soc* 4454 *1960*, DOI: 10.1039/JR9600004454.] *Alternative* purifications are *via* the ***picrate **m 183-184°** (from H_2O). [Clarke & Rothwell *J Chem Soc* 1885 *1960,* DOI: 10.1039/JR9600001885, or ***hydrobromide*** [Warnhoff *J Org Chem* **27** 4587 *1962*, DOI: 10.1021/jo01059a109]. The latter is precipitated from a solution of lutidine in *benzene by passing dry HBr gas, recrystallised from $CHCl_3$/MeCOEt, then decomposed with NaOH, and the free base is extracted into Et_2O, dried, evaporated and the residue is distilled. [*Beilstein* **20** II 180, **20** III/IV 2718, **20/6** V 19.]

2,5-Lutidine* (2,5-dimethylpyridine)** *[589-93-5]* has **m -15.3°, b 156.7°/759mm, 157°/atm, d_4^{20} 0.927, n_D^{25} 1.4982, pK^{25} 6.40.** Purify as above, distil with Na then fractionally distil through a Todd column packed with glass helices. The ***hydrochloride has **m 219°(dec**), and the ***picrate*** has **m 170.5°** (from EtOH or H_2O). [*Beilstein* **20** H 244, **20** II 160, **20** III/IV 2774, **20/6** V 27.]

2,6-Lutidine* (2,6-dimethylpyridine)** *[108-48-5]* has **m -5.8°, b 79°/87mm, 144.0°/760mm, d_4^{20} 0.92257, n_D^{20} 1.49779, pK^{25} 6.72.** Likely contaminants include 3- and 4-picoline (similar boiling points) which are removed with BF_3 (4ml for 100ml) or by distillation of commercial material from $AlCl_3$ (14g per 100ml). 2,6-Lutidine can be dried with KOH (do not use Na, see picolines below) or by refluxing with (and distilling from) BaO or CaH_2, prior to distillation. Also purified *via* its ***picrate, 2,6-lutidine **m 163-164.5°** (**166-167°**), then partitioned between ammonia and $CHCl_3/Et_2O$. The organic layer, after washing with dilute aqueous KOH, is dried (Na_2SO_4) and fractionally distilled. [Warnhoff *J Org Chem* **27** 4587 *1962*, DOI: 10.1021/jo01059a109.] *Alternatively*, purify *via* its ***urea complex***, as described above. Other purifications include azeotropic distillation with phenol [Coulson et al. *J Appl Chem* **2** 71 *1952*, DOI: 10.1002/jctb.5010020205], crystallisation by partial freezing, and vapour-phase chromatography using a 180-cm column of polyethylene glycol-400

(Shell, 5%) on Embacel (May and Baker) at 100°, with argon as carrier gas [Bamford & Block *J Chem Soc* 4989 *1961*, DOI: 10.1039/JR9610004989]. The ***hydrochloride*** has **m 235-237°, 239°** (from EtOH). [*Beilstein* **20** II 160, **20** III/IV 2776, **20/6** V 32.]

3,5-Lutidine **(2,5-dimethylpyridine)** *[591-22-0]* has **m -9°, -6.3°, b 169-170°/atm, 172.0°/767mm, d_4^{20} 0.9419, n_D^{20} 1.50613, n_D^{25} 1.5035, pK^{25} 6.15.** Dry 3,5-lutidine with CaH_2 and fractionally distil it through a Todd column packed with glass helices. Methods used for other isomers apply here too. The ***hydrochloride*** has **m 229°**(sublimes at 190-231°), and the ***picrate*** has **m 242-243°**(**dec**, from H_2O), **249-250°**(**dec**, from AcOH). [*Beilstein* **20** II 161, **20** III/IV 2788, **20/6** V 60.]

Lycorine *[476-28-8]* **$C_{16}H_{17}NO_4$, M 287.3, m 275-280°(dec), b 175-185°/0.002mm. $[\alpha]_D^{20}$ -91 (c 0.16, EtOH), $[\alpha]_D^{16}$ -127 (c 0.16, absEtOH), pK^{25} 6.9 (30% aqueous dimethylformamide).** It crystallises as orange crystals from MeOH (**m 281-283°**), $CHCl_3$/EtOH (**m 272-274°**), pyridine or from EtOH (**m 277° dec**, also **275-280° dec**). It has been distilled under high vacuum. The ***hydrochloride*** has **m 288°** (from MeOH/HCl), **m 217°** (**dec** with prior sintering, needles from H_2O), $[\alpha]_D^{20}$ +63 (EtOH), and the ***picrate*** has **m 196-197°**(from EtOH). [Cook et al. *J Chem Soc* 4176 *1954*, DOI: 10.1039/JR9540004176; Martin & Tu *J Org Chem* **46** 3763 *1981*, DOI: 10.1021/jo00331a049; *Beilstein* **27** II 547, **27** III/IV 6463.] Alkaloid.

(+)-Lysergic acid *[82-58-6]* **M 268.3, m 240°(dec), $[\alpha]_D^{20}$ +40° (pyridine), pK_1^{25} 3.32, pK_2^{25} 8.66, pK^{20} 8.50, pK^{40} 8.27.** It crystallises from water as a *hydrate*. The ***methyl ester*** crystallises from *C_6H_6 and has **m 168°**; the ***amide*** *[478-94-4]* has **m 242°**(**dec**) (from MeOH) and $[\alpha]_{546}$ +15° (c 0.5, pyridine). The *(-)-**hydrochloride*** has **m 208-210°**(**dec**, from MeOH). [Kornfeld et al. *J Am Chem Soc* **76** 5256 *1954*, Kornfeld et al. *J Am Chem Soc* **78** 3087 *1956*, DOI: 10.1021/ja01594a039; *Beilstein* **25** III/IV 934,]

Maltol **(3-hydroxy-2-methyl-4-pyrone)** *[118-71-8]* **$C_6H_6O_3$, M 126.1, m 160-164°, 161-162°, 162-162.5°.** It crystallises from $CHCl_3$, toluene, aqueous 50% EtOH or H_2O, and is volatile in steam. It can be readily sublimed in a vacuum. It forms a Cu^{2+} complex. [*Beilstein* **18/1** V 114.] It is a food flavouring agent.

Meconic acid (3-hydroxy-γ-pyrone-2,6-dicarboxylic acid) *[497-59-6]* **$C_7H_4O_7$, M 200.1, m 100° (loses H_2O), pK_1^{25}1.83, pK_2^{25} 2.3, pK_3^{20} 10.10.** Crystallise the acid from water (0.25g/ml) and dry it at 100° for 20 minutes to dehydrate the ***mono*** or ***dihydrate***. It decarboxylates above 120° or in boiling H_2O. It is soluble in MeOH (2%), EtOAc (2%) and Me_2CO (1%). The ***picrate*** has **m 206.5-208.5°**(**dec**, from H_2O). [Wibaut & Kleinpool *Recl Trav Chim Pays-Bas* **66** 24 *1947*, DOI: 10.1002/recl.19470660103; *Beilstein* **18** H 409, **18** I 523, **18** II 367, **18** III/IV 6136.]

Melamine (2,4,6-triamino-1,3,5-triazine) *[108-78-1]* **$C_3H_6N_6$, M 126.1, m >300°, 353°, pK^{25} 5.00.** Crystallise Melamine from water or dilute aqueous NaOH. It sublimes at ~240° on prolonged heating. [*Beilstein* **26** I 74, **26** II 132, **26** III/IV 1253.]

(±)-Mellein [(±)-3,4-dihydro-8-hydroxy-3-methyl-2-benzopyran-1-one, 8-hydroxy-3-methylisochroman-1-one] *[1200-93-7]* **M 178.2, m 37-39°, 39°, pK_{Est} ~9.5.** Purify it by recrystallisation from H_2O or aqueous EtOH. It has UV with λ_{max} at 247 and 314nm. [Arakawa et al. *Justus Liebigs Ann Chem* **728** 152 *1969*, DOI: 10.1002/jlac.19697280117; Blair & Newbold *Chem Ind (London)* 93 *1955*, *J Chem Soc* 2871 *1955*, DOI: 10.1039/JR9550002871.] The ***methyl ether*** has **m 66-67°** and UV with λ_{max} at 242nm (ε 7,400) and 305nm (ε 4,600). ***R*(-)-*Mellein*** has **m 56°**(from aqueous Me_2CO), $[\alpha]_D^{25}$ -102.5 (c 1, $CHCl_3$) and ***R*(+)-*mellein*** has **m 56-57°**(from hexane), $[\alpha]_D^{25}$ +102 (c 1, $CHCl_3$) or $[\alpha]_D^{25}$ +88 (c 1, MeOH). [*Beilstein* **18** III/IV 188, **18/1** V 274.]

2-Mercaptobenzimidazole *[583-39-1]* **$C_7H_6N_2S$, M 150.2, m 302-304°, 312°, pK^{20} 10.24.** Crystallise it from aqueous EtOH, AcOH or aqueous ammonia. It complexes with many metals. [Brown *J Chem Soc* 1974 *1958*, DOI: 10.1039/JR9580001974; *Beilstein* **24** II 65, **24** III/IV 287.]

2-Mercaptobenzothiazole *[149-30-4]* **$C_7H_5NS_2$, M 167.2, m 177-181°, 182°, pK^{25} 7.5 (50% aqueous AcOH).** Crystallise it repeatedly from 95% EtOH, or purify it by incomplete precipitation by dilute H_2SO_4 from a basic solution, followed by several crystallisations from acetone/H_2O or *benzene. It complexes with Ag, Au, Bi, Cd, Hg, Ir, Pt, and Tl. [*Beilstein* **27** II 233, **27** III/IV 2709.]

2-Mercaptoimidazole *[872-35-5]* **$C_3H_4N_2S$, M 100.1, m 221-222°, 226-228°(monohydrate), 228-231°, pK_1^{20} -1.6, pK_2^{20} 11.6.** Crystallise 2-mercaptoimidazole from Me_2CO or H_2O. Its UV has λ_{max} at 208 and 252nm (H_2O). [Fox et al. *J Am Chem Soc* **67** 496 *1945*, DOI: 10.1021/ja01219a506; *Beilstein* **24** II 7, **24** III/IV 61.]

2-Mercapto-1-methylimidazole *[60-56-0]* **$C_4H_6N_2S$, M 114.2, m 144-147°, 145-147°, 146-148°, pK_1^{20} -2.0, pK_2^{20} 11.9.** Crystallise it from EtOH. Its UV has λ_{max} at 251nm (H_2O), 260nm (EtOH) and 267nm ($CHCl_3$). [Lawson & Morley *J Chem Soc* 1103 *1956*, DOI: 10.1039/JR9560001103; *Beilstein* **24** H 17, **24** III/IV 61.]

6-Mercaptopurine monohydrate *[6112-76-1]* **$C_5H_4N_4S.H_2O$, M 170.2, m 314-315°(dec), ~315°(dec), 313-315°(dec), pK_1^{20} 0.5, pK_2^{20} 7.77, pK_3^{20} 10.84.** Crystallise 6-mercaptopurine from pyridine (30ml/g), wash it with pyridine, then triturate with water (25ml/g) and adjust to pH 5 by adding M HCl. Recrystallise it by heating, then cooling, the solution. Filter off the solid, wash it with water and dry it at 110°. It has also been crystallised from water (charcoal) as yellow crystals of the ***monohydrate*** which become ***anhydrous*** on drying at 140°. It has UV with λ_{max} at 230 and 312nm (ε 14,000 and 19,600) in 0.1N NaOH; 222 and 327nm (ε 9,2400 and 21,300), and 216 and 329nm (ε 8,740 and 19,300) in MeOH. It forms a ***1:1 complex*** with Zn^{2+}, Pb^{2+}, Co^{2+}, and Ni^{2+} in aqueous dioxane. It is an antineoplastic agent which inhibits *de novo* purine synthesis by incorporating thiopurine methyltransferase metabolites into DNA and RNA. [Albert & Brown *J Chem Soc* 2060 *1954*, DOI: 10.1039/JR9540002060; IR: Brown & Mason *J Chem Soc* 682 *1957*, DOI: 10.1039/JR9570000682; UV: Fox et al. *J Am Chem Soc* **80** 1669 *1958*, DOI: 10.1021/ja01540a041; UV: Mason *J Chem Soc* 2071 *1954*, DOI: 10.1039/JR9540002071; *Beilstein* **26** III/IV 2097.]

8-Mercaptoquinoline ($2H_2O$, thioxine) *[491-33-8]* **$C_9H_7NS.H_2O$, M 179.2, m 58-59°, pK_1^{25} 2.0, pK_2^{25} 8.40.** Thioxine readily oxidises in air to give diquinolyl-8,8'-disulfide (which is stable). It is more convenient to make 8-mercaptoquinoline by reduction of the disulfide. [Nakamura & Sekido *Talanta* **17** 515 *1970*, DOI: 10.1016/0039-9140(63)80055-7.] The ***hydrochloride*** (see thiooxine hydrochloride below) is more stable. [*Beilstein* **21** III/IV 1197, **21/3** V 30.]

3-Methoxycarbonyl-2,5-dihydrothiophen-1,1-dioxide (methyl 3-sulfolene-3-carboxylate) *[67488-50-0]* **$C_6H_8O_4S$, M 176.2, m 57-58°, 60-62°.** If the IR shows OH bands, then dissolve the dioxide in $CHCl_2$, wash it with aqueous Na_2CO_3 and H_2O, dry it over $MgSO_4$, filter, evaporate and wash the residue with cold Et_2O and dry *in vacuo*. Its ^{1}HNMR ($CDCl_3$) has δ at 7.00 (m 1H), 3.98 (bs 4H) and 3.80 (s Me). [McIntosh & Sieler *J Org Chem* **43** 4431 *1978*, DOI: 10.1021/jo00417a007; *Beilstein* **18/6** V 5.] It has been used as a stable precursor of 2-methoxycarbonyl-1,3-butadiene for cycloaddition reactions [McIntosh & Sieler *J Org Chem* **43** 4431 *1978*, DOI: 10.1021/jo00417a007].

5-Methoxyindole *[1006-94-6]* **C_9H_9NO, M 147.2, m 52-55°, 55°, 57°, b 176-178°/17mm, pK_{Est} ~0.** Crystallise 5-methoxyindole from cyclohexane petroleum ether or petroleum ether/Et_2O. [Saito & Kikugawa *J Heterocycl Chem* **16** 1325 *1979*, DOI: 10.1002/jhet.5570160707; *Beilstein* **21** III/IV 765, **21/3** V 18.]

5-(*p*-Methoxyphenyl)-1,2-dithiole-3-thione *[42766-10-9]* **M 240.2, m 111°.** Crystallise the thione from EtOAc, BuOAc or EtOH. It sublimes at 90°/0.001mm and complexes with Sb^{3+}, Sb^{5+}, Bi^{3+}, Sn^{4+}, Ag^+, Au^{3+} and Hg^{2+}. [*Beilstein* **19** III/IV 2538.]

6-Methylaminopurine *[443-72-1]* **$C_6H_7N_5$, M 149.2, m >300°, 312-314° (dec), pK_1^{20} <1, pK_2^{20} 4.15, pK_3^{20} 10.02.** The purine is best purified by recrystallising 2g from 50ml of H_2O and 1.2g of charcoal. [UV: Albert & Brown *J Chem Soc* 2060 *1954*; DOI: 10.1039/JR9540002060; UV: Mason *J Chem Soc* 2071 *1954*, DOI: 10.1039/JR9540002071; see also Elion et al. *J Am Chem Soc* **74** 411 *1952*, DOI: 10.1021/ja01122a037.] The ***picrate*** has **m** 265°(257°) [Bredereck et al. *Chem Ber* **81** 307 *1948*, DOI: 10.1002/cber.19480810406]. [*Beilstein* **26** III/IV 3565.]

Methyl 3-aminopyrazine-2-carboxylate *[16298-03-6]* **$C_6H_7N_3O_2$, M 153.1, m 169-172°, 172°.** The ester forms yellow needles from H_2O (100 parts using charcoal). If it contains the ***free acid*** (see IR), then dissolve it in CH_2Cl_2, wash it with saturated aqueous Na_2CO_3, brine, dry over $MgSO_4$ filter, evaporate and recrystallise the residue. The ***free acid*** has **m 203-204° (dec)** [UV: Brown & Mason *J Chem Soc* 3443 *1956*, DOI: 10.1039/JR9560003443] with pK_1 <1 and pK_2 3.70. The ***ammonium salt*** has **m 232°(dec)** (from aqueous

Me_2CO) and the ***amide*** has **m 239.2°** (from H_2O) [Ellingson et al. *J Am Chem Soc* **67** 1711 *1945*, DOI: 10.1021/ja01226a028]. [*Beilstein* **25** III/IV 4412.]

9-Methylcarbazole (*N*-methylcarbazole) *[1484-12-4]* **$C_{13}H_{11}N$, M 181.2, m 87°, 89°, 90-92°.** Purify *N*-methylcarbazole by chromatography on silica gel and eluting with $CHCl_3/Me_2CO/Et_2O$ (100:5:1 v/v), or by flash chromatography using petroleum ether, or by zone melting followed by recrystallisation from petroleum ether or EtOH. [Flo & Pindur *Annalen* 509 *1987*, DOI: 10.1002/jlac.198719870366; Kashima et al. *J Heterocycl Chem* **24** 913 *1987*, DOI: 10.1002/jhet.5570240405; UV: Armarego in *Physical Methods in Heterocyclic Chemistry* (Ed Katritzky, Academic Press, LCCC No 62-12037, Internet Public Domain) **Vol III** 158 *1971*; *Beilstein* **20** H 436.]

5-Methylcytosine [4-amino-5-methylpyrimidin-2(1*H*)-one] *[554-01-8]* **$C_5H_7N_3O$, M 125.1, m 270°(dec), pK_1 4.6, pK_2 12.4.** Crystallise it from water (solubility is 3.4w/v% at ~20°). The ***hydrochloride*** has **m 299-301°** (sintering at 280°) (from aqueous HCl/Me_2CO). [Hitchings et al. *J Biol Chem* **177** 357 *1949*, http://www.jbc.org/content/177/1/357; Cohn *J Am Chem Soc* **73** 1539 *1951*, DOI: 10.1021/ja01148a039; *Beilstein* **25** II 183, **25** III/IV 3727.]

2-Methyl-1,3-dithiane *[6007-26-7]* **$C_5H_{10}S_2$, M 134.3, b 53-54°/1.1mm, 56-59°/3mm, 66°/5mm, 79-80°/8-10mm, 85°/12mm, d_4^{20} 1.121, n_D^{20} 1.560.** Wash the dithiane with H_2O, 2.5 M aqueous NaOH, H_2O, brine, dry over K_2CO_3 (use toluene as solvent if the volume of reagent is small), filter, evaporate and distil the colourless residue. Its IR (film) has ν_{max} at 1455, 1371 and 1060 (all medium and CH_3), 1451m, 1422s, 1412m, 1275m, 1236m, 1190m, 1171w, 918m and 866w (all dithiane) cm^{-1} [Corey & Erickson *J Org Chem* **36** 3553 *1971*, DOI: 10.1021/jo00822a019; Seebach & Corey *J Org Chem* **40** 231 *1975*, DOI: 10.1021/jo00890a018]. [*Beilstein* **19** III/IV 49, **19/1** V 53.] It is a useful acyl anion equivalent [Smith & Xian *J Am Chem Soc* **128** 66 *2006*, DOI: 10.1021/jo00890a018].

Methylene Blue [3,7-bis-(dimethylamino)phenothiazin-5-ium chloride *[61-73-4]* **M 319.9, CI 52015, ε_{654} 94,000 (EtOH), ε_{664} 81,000 (H_2O), pK^{25} 3.8.** Crystallise the chloride from 0.1M HCl (16ml/g), the crystals are separated by centrifugation, washed with chilled EtOH and diethyl ether, and dried under vacuum. Crystallise it from 50% aqueous EtOH, wash it with absolute EtOH, and dry it at 50-55° for 24 hours. It has also been crystallised from *benzene/MeOH (3:1). It was salted out with NaCl from a commercial concentrated aqueous solution, then crystallised from water, and dried at 100° in an oven for 8-10 hours. [*Beilstein* **27** III/IV 5152.]

Methylene Green [3,7-bis-(dimethylamino)-4-nitrophenothiazin-5-ium chloride] *[2679-01-8]* **M 364.9, m >200°(dec), CI 52020, pK^{25} 3.2.** Crystallise the dye three times from water (18ml/g). [*Beilstein* **27** H 399.] The ***$ZnCl_2$ double salt*** [6722-15-2] **M** 866.0 has the same **CI**. [*Beilstein* **27** III/IV 5157.]

2-Methylene-oxetan-2-one (diketene) *[674-82-8]* **M 84.1, m -7°, b 41°/50.5mm, 66-68°/90mm, 127°/760mm, d_4^{20} 1.440, n_D^{20} 1.4376, n^{25} 1.4348.** Diketene polymerises violently in the presence of alkali. Distil it under reduced pressure, then fractionally crystallise it by partial freezing (using as a cooling bath made from a 1:1 solution of $Na_2S_2O_3$ in water, cool with Dry-ice until slushy, and store it in a Dewar flask). Freezing proceeds slowly, and takes about a day for half completion. The crystals are separated and stored in a refrigerator under N_2. [Miller & Carlson *J Am Chem Soc* **79** 3995 *1957*, DOI: 10.1021/ja01572a010; Andreades & Carlson *Org Synth* Coll Vol **5** 679 *1973*, DOI: 10.15227/orgsyn.045.0050; *Beilstein* **7** I 309, **7** II 525, **1** III 2947, **17** III/IV 4297, **17/9** V 115.] See ketene [463-51-4] in 'Aliphatic Compounds', in this Chapter.

2-Methylfuran (Silvan) *[534-22-5]* **C_5H_6S, M 82.1, m –90.19°, b 62.7-62.8°/731mm, 63-66°/atm, d_4^{20} 0.917, n_D^{20} 1.436.** Wash it with acidified saturated ferrous sulfate solution (to remove peroxides), separate, dry with $CaSO_4$ or $CaCl_2$, and fractionally distil it from KOH immediately before use. To reduce the possibility of spontaneous polymerisation, addition of about one-third of its volume of heavy mineral oil to 2-methylfuran prior to distillation has been recommended. [*Beilstein* **17** H 36, **17** I 18, **17** II 39, **17** III/IV 265, **17/1** V 322.]

1-Methylguanine *[938-85-2]* **$C_6H_7N_5O$, M 165.2, m >300°(dec), pK_1^{20} ~0, pK_2^{20} 3.13, pK_3^{20} 10.54.** Crystallise it from H_2O or 50% aqueous acetic acid. [*Beilstein* **26** III/IV 3892.]

7-Methylguanine *[578-76-7]* **$C_6H_7N_5O$, M 165.2, pK_1^{20} ~0, pK_2^{20} 3.50, pK_3^{20} 9.95.** Crystallise it from water. It has UV with λ_{max} at 280nm (pH 2.1). The ***picrate*** has **m 267°** (**270-272° dec**, also reported). [*Beilstein* **26** H 455, **26** I 134, **26** II 263, **26** III/IV 3890.]

N*-Methylimidazole** *[616-47-7]* **$C_4H_6N_2$, M 82.1, m -6°, b 81-84°/27mm, 197-198°/760mm, d_4^{20} 1.032, n_D^{20} 1.496, pK^{25} 7.25.** Dry it with sodium metal and then distil it. Store it at 0° under dry argon. The ***picrate has **m 159.5-160.5°** (from H_2O). [*Beilstein* **23** III/IV 568, **23/4** V 256.]
2-Methylimidazole* (2-methylglyoxaline)** *[693-98-1]* has **m 140-141°, 143-143°, 144.5-145.5°, b 267°/760mm, 267-268°/atm, pK^{25} 7.86.** Recrystallise 2-methylimidazole from *benzene or petroleum ether. The ***picrate has **m 215°** (from H_2O). [*Beilstein* **23** III/IV 594, **23/5** V 35.]
4(5)-Methylimidazole *[822-36-6]* has **m 44-47°, 47-48°, b 263°/760mm, pK^{25} 7.61.** Recrystallise 4-methylimidazole from *benzene or petroleum ether. It has **m 56°** after sublimation. The ***picrate*** has **m 162-163.5°** (from EtOH). [*Beilstein* **23** II 60, **23** III/IV 597, **23/5** V 89.]

2-Methylindole *[95-20-5]* **C_9H_9N, M 131.2, m 57-59°, 61°, b 273°/atm, pK^{25} -0.28 (C-3 protonation, aqueous H_2SO_4).** Crystallise it from *benzene. It has also been purified by zone melting. The ***picrate*** has **m 139°** (from Et_2O or Et_2O/MeOH). [Cohen et al. *J Am Chem Soc* **82** 2184 *1960*, DOI: 10.1021/ja01494a024; *Beilstein* **20** III/IV 3202, **20/7** V 59.]
3-Methylindole* (skatole)** *[83-34-1]* has **m 92-97°, 95°, b 265-266°/atm, pK^{25} -4.55 (C-3-protonation, aqueous H_2SO_4).** Crystallise skatole from *benzene or petroleum ether (**m 96.5°**). It has also been purified by zone melting. The ***picrate has **m 182°** (from Et_2O or Et_2O/MeOH). [*Beilstein* **20** III/IV 3206, **20/7** V 69.]

N*-Methylmorpholine (4-methylmorpholine)** *[109-02-4]* **$C_5H_{11}NO$, M 101.2, m -66°, b 115-116°/750mm, 116-117°/764mm, d_4^{20} 0.919, n_D^{20} 1.436, pK^{25} 7.41.** Dry it by refluxing with BaO or sodium, then fractionally distil it through a helices-packed column. The ***picrate has **m 227°**, the ***thiocyanate salt*** has **m 103°** (from butanone). [Hall *J Phys Chem* **60** 63 *1956*, DOI: 10.1021/j150535a017; *Beilstein* **27** I 203, **27** III/IV 22.]

4-Methylmorpholine-4-oxide (NMO) *[7529-22-8]* **$C_5H_{11}NO_2$, M 117.2, m 180-184° (anhydr).** When the oxide is dried for 2-3 hours at high vacuum, it dehydrates. Add MeOH to the oxide and distil off the solvent under vacuum until the temperature is *ca* 95°. Then add Me_2CO at reflux and cool to 20°. The crystals are filtered off, washed with Me_2CO and dried. The degree of hydration may vary and may be important for the desired reactions. [van Rheenen et al. *Tetrahedron Lett* **17** 1973 *1976*, DOI: 10.1016/S0040-4039(00)78093-2; Schneider & Hanze *US Pat 2 769 823*; see also Sharpless et al. *Tetrahedron Lett* **17** 2503 *1976*, DOI: 10.1016/S0040-4039(00)78130-5.] It is a non-metallic catalyst for the cyanoethylation of ketones [Zhou et al. *Synlett* **6** 1077 *2004*, DOI: 10.1055/s-2004-820045], and a co-oxidant for Sharpless asymmetric dihydroxylation in ionic liquids [Branco & Afonso *J Org Chem* **69** 4381 *2004*, DOI: 10.1021/jo035588h]. ***4-Methylmorpholine-4-oxide monohydrate*** *[70187-32-5]* **$C_5H_{11}NO_2$. H_2O, M 135.2,** has **m 71-73°, 71-75°.** The ***hydrate*** is a reagent for an improved catalytic OsO_4 oxidation of olefins to *cis*-1,2-diols [Van Rheenen et al. *Tetrahedron Lett* **17** 1973 *1976,* DOI:10.1016/S0040-4039(00)78093-2; Priebe & Zamojski *Pol J Chem* **54** 731 *1980*, see review by Schroeder *Chem Rev* **80** 187 *1980*, DOI: 10.1021/cr60324a003], and for a ruthenium catalysed oxidation of alcohols to ketones see Sharpless et al. [*Tetrahedron Lett* **17** 2503 *1976*, DOI: 10.1016/S0040-4039(00)78130-5]. A 50wt% solution of NMO is commercially available.

3-Methyl-2-oxazolidone *[19836-78-3]* **$C_4H_7NO_2$, M 101.1, m 15°, b 88-91°/1mm, d_4^{20} 1.172, n_D^{20} 1.455.** Purify the oxazolidone by successive fractional freezing, then dry it in a dry-box over 4A molecular sieves for 2 days. Distil it under high vacuum and store it dry as before. [*Beilstein* **27** III/IV 2517.]

3-Methyl-3-oxetanemethanol (3-hydroxymethyl-3-methyloxetane) *[3143-02-0]* **$C_5H_{10}O_2$, M 102.1, b 80°/4mm, 92-93°/12mm, d_4^{20} 1.033, n_D^{25} 1.4449.** Purify the oxetane by fractionation through a glass column [Pattison *J Am Chem Soc* **79** 3455 *1957*, DOI: 10.1021/ja01570a038; Corey & De *J Am Chem Soc* **106** 2735 *1984*, DOI: 10.1021/ja00321a063]. [*Beilstein* **17** III/IV 1128.] It has been used for protecting carbonyl groups in a synthesis of α-substituted γ-lactams [Raghavan & Johnson *J Org Chem* **71** 2151 *2006*, DOI: 10.1021/jo035588h].

5-Methyl-1,10-phenanthroline *[3002-78-6]* **$C_{13}H_{10}N_2$, M 194.2, m 67°(monohydrate), 113°, 113-114° (anhydrous), pK^{25} 5.28.** Crystallise it from *benzene/petroleum ether or from H_2O as the ***monohydrate***. It complexes with many metals. [*Beilstein* **23** III/IV 1714.]
5-Methylphenazinium methyl sulfate* (PMS)** *[299-11-6]* **$C_{13}H_{11}N_2$. CH_3SO_4, M 306.3,** has **m 155-157°(dec), 158-160°(dec), (198°dec by rapid heating), pK^{25} –3.5.** It forms yellow-brown prisms from EtOH (charcoal), or EtOH/Et_2O. Its solubility in H_2O at 20° is 10%. In the presence of aqueous KI it forms a ***semiquinone which crystallises as blue leaflets from EtOH. [Wieland & Roseeu *Chem Ber* **48** 1117 *1915*, DOI: 10.1002/cber.191504801155; Voriskova *Coll Czech Chem Commun 12* 607 *1947*, DOI: org/10.1135/cccc19470607; Bülow *Chem Ber* **57** 1431 *1924*, DOI: 10.1002/cber.191504801155; Campbell et al. *J Chem Soc* 404 1938, DOI: 10.1039/JR9380000404; Morley *J Chem Soc* 4008 *1952*, DOI: 10.1039/JR9520004008; *Beilstein* **23** I 59, **23** II 234, **23** III/IV 1658, **23/8** V 395.] Together with ascorbic acid, it is used to determine nitric oxide reductase.

***N*-Methylphenothiazine (10-methylphenothiazine)** *[1207-72-3]* **$C_{13}H_{11}NS$, M 213.2, α-form m 99.3°, 99-101°, 100-102°, and b 360-365°/atm, ß-form m 78-79°.** Recrystallise it (three times) from EtOH to give the α-form (prisms). Recrystallisation from EtOH/*benzene gives the β-form (needles). It has also been purified by vacuum sublimation and is carefully dried in a vacuum line. It has been crystallised from toluene or MeOH and stored in the dark [Guarr et al. *J Am Chem Soc* **107** 5104 *1985*, DOI: 10.1021/ja00304a015; Olmsted et al. *J Am Chem Soc* **109** 3297 *1987*, DOI: 10.1021/ja00245a018]. Its solubility in H_2O (pH 6.5) is 0.0544mg/100ml, and in hexane it is 2083mg/100ml. Its UV has λ_{max} at 255nm (logε 4.60) (pH 6.3) and 255nm in hexane. [Cymerman-Craig & Warburton *Aust J Chem* **9** 294 *1956*, DOI:10.1071/CH9560294; *Beilstein* **27** H 65, **27** II 33, **27** III/IV 1215.]

3-Methyl-1-phenyl-5-pyrazolone *[89-25-8]* **$C_{10}H_{10}N_2O$, M 174.2, m 126-128°, 127°, 129°, b 287°/265mm, pK^{25} 2.7.** Crystallise the pyrazolone from hot H_2O, EtOH or EtOH/water (1:1). It complexes with metals. [Veibel et al. *Acta Chim Scand* **6** 1066 *1952*, DOI: 10.3891/acta.chem.scand.06-1066; *Beilstein* **24** II 9, **24** III/IV 71.] This reagent has been used for detecting reducing carbohydrates by ESI/MALDI-MS [Lattová et al. *J Am Mass Spectrom* **16** 683 2005, DOI: 10.1016/j.jasms.2005.01.021].

1-Methyl-4-phenyl-1,2,3,6-tetrahydropyridine hydrochloride (MPTP.HCl) *[23007-85-4]* **$C_{12}H_{15}N$. HCl, M 209.7, m 196-198°, pK_{Est} ~ 9.3, pK_a 8.07 (50% aqueous EtOH).** Purify MPTP by recrystallisation from Me_2CO/isoPrOH. The ***free base*** has **m 40-42°**(from heptane), **b 99-100°/1.3mm, 128-132°/12mm**, (**137-142°/0.8mm**), **n_D^{25} 1.5347**. The ***hydrochloride*** has **m 251-252°**(from Me_2CO/isoPrOH) and its solubility in H_2O is 10mg/ml at ~20°. [Schmidle & Mansfield *J Am Chem Soc* **78** 425 *1956*, DOI: 10.1021/ja01583a048; DeFeudis *Drug Dev Res* **15** 1 *1988*, DOI: 10.1002/ddr.430150102; *Beilstein* **20** III/IV 3240, **20/7** V 121.] It is a dopaminergic neurotoxin and used in *in vitro* studies of model Parkinsonism.

(±)-2-Methylpiperazine *[109-07-9]* **$C_5H_{12}N_2$, M 100.2, m 61-62°, 61-63°, 66°, b 147-150°/739mm, 155°/763mm, pK$_1^{25}$ 5.46, pK$_2^{25}$ 9.90.** Purify it by zone melting and by distillation. It is ***hygroscopic***. The ***picrate*** has **m 275-276°**. [*Beilstein* **23** II 16, **23** III/IV 393, **23/3** V 267.] ***R*(+)-*2-Methylpiperazine*** *[75336-86-6]* has **m 91-93°, $[\alpha]_D^{20}$ -16.5 (c 5, *C_6H_6),** and is obtained by optical resolution of (±)-2-methylpiperazine *via* separation of the diastereoisomeric (+)-base *(+)*-di-*O*-benzoyl tartrate and (-)-base *(+)*-di-*O*-benzoyl tartrate. ***S*(+)-*2-methylpiperazine*** *[74879-18-8]* with **m 91-93°, $[\alpha]_D^{20}$ +6.8 (c 1, EtOH),** is obtained *via* this resolution and its absolute configuration is deduced from its preparation by cyclising glycyl-*S*-alanine to ***S(-)-3-methyl-2,5-dioxopiperazine*** $[\alpha]_{546}^{20}$ -9.6 (c 1.35 H_2O) followed by reduction with $NaAl(OCH_2CH_2OMe)_2H_2$, and 4N-HCl to give ***S*(-)-*2-methylpiperazinium dihydrochloride*** which after sublimation at 190°/2mm and recrystallisation from MeOH/Et_2O has **m 286-289°** (effervescence and sublimation) and $[\alpha]_{546}^{20}$ -3.5 (c 1.2, 2N-HCl). [Armarego et al. *Journal of Chemical Research* 133 (S), 1951 (M) *1980*, Armarego et al. *JCS Chem Commun* 334 *1980*, DOI: 10.1039/C39800000334.]

(±)-3-Methylpiperidine *[626-56-2]* **$C_6H_{13}N$, M 99.2, b 125°/763mm, 125-126°/763mm, d_4^{20} 0.846, n_D^{25} 1.4448, pK^{25} 10.92.** Purify it *via* the ***hydrochloride*** (**m 172°**). The ***hydrobromide*** has **m 162-163°**(from iso-PrOH). [Chapman et al. *J Chem Soc* 1925 *1959*, DOI: 10.1039/JR9590001925; *Beilstein* **20** III/IV 1499, **20/4** V 100.]

2-Methylpyrazine *[109-08-0]* **$C_5H_6N_2$, M 94.1, m –28.8°, –29°, b 135°/761mm, 136-137°/atm, d_4^{20} 1.025, n_D^{20} 1.505, pK_1^{25} -5.25 (aqueous H_2SO_4), pK_2^{25} 1.47.** Purify it *via* the ***picrate*** and distil the ***free base***. The ***picrate*** has **m 133-134°**(from EtOH). [Wiggins & Wise *J Chem Soc* 4780 *1956*, DOI: 10.1039/JR9560004780; *Beilstein* **23** III/IV 911, **23/5** V 386.]

2-Methylpyridine (2-picoline, α–picoline) *[109-06-8]* **C_6H_7N, M 93.1, m –70°, b 128-129°/atm, 129.4°/760mm, d_4^{20} 0.9444, n_D^{20} 1.50102, pK^{25} 5.96.** Biddiscombe et al. [*J Chem Soc* 1957 *1954*, DOI: 10.1039/JR9540001957] steam distilled a boiling solution of the base in 1.2 equivalents of 20% H_2SO_4 until about 10% of the base had been carried over, along with non-basic impurities. Excess aqueous NaOH is then added to the residue, the free base is separated, dried with solid NaOH and fractionally distilled. 2-Methylpyridine can also be dried with BaO, CaO, CaH_2, $LiAlH_4$, or Linde type 5A molecular sieves. An alternative purification is *via* the ***$ZnCl_2$ adduct***, which is formed by adding 2-methylpyridine (90ml) to a solution of anhydrous $ZnCl_2$ (168g) and 42ml concentrated HCl in absolute EtOH (200ml). Crystals of the complex are filtered off, recrystallised twice from absolute EtOH (to give **m 118.5-119.5°**), and the ***free base*** is liberated by addition of excess aqueous NaOH. It is steam distilled, and solid NaOH is added to the distillate to form two layers, the upper one of which is then dried with KOH pellets, stored for several days with BaO and fractionally distilled. Instead of $ZnCl_2$, $HgCl_2$ (430g in 2.4L of hot water) can be used. The complex, which separates on cooling, can be dried at 110° and recrystallised from 1% HCl (to **m** 156-157°). ***The alkali metals, Na, Li or Cs should NOT be used for drying pyridine, and pyridine derivatives, as they form coloured pyridine radical anions leading to bipyridyls***. [see Schmulbach et al. *J Am Chem Soc* **90** 6600 *1968*, DOI: 10.1021/ja01026a006]. The ***hydrochloride*** has **m 78-79°**, and the ***picrate*** has **m 165.5°**(from EtOH) and 180°(from H_2O). [*Beilstein* **20** III/IV 2679, **20/5** V 464.] ***2-Picoline Borane Complex***, *[3999-38-0]* **C_6H_7N. M 107.0, m 44-46°, 48°**, can be purified by recrystallisation from hexane and stored for long periods without noticeable decomposition. It is unchanged after heating to ~150°, and is consequently much more stable than ***pyridine borane***. It is an alternative reagent for reductive aminations [Sato et al. *Tetrahedron* **60** 7899 *2004*, DOI: 10.1016/j.tet.2004.06.045]. ***α-Picoline hydrochloride*** *[14401-91-3]* C_6H_7N. HCl, M 129.6, **m 77-78°**, **85°, b 229°/atm**, is prepared from a ***1:1 mixture*** of α-picoline and HCl is distilled at 275°, then sublimed in a vacuum at 91-91.5°. [*Beilstein* **20** H 236, **20** III/IV 2685, **20/5** V 474.]

3-Methylpyridine **(3-picoline)** *[108-99-6]* has **m -19°, -18.5°, b 144°/767mm, d_4^{20} 0.957, n_D^{20} 1.5069, pK^{25} 5.70.** In general, the same methods of purification that are described for *2-methylpyridine* can be used. However, 3-methylpyridine often contains 4-methylpyridine and 2,6-lutidine, neither of which can be removed satisfactorily by drying and fractionation, or by using the $ZnCl_2$ complex. Biddiscombe et al. [*J Chem Soc* 1957 *1954*, DOI: 10.1039/JR9540001957], after steam distillation as for ***2-methylpyridine***, treated the residue with urea to remove 2,6-lutidine, then azeotropically distilled with acetic acid (the azeotrope had **b 114.5°/712mm**), and recovered the base by adding excess of aqueous 30% NaOH, drying with solid NaOH and carefully fractionally distilling. The distillate is then fractionally crystallised by slow partial freezing. An alternative treatment [Reithoff et al. *Ind Eng Chem (Anal Edn)* **18** 458 *1946*, DOI: 10.1021/i560155a023] is to reflux the crude base (500ml) for 20-24 hours with a mixture of acetic anhydride (125g) and phthalic anhydride (125g) followed by distillation until phthalic anhydride begins to pass over. The distillate is treated with NaOH (250g in 1.5L of water) and then steam distilled. Addition of solid NaOH (250g) to this distillate (*ca* 2L) led to the separation of 3-methylpyridine which is removed, dried (K_2CO_3, then BaO) and fractionally distilled. (Subsequent fractional freezing would probably be advantageous.) ***The alkali metals, Na, Li or Cs should***

NOT be used for drying pyridine, and pyridine derivatives, as they form coloured pyridine radical anions leading to bipyridyls. [see Schmulbach et al. *J Am Chem Soc* **90** 6600 *1968*, DOI: 10.1021/ja01026a006]. The ***hydrochloride*** has **m 85°**, and the ***picrate*** has **m 153°**(from Me_2CO, EtOH or H_2O). [*Beilstein* **20** III/IV 2710, **20/5** V 506.]

4-Methylpyridine **(4-picoline)** *[108-89-4]* has **m 2.4°, 4.25°, b 145.0°/765mm, d_4^{20} 0.955, n_D^{20} 1.5058, pK^{25} 4.99.** It can be purified as for ***2-methylpyridine***. Biddescombe and Handley's method (above) for 3-methylpyridine is also applicable. Lidstone [*J Chem Soc* 241 *1940*, DOI: 10.1039/JR9400000241] purified it *via* the ***oxalate*** (**m 137-138°**) by heating 100ml of 4-methylpyridine to 80° and adding slowly 110g of anhydrous oxalic acid, followed by 150ml of boiling EtOH. After cooling and filtering, the precipitate is washed with a little EtOH, then recrystallised from EtOH, dissolved in the minimum quantity of water and distilled with excess 50% KOH. The distillate is dried with solid KOH and again distilled. Hydrocarbons can be removed from 4-methylpyridine by converting the latter to its hydrochloride, crystallising from EtOH/diethyl ether, regenerating the free base by adding alkali and distilling. As a final purification step, 4-methylpyridine can be fractionally crystallised by partial freezing to effect a separation from 3-methylpyridine. Contamination with 2,6-lutidine is detected by its strong absorption at 270nm. ***The alkali metals, Na, Li or Cs should NOT be used for drying pyridine, and pyridine derivatives, as they form coloured pyridine radical anions leading to bipyridyls.*** [see Schmulbach et al. *J Am Chem Soc* **90** 6600 *1968*, DOI: 10.1021/ja01026a006]. The ***hydrochloride*** has **m 161°**, and the ***picrate*** has **m 167°**(from Me_2CO, EtOH or H_2O). [*Beilstein* **20** III/IV 2732, **20/5** V 543.]

2-Methylpyridin-5-yltrifluoromethanesulfonate (2-methyl-5-pyridine triflate) *[111770-91-3]* **$C_7H_6F_3NO_3S$, M 241.2, b 80-82°/1.9mm, d_4^{25} 1.412, n_D^{20} 1.442.** Distil the triflate under vacuum, or if it is discoloured dissolve it in CH_2Cl_2, wash it with N NaOH and half saturated K_2CO_3, dry it over solid K_2CO_3, filter, evaporate, and distil by bulb-to-bulb distillation at 65-70°/0.1mm, then redistil *in vacuo*. Its ^1H NMR [$(CD_3)_2SO$] has δ at 2.50 (s, 3H, Me), 7.45 (d, *J* = 9.2 Hz, 1H), 7.90 (dd, *J* = 9.2, 2.3 Hz, 1H) and 8.60 (d, *J* = 2.3 Hz, 1H). [Tilley & Zawoiski *J Org Chem* **53** 386 *1988,* DOI: 10.1021/jo00237a029; Ellingboe et al. *J Med Chem* **37** 542 *1994*, DOI: 10.1021/jm00030a013.]. When stirred with *m*-chloroperbenzoic acid in CH_2Cl_2 (16 hours, 25°), filtered, concentrated and purified by flash chromatography (2% MeOH/ CH_2Cl_2), the triflate gave colourless crystals of the ***triflate N-oxide*** **m 47-48°** with ^1H NMR [$(CD_3)_2SO$] with δ at 2.36 (s, 3H, Me), 7.56 (dd, *J* = 8.9, 2.3 Hz, 1H), 7.69 (d, *J* = 8.9 Hz, 1H) and 8.84 (d, *J* = 2.3 Hz, 1H) [Ellingboe et al. *J Med Chem* **37** 542 *1994*, DOI: 10.1021/jm00030a013].

***N*-Methylpyrrole (NMP)** *[96-54-8]* **C_5H_7N, M 81.1, m -57°, b 112-113°/atm, 115-116°/756mm, d_4^{20} 0.908, n_D^{20} 1.487, pK^{25} -3.4 (-2.90).** Dry *N*-methylpyrrole with $CaSO_4$, then fractionally distil it from KOH immediately before use. [*Beilstein* **20** III/IV 2080, **20/5** V 8.]

1-Methyl-2-pyrrolidinone (1-methyl-2-pyrrolidone) *[872-50-4]* **C_5H_9NO, M 99.1, m -24.4°, b 65-76°/1mm, 78-79°/12mm, 81-82°/10mm, 94-96°/20mm, 202°/760mm, d_4^{20} 1.0328, n_D^{20} 1.4678, pK^{25} -0.17 (also -0.92, and 0.2).** Dry the pyrrolidone by removing water as the *benzene azeotrope. Fractionally distil at 10 torr through a 100-cm column packed with glass helices. [Adelman *J Org Chem* **29** 1837 *1964*, DOI: 10.1021/jo01030a041; McElvain & Vozza *J Am Chem Soc* **71** 896 *1949*, DOI: 10.1021/ja01171a037.] It is a useful solvent for reactions. The ***hydrochloride*** has **m 86-88°** (from EtOH or Me_2CO/EtOH) [Reppe et al. *Justus Liebigs Ann Chem* **596** 1 *1955*, DOI: 10.1002/jlac.19555960102]. 8-Methylquinoline *[611-32-5]* has **m -80°, b 122.5°/16mm, 143°/34mm, 247.8°/760mm, d_4^{20} 1.703, n_D^{20} 1.61631, pK^{25} 4.60.** Purify it as for 2-methylquinoline. The ***phosphate*** and ***picrate*** have **m 158°** and **m 201°**, respectively. [*Beilstein* **20** III/IV 3500, **20/7** V 405.]

(±)-3-Methylsulfolane (3-methyltetrahydrothiophene-1,1-dioxide) *[872-93-5]* **$C_5H_{10}O_2S$, M 134.2, m 0.5°, 1.0°, b 101°/2mm, 104°/3mm, 125-130°/12mm, 278-282°/763.5mm, d_4^{20} 1.1885, n_D^{20} 1.4770.** Distil the sulfolane under vacuum and recrystallise it from Et_2O at -60° to -70°, if necessary. An IR film has strong bands at 570 and 500 cm^{-1}. [Eigenberger *J Prakt Chem [2]* **131** 289 *1931*, DOI: 10.1002/prac.19311310118; Freaiheller & Katon *Spectrochim Acta* **20** 1099 *1964*, DOI: 10.1016/0371-1951(64)80160-0; Whitehead et al. *J Am Chem Soc* **73** 3632 *1951*, DOI: 10.1021/ja01152a022; *Beilstein* **17** I 8, **17** III/IV 64.]

(±)-2-Methyltetrahydrofuran *[96-47-9]* **$C_5H_{10}O$, M 86.1, b 78-80°/atm, 80.0°/760mm, d_4^{20} 0.856, n_D^{20} 1.4053.** Likely impurities are 2-methylfuran, methyldihydrofurans and hydroquinone (stabiliser, which is removed by distillation under reduced pressures). It is washed with 10% aqueous NaOH, dried, vacuum distilled from CaH_2, passed through freshly activated alumina under nitrogen, and refluxed over sodium metal under vacuum. Store it over sodium. [Ling & Kevan *J Phys Chem* **80** 592 *1976*, DOI: 10.1021/j100547a008.] Distil it from sodium under vacuum, and store it with sodium-potassium alloy (this treatment removes water and prevents the formation of peroxides). *Alternatively*, it can be freed from peroxides by treatment with ferrous sulfate and sodium bisulfate, then solid KOH, followed by drying with, and distilling from, sodium, or type 4A molecular sieves under argon. It may be difficult to remove *benzene if it is present as an impurity (can be readily detected by its ultraviolet absorption in the 249-268nm region). [Ichikawa & Yoshida *J Phys Chem* **88** 3199 *1984*, DOI: 10.1021/j150659a013.] It has also been purifed by percolating through Al_2O_3 and fractionated collecting fraction **b** 79.5-80°. After degassing, the material is distilled onto degassed molecular sieves, then distilled onto anthracene and a sodium mirror. The solvent is then distilled from the green solution onto potassium mirror or sodium-potassium alloy, from which it is distilled again. [Kosower & Mohammad *J Am Chem Soc* **93** 2713 *1971*, DOI: 10.1021/ja00740a022.] It should be stored in the presence of 0.1% of hydroquinone or 2,6-di-*tert*-butyl-*p*-cresol as stabiliser. The ***R*(+)-*enantiomer*** has **b 78-80°/atm** and $[\alpha]_D^{20}$ +27.5 (neat), and the ***S*(-)-*enantiomer*** has **b 86°/atm** and $[\alpha]_D^{20}$ -27.0 (neat) [Iffland & Davis *J Org Chem* **42** 4150 *1977*, DOI: 10.1021/jo00445a038, Gagnaire & Butt *Bull Soc Chim Fr* 312 *1961*, *Beilstein* **17** III/IV 60, **17/1** V 78.] **HARMFUL VAPOURS.**

3-Methylthiophene *[616-44-4]* **C_5H_6S, M 98.2, m -69°, b 60°/116mm, 111-113°/atm, 115.5°/atm, d_4^{20} 1.024, n_D^{20} 1.531.** Dry it with Na_2SO_4, then distil it from sodium. [*Beilstein* **17** III/IV 277, **17/1** V 331.]

6(4)-Methyl-2-thiouracil *[56-04-2]* **$C_5H_6N_2OS$, M 142.2, m 330°(dec), 299-303°(dec), 323-324°(dec), d 1.36, pK^{25} 8.1.** Crystallise the thiouracil from a large volume of H_2O. Purify it further by dissolving in base, adding charcoal, filtering and acidifying with AcOH. Suspend the wet solid (*ca* 100g) in boiling H_2O (1L), stir and add AcOH (20ml), stir and refrigerate. Collect the product, wash it with cold H_2O (4 x 200ml), drain it for several hours then place it in an oven at 70° to constant weight. It has antithyroid properties. [IR: Short & Thompson *J Chem Soc* 168 *1952*, DOI: 10.1039/JR9520000168; Foster & Snyder *Org Synth* Coll Vol **4** 638 *1963*, DOI: 10.15227/orgsyn.035.0080; *Beilstein* **24** III/IV 1289.]

4-Methyl-1,2,4-triazoline-3,5-dione (MTAD) *[13274-43-6]* **$C_3H_3N_3O_2$, M 113.1, m 103-104°, m 107-109°.** MTAD is obtained as pink (red crystals) needles by sublimation at 40-50°/0.1mm (see 4-phenyl-1,2,4-triazoline-3,5-dione, PTAD below). [Cookson et al. *Org Synth* **51** 121 *1971*, DOI: 10.15227/orgsyn.051.0121; Cheng et al. *J Org Chem* **49** 2910 *1984*, DOI: 10.1021/jo00190a014; *Beilstein* **26** III/IV 538.] It is one of the most reactive of dienophiles towards dienes [Cookson et al. *Tetrahedron Lett* **3** 615 *1962*, DOI: 10.1016/S0040-4039(00)70917-8; Gillis & Hagarty *J Org Chem* **32** 330 *1967*, DOI: 10.1021/jo01288a016,] and mono-olefines [Pirkle & Stickler *JCS Chem Commun* 760 *1967*, DOI: 10.1039/C19670000760].

2-Methyltricycloquinazoline *[2642-52-6]* **$C_{22}H_{14}N_4$, M 334.4, m >300°.** Purify it by crystallisation from $^*C_6H_6$, toluene or xylene followed by vacuum sublimation. [cf. *Beilstein* **26** III/IV 1932.] **CARCINOGEN.**

5-Methyltryptamine hydrochloride (3-[2-aminoethyl]-5-methylindole hydrochloride) *[1010-95-3]* **$C_{11}H_{14}N_2$. HCl, M 210.7, m 289-291°(dec), 290-292°, $pK_{Est(1)}$~ -3 (protonation of ring NH), $pK_{Est(2)}$~ 9.0 (CH_2NH_2), $pK_{Est(3)}$~ 10.9 (acidic indole NH).** Recrystallise the hydrochloride from H_2O. The ***free base*** has **m 96-98°** (from $^*C_6H_6$/cyclohexane) or **m 99-100°** (from petroleum ether), and the ***picrate*** has **m 243°(dec)** (from EtOH). [Young *J Chem Soc* 3493 *1958*, DOI: 10.1039/JR9580003493; Gaddum et al. *Quart J Exp Physiol* **40** 49 *1955*, Röhm *Hoppe Seyler's Z Physiol Chem* **297** 229 *1954*, PMID: 14371990; *Beilstein* **22** III/IV 4364, **22/10** V 167.]

6-Methyluracil *[626-48-2]* **$C_5H_6N_2O_2$, M 126.1, m 270-280°(dec), 318°(dec), λ_{max} 260_{nm} logε 3.97, pK_1 ~1.1, pK_2 9.8.** Crystallise 6-methyluracil from EtOH or acetic acid. [*Beilstein* **24** III/IV 1281.]

1-Methyluric acid *[708-79-2]* **$C_6H_6N_4O_3$, M 182.1, m >350°, pK_1 5.75 (basic), pK_2 10.6 (acidic).** Recrystallise it from H_2O. Its solubility at 17.5° is 1g in 353ml of H_2O. [Bergmann & Dikstein *J Am Chem Soc* **77** 691 *1955*, DOI: 10.1021/ja01608a044.] It has UV with λ_{max} at 231 and 283nm (pH 3), and 217.5 and 292.5nm (pH >12) [Johnson *Biochem J* **51** 133 *1952*, DOI: 10.1042/bj0510133]. [*Beilstein* **26** II 299, **26** III/IV 2621.]
3-Methyluric acid *[39717-48-1]* has **m >350°, pK_1 5.75 (6.2), pK_2 >12.** Crystallise it from water. Its solubility at 17.5° is 1g in 19.7L of H_2O. It has UV with λ_{max} at 232 and 287 nm (pH 3), and 214 and 292.5nm (pH >12). [*Beilstein* **26** II 299, **26** III/IV 2621.]
7-Methyluric acid *[612-37-3; 30409-21-3]* has **m >380°, pK_1 5.6, pK_2 10.3.** Crystallise it from water. It has UV with λ_{max} at 234 and 286nm (pH 3), 237 and 293nm (8.5), and 222 and 296.5nm (pH >12) [*Beilstein* **26** H 525, **26** II 299, **26** III/IV 2622.]
9-Methyluric acid *[30345-24-5, 55441-71-9]* has **m 385-400°(dec), >400°, d^{25} 1.73g/ml, n_D^{20} 1.70 (predicted), pK_{Est} ~5.65.** Crystallise it from water (solubility is 2mg/ml at 25°). [*Beilstein* **26** III/IV 2622.]

1-Methylxanthine (1-methyl-purin-2,6(3-*H*,7-*H*)-dione) *[6136-37-4]* **$C_6H_6N_4O_2$, M 166.1, m >360° pK_1^{20} 1.3, pK_2^{20} 7.9, pK_3^{20} 11.8.** Crystallise it from water. It has UV with λ_{max} at 266nm (pH 2.08), 242.5 and 276nm (pH 9). [*Beilstein* **26** II 263, **26** III/IV 2329.]
3-Methylxanthine *[1076-22-8]* has **m >360° pK_1^{20} 8.45, pK_2^{20} 11.92.** Crystallise it from water. [*Beilstein* **26** II 263, **26** III/IV 2329.]
7-Methylxanthine *[552-62-5]* has **m >380°(dec) pK_1^{20} 8.42, pK_2^{20} >13.** Crystallise it from water. [*Beilstein* **26** II 263, **26** III/IV 2330.]
8-Methylxanthine *[17338-96-4]* has **m 292-293°(dec).** Crystallise it from water. [*Beilstein* **26** III/IV 2464.]
9-Methylxanthine *[1198-33-0]* has **m 384°(dec), pK_1^{20} 2.0, pK_2^{20} 6.12, pK_3^{20} 10.5 (>13).** Crystallise it from water. [*Beilstein* **26** II 263, **26** III/IV 2330.]

Morin (hydrate) (2',3,4',5,7-pentahydroxyflavone) *[90-34-6, 480-16-0 (anhydr), 6472-38-4 (dihydrate)]* **$C_{15}H_{10}O_7$. $2H_2O$, M 302.2 (338.3), m 289-292°, CI 75660, pK_1 5.3, pK_2 8.74.** Stir morin at room temperature with ten times its weight of absolute EtOH, then leave overnight to settle. Filter it off, and evaporate under a heat lamp to one-tenth its volume. An equal volume of water is added, and the precipitated morin is filtered off, dissolved in the minimum amount of EtOH and again precipitated with an equal volume of water. The precipitate is filtered off, washed with water and dried at 110° for 1 hour (yield *ca* 2.5%.). [Perkins & Kalkwarf *Anal Chem* **28** 1989 *1956*, DOI: 10.1021/ac60120a051.] It complexes with W and Zr. [*Beilstein* **18** H 239, **18** III/IV 3468, **18/5** V 492.] It protects cells against γ-radiation induced oxidative state [Zhang et al. *Basic & Clin Pharmacol & Toxicol* **108** 63 *2001* DOI: 10.111/j.1742-7843.2010.00629.x.]

Morpholine *[110-91-8]* **C_4H_9NO, M 87.1, m -7° to -5°, -4.9°, b 128.9°/760mm, d_4^{20} 1.0007, n_D^{20} 1.4540, n_D^{25} 1.4533, pK^{25} 8.33.** Dry morpholine with KOH, fractionally distil it, then reflux it with Na, and again fractionally distil it. Dermer & Dermer [*J Am Chem Soc* **59** 1148 *1937*, DOI: 10.1021/ja01285a503] precipitated it as the ***oxalate*** by adding slowly to slightly more than 1 molar equivalent of oxalic acid in EtOH. The precipitate is filtered off and recrystallised twice from 60% EtOH [***1:1 salt*** has **m 190-195°(dec)**]. Addition of the oxalate to concentrated aqueous NaOH regenerated the base, which is separated and dried with solid

KOH, then sodium, before being fractionally distilled. The ***hydrochloride*** has **m 178-179°** (from MeOH/Et_2O), and the ***picrate*** has **m 151.6°** (from aqueous EtOH). [*Beilstein* **27** II 3, **27** III/IV 15.]
§ A polystyrene supported morpholine is commercially available.

2-(*N*-Morpholino)ethanesulfonic acid (MES) *[4432-31-9]* **$C_6H_{13}NO_4S.\ xH_2O$, M 195.2 (anhyd), m >300°(dec), pK_1 1.99, pK_2 6.15.** Crystallise MES from hot EtOH containing a little water. Useful buffer in the pH range 5.5—6.7. The ***picrate*** crystallises from EtOH and has **m 178.8-182°**. [Malkiel & Mason *J Org Chem* **8** 199 *1943*, DOI: 10.1021/jo01191a001; *Beilstein* **27** III/IV 370.]

Murexide (ammonium purpurate, 5,5'-nitrilobarbituric acid) *[3051-09-0]* **$C_8H_8N_6O_6$, M 284.2, m >300°, λ_{max} 520nm (ε 12,000), pK_2 9.2, pK_3 10.9.** The sample may be grossly contaminated with uramil, alloxanthine, etc., and may be difficult to purify. It is better to synthesise it from pure alloxanthine [Davidson *J Am Chem Soc* **58** 1821 *1936*, DOI: 10.1021/ja01300a509]. Recrystallise a purer sample from hot water to give purple-red crystals with a green lustre which produce deep purple solutions in H_2O that turn deep blue on addition of NaOH. [Kuhn & Lyman *Chem Ber* **69** 1547 *1936*, DOI: 10.1002/cber.19360690656; *Beilstein* **25** I 709, **25** III/IV 4236.] It is a complexometric titration indicator.

α-Naphthoflavone (7,8-benzoflavone) *[604-59-1]* **$C_{19}H_{12}O_2$, M 272.3, m 153-155°, 153-157°, 155°, pK^{25} 8-9 (phenolic OH).** Recrystallise the yellow flavone from EtOH or aqueous EtOH. [IR: Cramer & Windel *Chem Ber* **89** 354 *1956*, DOI: 10.1002/cber.19560890227; UV Pillon & Massicot *Bull Soc Chim Fr* 26 *1954*, Smith et al. *J Chem Soc* 542 *1946*, DOI: 10.1039/JR9460000542; Mahal & Venkataraman *J Chem Soc* 1767 *1934*, DOI: 10.1039/JR9340001767.] It is a competitive inhibitor of human estrogen synthase (aromatase). [Kellis & Vickery *Science* **225** 1032 *1984*, DOI: 10.1126/science.6474163; *Beilstein* **17** III/IV 5550.] ***β-Naphthoflavone* (5,6-benzoflavone)** *[6051-87-2]* **$C_{19}H_{12}O_2$, M 272.3, m 164-166°, pK^{25} 8-9 (phenolic OH)** is purified in the same manner.

Naphthol AS-acetate (3-acetoxynaphthoic acid anilide) *[1163-67-3]* **$C_{19}H_{15}NO_3$, M 305.3, m 152°, 160°, 160-162°.** Recrystallise it from hot MeOH and dry *in vacuo* over P_2O_5. It has **m 252°** after sublimation at 210-215°. It is slightly soluble in AcOH, EtOH, $CHCl_3$ or $*C_6H_6$. It is a fluorogenic substrate for albumin esterase activity. [Chen & Scott *Anal Lett* **17** 857 *1984*, DOI: 10.1080/0003271811681085] At λ_{ex} 320nm it has fluorescence at λ_{em} 500nm. [Brass & Sommer *Chem Ber* **61** 993 *1928*, DOI: 10.1002/cber.19280610518; *Beilstein* **12** II 260, **12** III 960, **12** IV 923.]

1,5-Naphthyridine *[254-79-5]* **$C_8H_6N_2$, M 130.1, m 69-75°, 75°, b 112°/15mm, pK^{20} 2.84.** Recrystallise the base from light petroleum (60-70°) and sublime it at 40°/0.005mm colourless needles. It can also be distilled under a vacuum. The ***picrate*** crystallises from EtOH with **m 200°(dec)**. The ***dihydrochloride*** has **m 234°(dec)** after recrystallisation from EtOH/HCl/Et_2O. [Albert *J Chem Soc* 1790 *1960,* DOI: 10.1039/JR9600001790; UV: Armarego in *Physical Methods in Heterocyclic Chemistry* (Ed Katritzky, Academic Press, LCCC No 62-12037, Internet Public Domain) **Vol III** 133 *1971*, *Beilstein* **23** II 178, **23** III/IV 1235.]
1,8-Naphthyridine *[254-60-4]* has **m 99°, 98-99°, pK^{20} 3.36.** Purify 1,8-naphthyridine through an Al_2O_3 column and elute with toluene and petroleum ether, evaporate the eluate, crystallise the residue from petroleum ether (b 60-80°), and sublime it at 80°/13mm. The ***picrate*** *[15936-16-0]* has **m 207-208°** (from EtOH), and the ***methiodide*** has **m 180-181°** (from EtOH). [Albert *J Chem Soc* 1790 *1960,* DOI: 10.1039/JR9600001790; Armarego *J Chem Soc (C)* 377 *1967,* DOI: 10.1039/J39670000377, Hawes & Wibberley *J Chem Soc (C)* 1564 *1967*, DOI: 10.1039/J39670001564; UV: Armarego in *Physical Methods in Heterocyclic Chemistry* (Ed Katritzky, Academic Press, LCCC No 62-12037, Internet Public Domain) **Vol III** 134 *1971*, *Beilstein* **23** II 178, **23** III/IV 1237.]

(±)-Naringenin (4',5,7-trihydroxyflavanone) *[480-41-1, 67604-48-2]* **$C_{15}H_{12}O_5$, M 272.3, m 247-254°, 251° (phenolic pKs~ 8-11).** Crystallise it from EtOH or aqueous EtOH. It has UV with λ_{max} at 290nm (EtOH). The ***S*(-)-*enantiomer*** (natural form) has **m 255-256°** (from EtOH) and $[\alpha]_D^{20}$ -28.0 (c 2, EtOH), $[\alpha]_D^{20}$ -35.2 (c 1, pyridine). [*Beilstein* **18** H 503, **18** II 164, **18** III/IV 2630.] **Genistein (4',5,7-trihydroxyisoflavone)** *[446-72-0]* **$C_{15}H_{12}O_5$, M 270.2** crystallises from 60% aqueous EtOH or water with **m 297-298°** and **$[\alpha]_D^{20}$ -28 (c 0.6, 20mM NaOH).** [*Beilstein* **18/4** V 594.]

Neutral Red (2-amino-8-dimethylamino-3-methylphenazine HCl, Basic Red 5, CI 50040) *[553-24-2]* **$C_{15}H_{16}N_4$. HCl, M 288.8, m 290°(dec), pK^{25} 6.5.** Crystallise the dye from *benzene/MeOH (1:1). In aqueous solution the indicator is red at pH 6.8 and yellow at pH 8.0. Useful biological stain. [*Beilstein* **25** III/IV 3054.]

Nicotinaldehyde thiosemicarbazone *[3608-75-1]* **$C_7H_8N_4S$, M 180.2, m 222-223°, 225°.** Crystallise the derivative from EtOH, BuOH or water. Its ***hydrochloride*** *[2104-92-9]* crystallises from aqueous EtOH with **m 237-239°** (**dec**). [*Beilstein* **21** III/IV 3542 **21/7** V 342.]

Nicotinic acid (Niacin *is also used for the acid***, pyridine-3-carboxylic acid)** *[59-67-6]* **$C_6H_5NO_2$, M 123.1, m 232-234°, pK_1^{25} 2.00, pK_2^{25} 4.82.** Crystallise it from *C_6H_6, EtOH or H_2O. It sublimes without decomposition. [McElvain *Org Synth* Coll Vol **1** 385 *1941*, DOI: 10.15227/orgsyn.004.0049; *Beilstein* **22** III/IV 439, **22/2** V 57.] ***Nicotinic acid hydrazide*** *[553-53-7]* **$C_6H_7N_3O$, M 137.1, m 159-161°, pK_1^{25} 2.2, pK_2^{25} 3.63, pK_3^{25} 11.49(NH).** Crystallise it from aq EtOH or *C_6H_6. [*Beilstein* **22** III/IV 439, **22/2** V 121.]

Nile Blue A (a benzophenoxazinium sulfate dye) *[3625-57-8]* **$(C_{20}H_{20}N_3O)_2$. SO_4, M 732.9, m >300°(dec), CI 51180, pK^{25} 2.4.** Crystallise the dye from aqueous AcOH. It has UV with λ_{max} at 630nm (96% aqueous EtOH) and 635nm (H_2O). The ***betaine*** has UV with λ_{max} at 513nm (EtOH). [Crossley et al. *J Am Chem Soc* **74** 578 *1952*, DOI: 10.1021/ja01123a002; Merrill & Spencer *J Am Chem Soc* **70** 3683 *1948*, DOI: 10.1021/ja01191a043; *Beilstein* **27** II 457, **27** III/IV 5166.]

5-Nitrobarbituric acid (dilituric acid) *[480-68-2]* **$C_4H_3N_3O_5$, M 173.1, m 176°, 176-183°(dec), pK^{20} 10.25.** Crystallise diliuric acid from water as the ***trihydrate,*** **m 180-181°** (**dec**). Drying over 70% H_2SO_4 converts the trihydrate to the ***dihydrate***. Used for detection of traces of potassium and for precipitation of alkaloids. [Loeffler & Moore *J Am Chem Soc* **70** 3650 *1948*, DOI: 10.1021/ja01191a031]. [*Beilstein* **24** H 474, **24** II 273, **24** III/IV 1882.]

4'-Nitrobenzo-15-crown-5 *[60835-69-0]* **$C_{14}H_{19}NO_8$, M 313.3, m 84-85°, 93-95°.** Recrystallise the crown ether from EtOH, MeOH or *C_6H_6/hexane as for the 18-crown-6 compound below. It complexes with Na^+, K^+, NH_4^+, Ca^{2+}, Mg^{2+} and Cd^{2+}. The ^{1}HNMR spectrum ($CDCl_3$) has δ (ppm) at 3.6-4.4 (m 16CH_2), 6.8 (d 1H arom), 7.65 (d 1H arom), 7.80 (dd 1H arom J_{ab} = 9Hz and J_{bc} = 3Hz) [Schmid et al. *J Am Chem Soc* **98** 5198 *1976*, DOI: 10.1021/ja00433a024; Kikukawa et al. *Bull Chem Soc Jpn* **50** 2207 *1977*, DOI org/10.1246/bcsj.50.2207; Toke et al. *Justus Liebigs Ann Chem* 349, *1988*, DOI: 10.1002/jlac.198819880408; 761 *1988* DOI: 10.1002/jlac.198819880810; Lindner et al. *Z Anal Chem* **322** 157 *1985*].
4'-Nitrobenzo-18-crown-6 *[53408-96-1]* **$C_{16}H_{23}NO_8$, M 357.4,** has **m 82-86°, 83-84°.** If impure and discoloured, then chromatograph it through Al_2O_3 and elute with *C_6H_6/hexane (1:1) containing 1% MeOH. The fractions are followed by TLC on Al_2O_3 (with Dragendorff's reagent for detection: R_F 0.6 in the above solvent system). Recrystallise the residues from the required fractions from *C_6H_6/hexane to give yellowish leaflets. It complexes with Na or K ions with $\log K_{Na}$ 3.95 and $\log K_K$ 4.71. [Petranek & Ryba *Coll Czech Chem Commun* **39** 2033 *1974*, DOI: 10.1135/cccc19742033.]

4-(4-Nitrobenzyl)pyridine (PNBP) *[1083-48-3]* **$C_{12}H_{10}N_2O_2$, M 214.2, m 69-71°, 70-71°, 74°, pK_{Est} ~5.0.** Crystallise PNBP from aqueous EtOH or cyclohexane. The ***hydrochloride*** has **m 194-196°(dec**, from EtOH), and the ***picrate*** has **m 168°(dec**, from EtOH/EtOAc). [*Beilstein* **20** II 272, **20/7** V 564.]

5-Nitroindole *[6146-52-7]* **$C_8H_6N_2O_2$, M 162.1, m 140-142°, 141-142°, pK^{25} -7.4 (aqueous H_2SO_4).** Decolourise (charcoal) 5-nitroindole and recrystallise it twice from aqueous EtOH or recrystallise it from octane. It has UV has λ_{max} at 265 and 324nm (EtOH). [*Beilstein* **20** III/IV 3194, **20/7** V 41.]

Nitron [1,4-diphenyl-3-phenylamino-(1*H*)-1,2,4-triazolium (hydroxide) inner salt] *[2218-94-2]* **$C_{20}H_{16}N_4$, M 312.4, m 189°(dec), 189-190°(dec).** Crystallise it from EtOH, chloroform or EtOH/*C_6H_6. [*Beilstein* **25** III/IV 1075.] It is used for the spectroscopic determination of nitrate and perchlorate.

5-Nitro-1,10-phenanthroline *[4199-88-6]* **$C_{12}H_7N_3O_2$, M 225.2, m 197-198°, 203°, 203-204°, pK^{25} 3.33.** Crystallise the phenanthroline from *benzene/petroleum ether, until anhydrous. It also crystallises from H_2O with **m 202°**, and EtOAc with **m 203°.** Its pK^{25} varies from 3.20 to 2.69 with varying MeOH/H_2O ratios from 0

to 0.95 moles/L, and from 3.20 to 1.95 in varying EtOH/H_2O ratios from 0 to 0.94 moles/L [Ram et al. *J Prakt Chem* **319** 719 *1977*, DOI: 10.1002/prac.19773190504]. It forms complexes with Cu^{2+}, Zn^{2+}, In^{2+}, Fe^{2+}, Co^{2+}, Ni^{2+}. [*Beilstein* **23** III/IV 1682, **23/8** V 425.]

3-Nitro-2-pyridinesulfenyl chloride *[68206-45-1]* **$C_5H_3ClN_2O_2S$, M 190.2, m 205°(dec), 217-222°(dec).** The chloride crystallises as yellow needles from CH_2Cl_2. When pure, it is stable for several weeks at room temperature, and no decomposition was observed after 6 months at <0°. It is moisture sensitive. Its UV (MeCN) has λ_{max} at 231nm (ε 12,988), 264nm (ε 5,784) and 372nm (ε 3,117). [NMR and UV: Matsueda & Aiba *Chem Lett* 951 *1978*, DOI: org/10.1246/cl.1978.951; Wagner et al. *Chem Ber* **75** 935 *1942*, DOI: 10.1002/cber.19420750802.]

5-Nitroquinoline *[607-34-1]* **$C_9H_6N_2O_2$, M 174.2, m 70°, 71-73°, pK^{20} 2.69.** Crystallise 5-nitroquinoline from pentane, then from *benzene. The ***hydrochloride*** has **m 224°** and the ***picrate*** has **m 206°, 214°**(from MeOH). [*Beilstein* **20** H 371, **20** II 235, **20** III/IV 3397.]
8-Nitroquinoline *[607-35-2]* has **m 88-89°, 89-91°, 91-92°, pK^{20} 2.55.** Crystallise 8-nitroquinoline from hot water, MeOH, EtOH or EtOH/diethyl ether (3:1). It sublimes at 70°/2mm. [*Beilstein* **20** H 373, **20** III/IV 3399.]

4-Nitroquinoline 1-oxide *[56-57-5]* **$C_9H_6N_2O_3$, M 190.2, m 154-155°, 154-156°, 157°.** The *N*-oxide recrystallises from aqueous acetone as yellow needles or platelets. [Ochiai *J Org Chem* **18** 534 *1953*, DOI: 10.1021/jo01133a010; *Beilstein* **20** III/IV 3396.]

5-Nitrouracil (2,4-dihydroxy-5-nitropyrimidine) *[611-08-5]* **$C_4H_3N_3O_4$, M 157.1, m 280-285°, >300°, pK_1^{20} 0.03, pK_2^{20} 5.55, pK_3^{20} 11.3.** The uracil recrystallises in prisms from boiling H_2O as the ***monohydrate*** and loses H_2O on drying *in vacuo*. [UV: Brown *J Chem Soc* 3633(3647) *1959*, DOI: 10.1039/JR9590003633, Note; Brown *J Appl Chem* **2** 239 *1952*, DOI: 10.1002/jctb.5010020502; Johnson *J Am Chem Soc* **63** 263 *1941*, DOI: 10.1021/ja01846a063; *Beilstein* **24** I 313, **24** II 171, **24** III/IV 1236.]

4-Nonadecylpyridine (hydrogen ionophore II [ETH 1907] - Proton ionophore) *[70268-36-9]* **$C_{24}H_{43}N$, M 345.6, b 180°/0.07mm, pK_{Est}~ 6.0.** Dissolve the waxy ionophore (*ca* 60g) in $CHCl_3$ (200ml), wash it with H_2O (3 x 200ml), dry it and evaporate it to dryness, then distil it in a vacuum. A waxy solid is formed on cooling the distillate. Its UV has λ_{max} at 257nm (ε 1.86 x 10^3 $M^{-1}cm^{-1}$), 308nm (ε 1.7 x 10^2 $M^{-1}cm^{-1}$). [IR, NMR UV: Valenty et al. *Inorg Chem* **18** 2160 *1979*, DOI: 10.1021/ic50198a023.]

Octadecyl isonicotinate (hydrogen ionophore IV ETH 1778) *[103225-02-1]* **$C_{24}H_{41}NO_2$, M 375.6, m 57.5°, pK_{Est}~ 3.5**. Dissolve it in Et_2O and wash it 3 times with H_2O. Dry the extract ($MgSO_4$), evaporate, and recrystallise the residue from EtOAc/hexane (4:1). Used as an amperometric proton selective sensor [Faisal, Pereira, Rho & Lee *Phys Chem Chem Phys* **12(46)** 15184 *10/2010*, DOI: 10.1039/c0cp00750a; Oesch et al. *Anal Chem* **58** 2285 *1986*, DOI: 10.1021/ac00124a037.]

Oxalylindigo *[2533-00-8]* **$C_{18}H_8N_2O_4$, M 316.3.** It crystallises twice from nitrobenzene as small yellow needles and is dried by heating *in vacuo* for several hours. It is an example of a *cis*-indigo structure. [Schanze et al. *J Am Chem Soc* **108** 2646 *1986*, DOI: 10.1021/ja00270a024; Pummerer & Reuss *Chem Ber* **80** 242 *1947*, DOI: 10.1002/cber.19470800311; van Alphen *Recl Trav Chim Pays-Bas* **58** 378 *1939*, DOI: 10.1002/recl.19390580502.]

2-Oxazolidinone (ethylene carbamate) *[497-25-6]* **$C_3H_9NO_2$, M 87.1, m 83-87°, 88-90°, 89-90°, 91°, b 152°/0.4mm, 200°/12mm, 220°/48mm.** It is prepared by reaction of ethanolamine with phosgene or diethylcarbonate. It can be prepared from ethanolamine (2g) in $CHCl_3$ (200ml, EtOH free by passing through an Al_2O_3 column) by bubbling $COCl_2$ through the solution which is allowed to stand for 3 hours, the acid is neutralised with powdered $PbCO_3$, filtered, evaporated to dryness and the solid residue is recrystallised from $CHCl_3$. *Alternatively*, ethanolamine (61g), Et_2CO_3 (150ml) and NaOMe (0.5g) are heated in an oil bath; and after the EtOH (~112ml) has distilled off, the residue solidifies on cooling and is recrystallised from $CHCl_3$ (100ml) to give the ***oxazolidinone*** (57g, 65%), **m 87-89°**. Its IR (film) has ν_{max} at 3000, 2920 (CH), 1766 (carbamate, C=O), 1690 (amide, C=O), 1465, 1382 and 1357 (CH_2), 1298 (C-N), 1212, 1140 and 1030 (COC,

C-O), 953 cm^{-1}; and ^1H NMR ($CDCl_3$) with δ at 6.68 (NH, br s, 1H), 4.47 (H_5, t, ^3J = 8Hz, 2H), 3.63 (H_4, t, ^3J = 8Hz, 2H); and for ^{13}C NMR see references [Hammer et al. *J Org Chem* **46** 1521 *1981*, DOI: 10.1021/jo00321a002.] [Homeyer US Pat 2,399,118 *1964*, *Chem Abs* **40** 4084 *1964*.] It can be recrystallised from $*C_6H_6$, dichloroethane, $CHCl_3$ or EtOH. It is a cyclic urethane, and is not very stable in aqueous solvents. The ***N-acetyl derivative*** *[1432-43-5]* **M 129.1, m 69-70°**, is formed by boiling 2-oxazolidinone (3g) with Ac_2O (20ml) and NaOAc (1g) for 1.5 hours, and recrystallised from $*C_6H_6/Et_2O$ or sublimed at 65° *in vacuo*. [Homeyer US Pat 2,399,118 *1964*, *Chem Abs* **40** 4084 *1964*.] The ***N-methyl derivative*** *[19836-78-3]* **M 101.1, b 120°/0.1mm**, is made from *N*-methyl ethanolamine with $COCl_2/CHCl_3/PbCO_3$ or as in the preparation of the parent compound [with $(EtO)_2CO$], and distilled in a vacuum. It is **TOXIC**. The yellow ***picrolonate*** has **m 137-138°**. [cf. Fränkel & Cornelius *Chem Ber* **51** 1654 *1918*, DOI: 10.1002/cber.19180510251; Ben-Ishai *J Am Chem Soc* **78** 4962 *1956*, DOI: 10.1021/ja01600a042; *Beilstein* **27** H 135, **27** I 259, **27** III/IV 2516.]

Oxetane (1.3-trimethylene oxide) *[503-30-0]* **C_3H_6O, M 58.1, m -97°, b 45-46°/736mm, 47-49°/atm, 48°/760mm, d_4^{20} 0.892, n_D^{20} 1.395.** Distil it twice from sodium and fractionate it through a small column at 47.0-47.2°/atm. Also purified by preparative GC using a 2m silica gel column. *Alternatively*, add KOH pellets (50g for 100g of oxetane) and distil through an efficient column packed with 1/4in Berl Saddles; and the main portion at b 45-50° is redistilled over fused KOH. [Noller *Org Synth* Coll Vol **3** 835 *1955*, DOI: 10.15227/orgsyn.029.0092; Dittmer et al. *J Am Chem Soc* **79** 4431 *1957*, DOI: 10.1021/ja01573a051.]

Oxetan-2-one (β-propiolactone, propan-3-olide) *[57-57-8]* **$C_3H_4O_2$, M 72.1, m -35°, -33°, -31.2°, b 51°/10mm, 83°/45mm, 162°/atm, d_4^{20} 1.1460, n_D^{25} 1.4117.** Fractionally distil the lactone from sodium under reduced pressure. It gives an acidic solution in H_2O due to hydrolysis. Produces insoluble polymers on storage. It irritates the skin and is a possible **carcinogen**. [*Beilstein* **17** I 130, **17** III/IV 4157.]

Oxine Blue (8-hydroxy-5-*p*-diethylaminophenylimino-5,8-dihydroquinoline) *[3733-85-5]* **$C_{19}H_{19}N_3O$, M 369.4, m 134-135°, pKa 4.70.** Recrystallise the dye from EtOH and dry it in a desiccator over H_2SO_4. Useful indicator (a few drops of 0.25% EtOH solution) for strong acids—strong base, and *vice versa*, titrations where it is orange below pH 3.9 and blue above pH 5.50 (see pKa). [Prepn details: Bishop *Indicators* pp 127-128, Oxford Pergamon Press *1972*, Library of Congress Catalog Card No 78-171464, ISBN 0080166172, 9780080166179, Lev *Zhur Anal Khim* **11** 359 *1956*.]

Paraldehyde (acetaldehyde trimer, 2r,4c,6c-trimethyl-1,3,5-trioxane, *all-cis*) *[123-63-7]* **$C_6H_{12}O_3$, M 132.2, m 12.5°, b 124°/751mm, 123-124°/atm, d_4^{20} 0.995, n_D^{20} 1.407.** Wash paraldehyde with water and fractionally distil it. *Alternatively*, it is purified by drying with anhydrous Na_2SO_4, then cooled to 5°, and the frozen material is separated by decantation. The solid is distilled (**b 121-124°/atm**), the distillate is collected, stored over anhydrous Na_2SO_4 for several days and re-distilled at atmospheric pressure before use [Le Fevre et al. *J Chem Soc* 290 *1950*, DOI: 10.1039/JR9500000290]. The ***2r,4c,6t-trimethyl-1,3,5-trioxane*** has **m 14.5°**, **b 125°/760mm**. [*Beilstein* **19** II 394, **19** III/IV 4715. **19/9** V 112.]

Patulin [hydroxyl-4*H*-furo(3.2-c)pyran-2(6*H*)-one, Clavatin] *[149-29-1]* **$C_7H_6O_4$, M 154.1, m 110°, 111-112°, $[\alpha]_D^{20}$ -74 ($CHCl_3$).** Recrystallises it from Et_2O, EtOH or $*C_6H_6$ (prisms or thick plates), and sublime it at 90°/high vacuum. The ***acetate*** has **m 118-120°** (from 50% aqueous EtOH). [Bergel et al. *J Chem Soc* 415 *1944*, DOI: 10.1039/JR9440000415; *Beilstein* **18** III/IV 1184, **18/3** V 5.] Highly **TOXIC, CARCINOGENIC.**

Pentachloropyridine *[2176-62-7]* **C_5Cl_5N, M 251.3, m 122-124°, 123°, 123-127°, 124°, 124-125°, 125.5°, 125-126°, b 279-280°/atm, pK^{20} -6.02 (aqueous H_2SO_4).** Purify it by recrystallisation from EtOH or aqueous EtOH and sublime at 150°/3mm. [den Hertog et al. *Recl Trav Chim Pays-Bas* **69** 673 *1950*, DOI: 10.1002/recl.19500690604; Schickh et al. **69** 2593 *1936*, DOI: 10.1002/cber.19360691202; *Beilstein* **20/5** V 422.]
Pentafluoropyridine *[700-16-3]* **C_5F_5N, M 169.1, m -41.5°, b 83.5°, 84°, 83-85°, d_4^{20} 1.609, n_D^{20} 1.3818, pK_{Est} ~<0.** Distil it through a concentric tube column; it has λ_{max} in cyclohexane at 256.8nm. [Chambers et al. *J Chem Soc* 3573 *1964*, DOI: 10.1039/JR9640003573; ^{19}F NMR: Bell et al. *J Fluorine Chem* **1** 51 *1971*, DOI:10.1016/S0022-1139(00)82533-6.] The ***hexafluoroantimonate*** has **m 98-102°(dec)** after crystallisation from liquid SO_2. [*Beilstein* **20/5** V 401.]

3,3,6,9,9-Pentamethyl-2,10-diazabicyclo[4.4.0]dec-1-ene (PMDBD, 1,2,3,4,4a,5,6,7-octahydro-2,2,4a,7,7-pentamethylnaphthyridine) *[69340-58-5]* **$C_{13}H_{24}N_2$, M 208.3, m 15°, b 65°/0.07mm, d $_4^{20}$ 0.924, n $_D^4$ 1.4840, pK >11 ($MeOCH_2CH_2OH/H_2O$, 1:1).** The pentamethylhydronaphthyridine is obtained by intramolecular cyclisation of 5-amidino-2,5,8-trimethylnona-2-7-diene [190.0g, 0.914mol, prepared from 2mols BuLi, one mol of propionitrile and 2mols of 3-methylbut-2-enyl bromide (isoprenehydrobromide) in THF at -78°, followed by $NaNH_2$ in boiling *C_6H_6] in CH_2Cl_2 (500ml) solution at 0°, by bubbling dry HCl gas through it until the pH is 4. The solution is evaporated *in vacuo* until free from HCl vapour to give a dark hygroscopic hydrochloride which is heated in a flask (protected from air with a $CaCl_2$ tube) at 200°, whereby excess of HCl is released after 30 minutes (cyclisation begins at *ca* 125°), and heating is continued for 18 hours. The dark brown residue is treated with H_2O (1.0L), acidified with 2N H_2SO_4 (500ml) and the aqueous phase is extracted with Et_2O (2 x 100ml), the aqueous phase is basified (cooling is necessary) with NaOH (*ca* 100g) to pH >10. The brown oil that separates is extracted with Et_2O (2 x 500ml), dried over K_2CO_3, filtered, and evaporated to give a viscous oil (190g) which is distilled through a Vigreux column at 0.05mm, and after a small fore run (3.8g), a colourless viscous oil of the ***naphthyridine*** distils (156.6g, 80% yield, b 60-67°). An analytical sample has **m ~15°** and b **65°/0.07mm**. Store it in an inert dry atmosphere as it absorbs CO_2 in the presence of moisture to form a ***bicarbonate*** (see below). Its UV/VIS has λ_{max} (ε) at 219 (11,600) nm; the IR ($CHCl_3$) of the ***hydrochloride*** has an immonium band at ν_{max} 2500 cm^{-1}; the ^1H NMR (CCl_4) of the ***free base*** has δ at 1.08-1.13 (2s, 12H, $4CH_3$), 1.19 (s, 3H, CH_3), 1.2-2.0 (m, 8H), 3.38 (s, NH); see reference for full IR and MS
The ***hydrochloride***, when recrystallised twice from CH_2Cl_2/Et_2O (15 hours at 0°), has **m 195-196°**, and the ^1H NMR (CCl_4) has δ at 1.34-1.13 (2s, 9H, $3CH_3$), 1.42 (s, 6H, $2CH_3$), 1.6-2.3 (m, 8H), 9.78 (br s, 2H NH).
The ***hydrogen carbonate salt*** is formed from the free base and moist CO_2 in 2 minutes, then by extraction with CH_2Cl_2, drying (K_2CO_3) and evaporating gives a labile salt decomposing at **122-125°**, and for ^1H NMR see references. The ***benzoate*** crystallises from CH_2Cl_2 with **m 183-185°**, the ***hydrogen sulfate*** crystallises from CH_2Cl_2/hexane with **m 208-209°**, the ***tosylate*** has **m 114°**, and the ***dihydrogen phosphate*** crystallises from MeOH/Et_2O with **m 225-228°**. [Heinzer, Soukup and Eschenmoser *Helv Chim Acta* **61** 2851 *1978*, DOI: 10.1002/hlca.19780610812; Sternbach et al. *Angew Chem* **91** 670 *1979*, DOI: 10.1002/ange.19790910827; *Beilstein* **23/5** V 302.] The strong basicity, proximity of the nitrogen atoms, and the steric hinderance from methyl groups around them, confer remarkable coordination properties [Sternbach et al. *Angew Chem* **91** 670 *1979*, DOI: 10.1002/ange.19790910827; Boyle et al. *JCS Chem Commun* 239 *1992*, DOI: 10.1039/C39920000239; Denmark *J Org Chem* **46** 3144 *1981*, DOI: 10.1021/jo00328a038].

Pentaquine monophosphate (1,4-pentanediamine, *n*-[6-methoxy-8-quinolinyl)-*N'*-[1-methylethyl) (1:1) phosphate] *[5428-64-8]* **$C_{18}H_{27}N_3O_2$. H_3PO_4, M 399.4, m 189-189.5°, 189-190°, pK^{70} 8.22.** Crystallise it from H_2O or 95% EtOH (pale yellow crystals), and dry at 50° *in vacuo*. The ***free base*** has **b 165-170°/0.02mm**, **n $_D^{25}$ 1.5785**. The ***picrate*** crystallises from Me_2CO/EtOH with **m 164.5-165.5°**. [Drake et al. *J Am Chem Soc* **68** 1529 *1946*, DOI: 10.1021/ja01212a041; *Beilstein* **22** III/IV 5814.] It is an antimalarial.

Phenanthridine (benzo[c]quinoline, 3,4-benzoquinoline) *[229-87-8]* **$C_{13}H_9N$, M 179.2, m 104-107°, 106.5°, 108-109°, b 349°/769mm, 350°/atm, pK^{20} 4.61 (4.48).** Purify it *via* the $HgCl_2$ addition compound formed when phenanthridine (20g) in 1:1 HCl (100ml) is added to aqueous $HgCl_2$ (60g in 3L), and the mixture is heated to boiling. The ***$HgCl_2$ complex*** separates as yellow red crystals with **m 195-198°** [Arcus & Mesley *J Chem Soc* 178 *1953*, DOI: 10.1039/JR9530000178]. Concentrted HCl is then added until all of the solid has dissolved. The compound separates on cooling and is decomposed with aqueous NaOH (*ca* 5M). Phenanthridine is extracted into Et_2O, evaporated, and the residue is crystallised from petroleum ether (b 80-100°) or EtOAc. [Cumper et al. *J Chem Soc* 4518 *1962*, DOI: 10.1039/JR9620004518.] It is also purified by chromatography on activated alumina from *benzene solution, with diethyl ether as eluent. Evaporation of ether gives crystalline material which is freed from residual solvent under vacuum, then further purified by fractional crystallisation, under N_2, from its melt. It was purified by zone melting and sublimes in a vacuum. The ***picrate*** has **m 218.5-219.5°** (from *iso*-PrOH) (also reported are **m 244-245°** and **247-248°**, from EtOH or H_2O). [Slough & Ubbelhode *J Chem Soc* 911 *1957*, DOI: 10.1039/JR9570000911.] [*Beilstein* **20** H 466, **20** III/IV 4016, **20/8** V 223.]

1,10-Phenanthroline (*o*-phenanthroline) *[66-71-7 (anhydr); 5144-89-8 (H_2O)]* **$C_{12}H_8N_2$, M 198.2, m 98-101°, 100-104°, 108-110° (hydrate), 114-117°, 118° (anhydrous), b >300°, pK $_1^{25}$ -0.7 (aqueous $HClO_4$), pK $_2^{25}$ 4.86 (4.96).** Crystallise its ***picrate*** (**m 191°**) from EtOH; then the ***free base*** is liberated with aqueous alkali,

dried at 78°/8mm over P_2O_5 and crystallised from petroleum ether (b 80-100°). [Cumper et al. *J Chem Soc* 1188 *1962*, DOI: 10.1039/JR9620001188.] It can be purified by zone melting. It has also been crystallised from hexane, *benzene/petroleum ether (b 40-60°) or sodium-dried *benzene, dried and stored over H_2SO_4. The ***monohydrate*** is obtained by crystallisation from aqueous EtOH or ethyl acetate. It has been crystallised from H_2O (300 parts) to give the ***monohydrate*** **m 102-103°** which sublimes at 10^{-3}mm [Fielding & LeFevre *J Chem Soc* 1811 *1951*, DOI: 10.1039/JR9510001811.] The ***anhydrous*** compound has **m 118°** (after drying at high vacuum at 80°) and is also obtained by recrystallisation from petroleum ether or $*C_6H_6$ (70 parts) and drying at 78°/8mm. [UV: Badger et al. *J Chem Soc* 3199 *1951*, DOI: 10.1039/JR9510003199.] It has a pKa in H_2O of 4.857 (25°) or 5.02 (20°) and 4.27 in 50% aqueous EtOH (20°). [Albert et al. *J Chem Soc* 2240 *1948*, DOI: 10.1039/JR9480002240]. [*Beilstein* **23** H 227, **23** II 235, **23/8** V 419.]

1,10-Phenanthroline hydrochloride **(*o*-phenanthroline hydrochloride)** *[3829-86-5 (HCl.H_2O), 18851-33-7 (xHCl.H_2O)]* **$C_{12}H_8N_2$. HCl. H_2O, M 243.7,** has **m 212-219°.** The hydrochloride crystallises from 95% EtOH, **m** 212-219° as the ***monohydrate***; the ***half hydrate*** has **m** 217°. The ***3HCl*** has **m 143-145°** (sinters at 128°). [Thevenet et al. *Acta Cryst Sect B* **33** 2526 *1977*, DOI: 10.1107/S0567740877008838]. [*Beilstein* **23** II 235, **23/8** V 415, 421.]

4,7-Phenanthroline-5,6-dione *[84-12-8]* **$C_{12}H_6N_2O_2$, M 210.2, m 295°(dec).** The dione crystallises from MeOH, and the white crystals are dried at 100°/0.1mm/6hrs. The ***mono-oxime*** forms yellow crystals from MeOH with **m 250°(dec)**, the ***di-oxime*** forms yellow crystals from MeOH with **m 300°(dec)** and the ***mono-semihydrazone*** forms yellow crystals from MeOH with **m 195°(dec)**. [Druey & Schmidt *Helv Chim Acta* **33** 1080 *1950*, DOI: 10.1002/hlca.19500330438; Shabir & Forrow *J Chromatogr Sci* **43** 207 *2005*, DOI:10.1093/chromsci/43.4.207; *Beilstein* **24** III/IV 1741.]

Phenazine (dibenzo[*b,e*]pyrazine) *[92-82-0]* **$C_{12}H_8N_2$, M 180.2, m 172-176°, 171°, pK_1^{20} -4.9 (aqueous H_2SO_4), pK_2^{20} 1.21.** Phenazine crystallises from EtOH, $CHCl_3$ or ethyl acetate, after pre-treatment with activated charcoal. It can be sublimed *in vacuo* and purified by zone refining. [*Beilstein* **23/8** V 389.] The ***5-methylphenazinium methyl sulfate*** *[299-11-6]* $C_{13}H_{11}N_2$. CH_3SO_4, M 306.3, **m 158-160°(dec)**, is used with ascorbic acid to determine nitric oxide reductase activity [Heiss et al. *J Bacteriol* **171(6)** 3288 *1989*, DOI: jb.asm.org/content/171/6/3288.full.pdf].

Phenosafranine (3,7-diamino-5-phenylphenazinium chloride, CI 50200) *[81-93-6]* **$C_{18}H_{15}ClN_4$, M 322.8, m >300°, λ_{max} 530nm (H_2O).** Crystallise the dark green powder from dilute HCl. The red solution has UV with λ_{max} at 517-521nm in H_2O. The ***picrate*** decomposes on heating and has a solubility of 0.0048% in H_2O at 18°. [*Beilstein* **23** H 395, *Beilstein* **25** H 394, **25** I 654, **25** II 338, **25** III/IV 3050.] It is a biological stain.

Phenothiazine *[92-84-2]* **$C_{12}H_9NS$, M 199.3, m 182-187°, 184-185°, 185°, b 371°/atm.** Crystallise it from *benzene, toluene, hexane or Me_2CO (charcoal) after boiling for 10 minutes under reflux. Filter the crystals off and dry them in an oven at 100°, then in a vacuum desiccator over paraffin chips. Also recrystallise it twice from water and dry it in an oven at 100° for 8-10 hours. It sublimes at 130°/1mm and has UV with λ_{max} at 253nm in heptane. [*Beilstein* **27** I 225, **27** II 32, **27** III/IV 1214.] Insecticide and anthelmintic.

Phenoxazine *[135-67-1]* **$C_{12}H_9NO$, M 199.2, m 156°, 156-158°, 158-159°, b 215°/4mm.** Crystallise phenoxazine from EtOH and sublime it *in vacuo*. If too impure then extract it in a Soxhlet extractor using toluene. Evaporate the solvent and dissolve the residue (*ca* 100g) in $*C_6H_6$ (1L), **CARCINOGEN** (use an efficient fume cupboard) and chromatograph it through an Al_2O_3 column (50 x 450 mm) using $*C_6H_6$. The eluent (*ca* 3L) is evaporated to *ca* 150ml and cooled when *ca* 103g of phenoxazine **m** 149-153° are obtained. Sublimation yields platelets **m 158-159°**. It forms a green ***picrate*** **m 141.5-142°**. [Gilman & Moore *J Am Chem Soc* **79** 3485 *1957*, DOI: 10.1021/ja01570a048; Müller et al. *J Org Chem* **24** 37 *1959*, DOI: 10.1021/jo01083a011; *Beilstein* **27** I 223, **27** III/IV 1209.]

2-Phenyl-1-azaindolizine (-phenylimidazo[1,2-a]pyridine) *[4105-21-9]* **$C_{13}H_{10}N_2$, M 194.2, m 140°, pK_{Est} ~1.9.** Crystallise the indolizine from EtOH, *benzene/petroleum ether, hexane (**m 135-136°**) or cyclohexane (**m 136-137°**). The ***hydrochloride 2H_2O*** has (**m 114-116°**, from H_2O), and the ***picrate*** has **m 228-229°** (from AcOH) and **236-238°** (from Me_2CO). The ***hydrobromide*** has **m 161-163°** (**165°**), after recrystallisation from

EtOH/EtOAc and drying at 56°/0.05mm. [Adams & Dix *J Am Chem Soc* **80** 4618 *1958*, DOI: 10.1021/ja01550a051; *Beilstein* **23** III/IV 1705.]

2-Phenyl-1,3-diazahexahydroazulene *[2161-31-1]* **$C_{13}H_{18}N_2$, M 212.3.** Recrystallise the azulene three times from de-aerated cyclohexane in the dark. Dry it *in vacuo*.

9-Phenyl-3-fluorone (2,6,7-trihydroxy-9-phenylxanthen-3-one) *[975-17-7]* **$C_{19}H_{12}O_5$, M 320.3, m >300°(dec), 350°, λ_{max} 462nm (ε 4.06 x 10^4, in 1M HCl aqueous EtOH).** Recrystallise it from warm, acidified EtOH by addition of ammonia. The crude material (1g) can be extracted with EtOH (50ml) in a Soxhlet apparatus for 10 hours to remove impurities. Impurities can be detected by paper electrophoresis. The ***triacetate*** forms yellow needles from EtOH (**m 230-233°**). [Petrova et al. *Anal Lett* **5** 695 *1972*, DOI: 10.1080/00032717208064350; *Beilstein* **18** H 199, **18** I 404, **18** III/IV 2824.] Possible eye, skin and respiratory tract irritant.

2-Phenylindolizine *[25379-20-8]* **$C_{14}H_{11}N$, M 193.2, m 211-214°, 214°(dec), pK_{Est} ~4.4.** Crystallise 2-phenylindolizine from EtOH. The ***0.25HCl*** crystallises from MeCN with **m 109°**, and the ***picrate*** has **m 161°** when crystallised from EtOAc. [*Beilstein* **20** II 304, **20** III/IV 4033, **20/8** V 244.]

1-Phenyl-5-mercaptotetrazole *[86-93-1]* **$C_7H_6N_4S$, M 178.2, m 143-147° (dec), 145° (dec), pK^{25} 3.65 (5% aqueous EtOH).** Purify the tetrazole by recrystallisation from EtOH or $CHCl_3$ (**m** 152°) [Tautomerism: Kauer & Sheppard *J Org Chem* **32** 3580 *1967*, DOI: 10.1021/jo01286a064; UV: Lieber et al. *Can J Chem* **37** *563 1959*, DOI: 10.1139/v59-077]. The ***ammonium salt*** crystallises from EtOH and decomposes at 176°. The ***sodium salt*** [15052-19-4] M 200.2, crystallises from EtOH/*C_6H_6, melts at 96° and decomposes at 145° [Stollé *J Prakt Chem* [2] **133** 60 *1932*, DOI: 10.1002/prac.19321330106]. It is used for the determination of Bi and Pd. [Fresenius *Z Anal Chem* **261** 151 *1972*, *Beilstein* **26** III/IV 2065.]

4-(3-Phenylpropyl)pyridine [1-phenyl-3(4-pyridyl)propane] *[2057-49-0]* **$C_{14}H_{15}N$, M 197.3, b 150-152°/5-6mm, 322°/atm, d_4^{25} 1.03, n_D^{20} 1.563, pK_{Est} ~6.0.** This is prepared from the potassium salt of 4-picoline [obtained by dissolving K metal (1 mol) and a few mg of ferric oxide as catalyst in liquid NH_3 until the blue colour is discharged, indicating the formation of KNH_2, to which is added 4-picoline (1 mol) rapidly forming a reddish-amber solution] and phenethyl bromide (1 mol, see *[103-63-9]*), allowing the NH_3 to evaporate (6-10 hours, in an efficient fume cupboard), adding H_2O, the mixture is extracted into Et_2O, evaporated to dryness and the residual oil is distilled, preferably under a vacuum to give the desired ***phenylpropylpyridine***, **b 150-152°/5-6mm**, in 56% yield. The ***hydrochloride***, obtained by evaporating a concentrated HCl solution of the base on a steam bath and the residual solid, recrystallised from EtOH/Et_2O, has **m 143.5°** and is hygroscopic. The ***N-oxide*** *[34122-28-6]* **$C_{14}H_{15}NO$**, M 213.3, has **m 58-65°**. [Bergstrom et al. *J Org Chem* **10** 452 *1945*, DOI: 10.1021/jo01181a011; *Beilstein* **20** III/IV 3687.]

4-Phenylpyridine-2-carbonitrile *[18714-16-4]* **$C_{12}H_8N_2$, M 180.1, m 97-101°, b 342.4°/760mm, pK_{Est} <0.** Purify the nitrile by recrystallisation from petroleum ether (**m 99-100°**). [Case & Kasper *J Am Chem Soc* **78** 5842 *1956*, DOI: 10.1021/ja01603a036; *Beilstein* **22** III/IV 1261.]

Phenyl 2-pyridyl ketoxime *[1826-28-4]* **$C_{12}H_{10}N_2O$, M 198.2, m 151-152°, 154-156°, pK_1^{25} 3.84, pK_2^{25} 10.71 for *E*-isomer.** The ***E-isomer*** crystallises from EtOH (charcoal). It isomerises to the ***Z-isomer*** on melting or in boiling *o*-xylene, and crystallises from EtOH or cyclohexanol with **m 166-168°**. [*Beilstein* **21** H 330, **21** III/IV 4120, **21/8** V 568.]

6-Phenylquinoline *[612-95-3]* **$C_{15}H_{11}N$, M 205.3, m 110.5-111.5°, pK_{Est} ~5.2**. Crystallise 6-phenylquinoline from EtOH (charcoal). The ***picrate*** has **m 105°** (from Me_2CO). It has UV with λ_{max} at 253nm in aqueous EtOH and 263 and 325nm in aqueous HCl. [*Beilstein* **20** H 483, **20** III/IV 4151.]

2-Phenylquinoline-4-carboxylic acid (Cinchophen, Atophen) *[132-60-5]* **$C_{16}H_{11}NO_2$, M 249.3, m 214-215°, 215°, $pK_{Est(1)}$~0.5 (CO_2H), $pK_{Est(2)}$~5.1 (N).** It crystallises from EtOH (*ca* 20ml/g), in several modifications with **m 196°** and **216°**(subliming at 65°). [*Beilstein* **22** H 103, **22** II 518, **22** II 70, **22** III/IV 1358.]

1-Phenyl-5-sulfanilamidopyrazole *[526-08-9]* **$C_{15}H_{14}N_4O_2S$, M 314.4, m 177-178°, 178-179°.** Crystallise it from EtOH or aqueous EtOH. Methylation with Me_2SO_4/NaOH occurred on the amido nitrogen atom to give the ***N^1-methyl derivative*** with **m 212-213.5°** (from EOH). [Schmidt & Druey *Helv Chim Acta* **41** 306 *1958*, DOI: 10.1002/hlca.660410138; Eichenberger et al. *Helv Chim Acta* **48** 524 *1963*, DOI: 10.1002/hlca.19650480310; *Beilstein* **25** III/IV 2029.]

4-Phenyl-1,2,4-triazolidine-3,5-diol (4-phenylurazole) *[15988-11-1]* **$C_8H_7N_3O_2$, M 175.2, m 207-209°.** Crystallise 4-phenylurazole from water or 95% EtOH. Dissolve 35g in 80ml of boiling 95% EtOH and on cooling 90-95% is recovered with **m 209-210°**. It has IR with ν_{max} at 1685 and 3120cm^{-1}. [Cookson et al. *Org Synth* **51** 121 *1971*, DOI: 10.15227/orgsyn.051.0121; *Beilstein* **26** I 64, **26** III/IV 540.]

4-Phenyl-1,2,4-triazole-3,5-dione (PTAD) *[4233-33-4]* **$C_8H_5N_3O_2$, M 177.2, m 165°(dec), 165-170°(dec), 170-177°(dec).** PTAD forms carmine red needles by sublimation (ice cold finger) at 100°/0.1mm, and/or by recrystallisation from EtOH. Its IR has ν_{max} at 1760 and 1780 cm^{-1}. [Cookson et al. *Org Synth* **51** 121 *1971*, DOI: 10.15227/orgsyn.051.0121; Moore et al. *J Org Chem* **39** 3799 *1974*, DOI: 10.1021/jo00939a049; *Beilstein* **26** I 57, **26** III/IV 540.] Useful reagent for selective oxidation of thiols to disulfides [Christoforou et al. *Tetrahedron Lett* **47** 9211 *2006*, DOI: 10.1016/j.tetlet.2006.10.134].

9-Phenyl-9-xanthenol (hydroxypixyl) *[596-38-3]* **$C_{19}H_{14}O_2$, M 274.3, m 158-161°, 158.5-159°, 159°.** Dissolve hydroxypixyl in AcOH and add H_2O whereby it separates as colourless prisms. It is slightly soluble in $CHCl_3$, soluble in *C_6H_6 but insoluble in petroleum ether. It sublimes on heating. Its UV in H_2SO_4 has λ_{max} at 450nm (ε 5620) and 370nm (ε 24,900) and the ***$HClO_4$ salt*** in $CHCl_3$ has λ_{max} at 450 (ε 404) and 375nm (ε 2420). [Sharp *J Chem Soc* 2558 *1958*, DOI: 10.1039/JR9580002558; Bünzly & Decker *Chem Ber* **37** 2931 *1904*, DOI: 10.1002/cber.19040370371; Chattopadhyaya & Reece *JCS Chem Commun* 639 *1978*, DOI: 10.1039/C39780000639; Gomberg & Cone *Justus Liebigs Ann Chem* **370** 142 *1909*, DOI: 10.1002/jlac.19093700110; *Beilstein* **17** I 80, **17** II 161, **17** III/IV 1704, **17/4** V 675.]

'Phosphine' [dye CI 793, Chrysaniline mononitrate, 3-amino-9-(4-aminophenyl)-acridinium mononitrate) *[10181-37-0]* **$C_{19}H_{15}N_3.HNO_3$, M 348.4, m >250°(dec), pK^{20} 7.71 (50% aqueous EtOH).** Crystallise the dye from *benzene/EtOH. The ***free base*** crystallises from *C_6H_6 in yellow crystals **m 229-230°**. [Dunstan & Hewitt *J Chem Soc* **89** 483 *1906*, DOI: 10.1039/CT9068900482; pK; Albert & Goldacre *J Chem Soc* 706 *1946*, DOI: 10.1039/JR9460000706; *Beilstein* **22** H 91, **22** I 651, **22** II 403, **22** III/IV 5513.]

Phthalazine *[253-52-1]* **$C_8H_6N_2$, M 130.2, m 89-92°, 90-91°, b 175°/17mm, 189°/29mm, 190°/30mm, pK^{20} 3.47.** Phthalazine crystallises from diethyl ether or *benzene, and sublimes under a vacuum. The ***hydrochloride*** forms needles from EtOH with **m 235-236°(dec)** and the ***picrate*** has **m 208-210°**. [Armarego *J Appl Chem* **11** 70 *1961*, DOI: 10.1002/jctb.5010110207; Gabriel & Eschenbach *Chem Ber* **30** 3022 *1897*, DOI: 10.1002/cber.189703003116; Stephenson *Chem & Ind* 174 *1957*, *Beilstein* **23** H 174, **23** III/IV 1233.]

Phthalazine-1,4-dione (phthalhydrazide) *[1445-69-8]* **$C_8H_6N_2O_2$, M 162.2, m 330-333°, 336°, 346°, pK_1^{20} - 3.29 pK_2^{20} -0.99, pK_3^{20} 5.67, pK_4^{20} 13.0.** Recrystallise it twice from 0.1M KOH [Merenyi et al. *J Am Chem Soc* **108** 7716 *1986*, DOI: 10.1021/ja00284a040], EtOH or dimethylformamide and it sublimes >300°. [*Beilstein* **24** H 371, **24** II 194.]

Phthalazone (1-hydroxyphthalazine) *[119-39-1]* **$C_8H_6N_2O$, M 146.2, m 183-184°, 186-188°, b 337°/760mm, pK_1^{20} -2.2, pK_2^{20} -1.4, pK_3^{20} 11.99.** Phthalazone crystallises from H_2O or EtOH and sublimes *in vacuo*. [*Beilstein* **24** H 142, **24 24** III/IV 400.]

2-Picoline-*N*-oxide (2-methylpyridine-1-oxide) *[931-19-1]* **C_6H_7NO, M 109.1, m 41-45°, b 89-90°/0.8-0.9mm, 90-100°/1mm, 110°/4mm, 135°/5mm, 123°/9mm, 123-124°/15mm, 259-261°/atm, n_D^{25} 1.5854 (supercooled), pK^{25} 1.10.** Purify the *N*-oxide by fractional distillation, and it can be recrystallised from *C_6H_6/hexane but is ***hygroscopic***. [Bullitt & Maynard *J Am Chem Soc* **76** 1370 *1954*, DOI: 10.1021/ja01634a054; Ross et al. *J Am Chem Soc* **78** 3625 *1956*, DOI: 10.1021/ja01596a019; IR: Wiley & Slaymaker *J Am Chem Soc* **79** 2233 *1957*, DOI: 10.1021/ja01566a054.] The ***picrate*** has **m 125-126.5°** (from EtOH) [Boekelheide & Linn *J Am Chem Soc* **76** 1286 *1954*, DOI: 10.1021/ja01634a026]. The ***phthalate*** has **m**

115-116° (from EtOH) [den Hertog et al. *Recl Trav Chim Pays-Bas* **70** 591 *1951*, DOI: 10.1002/recl.19510700705.]. [*Beilstein* **20** III/IV 2689, **20/5** V 479.]

3-Picoline-N-oxide **(3-methylpyridine-1-oxide)** *[1003-73-2]* has **m 37-39°, 37-38° (evacuated capillary), 84-85°/0.3mm, 101-103°/0.7-0.8mm, 114-115°/1.5mm, 118°/2mm, 150°/15mm, pK^{25} 1.08.** Purify the *N*-oxide by careful fractionation *in vacuo*. The distillate remains supercooled for several days before solidifying. It is a slightly ***hygroscopic*** solid which could melt in the hand. The ***picrate*** has **m 149-151°** (from EtOH). [Taylor & Crovetti *Org Synth* Coll Vol **4** 654 *1963*, DOI: 10.15227/orgsyn.036.0053; IR: Katritzky et al. *J Chem Soc* 3680 *1959*, DOI: 10.1039/JR9590003680; Jaffé & Doak *J Am Chem Soc* **77** 4441, 4481 *1955*, DOI: 10.1021/ja01622a001; Boekelheide & Linn *J Am Chem Soc* **76** 1286 *195*, DOI: 10.1021/ja01634a026]. [*Beilstein* **20** III/IV 2719**, 20/5** V 517.]

4-Picoline-N-oxide **(4-methylpyridine-1-oxide)** *[1003-67-4]* has **m 182-184°, 185-186°, 186-188°, pK^{25} 1.29.** Recrystallise the *N*-oxide from EtOH/EtOAc, Me_2CO/Et_2O or $*C_6H_6$. [Bullitt & Maynard *J Am Chem Soc* **76** 1370 *1954*, DOI: 10.1021/ja01634a054; Boekelheide & Linn *J Am Chem Soc* **76** 1286 *1954*, DOI: 10.1021/ja01634a026]. [*Beilstein* **20** III/IV 2741, **20/5** V 558.]

Picolinic acid (pyridine-2-carboxylic acid) *[98-98-6]* **$C_6H_5NO_2$, M 123.1, m 138°, 138-142°, pK_1^{25} 1.03 (1.36), pK_2^{25} 5.30 (5.80).** Crystallise the acid from water or *benzene. The ***picrate*** has **m 185-187°** (from MeOH). [*Beilstein* **22** H 33, **22** I 502, **22** II 30, **22** III/IV 303, **22/2** V 3.]

***N*-4-Picolinoylbenzimidazole** *[100312-29-6]* **$C_{13}H_9N_3O$, M 173.3, m 105-107°.** Recrystallise the imidazole three times from hexane [Fife & Przystas *J Am Chem Soc* **108** 4631 *1986*, DOI: 10.1021/ja00275a059].

Picrolic acid [3-methyl-4-nitro-1-(4-nitrophenyl)-2-pyrazolin-5-one, picrolonic acid] *[550-74-3]* **$C_{10}H_8N_4O_5$, M 264.2, m 116.1-117.2°, 116.5°(dec at 125°) 120°(dec), 125°, b 548.8°/760mm, d 1.65.** Crystallise picrolic acid from water or EtOH (solubility is 0.123% at 15° and 1.203% at 100° in H_2O; and 1.107% at 0° and 11.68% at 81° in EtOH). It forms Ca, Cu Hg, Mg, Na, Sr, Pb and many other metal complexes, also used for analysis of alkaloids, tryptophan and phenylananine as well as a precipitant for organic bases and alkaloids. [Maquestiau et al. *Bull Soc Chim Belg* **82** 233 *1973*, DOI: 10.1002/bscb.19730820306; Iseki et al. *Chem Ber* **74** 1420 *1941*, DOI: 10.1002/cber.19410740811]. [*Beilstein* **24** H 51, **24** I 218, **24** II 25, **22** III/IV 105.]

Pinacyanol chloride (Quinaldine Blue) *[2768-90-3]* **$C_{25}H_{25}ClN_2$, M 388.9, CI 808, m 270°(dec).** Crystallise the chloride from EtOH (blue-green prisms) or EtOH/diethyl ether. The crystals lose EtOH at ~100° and decompose at ~270°. It is dichroic with λ_{max} at 560nm and 604nm. It is used as a histological stain for chromosomes. The ***iodide*** *[605-91-4]* crystallises from MeOH or EtOH with **m 298-299°(dec)**. [*Beilstein* **23** H 320, 23 I 90, II 282, III/IV 2064, **23/10** V 129.]

dl*-Pipecolinic acid (piperidine-2-carboxylic acid)** *[535-75-1, 4043-87-2]* **$C_6H_{11}NO_2$, M 129.1, m 264°, 280°(dec), 282°(dec), pK_1^{25} 2.29, pK_2^{25} 10.77.** It crystallises from water. The ***(±)-picrate has **m 158-159°** (from EtOH or $*C_6H_6$). [*Beilstein* **22** H 7, **22** III/IV 97, **22/1** V 220.] The ***R(+)-enantiomer*** *[1723-00-8]* has **m 277°(dec)** and $[\alpha]_D^{20}$ +27 (c 4, H_2O), and the ***S(-)-enantiomer*** *[3105-95-1]* has **m 277°(dec)** and $[\alpha]_D^{20}$ -26 (c 4, H_2O). [cf. p 603, *Beilstein* **22** III/IV 96, **22/1** V 220.]

Piperazine *[110-85-0]* **$C_4H_{10}N_2$, M 86.1, m 44° (hexahydrate** *142-63-2***), 109-112°, 110-112°, b 125-130°/760mm, 145-146°/760mm, pK_1^{25} 5.33, pK_2^{25} 9.73.** Piperazine crystallises from EtOH or anhydrous *benzene and is dried at 0.01mm. It can be sublimed under vacuum and purified by zone melting. The ***hydrochloride*** has **m 172-174°** (from EtOH), and the ***dihydrochloride*** crystallises from aqueous EtOH and has **m 318-320°** (**dec**, sublimes at 295-315°). The ***picrate*** has **m** ~200°, and the ***picrolonate*** crystallises from dimethylformamide (**m 259-261°**). [*Beilstein* **23** H 4, **23** I 4, **23** II 3, **23** III/IV 15, **23/1** V 30.]

§ Piperazine on polystyrene support is commercially available. ***Piperazine dihydrochloride*** **(H_2O)** *[142-64-3 (2HCl); 6094-40-2 (xHCl), 207605-49-0]* **$C_4H_{10}N_2$. 2HCl, M 177.1,** has **m 82.5-83.5°.** Crystallise the salt from aqueous EtOH and dry it at 110°. [*Beilstein* **23** III/IV 17, **23/1** V 30.] ***Piperazine phosphate*** **(H_2O)** *[18534-18-4]* **$C_4H_{10}N_2$. H_3PO_4, M 197.6.** Crystallise it twice from water, air-dry and store for several days over Drierite. The salt dehydrates slowly if heated at 70°. [*Beilstein* **23** III/IV 18, **23/1** V 30.]

Piperazine-*N*,*N*'-bis(2-ethanesulfonic acid) (PIPES) *[5625-37-6]* **$C_8H_{18}N_2O_6S_2$, M 302.4, pK_1^{25} <3, pK_2^{25} 6.82 (7.82).** Purify PIPES from boiling water (maximum solubility is about 1g/L) or as described for ADA (see *[26239-55-4]* in 'Aliphatic Compounds' in this Chapter). The ***disodium salt*** *[76836-02-7]* **$C_8H_{16}N_2NaO_6S_2$, M 346.3,** decomposes at high temperature, and is purified by dissolving in the minimum volume of H_2O and adding EtOH until crystallisation is complete, filter it off and dry it *in vacuo*. Apart from being a very good buffer in the natural pH range (~pH 7, see pKa) it is used as an organisms buffer, like the free acid. [Good et al. *Biochemistry* **5(2)** 467 *1966*, DOI: 10.1021/bi00866a011; *Beilstein* **23/12** V 380.]

Piperidine *[110-89-4]* **$C_5H_{11}N$, M 85.2, m -13°, -9°, b 35.4°/40mm, 106°/760mm, d_4^{20} 0.862, n_D^{20} 1.4535, n_D^{25} 1.4500, pK^{25} 11.20 (basic).** Dry piperidine with BaO, KOH, CaH_2, or sodium, and fractionally distil (optionally from sodium, CaH_2, or P_2O_5). Purify from pyridine by zone melting. [*Beilstein* **22** H 6, **22** I 5, **22** II 3, **22** III/IV 287, **22/2** V 3.] § Piperidine on polystyrene support is commercially available. ***Piperidinium chloride*** *[6091-44-7]* **$C_5H_{11}N$. HCl, M 121.6,** has **m 244-245°, 245-248°, 247-248°.** Crystallise the salt from EtOH/diethyl ether in the presence of a small amount of HCl. [*Beilstein* **20** H 6, **20** II 10, **20** III/IV 295, **20/2** V 13.] ***Piperidinium nitrate*** *[6091-45-8]* **$C_5H_{11}N$. HNO_3, M 145.2,** has **m 141°, (155-157° from EtOH).** The nitrate crystallises from acetone/ethyl acetate or EtOH. [*Beilstein* **20** H 12, **20** II 10, **20** III/IV 295, **20/2** V 14.]

Piperidine-2,6-dione (glutarimide) *[1121-89-7]* **$C_5H_7NO_2$, M 113.1, m 163-165°, 155-157°, 154°, 152-154°, pK^{25} 11.43 (acidic).** Purify it by dissolving 75g in 200ml of H_2O, boil for 30 minutes with 2g of charcoal, filter, evaporate to dryness and recrystallise the residue from 125m L of 95% EtOH to give 70g of white crystals, **m 152-154°**. It also crystallises from Me_2CO (**m 163-165°**) or EtOH (**m 153-154°**). The ***N-bromo derivative*** (a brominating agent) crystallises from H_2O with **m 180-185°**. [Paris et al. *Org Synth* Coll Vol **4** 496 *1963*, DOI: 10.15227/orgsyn.037.0047; *Beilstein* **21** H 382, **21** I 331, **21** II 307, **21** III/IV 4582.]

4-Piperidone [piperidin-4(1*H*)-one, γ-] *[41661-47-6]* **C_5H_9NO, M 99.1 (anhydrous), cannot be distilled without decomposition although a boiling point of 79° has been reported, pK^{25} 8.6 (acidic).** It is a yellow irritating oil which is an alkaloid in the leaves and branches of *Dichilus* species (leguminosae), e.g. *D. strictus, D. gracilis, D. lebeckioides, D. pilosus* and *D. reflexus*. It decomposes on distillation and is purified and stored as the ***monohydrate monohydrochloride*** [*anhydrous 41979-39-9*; *hydrate 40064-34-4*], M 135.6 (*anhydrous salt*), which is in fact ***4,4-dihydroxy-piperidinium chloride*** that recrystallises from H_2O with **m 94-96°, 97-100°** (+ 1 H_2O), or from EtOH/Et_2O with **m 139-141°** (+ 1.5 EtOH); and the ***anhydrous salt*** has **m 147-149°**. See above for the *N*-acetyl- *N*-benzyl and *N*-methyl derivatives. The ***N-benzoyl*** derivative *[24686-78-0]*, M 203.2, has **m 49-50°** and **b 158-160°/0.2mm**, and the ***oxime*** *[79858-41-6]*, M 114.1, crystallises from dry *C_6H_6 in needles **m 117-118°** (anhydrous), and is hygroscopic. [*Beilstein* **21/6** V 419.]

Piperine (1-piperoylpiperidine) *[94-62-2]* **$C_{17}H_{19}NO_3$, M 285.4, m 129-129.5°, 131-135°, pK^{15} 1.98.** Piperine crystallises as light yellow crystals from EtOH or EtOAc (**m** 132°), aqueous EtOH (**m 128-129°**), Et_2O (**m 129°**), or *benzene/ligroin. [*Beilstein* **20** H 79, **20** I 23, **20** II 53, **20** III/IV 1341, **20/3** V 469.] It was originally isolated from black pepper, has no taste at first but produces a burning after-taste and has insecticidal properties.

Poly(*N*-vinylcarbazole) (PVK) *[25067-59-8]* **$(C_{14}H_{11}N)_n$, M_{avr} 25,000-50,000, m >300°, d 1.2g/ml.** Precipitate it seven times from tetrahydrofuran with MeOH, with final freeze-drying from *benzene. Dry it under vacuum. Also available is polymer with **M_{avr} 1,000,000, powder m 220°.**

Poly(4-vinylpyridine, Reillex 402) *[25232-41-1]* **$(C_7H_7N)_n$, M $(105.1)_n$, M_{avr} ~60,000 has T_g(onset of anneal) 137°; M_{avr} ~160,000 has T_g(onset of anneal) 142°** (all soluble in DMF,AcOH and lower alcohols)**.** Purify them by repeated precipitation from solutions in EtOH with dioxane, and then EtOH with ethyl acetate. Finally, freeze-dry a *tert*-butanol solution.
Poly(N-vinylpyrrolidone) *[9003-39-8]* **$(C_6H_9NO)_n$, M $(111.1)_n$, crosslinked** *[25249-54-1]* has **m >300°.** Purify it by dialysis, and freeze-drying. Also by precipitation from $CHCl_3$ solution by pouring into ether. Dry it in a vacuum over P_2O_5. For the crosslinked polymer, purification is by boiling for 10 minutes in 10% HCl and then washing with glass-distilled water until free from Cl ions. Finally, Cl ions are removed more readily by neutralising with KOH and continued washing.

(±)-Primaquine diphosphate (*RS*- 8-[4-amino-1-methylbutylamino]-6-methoxyquinoline di-phosphate) *[63-45-6]* **$C_{15}H_{21}N_3O.\ 2H_3PO_4$, M 455.4, m 197-198°, 204-206°(dec), $pK_{Est(1)}$~ 3.38 (ring N^+), $pK_{Est(2)}$~ 10.8 NH_3^+).** It forms yellow crystals from 90% aqueous EtOH and is moderately soluble in H_2O. The ***oxalate salt*** has **m 182.5-185°** (from 80% aqueous EtOH), and the ***free base*** is a viscous liquid **b 165-170°/0.002mm**, **175-177°/2mm**. [Elderfield et al. *J Am Chem Soc* **77** 4816 *1955*, DOI: 10.1021/ja01623a038; Elderfield et al. *J Am Chem Soc* **77** 4819 *1955*, DOI: 10.1021/ja01623a039; Elderfield et al. *J Am Chem Soc* **68** 1524 *1964*, DOI: 10.1021/ja01212a040; *Beilstein* **22** III/IV 5817.]

Proclavine (3,6-diaminoacridine) *[92-62-6]* **$C_{13}H_{11}N_3$, M 209.2, m 284-286°, pK_1^{25} -2.7, pK_2^{25} 0.55, pK_3^{25} 9.49.** It crystallises from aqueous MeOH. The ***picrate*** crystallises from aqueous pyridine with **m ~185°**. [*Beilstein* **22** H 487, **22** I 649, **22** II 397, **22** III/IV 5487, **22/11** V 322, also see Elderfield references above.] For proflavin see 3,6-diaminoacridine hydrochloride.

Propidium iodide (3,8-diamino-5-(3-diethylaminopropyl)-6-phenylphenantridinium iodide methiodide) *[25535-16-4]* **$C_{27}H_{34}I_2N_4$, M 668.4, m 210-230°(dec), $pK_{Est(1)}$~ 4 (aniline NH_2), $pK_{Est(2)}$~ 8.5 (EtN_2).** It crystallises as red crystals from H_2O containing a little KI. It fluoresces strongly and intercalates with nucleic acids; useful in flow cytometry. [Watkins *J Chem Soc* 3064 *1952*, DOI: 10.1039/JR9520003059, *Beilstein* **22** III/IV 5519.] **TOXIC.**

(±)-Propylene carbonate (4-methyl-1,3-dioxalan-2-one) *[108-32-7]* **$C_4H_6O_3$, M 102.1, m -55°, b 79-80°/0.08mm, 110°/0.5-1mm, 112-114°/2mm, 241°/760mm, d_4^{25} 1.187, n_D^{20} 1.421.** It is manufactured by reaction of 1,2-propylene oxide with CO_2 in the presence of a catalyst (quaternary ammonium halide). Contaminants include propylene oxide, carbon dioxide, 1,2- and 1,3-propanediols, allyl alcohol and ethylene carbonate. It can be purified by percolation through molecular sieves (Linde 5A, dried at 350° for 14 hours under a stream of argon), followed by distillation under a vacuum. [Jasinski & Kirkland *Anal Chem* **39** 1663 *1967*, DOI: 10.1021/ac50156a051.] It can be stored over molecular sieves under an inert gas atmosphere. When purified in this way it contains less than 2 ppm of water. Activated alumina and dried CaO have also been used as drying agents prior to fractional distillation under reduced pressure. It has been dried with 3A molecular sieves and distilled under nitrogen in the presence of *p*-toluenesulfonic acid, then redistilled and the middle fraction collected. [*Beilstein* **19** III/IV 1564, **19/4** V 21.] ***R(+)*-propylene carbonate (4-methyl-1,3-dioxalan-2-one)** *[16606-55-6]* **$C_4H_6O_3$, M 102.1,** has **b 240°/760mm, d_4^{25} 1.189, n_D^{20} 1.422,** and **$[\alpha]_D^{20}$ +2 (neat),** and ***S(-)*-propylene carbonate (4-methyl-1,3-dioxalan-2-one)** *[51260-39-0]* has **$[\alpha]_D^{20}$ -2 (neat)** could be purified in the same way as the racemate.

dl*-Propylene oxide (methyloxirane, 1,2-epoxypropane)** *[75-56-9]* **M 58.1, m -112°, b 34.5°/70mm d_4^{20} 0.829, n_D^{20} 1.3664.** Dry the oxide with Na_2SO_4 or CaH_2 and fractionally distil it through a packed column (glass helices), after refluxing with Na, CaH_2, or KOH pellets. [*Beilstein* **17** I 4, **17** II 131, **17** III/IV 17, **17/1** V 17.] The ***R(+)enantiomer *[15448-47-2]* and the ***S(-)enantiomer*** [16088-62-3] have **b** 33-34°/atm and $[\alpha]_D^{20}$ (+)14.6 and (-)14.6 (neat) respectively. [*Beilstein* **17/1** V 17.]

Protopine {Fumarine, Macleyine, 4,6,7,14-tetrahydro-5-methyl-bis[1,3]-benzodioxolo[4,5-*c*:5',6'-*g*]azecine-13(5*H*)-one} *[130-86-9]* **$C_{20}H_{19}NO_5$, M 353.4, m 208°, 209°, 211°, pK^{25} 5.99.** It crystallises fromEtOH/$CHCl_3$. The ***picrate*** has **m ~240°(dec)**. [*Beilstein* **27** H 558, **17** I 568, **17** II 620, **17** III/IV 6881.] It is an analgesic, inhibits histamine H1 receptors and platelet aggregation. [For anti-thrombotic and anti-inflammatory activities see Saeed et al. *Pharmacol Research* **36** 1 *1997*; DOI: 10.1006/phrs.1997.0195; for Anticholine-sterase and Antiamnesic Activities see Kim et al. *Planta Med* 65 218 1999, DOI: 10.1055/s-1999-13983.]

Pteridine *[91-18-9]* **$C_6H_4N_4$, M 132.2, m 139.5-140°, pK_1^{20} 4.05 (equilibrium, hydrate), pK_2^{20} 11,90 (OH of hydrate).** It crystallises from EtOH (5 parts with 80% recovery), *benzene, *n*-hexane, *n*-heptane or light petroleum (b 60°-80°, 300 parts with 80% recovery). It is best purified by sublimation at 120-130°/20mm. Store at 0°, in the dark. The yellow crystalline plates turn green in the presence of light and on long standing in the dark, and sublimation leaves some dark-coloured material behind. The crystals induce sneezing. [Albert et al. *J Chem Soc* 474 *1951*, DOI: 10.1039/JR9510000474; for hydrated species see Albert & Armarego *Adv Heterocycl Chem* **4** 1 *1965*, DOI:10.1016/S0065-2725(08)60873-9; D. J. Brown *Fused Pyrimidines*: *Pteridines*

1H-Pyrazole-4-carboxylic acid *[37718-11-9]* **$C_4H_4N_2O_2$, M 112.1,** has **m 282° (decarboxylates), $pK_{Est(1)}$ ~3.6, $pK_{Est(2)}$ ~12 (acidic NH).** This acid, also obtained by decarboxylating the more water soluble 3,4,5-tricarboxylic acid, crystallises in yellow prisms from H_2O. [Buchner & Fritsch *Justus Liebigs Ann Chem* **273** 252 *1893*, DOI: 10.1002/jlac.18932730211; Knorr & Rothenburg *Chem Ber* **28** 688 *1895*, DOI: 10.1002/cber.189502801157; *Beilstein* **25** H 116.]

Pyrazole-3,5-dicarboxylic acid *[3112-31-0]* **$C_5H_4N_2O_4$, M 174.1, m 287-289°(dec), 292-285°(dec), 295-297°(dec), $pK_{Est(1)}$~1.2 (CO_2H), $pK_{Est(2)}$~3.7 (CO_2H), $pK_{Est(3)}$~12 (NH).** It crystallises from water as a ***monohydrate***, or EtOH. Dry it in a vacuum at 100°. The ***dimethyl ester*** crystallises from Et_2O or *C_6H_6 with **m 155°**. [Buchner & Papendieck *Justus Liebigs Ann Chem* **273** 246 *1893*, DOI: 10.1002/jlac.18932730210; Buchner & Papendieck *Justus Liebigs Ann Chem* **273** 232 *1893,* DOI: 10.1002/jlac.18932730208; *Beilstein* **25** III/IV 1047.]

Pyridazine *[289-80-5]* **$C_4H_4N_2O$, M 80.1, m -8°, b 87/14mm, 208°/atm, d_4^{20} 1.103, $n_D^{23.5}$ 1.5321, pK^{20} -7.1 (H_o scale aq H_2SO_4).** If it looks *dubious* then dissolve it in dry Et_2O, shake this with K_2CO_3, filter, and distil, preferably under a vacuum. The ***hydrochloride***, yellow crystals **m 161-163°** (sealed tube), is obtained by crystallization (EtOH/Et_2O) and sublimation *in vacuo*. [Mizzoni & Spoerri *J Am Chem Soc* **73** 1873 *1951*, DOI: 10.1021/ja01148a537; *Beilstein* **23/5** 321.]
Pyridazine N-oxide **(pyridazine 1-oxide)** *[1457-42-7]* **$C_4H_4N_2O$, M 96.1,** has **m 38-39°, b 138-140°/4mm, pK_{Est} <1.** Purify the oxide by distillation in a vacuum and by sublimation *in vacuo*. When a solution of the oxide in MeOH is treated with an aqueous solution of $CuCl_2$, the **$[C_4H_4N_2O]_2$—$CuCl_2$-$2H_2O$-*complex*** (**m 182-183°**) is formed from which the oxide can be recovered. Its 1H NMR (60MHz, $CDCl_3$, TMS) has t 1.70(m H-3), 3.00 (ddd, H-4), 2,43 (ddd, H-5), 1.92 (ddd, H-6) ($J_{4,5}$ = 7.5, $J_{5,6}$ = 6.0, $J_{4,6}$ = 1.0, $J_{3,5}$ = 2.4, $J_{3,6}$ = 0.6 Hz).

[Pollak et al. *J Org Chem* **35** 2478 *1970*, DOI: 10.1021/jo00833a003; Klinge et al. *Recl Trav Chim Pays-Bas* **95** 21 *1976*, DOI: 10.1002/recl.19760950106; Ohsawa et al. *Tetrahedron Lett* **19** 1979 *1978*, DOI: 10.1016/S0040-4039(01)94726-4; Koelsch & Gumprecht *J Org Chem* **23** 1605 *1958*, DOI: 10.1021/jo01105a003; *Beilstein* **23** III/IV 890.]

Pyridazin-3,6-diol (pyridazine-(1*H*,2*H*-3,6-dione, maleic hydrazide) *[123-33-1]* **$C_4H_4N_2O_2$, M 112.1, m 299-301°(dec), 305°(dec), 306°(dec), pK_1^{25} 5.67, pK_2^{25} 13.3.** Crystallise the hydrazide from water. Dry it at ~100° over P_2O_5. [*Beilstein* **24** III/IV 1186.] Plant growth substance used in agriculture.

Pyridine *[110-86-1]* **C_5H_5N, M 79.1, m -41.8°, b 115.6°/atm, d_4^{20} 0.9831, n_D^{20} 1.51021, pK^{25} 5.23.** Likely impurities are H_2O and amines such as the picolines and lutidines. Pyridine is *hygroscopic* and is miscible with H_2O and organic solvents. It can be dried with solid KOH, NaOH, CaO, or BaO, followed by fractional distillation. Other methods of drying include standing with Linde type 4A molecular sieves, CaH_2 or $LiAlH_4$, azeotropic distillation of the H_2O with toluene or *benzene, or treated with phenylmagnesium bromide in ether, followed by evaporation of the ether and distillation of the pyridine. A recommended [Lindauer & Mukherjee *Pure Appl Chem* **27** 265 *197I*, DOI: org/10.1351/pac197127010265] method dries pyridine over solid KOH (20g/Kg) for 2 weeks and fractionally distils the supernatant over Linde type 5A molecular sieves and solid KOH. The product is stored under CO_2-free nitrogen. Pyridine can be stored in contact with BaO, CaH_2 or molecular sieves. Non-basic materials can be removed by steam distilling a solution containing 1.2 equivalents of 20% H_2SO_4 or 17% HCl until about 10% of the base has been carried over along with the non-basic impurities. The residue is then made alkaline, and the base is separated, dried with NaOH and fractionally distilled. ***The alkali metals, Na, Li or Cs should NOT be used for drying pyridine, and pyridine derivatives, as they form coloured pyridine radical anions leading to bipyridyls.*** [see Schmulback et al. *J Am Chem Soc* **90** 6600 *1968,* DOI: 10.1021/ja01026a006]. ***Alternatively***, pyridine can be treated with oxidising agents. Thus pyridine (800ml) has been stirred for 24 hours with a mixture of ceric sulfate (20g) and anhydrous K_2CO_3 (15g), then filtered and fractionally distilled. Hurd and Simon [*J Am Chem Soc* **84** 4519 *1962,* DOI: 10.1021/ja00882a030] stirred pyridine (135ml), water (2.5L) and $KMnO_4$ (90g) for 2 hours at 100°, then set aside for 15 hours before filtering off the precipitated manganese oxides. Addition of solid KOH (*ca* 500g) caused pyridine to separate. It was decanted, refluxed with CaO for 3 hours and distilled. Separation of pyridine from some of its homologues can be achieved by crystallisation of the oxalates. Pyridine is precipitated as its ***oxalate*** by adding it to the stirred solution of oxalic acid in acetone. The precipitate is filtered, washed with cold acetone, and pyridine is regenerated and isolated. Other methods are based on complex formation with $ZnCl_2$ or $HgCl_2$. Heap, Jones and Speakman [*J Am Chem Soc* **43** 1936 *1921,* DOI: 10.1021/ja01441a023] added crude pyridine (1L) to a solution of $ZnCl_2$ (848g) in 730ml of water, 346ml of concentrated HCl and 690ml of 95% EtOH. The crystalline precipitate of **$ZnCl_2$.(pyridine)$_2$** was filtered off, recrystallised twice from absolute EtOH, then treated with a concentrated NaOH solution, using 26.7g of solid NaOH to 100g of the complex. The precipitate was filtered off, and the pyridine was dried with NaOH pellets and distilled. Similarly, Kyte, Jeffery and Vogel [*J Chem Soc* 4454 *1960,* DOI: 10.1039/JR9600004454] added pyridine (60ml) in 300ml of 10% (v/v) HCl to a solution of $HgCl_2$ (405g) in hot water (2.3l). On cooling, crystals of ***pyridine-$HgCl_2$ (1:1) complex*** separated and were filtered off, crystallised from 1% HCl (to **m** 178.5-179°), washed with a little EtOH and dried at 110°. The free base was liberated by addition of excess aqueous NaOH and separated by steam distillation. The distillate was saturated with solid KOH, and the upper layer was removed, dried further with KOH, then BaO and distilled. Another possible purification step is fractional crystallisation by partial freezing. Small amounts of pyridine have been purified by vapour-phase chromatography, using a 180-cm column of polyethyleneglycol-400 (Shell 5%) on Embacel at 100°, with argon as carrier gas. The Karl Fischer titration can be used for determining water content. A colour test for pyrrole as a contaminant is described by Biddiscombe et al. [*J Chem Soc* 1957 *1954,* DOI: 10.1039/JR9540001957]. The ***1:1-hydrochloride*** crystallises from EtOH with **m 144°, b 218-219°/760mm** (see below) and is hygroscopic. The ***1:2-hydrochloride*** has **m 46°** *[58888-58-7]* and the ***picrate*** has **m 165-166°** *[1152-90-5].* [*Beilstein* **20** H 181, **20** I 54, **20** II 96, **20** III/IV 2205, **20/5** V 160.] § Polystyrene-supported pyridine is commercially available. ***Pyridine hydrobromide perbromide*** **(pyridinium bromide perbromide)** *[39416-48-3]* **$C_5H_5N.HBr.Br_2$, M 319.9,** has **m 130° (dec), 132-134°(dec), 135°(dec).** It is a very good stable brominating agent-liberating one mol of Br_2. Purify it by recrystallisation from glacial acetic acid (33g from 100ml of AcOH) to give orange-red crystals. Fieser prepared it by dissolving pyridine (15ml) in 48% HBr with cooling, then adding gradually bromine (25g) with cooling and swirling (fume cupboard). The solid that separated is collected, rinsed with

AcOH, and without drying is recrystallised from AcOH (100ml) to give red needles (33g, 69%). [Englert & McElvain *J Am Chem Soc* **51** 865 *1929*, DOI: 10.1021/ja01378a031; Fieser **1** 967; *Beilstein* **20/5** V 181.]
Pyridine hydrochloride *[628-13-7]* **C_5H_5N. HCl M 115.6,** has **m 144°, 145-147°, b 218°/760mm, 222-224°/atm.** Crystallise the salt from $CHCl_3$/EtOAc and wash it with Et_2O. It is ***hygroscopic***. [*Beilstein* **20** H 185, **20** I 57, **20** II 103, **20** III/IV 2230, **20/5** V 180.]

Pyridine-2-aldehyde (picolinaldehyde) *[1121-60-4]* **C_6H_5NO, M 107.1, b 81.5°/25mm, 181°/atm, d_4^{20} 1.121, n_D^{20} 1.535, pK_1^{25} 3.84, pK_2^{25} 12.68.** Purification is achieved by bubbling sulfur dioxide into a solution of 50g of the aldehyde in 250ml of boiled water, under nitrogen, at 0°, until precipitation is complete. The ***bisulfite addition compound*** is filtered off rapidly and, after washing with a little water, is refluxed in 17% HCl (200ml) under nitrogen until a clear solution is obtained. Neutralisation with $NaHCO_3$ and extraction with ether separated the aldehyde which is recovered by drying the extract, then distilling twice, under nitrogen. [Kyte et al. *J Chem Soc* 4454 *1960*, DOI: 10.1039/JR9600004454; *Beilstein* **21** I 287, **21** III/IV 3495, **21/7** V 293.]

Cl, M 172.6, m 226-227°(dec)** (from EtOH/Et_2O), is a prototypical reactivator of acetylcholine esterase that was inactivated by organophosphorus poisons, e.g. insecticides, or nerve gases [Kondritzer et al. *J Pharm Sci* **50** 109 *1961,* DOI: 10.1002/jps.2600500204]. The ***methoiodide*** (Pralidoxime, 2-PAM iodide) *[94-63-3]* **$C_7H_9N_2O$. I, M 266.1,** has **m 225-226°(dec)** (from EtOH),
Pyridine-3-aldoxime *[1193-92-6]* has **m 150°, 150-153°, pK_1^{20} 4.07, pK_2^{20} 10.39.** Crystallise the oxime from water. [*Beilstein E-isomer* **21** III/IV 3521, **21/7** V 339.]
Pyridine-4-aldoxime *[696-54-8]* has **m 129°, 130-133°, pK_1^{20} 4.73, pK_2^{20} 10.03.** Crystallise the oxime from water. [*Beilstein E-isomer* **21** III/IV 3533, **21/7** V 355.]

2,6-Pyridinedialdoxime *[2851-68-5]* **$C_7H_7N_3O_2$, M 165.1, m 212°, 216°, $pK_{Est(1)}$~3.0, $pK_{Est(2)}$~10.** Crystallise it several times from water or EtOH to give colourless needles. It is a tridentate chelate for metal ions, e.g. Fe^{2+}. [Lions & Martin *J Am Chem Soc* **79** 2733 *1957*, DOI: 10.1021/ja01568a018; *Beilstein* **21** III/IV 4746.]

Pyridine-2,5-dicarboxylic acid (isocinchomeronic acid) *[100-26-5]* **$C_7H_5NO_4$, M 167.1, m 242-247°, 254°, (267°, dec), pK_1^{25} 0.60, pK_2^{25} 2.49, pK_3^{25} 5.12.** Crystallise it from H_2O or dilute HCl. Attempted sublimation provides nicotinic acid *via* decarboxylation. [Napoli *J Inorg Nucl Chem* **32** 1907 *1970*, DOI:10.1016/0022-1902(70)80600-5; *Beilstein* **22** H 153, **22** I 533, **22** II 105, **22** III/IV 1632, **22/4** V 124.]
Pyridine-3,4-dicarboxylic acid **(cinchomeronic acid)** *[490-11-9]* has **m 253-255°, 256°, 262°(dec), pK_1^{25} 1.50 (0.6), pK_2^{25} 2.43 (2.95), pK_3^{25} 4.78 (5.07).** It has been prepared by the oxidation of isoquinoline with concentrated HNO_3 (44% yield) and crystallised from H_2O or dilute aqueous HCl. It has also been purified *via* the ***dimethyl ester*** which is distilled (**b 95-100°/1.5mm**) and hydrolysed with 3.5N HCl, evaporated and recrystallised. [Armarego & Evans *J Appl Chem* **12** 45 *1962*, DOI: 10.1002/jctb.5010120108; Foye et al. *J Med Chem* **9** 61 *1966*, DOI: 10.1021/jm00319a016; *Beilstein* **22** H 155, **22** I 534, **22** II 106, **22** III/IV 1641, **22/4** V 135.]

Pyridine *N*-oxide *[694-59-7]* **C_5H_5NO, M 95.1, m 62-67°, 67°, 68-69°, b 100-105°/1mm, 270°/atm, pK^{24} 0.79.** Purify the N-oxide by crystallisation from Et_2O and by vacuum sublimation. The ***hydrochloride***, **m 179.5-181°**, crystallises from *i*-PrOH. The ***picrolonate*** has yellow needles with **m 182-184°**. [Katritzky *J Chem Soc* 2404 *1956*, DOI: 10.1039/JR9560002404, *Beilstein* **20** III/IV 2305, **20/5** V 217.]

Pyridine 3-sulfonic acid *[636-73-7]* **$C_5H_5NO_3S$, M 159.2, m 365-366°(dec), 357°(sec), pK^{25} 2.89 (12% aqueous EtOH), 3.22 (H_2O)(protonation on N).** Purify the acid by recrystallisation from H_2O or aqueous EtOH as needles or plates. [pKa: Evans & Brown *J Org Chem* **27** 3127 *1962*, DOI: 10.1021/jo01056a034; IR: Arnett & Chawla *J Am Chem Soc* **100** 214 *1978*, DOI: 10.1021/ja00469a037] Its UV in 50% aqueous EtOH has λ_{max} at 208 and 262nm. The ***ammonium salt*** has **m 243°** (from H_2O), the ***sulfonyl chloride*** has **m 133-134°** (from petroleum ether), the ***amide*** has **m 110-111°** (from H_2O), the ***hydrochloride*** has **m >300°(dec)**, and the ***N-methyl betaine*** has **m 130°** (from H_2O). [Gastel & Wibaut *Recl Trav Chim Pays-Bas* **53** 1031 *1934*, DOI: 10.1002/recl.19340531106; McIlvain & Goese *J Am Chem Soc* **65** 2233 *1943*, DOI: 10.1021/ja01251a063; Machek *Monatsh Chem* **72** 77 *1939*, DOI: 10.1007/BF02716118; *Beilstein* **22** I 616, **22** II 309, **22/7** V 552.]

2-Pyridinethiol (2-mercaptopyridine) *[2637-34-5; 73018-10-7]* **C_5H_5NS, M 111.2, m 127.4°, 127-130°, 130-132°, pK_1^{20} -1.07, pK_2^{20} 9.97.** If impure, dissolve it in $CHCl_3$, wash it with dilute AcOH, H_2O, dry ($MgSO_4$), evaporate under reduced pressure and recrystallise the residue from $*C_6H_6$ or H_2O. ***2-Methylmercaptopyridine*** (**b 100-104°/33mm**, pK^{20} 3.59) was formed by treatment with MeI/NaOH. [Albert & Barlin *J Chem Soc* 2384 *1959*, DOI: 10.1039/JR9590002384; *Beilstein* **21** H 45, **21** III/IV 373, **21/7** V 147.]
4-Pyridinethiol **(4-mercaptopyridine)** *[4556-23-4]* has **m 177°, 179-189°, 186°, pK_1^{20} 1.43, pK_2^{20} 8.86.** Purify the thiol by dissolving ~45g in boiling H_2O (100ml) (charcoal), filter and precipitate it by adding 50% aqueous NaOH (~80ml) to pH ~6. Dissolve the precipitate in EtOH, evaporate it to dryness, then crystallise it from boiling EtOH (~100ml, charcoal) to give yellow flat hexagonal plates (**m 186°**). It sublimes readily *in vacuo*. [King & Ware *J Chem Soc* 873 *1939*, DOI: 10.1039/JR9390000873.] The ***picrate*** forms yellow needles from H_2O with **m 222°(dec)**. The ***4-methylmercaptopyridine*** derivative crystallises from petroleum ether (**m 47°**, also **44-45°** was reported, with a **pK^{20}** of **5.97**) and was prepared by treatment with MeI/NaOH. Its ***picrate*** has **m 245°** (from H_2O, MeOH or EtOH). The ***N-methyl-4-pyridinethiol*** derivative has **m 168.5-170°** (from EtOH), a **pK^{20}** of **1.30** and is soluble in $CHCl_3$. [Albert & Barlin *J Chem Soc* 2384 *1959*, DOI: 10.1039/JR9590002384; *Beilstein* **21** II 35, **22** III/IV 373, **22/7** V 147.]

1-(2-Pyridylazo)-2-naphthol (PAN) *[85-85-8]* **$C_{15}H_{11}N_3O$, M 249.3, m 142°, 138-141°, 142°, pK_1^{30-36} 2.9, pK_2^{30-36} 11.2.** Purify PAN by repeated crystallisation from EtOH or MeOH. It can also be purified by sublimation under vacuum. Purity can be checked by TLC using a mixed solvent (petroleum ether/Et_2O/EtOH; 10:10:1) on a silica gel plate. It has pK_1 1.9 and pK_2 12.2 in 20% aqueous ethoxyethanol. It chelates with copper [Pease & Williams *Anal Chem* **31** 1044 *1959*, DOI: 10.1021/ac60150a027]. [*Beilstein* **22** I 694, **22** III/IV 7073, **22/4** V 618.]

4-(2-Pyridylazo)-resorcinol (PAR) *[1141-59-9]* **$C_{11}H_9N_3O_2$, M 215.2, m 192-202°(dec), >195°(dec), λ_{max} 415nm, ε 2.59 x 10^4 (pH 6-12), pK_1^{25} 2.69 (3.1), pK_2^{25} 5.50 (5.8), pK_3^{25} 12.5 (11.9).** Purify PAR as the sodium salt by recrystallisation from 1:1 EtOH/water. Purity can be checked by TLC using a silica gel plate and a mixed solvent (*n*-BuOH:EtOH:2M NH_3; 6:2:2). [*Beilstein* **22** I 694, **22** III/IV 7074, **22/14** V 619.]

3-(2-Pyridyl)-5,6-diphenyl-1,2,4-triazine *[1046-56-6]* **$C_{20}H_{14}N_4$, M 310.4, m 191-192°, 191-193°.** Purify it by repeated recrystallisation from EtOH/dimethylformamide. It is a reagent for estimating Fe(II) and Ru(II). [Chriswell & Schilt *Anal Chem* **46** 992 *1974*, DOI: 10.1021/ac60344a021; Karma & Ayers *Anal Chim Acta* **78** 423 *1975*, DOI:10.1016/S0003-2670(00)00163-X.]

1-(4-Pyridyl)ethanol *[R-(+) 27854-88-2; S-(-) 54656-96-1]* **C_7H_9NO, M 123.2, m 63-65°, 67-69°, b 138-140°/30mm, 254°/760mm, $[\alpha]_D^{20}$ *R*(+) +49.8 and *S*(-) -49.8 (c 0.5, EtOH), and *R*(+) +55 and *S*(-) -55 (c 1, $CHCl_3$), pK_{Est} ~5.4.** Purify it by recrystallisation from petroleum ether. The **m** recorded after sublimation was **59.9-60.2°**, and **55°** after crystallisation from $*C_6H_6$/petroleum ether or petroleum ether/$*C_6H_6$. The ***(-)-di-O-benzoyl tartrate salt*** has **m 146-148°** (from EtOH). [UV, ORD: Gottarelli & Samori *JCS Perkin Trans 2* 1462 *1974*, DOI: 10.1039/P29740001462.] The ***racemate*** recrystallises from Et_2O with **m 74-76°, b 90-94°/1mm**. The ***picrate*** has **m 125-126°** (from $*C_6H_6$). [Ferles & Attia *Coll Czech Chem Commun* **38** 611 *1973*, UV, NMR: Nielson et al. *J Org Chem* **29** 2898 *1964*, DOI: 10.1021/jo01033a022; *Beilstein* **21/2** V 217.]

5-(3-Pyridyl)-4*H*-1,2,4-triazole-3-thiol [1,2-dihydro-5-(3-pyridinyl)-3*H*-1,2,4-triazole-3-thione] *[32362-88-2]* **$C_7H_6N_4S$, M 178.2, m 285-286°, 296-302°, $pK_{Est(1)}$ ~ 3.0 (py N), $pK_{Est(2)}$ ~ 9 (SH).** This thio-1,2,4-triazole

was prepared by fusing nicotinoylhydrazide with thiourea at ~150º then at 160-165º (30 minutes), cooled, EtOH was added and the white solid was filtered off [Beyerman et al. *Recl Trav Chim Pays-Bas* **73** 109 *1954*, DOI: 10.1002/recl.19540730205]; or by heating 1-nicotinoyl-3-thiosemicarbazide in 5% aqueous NaOH at 100º (4 hours), cooled, acidified with AcOH, and filtered off [Yale & Piala *J Med Chem* **9** 42 *1966*, DOI: 10.1021/jm00319a010]. It was recrystallised from 95% EtOH, *n*-BuOH/H_2O, H_2O, and 0.5% aqueous HCl provides the *hydrochloride*, which is dried *in vacuo* [over P_2O_5 or H_2SO_4]. [Yoshida & Asai *J Pharm Soc Jpn* **74** 948 *1954*, *Chem Abstr* **49** 10937 *1955*, *Beilstein* **26** IV 2129].

5-(4-Pyridyl)-4*H*-1,2,4-triazole-3-thiol [1,2-Dihydro-5-(4-pyridinyl)-3*H*-1,2,4-triazole-3-thione] *[14910-06-6]* **$C_7H_6N_4S$, M 178.2, , m 301-303º (dec), 305-308º (dec), 308-313º, 320-322º (dec), 321-322º (dec), $pK_{Est(1)}$ ~ 3.5 (py N), $pK_{Est(2)}$ ~ 9 (SH).** This thio-1,2,4-triazole was prepared and purified as for the 3-pyridyl-isomer above but by using isonicotinic acid derivatives. It has mild diuretic and natriuretic activity. [Blackman et al. *J Chem Soc C* 661 *1967*, DOI: 10.1039/J39670000661, Beyerman et al. *Recl Trav Chim Pays-Bas* **73** 109 *1954*, DOI: 10.1002/recl.19540730205; Yale & Piala *J Med Chem* **9** 42 *1966*, DOI: 10.1021/jm00319a010; Yoshida & Asai *J Pharm Soc Jpn* **74** 948 *1954*, *Chem Abstr* **49** 10937 *1955*, *Beilstein* **26** IV 2129]. ***5-(4-Pyridyl)-4H-1,2,4-triazole-3-sulfonic acid hydrate*** was obtained by oxidising the 3-thiol with saturated aqueous $KMnO_4$ at 25º (1 hour), decomposed with EtOH, filtered, precipitated as the Ag salt, filtered off, and decomposed with 5% HCl, then evaporated, and the residue was recrystallised from H_2O. It decomposed on heating. [Blackman et al. *J Chem Soc C* 661 *1967*, DOI: 10.1039/J39670000661.]

α-Pyrone (2*H*-pyran-2-one, coumalin) *[504-31-4]* **$C_7H_6N_4S$, M 96.1, m 5º, 8-9º, b 102-103º/20mm, 110º/26mm, 104º/ 30mm, 115-118º/37mm, 206-207º/atm, d_4^{20} 1.1972, n_D^{20} 1.5298, pK^{25} -1.14 (aqueous H_2SO_4).** Dissolve α-pyrone in Et_2O, wash it with brine, dry (Na_2SO_4), filter, evaporate, distil the residue under vacuum and redistil it. It is a colourless liquid. Its IR has ν_{max} at 1622 and 1752cm^{-1} ($CHCl_3$). [Zimmermann et al. *Org Synth* Coll Vol **5** 982 *1973*, DOI: 10.15227/orgsyn.046.0101; Nakagawa et al. *Org Synth* **56** 49 *1977*, DOI: 10.15227/orgsyn.056.0049; Fried & Elderfield *J Org Chem* **6** 566 *1941*, DOI: 10.1021/jo01204a010.] The ***picrate*** has **m 106-107º** (from EtOH). [*Beilstein* **17** H 271, **17** II 305, **17** III/IV 4399, **17/9** V 288.]
γ-Pyrone* (4*H*-pyran-4-one)** *[108-97-4]* has **m 32.5-32.6º, 33º, 32-34º, b 88.5º/7mm, 91-91.5º/9mm, 95-97º/13mm, 105º/23mm, 215º/atm, pK^{25} 0.10.** Purify γ-pyrone by vacuum distillation; the distillate crystallises and is ***hygroscopic. It is non-steam volatile. The ***hydrochoride*** has **m 139º** (from EtOH), and the ***picrate*** has **m 130.2-130.3º** (from EtOH or H_2O). [Mayer *Chem Ber* **90** 2362 *1957*, DOI: 10.1002/cber.19570901035; IR: Jones et al. *Can J Chem* **37** 2007 *1959*, DOI: 10.1139/v59-293; Neelakatan *J Org Chem* **22** 1584 *1957*, DOI: 10.1021/jo01363a012; *Beilstein* **17** H 271, **17** I 145, **17** II 305, **17** III/IV 4399, **17/9** V 290.]

Pyronin G [3,6-bis(dimethylamino)xanthenylium chloride] *[92-32-0]* **$C_{17}H_{19}ClN_2O$, M 302.8, m 250-260º, CI 45005, λmax 522nm, pK_{Est} ~7.6.** Commercial material may contain a large quantity of zinc. Purify it by dissolving 1g in 50ml of hot water containing 5g NaEDTA. Cool to 0º, filter, evaporate to dryness and the residue is extracted with EtOH. The solution is evaporated to 5-10ml, filtered, and the dye is precipitated by addition of excess of dry diethyl ether. It is centrifuged, and the crystals are washed with dry ether. The procedure is repeated, then the product is dissolved in $CHCl_3$, filtered and evaporated. The dye is stored in a vacuum. It forms lustruous green crystals of the $FeCl_3$ complex. [*Beilstein* **18** H 596, **18** III/IV 7361, **18/10** V 181.] Bacterial and biological stain.

Pyrrol-2,5-dione (maleimide, 2,5-pyrroledione) *[541-59-3]* **$C_4H_3NO_2$, M 97.1, m 91-93º, 92.6-93º, $d_D^{105.5}$ 1.2493, $n_D^{110.7}$ 1.49256.** Purify it by sublimation in a vacuum. The UV has λ_{max} at 216 and 280nm in EtOH. [de Wolf & van de Straete *Bull Soc Chim Belg* **44** 288 *1935*, UV: Rondestvedt et al. *J Am Chem Soc* **78** 6115 *1956*, DOI: 10.1021/ja01604a044; IR: Chiorboli & Mirone *Ann Chim (Rome)* **42** 681 *1952*.] Used in Rhodium-catalysed conjugate for arylation with arylboronic acids [Iyer et al. *Tetrahedron Lett* **48** 4413 *2007*, DOI:10.1016/j.tetlet.2007.04.084]. [*Beilstein* **21/10** V 3.]

Pyrrole *[109-97-7]* **C_4H_5N, M 67.1, m -23.4º, b 66º/80mm, 129-130º/atm, d_4^{20} 0.966, n_D^{20} 1.5097, pK_1^{25} -4.4 (Protonation on carbon), pK_2^{25} 17.51 (aqueous KOH, H- scale).** Dry pyrrole with NaOH, CaH_2 or $CaSO_4$. Fractionally distil it under reduced pressure from CaH_2. Store it under nitrogen as it turns brown in air. Redistil it immediately before use. It polymerises in the presence of acids, and with dilute HCl it gives 'pyrrole red'

which is an amorphous orange coloured solid. The ***picrate*** forms orange-red crystals with **m 69°(dec)**. [*Beilstein* **20** H 4, **20** I 3, **20** II 3, **20** III/IV 61, **20/5** V 3.]

1*H*-Pyrrole-1-propanoic acid (3-[pyrrol-1-yl]propionic acid) *[89059-06-3]* **$C_7H_9NO_2$, M 139.2, m 59-64°, 62°, 62.5°, pK_{Est} ~4.5.** Recrystallise the acid from petroleum ether (b 80-100°) and dry it *in vacuo*. It readily forms the N-Na and N-K salts. The ***ethyl ester*** has **b 122°/23mm**. The ***amide*** forms colourless needles from *C_6H_6 with **m 81°** and is soluble in cold H_2O. [Clemo & Ramage *J Chem Soc* 49 *1931*, DOI: 10.1039/JR9310000049; Jefford & Johncock *Helv Chim Acta* **66** 2666 *1983*, DOI: 10.1002/hlca.19830660835.]

Pyrrolidine (tetrahydropyrrole) *[123-75-1]* **C_4H_9N, M 71.1, b 87.5-88.5°, d_4^{20} 0.860, n_D^{20} 1.443, pK^{25} 11.31.** Dry pyrrolidine with BaO or sodium, then fractionally distil it, under N_2, through a Todd column packed with glass helices. It is a strong base, store away from CO_2. [*Beilstein* **20** H 159, **20** I 36, **20** II 79, **20** III/IV 2072, **20/1** V 162.]

Quercetin ($2H_2O$) **(3,3',4',5,6-pentahydroxyflavone)** *[6151-25-3 ($2H_2O$); 117-39-3 (anhydrous)]* **$C_{15}H_{10}O_7$. $2H_2O$, M 338.3, m *ca* 315°(dec), 317.4-317.9°(dec), (phenolic pKs 7—10).** Crystallise the yellow flavone from aqueous EtOH and dry at 100°. It also sublimes in a vacuum. Its IR has ν_{max} at 2.5μ and 16.7μ (KBr). It complexes with Cu^{2+}, Al^{3+}, Ca^{2+}, Ge^{4+}, Zn^{2+}, Ti^{4+}, Zr^{4+}, Th^{4+}, UO^{4+}. [*Beilstein* **18** H 242, **18** I 242, **18** II 236, **18** III/IV 3470, **18/5** V 494.] It exhibits anti-cancer activity.

Quinaldic (quinoline-2-carboxylic) acid *[93-10-7]* **$C_{10}H_7NO_2$, M 173.2, m 155-157°, 156-157°, pK_1^{25} 1.45, pK_2^{25} 2.49 (2.97).** Crystallise quinaldic acid from *C_6H_6 or AcOH. It is used for the estimation of many metals. The ***methyl ester*** has **m 86-87°** (from hexane) and pK^{25} 1.76. [Chauduri et al. *Frez Z Anal Chem* **281** 361 *1976, Beilstein* **22** H 71, **22** II 55, **22** III/IV 1149, **22/3** V 183.] It forms insoluble salts with copper, uranium and zinc; and is used for their determination.

Quinazoline *[253-82-7]* **$C_8H_6N_2$, M 130.2, m 46-48°, 48.0-48.5°, b 120-121°/17-18mm, 241°/764mm, 243°/772mm, pK_1^{20} -4.51 (aqueous H_2SO_4, anhydrous dication), pK_2^{20} 2.01 (anhydrous monocation), pK_3^{20} 4.3 (equilibrium with 3,4-hydrated species), pK_4^{20} 12.1 (hydrated anion).** Purify quinazoline by passage through an activated alumina column in *C_6H_6 or petrolum ether (b 40-60°). Distil it under reduced pressure, sublime it under vacuum and recrystallise it from petroleum ether. The ***hydrochloride hydrate*** has **m 127-128°** (from EtOH/HCl/ Et_2O). The ***picrate*** has **m 188-189°** (from MeOH). [Armarego *J Appl Chem* **11** 70 *1961*, DOI: 10.1002/jctb.5010110207; Armarego *Quinazolines, Fused Pyrimidines Part I* Brown Ed, Wiley-Interscience *1967*, Brown *Quinazolines Supplement I* Taylor Ed, Wiley-Interscience *1996*, ISBN 0-471-14565-3; for covalent hydration see Albert & Armarego *Adv Heterocycl Chem* **4** 1 *1965*, DOI:10.1016/S0065-2725(08)60873-9; Elderfield et al. *J Org Chem* **12** 405 *1947*, DOI: 10.1021/jo01167a007; *Beilstein* **23** H 175, **23** II 177, **23** III/IV 1221.]

Quinoline *[91-22-5]* **C_9H_7N, M 129.2, m -20°, -16°, b 113-114°/17mm, 236°/758mm, d_4^{20} 1.0937, n_D^{20} 1.625, pK^{25} 4.80 (4.93).** Dry quinoline with Na_2SO_4 and distil it from zinc dust in a vacuum. It has also been dried by boiling with acetic anhydride, then fractionally distilled. Calvin and Wilmarth [*J Am Chem Soc* **78** 1301 *1956*, DOI: 10.1021/ja01588a009] cooled redistilled quinoline in ice and added enough HCl to form its hydrochloride. Diazotization removed aniline, the diazo compound being broken down by warming the solution to 60°. Non-basic impurities were removed by ether extraction. Quinoline was then liberated by neutralising the hydrochloride with NaOH, then dried with KOH and fractionally distilled at low pressure. Addition of cuprous acetate (7g/L of quinoline) and shaking under hydrogen for 12 hours at 100° removed impurities due to the nitrous acid treatment. Finally the hydrogen was pumped off, and the quinoline was distilled. Other purification procedures depend on conversion to the ***phosphate*** (**m 159°**, precipitated from MeOH solution, filtered, washed with MeOH, then dried at 55°) or the ***picrate*** (**m 201°**) which, after recrystallisation, were reconverted to quinoline. The method using the picrate [Packer et al. *J Am Chem Soc* **80** 905 *1958*, DOI: 10.1021/ja01537a039] is as follows: quinoline is added to picric acid dissolved in the minimum volume of 95% EtOH, giving yellow crystals which were washed with EtOH, air-dried and crystallised from acetonitrile. These were dissolved in dimethyl sulfoxide (previously dried over 4A molecular sieves) and passed through a basic alumina column, onto which the picric acid is adsorbed. The ***free base*** in the effluent is extracted with *n*-

pentane and distilled under vacuum. Traces of solvent can be removed by vapour-phase chromatography. [Moomaw & Anton *J Phys Chem* **80** 2243 *1976*, DOI: 10.1021/j100561a022.] The $ZnCl_2$ and dichromate complexes have also been used [Cumper et al. *J Chem Soc* 1176 *1962*, DOI: 10.1039/JR9620001176]. [*Beilstein* **20** H 339, **20** I 134, **20** II 222, **20** III/IV 3334, **20/7** V 276.] ***Quinoline ethiodide* (1-ethylquinolinium iodide)** *[634-35-5]* **$C_{11}H_{12}IN$, M 285.1,** has **m 157-160°, 158-159°.** Crystallise it from aqueous EtOH or EtOH/peroxide free Et_2O. [*Beilstein* **20** I 139, **20** II 231, **20** III/IV 3357, **20/7** V 276.]

2-Quinolinealdehyde *[5470-96-2]* **$C_{10}H_7NO$, M 157.2, m 70-72°, 71°, pK_{Est} ~3.3.** Distil it in steam and recrystallise it from H_2O. Protect it from light. The ***semicarbazone*** has **m 254°** (from aqueous EtOH), and the ***picrate*** has **m 197-199°**. [*Beilstein* **21** H 322, **21** III/IV 4034, **21/8** V 442.]

8-Quinolinecarboxylic acid *[86-59-9]* **$C_{10}H_7NO_2$, M 173.2, m 183-185°, 186-187.5°, pK_1^{25} 1.82, pK_2^{25} 6.87.** Crystallise the acid from water, aqueous EtOH, EtOH or *C_6H_6. The ***ethyl ester*** has **m 45°** and **b 194-197°/13mm**. [*Beilstein* **22** H 81, **22** III/IV 1200, **22/3** V 217.] Forms complexes with Ag, Cd, Cu, Fe, Hg, Pb and Tl, and for estimation of Cu.

Quinoxaline *[91-19-0]* **$C_8H_6N_2$, M 130.2, m 28° (anhydrous), 29-32°, 37°(H_2O), b 108-110°/0.1mm, 140°/40mm, 220-223°/atm, pK_1^{20} -5.52 (-5.8, dication), pK_2^{20} 0.56 (c 0.5), 0.72 (c 1.0) (monocation).** Crystallise quinoxaline from petroleum ether. It crystallises as the ***monohydrate*** on addition of water to a petroleum ether solution. It has UV with λ_{max} at 242 and 331nm (H° –2); 234 and 316nm (pH 7.1). The ***picrate*** has **m 161-162°**. [Albert & Phillips *J Chem Soc* 1294 1956, DOI: 10.1039/JR9560001294; Brown *Chemistry of Heterocyclic Compounds: Quinoxaline (Supplement 1)* **vol 61** pp 510 *2004*, Wiley-Interscience NY, ISBN: 0471264954; *Beilstein* **23** H 176, **23** II 177, **23** III/IV 1226, **23/7** V 135.]

Quinoxaline-2,3-dithiol *[1199-03-7, 40158-04-1]* **$C_8H_6N_2S_2$, M 194.1, m 345°(dec), pK_1 6.9, pK_2 9.9.** Purify the dithiol by repeated dissolution in alkali and re-precipitation by acetic acid. It complexes with Ag^+, Cd^{2+}, Pb^{2+}, Bi^{3+} and Ni^{2+} in aqueous NH_3. It is used for the gravimetric analysis of Ni [Dalziel & Slawinski *Talanta* **15** I1385 *1968*, DOI: 10.1016/0039-9140(68)80198-5]. [*Beilstein* **24** III/IV 1428.]

Quinuclidine (1-azabicyclo[2.2.2]octane) *[100-76-5]* **$C_7H_{13}N$, M 111.2, m 157-160°, 158°(sublimes), 158-159°, pK^{25} 10.95.** Crystallise it from diethyl ether, or petroleum ether (b 40-50°) and cooling at 0°. It sublimes as colourless dendrites on heating during melting point determination in a sealed tube. It is a strong organic base. The ***hydrochloride*** *[39896-06-5]* has **m 364-365°(dec)** (from EtOH or n-BuOH), and the ***picrate*** has **m 275°** (also **254°**) (from aqueous EtOH). [Clemo & Metcalfe *J Chem Soc* 1989 *1937*, DOI: 10.1039/JR9370001989; Leonard & Elkin *J Org Chem* **27** 463 *1962*, DOI: 10.1021/jo01059a502; *Beilstein* **20** H 144, **20** II 71, **20** III/IV 1966, **20/4** V 335.]

Rhamnetin (3,3'-4',5-tetrahydroxy-7-methoxy flavone, 7-methyl quercitin) *[90-19-7]* **$C_{16}H_{12}O_7$, M 316.3, m >300°(dec), several phenolic pKs ~7-10.5.** Crystallise rhamnetin from EtOH (**m 292-293°**), aqueous EtOH (**m 294-296°**) or MeOH (**m 290-294°**), or Me_2CO/MeOH. [Kuhn & Low *Chem Ber* **77** 211 *1944*, DOI: 10.1002/cber.19440770313; Jurd *J Am Chem Soc* **80** 5531 *1958*, DOI: 10.1021/ja01553a054.] The ***tetra-acetate*** has **m 189-190°** (from Me_2CO/MeOH). [*Beilstein* **18** H 245, **18** II 237, **18** III/IV 3474.]

Rhodamine 3B chloride [3,5-bis-(diethylamino)-9-(2-carboxyphenyl)xanthylium chloride] *[81-88-9]* **$C_{28}H_{31}ClN_2O_3$, M 479.0, m 210-211°(dec), CI 45170, λ_{max} 543nm, {Free base** *[509-34-2]* **CI 749}, pK^{25} 5.53.** Major impurities are partially dealkylated compounds not removed by recrystallisation. Purify the dye by chromatography, using ethyl acetate/isopropanol/ammonia (880)(9:7:4, R_F 0.75 on Kieselgel G). It has also been crystallised from a concentrated solution in MeOH by slow addition of dry diethyl ether; or from EtOH containing a drop of concentrated HCl by slow addition of ten volumes of dry diethyl ether. The solid is washed with ether and air dried. The dried material has also been extracted with *benzene to remove oil-soluble material prior to recrystallisation. Store it in the dark. It is a colorimetric reagent for Cd, and suitable as a laser dye, and a powerful dye. [*Beilstein* **18** II 486, **18** III/IV 8246, **19/8** V 669.]

Rhodamine 6G [Basic Red 1, 3,5-bis-(ethylamino)-9-(2-ethoxycarbonylphenyl)-2,7-dimethylxanthylium chloride] *[989-38-8]* **$C_{28}H_{31}ClN_2O_3$, M 479.3, CI 45160, λmax 524nm, pK^{25} 5.58.** Crystallise the dye from MeOH or EtOH, and dry it in a vacuum oven. It is a powerful dye, and has found use in identifying lipid materials on TLC plates, as it fluoresces under UV light. [*Beilstein* **18** III/IV 8244, **18/12** V 283.]

Rhodanine (2-mercaptothiazolidin-4-one) *[141-84-4]* **$C_3H_3NOS_2$, M 133.2,** has **m 165-169°, 168.5° (capillary), pK^{20} 5.18.** Crystallise rhodanine from glacial acetic acid or water. It is used to estimate Ag and gallic acid [Thies & Fischer *Mikrochimica Acta* **182** 809 *1973*, DOI: 10.1007/BF01218140]. [*Beilstein* **27** H 242, **27** I 309, **27** II 288, **27** III/IV 3188.]

Saccharin (1,2-benzisothiazol-3(2*H*)-one 1,1-dioxide, *o*-benzoic acid sulfimide) *[81-07-2]* **$C_7H_5NO_3S$, M 183.2, m 226-229°, 227-229°, 229°, 228.8-229.7°, pK_1^{25} 1.31, pK_2^{25} 12.8.** Purify saccharin by recrystallisation from Me_2CO [solubility 7.14% at 0°, 14.4% at 50°], or aqueous isoPrOH to give a fluorescent solution. It sublimes *in vacuo*. It is an artificial sweetener which is 500 times sweeter than sucrose. [DeGarmo et al. *J Am Pharm Assoc (Sci Ed)* **41** 17 *1952*, *Beilstein* **27** H 168, 870, **27** I 266, **27** II 214, **27** III/IV 2649.]

Safranine O (Safranine T, 3,7-diamino-2,8-dimethyl-5-phenylphenazinium chloride, cotton Red) *[477-73-6]* **$C_{20}H_{19}ClN_4$, M 350.9, λ_{max} 530nm, pK^{25} 6.4.** Crystallise it from *benzene/MeOH (1:1) or water. Dry it *in vacuo* over H_2SO_4. It has UV: λ_{max} at 520nm (H_2O) and 530nm (EtOH). It is a certified dye for staining chromosomes, Gram negative bacteria and plant cells. [*Beilstein* **25** H 403, **25** I 657, **25** III/IV 3056.]

Safrole (5-allyl-1,3-benzodioxole, 4-allyl-1,2-methylenedioxybenzene) *[94-59-7]* **$C_{10}H_{10}O_2$, M 162.1, m~ 11°, b 69-70°/1.5mm, 104-105°/6mm, 231.5-232°/atm, 235-237°/atm, d_4^{20} 1.0993, n_D^{20} 1.53738.** Safrole has been purified by fractional distillation, although it has also been recrystallised from low boiling petroleum ether at low temperatures. [IR: Briggs et al. *Anal Chem* **29** 904 *1957*, DOI: 10.1021/ac60126a014; UV: Patterson & Hibbert *J Am Chem Soc* **65** 1862 *1943*, DOI: 10.1021/ja01250a021.] The ***maleic anhydride adduct*** forms yellow crystals from toluene **m 257°** [Hickey *J Org Chem* **13** 443 *1948*, DOI: 10.1021/jo01161a020], and the *picrate* forms orange-red crystals from $CHCl_3$ [Baril & Megrdichian *J Am Chem Soc* **58** 1415 *1936*, DOI: 10.1021/ja01299a031]. It is a sweet smelling oil. [*Beilstein* **19** I 617, **19** II 29, **19** III/IV 275, **19/1** V 553.]

Scopoletin (7-hydroxy-6-methoxycoumarin) *[92-61-5]* **$C_{10}H_8O_4$, M 192.2, m 203-205°, 206°, 208-209°, pK^{25} 8.96 (70% aqueous EtOH).** Crystallise it from water, acetic acid or *C_6H_6/MeOH. It is dimorphic with a second **m** at **193-195°**. It sublimes at 120-130°/12mm. This dye is used for detecting release of oxygen reactive species, is a peroxynitrite scavenger and a cholinesterase inhibitor. [*Beilstein* **18** III/IV 1323, **18/3** V 203.]

Styrene oxide (phenyloxirane) *[96-09-3]* **C_8H_8O M 120.2, m -37°, b 84-86°/16.5mm, 194°/atm, d_4^{20} 1.053, n_D^{25} 1.535.** Fractional distillation under reduced pressure does not remove phenylacetaldehyde. If this material is present, the styrene oxide is treated with hydrogen under 3 atmospheres pressure in the presence of platinum oxide. The aldehyde, but not the oxide, is reduced to ***ß-phenylethanol***, and separation is now readily achieved by fractional distillation. [Schenck & Kaizermen *J Am Chem Soc* **75** 1636 *1953*, DOI: 10.1021/ja01103a035; *Beilstein* **17/1** V 577.]

2-Sulfobenzoic cyclic anhydride (2,1-benzoxathiazol-3-one-1,1-dioxide) *[81-08-3]* **$C_7H_4O_4S$, M 184.2, m 126-127°, 129.5°, 130°, b 184-186°/18mm.** The anhydride is purified by distillation in a vacuum and readily solidifies to a crystalline mass on cooling. [Heitman *J Am Chem Soc* **34** 1591 *1912*, DOI: 10.1021/ja02212a019.] ***Alternatively***, purify it by dissolving it in the minimum volume of toluene and refluxing for 2 hours using a Dean-Stark trap. Evaporate under reduced pressure and distil the anhydride at 18mm. It is then recrystallised three times from its own weight of dry *C_6H_6. It is sensitive to moisture and should be stored in the dark in a dry atmosphere. The ***O-methyloxime*** has **m 110-112°** [Levy *Tetrahedron Lett* **13** 3289 *1972*, DOI: 10.1016/S0040-4039(01)94025-0]. If the sample has hydrolysed extensively (presence of OH band in the IR) then treat with an equal bulk of $SOCl_2$, reflux it for 3 hours ($CaCl_2$ tube), evaporate and distil the residue in a vacuum, then recrystallise it from *C_6H_6, Et_2O/*C_6H_6 or $CHCl_3$ (EtOH free by passing through Al_2O_3, or standing over $CaCl_2$). [Clarke & Dreger *Org Synth* Coll Vol **1** 495 *1941*, DOI: 10.15227/orgsyn.009.0080.] It

is used for modifying ζ-amino functions of lysyl residues in proteins [Bagree et al. *FEBS Lett* **120** 275 *1980*, DOI: 10.1016/0014-5793(80)80315-2]. [*Beilstein* **19** I 659, **19** II 137, **19** III/IV 1641, **19/4** V 215.]

Sulfolane (tetramethylenesulfone) *[126-33-0]* **$C_4H_8O_2S$, M 120.2, m 20-26°, 28.5°, b 104°/0.2mm, 153-154°/18mm, 285°/760mm, d_4^{20} 1.263, n_D^{30} 1.4820.** It is prepared commercially by a Diels-Alder reaction of between 1,3-butadiene and sulfur dioxide, followed by Raney nickel hydrogenation. The principal impurities are water, 3-sulfolene, 2-sulfolene and 2-isopropyl sulfolanyl ether. It is dried by passage through a column of molecular sieves. Distil it under reduced pressure through a column packed with stainless steel helices. Again dry it with molecular sieves and distil. [Cram et al. *J Am Chem Soc* **83** 3678 *1961*, DOI: 10.1021/ja01478a029; Coetzee *Pure Appl Chem* **49** 211 *1977*, DOI: 10.1351/pac197749020211.] *Alternatively*, it is stirred at 50°, and small portions of solid $KMnO_4$ are added until the colour persists during 1 hour. Dropwise addition of MeOH then destroys the excess $KMnO_4$; the solution is filtered, freed from potassium ions by passage through an ion-exchange column and dried under vacuum. It has also been distilled in a vacuum from KOH pellets. It is *hygroscopic*. [See Sacco et al. *J Phys Chem* **80** 749 *1976*, DOI: 10.1021/j100548a018; Sacco et al *JCS Faraday Trans 1* **73** 1936 *1977*, DOI: 10.1039/F19777301936; Petrella & Sacco *JCS Faraday Trans 1* **74** 2070 *1978*, DOI: 10.1039/F19787402070; Conway et al. *Trans Faraday Soc* **62** 2738 *1966*, DOI: 10.1039/TF9666202738.] Coetzee has reviewed the methods of purification of sulfolane, and also the removal of impurities. [Coetzee in *Recommended Methods of Purification of Solvents and Tests for Impurities*, Coetzee Ed. Pergamon Press, 1982, *Beilstein* **17** I 5, **17** III/IV 37, **17/1** V 39.]

2,2':6',2"-Terpyridyl *[1148-79-4]* **$C_{15}H_{11}N_3$, M 233.3, m 89-91°, 91-92°, pK_1^{23} 2.64, pK_2^{23} 4.33.** Crystallise it from Et_2O, toluene or from petroleum ether, then aqueous MeOH, followed by sublimation in a vacuum at 90°. It is used for estimating Ag and Ru. [Kamra et al. *Anal Chim Acta* **81** 117 *1976*, DOI:10.1016/S0003-2670(00)89466-0; *Beilstein* **26** III/IV 258.]

Terthiophene (2,5-di[thienyl]thiophene; α–terthienyl) *[1081-34-1]* **$C_{12}H_8S_3$, M 248.4, m 93-95°, 94-95.5°, 94-96°.** Possible impurities are bithienyl and polythienyls. Suspend it in H_2O and steam distil it to remove bithienyl. The residue is cooled and extracted with $CHCl_3$, dried ($MgSO_4$), filtered, evaporated and the residue chromatographed on Al_2O_3 using petroleum ether/3% Me_2CO as eluent. The terphenyl zone is then eluted from the Al_2O_3 with Et_2O, the extract is evaporated and the residue is recrystallised from MeOH (40ml per g). The platelets are washed with cold MeOH and dried in air. [UV: Sease & Zechmeister *J Am Chem Soc* **69** 270 *1947*, DOI: 10.1021/ja01194a031; Uhlenbroek & Bijloo *Recl Trav Chim Pays-Bas* **79** 1181 *1960*, DOI: 10.1002/recl.19600791113.] It has also been recrystallised from MeOH, *C_6H_6, petroleum ether or AcOH. [UV: Zechmeister & Sease *J Am Chem Soc* **69** 273 *1947*, DOI: 10.1021/ja01194a032; Steinkopf et al. *Justus Liebigs Ann Chem* **546** 180 *1941*, DOI: 10.1002/jlac.19415460112.] It is a phototoxic nematocide [Cooper & Nitsche *Bioorg Chem* **13** 362 *1985*, DOI:10.1016/0045-2068(85)90036-7; *Chan* et al. *Phytochem* **14** 2295 *1975*, DOI:10.1016/S0031-9422(00)91121-X]. [*Beilstein* **19** III/IV 4763, **19/9** V 226.]

2,4,5,6-Tetraaminopyrimidine sulfate *[5392-28-9]* **$C_4H_8N_6 . H_2SO_4$, M 238.2, m 255° (dec), >300°, >350° (dec), pK^{20} 6.82.** Purify the salt by recrystallisation from H_2O, 2N H_2SO_4 (20 parts, 67% recovery) or 0.1N H_2SO_4 (40 parts, 62% recovery), and dried in air. [UV: Konrad & Pfleiderer *Chem Ber* **103** 722 *1970*, DOI: 10.1002/cber.19701030311; Malletta et al. *J Am Chem Soc* **69** 1814 *1947*, DOI: 10.1021/ja01199a073; Cavalieri et al. *J Am Chem Soc* **70** 3875 *1948*, DOI: 10.1021/ja01191a102; *Beilstein* **25** H 423, **25** III/IV 3106.]

1,4,8,11-Tetraazacyclotetradecane (cyclam) *[295-37-4]* **$C_{10}H_{24}N_4$, M 200.33, m 173° (closed capillary and sublimes at 125°), 183-185°, 184-186°, 185°, $pK_{Est(1)}$~3.8, $pK_{Est(2)}$~6.0, $pK_{Est(3)}$~9.0, $pK_{Est(4)}$~9.6.** Purify cyclam by recrystallisation from dioxane (white needles), and it sublimes above 120°. It has been distilled, **b 132-140°/4-8mm**. It forms complexes with metals and gives a sparingly soluble ***nitrate salt***, **m 205°(dec)**, which crystallises from H_2O and is dried at 150°. [UV: Bosnich et al. *Inorg Chem* **4** 1102 *1963*, DOI: 10.1021/ic50030a003; van Alphen *Recl Trav Chim Pays-Bas* **56** 343 *1937*, DOI: 10.1002/recl.19370560405; *Beilstein* **26** III/IV 1647.]

Tetrabenazine (±-2-oxo-3-isobutyl-9,10-dimethoxy-1,2,3,4,6,7-hexahydro-11b*H*-benzo[a]-quinolizine) *[58-46-8]* **$C_{19}H_{27}NO_3$, M 317.4, m 127-128°, pK_{Est} ~ 8.** Crystallise it from MeOH. The ***hydrochloride*** has **m 208-**

210°, and the ***oxime*** has **m 158°** (from EtOH). [*Beilstein* **21** III/IV 6488.] Drug for the treatment of hyperkinetic movement associated with Huntingdon's disease [Jankovic & Beach *Neurology* **48** 358 *1997*, DOI: 10.1212/WNL.48.2.358; Robertson *Brain* **123(3)** 425 *2000*, DOI: 10.1093/brain/123.3.425].

2,3,4,6-Tetrachloropyridine *[14121-36-9]* **C_5HCl_4N, M 216.9, m 74-75°, (? 37-38°), b 130-135°/16-20mm, 248.5-249.5°/760mm, pK_{Est} ~ -5.7.** Crystallise it from 50% EtOH and/or distil it. The ***N-oxide*** has **m 210°** (from EtOH/$CHCl_3$). [Chivers & Suschitzky *J Chem Soc* 2867 *1971*, DOI: 10.1039/J39710002867; *Beilstein* **20** III/IV 6488, **20/5** V 421.]

Tetrahydrofuran (oxalane, THF) *[109-99-9]* **C_4H_8O, M 72.1, m -108°, b 25°/176mm, 65-67°/atm, 66°/760mm, d_4^{20} 0.889, n_D^{20} 1.4070, pK^{25} -2.48 (aqueous H_2SO_4).** It is obtained commercially by catalytic hydrogenation of furan from pentosan-containing agricultural residues. It was purified by refluxing with, and distilling from $LiAlH_4$ which removes water, peroxides, inhibitors and other impurities [Jaeger et al. *J Am Chem Soc* **101** 717 *1979*, DOI: 10.1021/ja00497a039.]. Peroxides can also be removed by passage through a column of activated alumina, or by treatment with aqueous ferrous sulfate and sodium bisulfate, followed by solid KOH. In both cases, the solvent is then dried and fractionally distilled from sodium. Lithium wire or vigorously stirred molten potassium have also been used for this purpose. CaH_2 has also been used as a drying agent. Several methods are available for obtaining the solvent almost anhydrous. Ward [*J Am Chem Soc* **83** 1296 *1961*, DOI: 10.1021/ja01467a010] dried it vigorously with sodium-potassium alloy until a characteristic blue colour was evident in the solvent at Dry-ice/cellosolve temperatures. The solvent is kept in contact with the alloy until distilled for use. Worsfold and Bywater [*J Chem Soc* 5234 *1960*, DOI: 10.1039/JR9600005234], after refluxing and distilling from P_2O_5 and KOH, in turn, refluxed the solvent with sodium-potassium alloy and fluorenone until the green colour of the disodium salt of fluorenone was well established. [*Alternatively*, instead of fluorenone, benzophenone, which forms a blue ketyl, can be used.] The tetrahydrofuran was then fractionally distilled, degassed and stored above CaH_2. *p*-Cresol or hydroquinone inhibit peroxide formation. The method described by Coetzee and Chang [*Pure Appl Chem* **57** 633 *1985,* DOI: 10.1351/pac198557040633] for 1,4-dioxane also applies here. Distillations should always be done in the presence of a reducing agent, e.g. $FeSO_4$. [*Beilstein* **17** H 10, **17** I 5, **17** II 15, **17** III/IV 24, **17/1** V 27.] **It irritates the skin, eyes and mucous membranes, and the vapour should never be inhaled. It is HIGHLY FLAMMABLE, and the necessary precautions should be taken. Rapid purification:** Purification as for diethyl ether.

l*-Tetrahydropalmatine (2,3,9,10-tetramethoxy-6*H*-dibenzo[a,g]quinolizidine)** *[10097-84-4]* **$C_{21}H_{25}NO_4$, M 355.4, m 147°, 148-149°, $[\alpha]_D^{20}$ -291 (EtOH).** It crystallises from MeOH or EtOH (Norit) by addition of water as colourless prisms [see Kametani & Ihara *J Chem Soc (C)* 530 *1967*, DOI: 10.1039/J39670000530; Bradsher & Dutta *J Org Chem* **26** 2231 *1961*, DOI: 10.1021/jo01351a018]. When crystallised from Me_2CO/Et_2O, it has **m 142°**. The ***hydrate has **m 115°**(effervescence). The **(±)-*hydrochloride***, prepared by bubbling HCl through a dry ethereal solution of the base, is then recrystallised from MeOH to give colourless needles with **m 215-216°**. The ***picrate*** has **m 188°(dec)** (from aqueous EtOH). [*Beilstein* **21** III/IV 2769.]

Tetrahydropyran (oxane, THP) *[142-68-7]* **$C_5H_{10}O$, M 86.1, m -49.2°, -45°, b 88.0°/atm, d_4^{20} 0.885, n_D^{20} 1.4202, pK^{25} -2.79 (aqueous H_2SO_4).** Dry oxane with CaH_2, then pass it through a column of silica gel to remove olefinic impurities and fractionally distil it. Free it from peroxides and moisture by refluxing with sodium, then distil it from $LiAlH_4$. *Alternatively*, peroxides can be removed by treatment with aqueous ferrous sulfate and sodium bisulfate, followed by solid KOH, and fractional distillation from sodium. It forms an azeotrope with H_2O (b 71°, 8.5% H_2O). Add a stabiliser to avoid peroxide formation due to presence of air. [*Beilstein* **17** H 12, **17** I 6, **17** II 18, **17** III/IV 51, **17/1** V 64.]

Tetrahydro-4*H*-pyran-4-one *[29943-42-8]* **$C_5H_8O_2$, M 100.1, b 57-59°/11mm, 65-66°/15mm, 67-68°/18mm, 73°/20mm, 164.7°/atm, 166-166.5°/atm, d_4^{20} 1.0844, n_D^{20} 1.4551.** Purify the pyrone by repeated distillation, preferably in a vacuum. [Baker *J Chem Soc* 296 *1944*, DOI: 10.1039/JR9440000296; IR: Olsen & Bredoc *Chem Ber* **91** 1589 *1958*, DOI: 10.1002/cber.19580910804.] The ***oxime*** has **m 87-88°** and **b 110-111°/13mm** [Cornubert et al. *Bull Soc Chim Fr* 36 *1950*]. The ***4-nitrophenylhydrazone*** forms orange-brown needles from EtOH, **m 186°** [Cawley & Plant *J Chem Soc* 1214 *1938*, DOI: 10.1039/JR9380001214]. [*Beilstein* **17** I 131, **17** II 287, **17** III/IV 4171, **17/9** V 21.]

Tetrahydrothiophene (thiophane) *[110-01-0]* **C_4H_8S, M 88.2, m -96°, b 14.5°/10mm, 40.3°/39.7mm, 120.9°/760mm, d_4^{20} 0.997, n_D^{20} 1.5289.** The crude material is purified by crystallisation of the mercuric chloride complex to a constant melting point. It is then regenerated, washed, dried, and fractionally distilled. [Whitehead et al. *J Am Chem Soc* **73** 3632 *1951*, DOI: 10.1021/ja01152a022.] It has been dried over Na_2SO_4 and distilled in a vacuum and the purity is checked by ^{1}H NMR [Roberts & Friend *J Am Chem Soc* **108** 7204 *1986*, DOI: 10.1021/ja00283a011; for the **C_4H_8S**-AuCl complex see Uson et al. *Inorg Synth* **26** 85 *2007*; DOI: 10.1002/9780470132579.ch17]. [*Beilstein* **17** I 5, **17** II 15, **17** III/IV 34, **17/1** V 36.]

Tetrahydro-4*H*-thiopyran-4-one *[1072-72-6]* **C_5H_8OS, M 116.2, m 60-62°, 61-62°, 64-65°, 65-66°, 65-67°.** Purify it by recrystallisation from diisopropyl ether or petroleum ether and dry it in air. If too impure, then dissolve it in Et_2O, wash with aqueous $NaHCO_3$, then H_2O, dry ($MgSO_4$), filter, evaporate and the residue is recrystallised as before. [Cardwell *J Chem Soc* 715 *1949*, DOI: 10.1039/JR9490000715.] The ***oxime*** can be recrystallised from $CHCl_3$/petroleum ether (at -20°) and has **m 84-85°** [Barkenbus et al. *J Org Chem* **20** 871 *1955*, DOI: 10.1021/jo01125a011]. The ***2,4-dinitrophenylhydrazone*** has **m 186°** (from EtOAc) [Barkenbus et al. *J Org Chem* **16** 232 *1951*, DOI: 10.1021/jo01142a011]. The ***S-dioxide*** is recrystallised from AcOH, **m 173-174°**, and ***1,4-thiapyrone-1,1-dioxide oxime*** has **m 197.8° dec** (from MeOH). [Fehnel & Carmack *J Am Chem Soc* **70** 1813 *1948*, DOI: 10.1021/ja01185a048; *Beilstein* **17** II 287, **17** III/IV 4172, **17/1** V 21].

Tetramethylene sulfoxide (tetrahydrothiophen 1-oxide) *[1600-44-8]* **C_4H_8OS, M 104.2, b 45°/3mm, 235-237°/atm, d_4^{20} 1.175, n_D^{20} 1.525.** Shake the oxide with BaO for 4 days, then distil it from CaH_2 under reduced pressure. It can also be purified by distillation under reduced pressure over Lind 13X molecular sieves (conditioned by calcination at 400°/4hrs under N_2). Store below 5° as its shelf life at ~20° is *ca* 3 months. It is an excellent reagent for oxidising thiols and dithiols to the respective disulfides, requiring one mol of reagent per 2mols of SH [Wallace *J Am Chem Soc* **86** 2018 *1964*, DOI: 10.1021/ja01064a022; Wallace & Mahon *J Am Chem Soc* **86** 4099 *1965*, DOI: 10.1021/ja01073a039]. 2,2,6,6-Tetramethylpiperidinyl-1-oxy (TEMPO) *[2564-83-2]* **$C_9H_{18}NO$, M 156.3, m 36-38°, 37-39°.** Purify TEMPO by sublimation (33°, water aspirator, **m 39°**). [Hay & Finke *J Am Chem Soc* **109** 8012 *1987*, DOI: 10.1021/ja00260a011; Rozantzev & Neiman *Tetrahedron* **20** 131 *1964*, DOI: 10.1016/S0040-4020(01)98404-2; Keana *Chem Rev* **78** 37 *1978*, DOI: 10.1021/cr60311a004].

2,2,6,6-Tetramethyl-4-piperidone hydrochloride (triacetoneamine HCl) *[33973-59-0]* **$C_9H_{17}NO$. HCl, M 191.7, m 190°(dec), 198-199°(dec), pK^{25} 7.90**. Purify the salt by recrystallisation from EtOH/Et_2O, MeCN or Me_2CO/MeOH. The ***free base*** *[826-36-8]* $C_9H_{17}NO$, M 155.2, has **m 37-39°** (after sublimation, also **m 34-38°), b 102-105°/18mm**, and the ***hydrate*** has **m 56-58°** (wet Et_2O); the ***hydrobromide*** has **m 203°** (from EtOH/Et_2O), and the ***picrate*** has **m 196°** (from aqueous EtOH). [Sandris & Ourisson *Bull Soc Chim Fr* 345 *1958*, *Beilstein* **21** H 249, 246, **21** I 273, **21** II 222, **21** III/IV 3278, **21/6** V 538.]

1,3,7,9-Tetramethyl uric acid *[2309-49-1]* **$C_9H_{12}N_4O_3$, M 224.2, m 225°, 226°, 228°, pK_{Est}<0.** Crystallise the uric acid from H_2O or MeOH. [Lister *Purines Part II, Fused Pyrimidines* Brown Ed, Wiley-Interscience pp254-225 *1971*, ISBN 0-471-38205-1, *Beilstein* **26** H 532, **26** I 156, **26** II 302, **21** III/IV 2623.]

1,3,5,5-Tetranitrohexahydropyrimidine *[81360-42-1]* **$C_4H_6N_6O_8$, M 266.1, m 153-154°.** Crystallise the nitropyrimidine from EtOH (5x) and sublime it (~65°/0.05mm). It has ^{1}H NMR ($CDCl_3$ with 1drop of Me_2SO-d_6) with δ at 6.13 (s, NCH_2N), 5.23 (s, CCH_2N). [Cichra & Adiolph *J Org Chem* **47** 2474 *1982*, DOI: 10.1021/jo00133a047; Shackelford *J Labelled Comp Radiopharm* **29** 1197 *1991*, DOI: 10.1002/jlcr.2580291104].

4,7,13,18-Tetraoxa-1,10-diazabicyclo[8.5.5]eicosane (Cryptand 211, Kryptofix 221) *[31250-06-3]* **$C_{14}H_{28}N_2O_4$, M 288.1, b 130°/0.002mm, d_4^{20} 1.097, n_D^{20} 1.505, pK_{Est} ~ 7.9.** Redistil Cryptand 211 under high vacuum, dry it under high vacuum over 24 hours, and store it under nitrogen. [Alberto et al. *J Am Chem Soc* **121** 3135 *2001*, DOI: 10.1021/ja003932b.]

1,7,10,16-Tetraoxa-4,13-diazacyclooctadecane (4,13-diaza-18-crown-6) *[23978-55-4]* **$C_{12}H_{26}N_2O_4$, M 262.3, m 118-116°, pK_{Est} ~ 8.8.** Twice recrystallise it from *benzene/*n*-heptane, and dry it for 24 hours under high vacuum to remove adhered solvent. It complexes with alkali metal ions in MeCN and MeOH at 25°.

[Weber & Vögtle *Top Curr Chem* (Springer Verlag, Berlin) **98** 1 *1981*, ISBN: 978-3-540-10793-4 (Print) 978-3-540-38706-0; D'Aprano & Sesta *J Phys Chem* **91** 2415 *1987*, DOI: 10.1021/j100293a042.]

5,10,15,20-Tetraphenylporphyrin (TPP) *[917-23-7]* **$C_{44}H_{30}N_4$, M 614.7, m 450° (sublimes >400°), λ_{max} 482nm.** Purify TPP by chromatography on neutral (Grade I) alumina, and recrystallisation from CH_2Cl_2/MeOH or *C_6H_6. It forms complexes with metals. [Yamashita et al. *J Phys Chem* **91** 3055 *1987*, DOI: 10.1021/j100295a082; *Beilstein* **26** III/IV 1958.]
5,10,15,20-Tetra-4'-pyridinylporphyrin *[16834-13-2]* **$C_{40}H_{26}N_8$, M 618.7,** has **m >300°(dec), λ_{max} 412nm.** Purify it by chromatography on alumina (neutral, Grade I), with $CHCl_3$/MeOH (80:20) followed by recrystallisation from CH_2Cl_2/MeOH [Yamashita et al. *J Phys Chem* **91** 3055 *1987*, DOI: 10.1021/ j100295a082;]. It complexes with metals, e.g. Zn. [Kalyanasundaram *Inorg Chem* **23** 2453 *1984*, DOI: 10.1021/ic00184a019; Okuno et al. *Synthesis* 537 *1980*, DOI: 10.1055/s-1980-29111.]

Tetrathiafulvalene (TTF, 2,2'-bi-1,3-dithiole) *[31366-25-3]* **$C_6H_4S_4$, M 204.4, m 116-119°, 119.1-119.3°(corr), 122-124°.** Recrystallise TTF from cyclohexane (20%)/hexane (80%), (including Norite or Darco and drying with $MgSO_4$) which provides large (long) orange-yellow needles under an argon or N_2 atmosphere. TTF sublimes at 105°/0.1Torr. The 1H NMR (CDCl) has δ at 6.32ppm, and the IR (Nujol) has ν_{max} at 1530, 1250, 1090, 795, 780 and 730 cm^{-1}. [Melby et al. *J Org Chem* **39** 2456 *1974*, DOI: 10.1021/jo00930a043]. TTF is produced by Zn/AcOH reduction of 1,3-dithiole-2-thione, or better by reduction of ***1,3-dithiole-2-thione methiodide*** (see above) with $NaBH_4$ in MeOH. On treatment with H_2O_2 and HBF_4 it forms $(TTF)_3(BF_4)_2$. Similar ***tetrathiafulvalenium radical cation salts*** are readily prepared in high yields, e.g. $(TTF)_{14}(NCSe)_8$, $(TTF)_{11}I_8$, $(TTF)_2[Pt(CN)_4]$, $(TTF)_2[Cu(mnt)_2]$, $(TTF)_2[Ni(mnt)_2]$, $(TTF)_2[Pt(mnt)_2]$, and $(TTF)[Pt(mnt)_2]$, {where mnt is 2,3-dimercapto-2-butanenitrilo(2^-) (maleonitriledithiolato), i.e. [N=C-C(S^-)=C(S^-)=CN]}, which have high compressed pellet resistances $>10^6$ (Ohms, Ω) [Wudl & Kaplan *Inorg Synth* **19** 27 *1979*; DOI: 10.1002/9780470132500.ch7]. It has electrical properties superior to other comparable electron donors which with organic acceptors, e.g. **TCQN** (tetracyanoquinodimethane *[1518-16-7]*), under oxidising conditions it forms charge transfer complexes with ***metallic*** properties. It is an organic electron donor which intercalates with FeOCl producing solid-state low-dimensional conductive materials [Kauzlarich et al. *J Am Chem Soc* **109** 4561 *1987*, DOI:10.1021/ ja00249a019]. With chloranil it forms a coloured charge transfer mixed stack organic semiconductor. [Girlando et al. *J Chem Phys* **79** 1075 *1983*, DOI: 10.1063/1.445833.] [*Beilstein* **19/11** V 380.]

1,2,3,4-(1*H*)Tetrazole *[288-94-8]* **CH_2N_4, M 70.1, m 156°, 157.5-158°, pK^{25} 4.89 (acidic).** Crystallise the tetrazole from EtOH and sublime it under high vacuum at *ca* 120° (*care should be taken due to possible* **EXPLOSION**). It is used in the phosphite trimester method of oligonucleotide synthesis [Barone et al. *Nucleic Scids Res* **12** 4051 *1984*, PMCID:PMC318815]. [*Beilstein* **26** H 346, **26** I 108, **26** II 196, **26** III/IV 1652.]

2-Thenoyltrifluoroacetone [1-(2-thienyl)-4,4,4-trifluorobutan-1,3-dione] *[326-91-0]* **$C_8H_5F_3O_2S$, M 222.2, m 40-44°, 42-44°, b 96-98°/9mm, pK^{25} 6.4.** Crystallise the dione from hexane or *benzene. (An aqueous solution slowly decomposes it). It has ν_{max} at 1638(C=O), 1657(C=C)cm^{-1}. The ***oxime*** crystallises from H_2O or aqueous EtOH. It is used for the determination of Actinides and Lanthanides. [Chaston et al. *Aust J Chem* **18** 673 *1965*, DOI: 10.1071/CH9650673; Jeffrey et al. In *Vogel's Textbook of Qunatitative Chemical Analysis* 5thedn J Wiley & Sons, p170 *1989*, *Beilstein* **17** III/IV 5989, **17/11** V 128.]

2-Thenylamine (2-thiophenemethylamine) *[27757-85-3]* **C_5H_7NS, M 113.2, b 78.5°/15mm, 95-99°/28mm, d_4^{20} 1.137, n_D^{20} 1.5643, pK^{30} 8.92.** Distil the amine under reduced pressure (nitrogen), from BaO, through a column packed with glass helices. The ***hydrochloride*** has **m 193-194°** (from EtOH/Me_2CO), and the ***picrate*** has **m 181-18** [*Beilstein* **18** III/IV 7096.]

Thianthrene *[92-85-3]* **M $C_{12}H_8S_2$, 216.3, m 151-155°, 158°, b 364-366°/atm.** Crystallise thianthrene from Me_2CO (charcoal), AcOH or EtOH. It sublimes in a vacuum. [*Beilstein* **19** H 45, **19** I 619, **19** II 34, **19** III/IV 347, **19/2** V 49.]

5-Thiazolecarboxaldehyde *[1003-32-3]* **C_4H_3NOS, M 113.1, b 92-94°/16mm, d_4^{20} 1.304, n_D^{20} 1.5874, pK_{Est} ~0.6.** Dry the aldehyde over Na_2SO_4 and fractionate it in a vacuum. The ***2,4-dinitrophenylhydrazone*** forms

red crystals from MeOH with **m 238-240°**, and the ***semicarbazone*** has **m 210-212°** (from MeOH). [Erne et al. *Helv Chim Acta* **34** 143 *1951*, DOI: 10.1002/hlca.19510340117; *Beilstein* **27** III/IV 2615.]

Thiazoline-2-thiol *[96-53-7]* **$C_3H_5NS_2$, M 119.2, m 106-107°, 106-108°, pK_{Est} ~13.0.** Purify the thiol by dissolution in aqueous alkali, precipitation by addition of HCl and then recrystallisation from H_2O (as needles). [IR: Flett *J Chem Soc* 345(347) *1953*, DOI: 10.1039/JR9530000345; Mecke et al. *Chem Ber* **90** 975 *1957*, DOI: 10.1002/cber.19570900618; Gabriel & Stelzner *Chem Ber* **28** 2929 *1895*, DOI: 10.1002/cber.189502803110; *Beilstein* **27** III/IV 2540.]

4-(2-Thiazolylazo)-resorcinol *[2246-46-0]* **$C_9H_7N_3O_2S$, M 221.2, m 200-202°(dec), 211°(dec), 218-219°, λ_{max} 500 nm, pK_1^{25} 1.25, pK_2^{25} 6.53, pK_3^{25} 10.76.** Dissolve it in aqueous alkali, extract it with diethyl ether, and re-precipitate it with dilute HCl. The purity is checked by TLC on silica gel using petroleum ether/diethyl ether/EtOH (10:10:1) as the mobile phase. It complexes with Cu^{2+} (pH 3-4), Co^{2+} and Ni^{2+} (pH 7) and Zn^{2+}, and Cd^{2+} (pH 8.4). [*Beilstein* **27** III/IV 5988.]

Thiazolyl blue tetrazolium bromide (MTT, 3-[4,5-dimethyl-2-thiazolyl]-2,5-diphenyl-2*H*-tetrazolium bromide) *[298-93-1, 2348-71-2]* **$C_{18}H_{16}BrN_5S$, M 414.3, m 171°, 195°(dec).** It is recrystallised by dissolving in MeOH containing a few drops of HBr and then adding dry Et_2O to complete the crystallisation, wash the needles with Et_2O and dry them in a vacuum desiccator over KOH. [Beyer & Pyl *Chem Ber* **87** 1505 *1954*, DOI: 10.1002/cber.19540871020; *Beilstein* **27** III/IV 6045.]

Thietane (trimethylene sulfide) *[287-27-4]* **C_3H_6S, M 74.1, m -64°, -73.2°, b 93.8-94.2°/752mm, 94-94.5°/760m, 95°/atm, d_4^{20} 1.0200, n_D^{20} 1.5020.** Purify thietane by preparative gas chromatography on a dinonyl phthalate column. It has also been purified by drying over anhydrous K_2CO_3, and distilling through a 25cm glass helices-packed column (for 14g of thietane), then drying over $CaSO_4$ before sealing it in a vacuum. [Haines et al. *J Phys Chem* **58** 270 *1954*, DOI: 10.1021/j150513a022.] It is characterised as the ***dimethylsulfonium iodide*** **m 97-98°** [Bennett & Hock *J Chem Soc* 2496 *1927*, DOI: 10.1039/JR9270002496]. The ***S-oxide*** has **b 102°/25mm**, n_D^{21} 1.5075 [Tamres & Searles *J Am Chem Soc* **81** 2100 *1959*, DOI: 10.1021/ja01518a019]. [*Beilstein* **17** I 3, **17** II 12, **17** III/IV 14, **17/1** V 14.]

2-Thiobarbituric acid (TBA) *[504-17-6]* **$C_4H_4N_2O_2S$, M 144.2, m 235°(dec), 245°(dec), pK_1^{25} 2.25, pK_2^{25} 10.72 (2% aqueous EtOH).** Crystallise it from water. It is used for the quantitative determination of lipopolysaccharides, carrageenan, sialic acid, and detecting lipid oxidation and lipid hydroperoxides. [*Beilstein* **24** H 476, **24** I 414, **24** II 275, **24** III/IV 1884.]

1,1'-Thiocarbonyldiimidazole *[6160-65-2]* **$C_7H_6N_4S$, M 178.1, m 98-102°, 100-102°, 105-106°.** It forms yellow crystals on recrystallisation from tetrahydrofuran or by sublimation at 10^{-3}torr (bath temperature 70-80°). It is hydrolysed by H_2O and should be stored dry. Useful for thiating amides [Harpp & Mac Donald *Tetrahedron Lett* **24** 4927 *1983*, DOI:10.1016/S0040-4039(01)99813-2], in a modified Corey-Winter olefin synthesis [Vedejs et al. *Tetrahedron Lett* **14** 3793 *1973*, DOI:10.1016/S0040-4039(01)87038-6], and preparing thiocarbamates from alcohols for radical reactions with Bu_3SnH-AIBN [Hanessian et al. *Can J Chem* **65** 1859 *1987*, DOI: 10.1139/v87-312; RajanBabu et al. *J Am Chem Soc* **111** 1759 *1989*, DOI: 10.1021/ja00187a031]. [Staab & Walther *Justus Liebigs Ann Chem* **657** 98 *1962*, DOI: 10.1002/jlac.19626570113; Pullukat & Urry *Tetrahedron Lett* **8** 1953 *1967*, DOI:10.1016/S0040-4039(00)90762-7.]

Thiochrome {2,7-dimethyl-5*H*-thiachromine-8-ethanol; 3,8-dimethyl-2-hydroxyethyl-5*H*-thiazolo [2,3:1',2'] pyrimido[4',5'-*d*]pyrimidine} *[92-35-3]* **$C_{12}H_{14}N_4OS$, M 262.3, m 227-228°, pK_1^{20} 8.11, pK_2^{20} 12.6.** Crystallise thiochrome (found in Yeast) from chloroform. The ***monohydrochloride*** has **m 235-236°(dec)** (from EtOH) and the ***dihydrochloride*** has **m 237°(dec)**. [*Beilstein* **27** III/IV 9599.] Fluorescent compound used for detecting and estimating thiamine.

2-Thiocytosine (4-amino-2-mercaptopyrimidine) *[333-49-3]* **$C_4H_4N_2O_2S$, M 127.2, m 236-237°(dec), 285-290°(dec), pK_1^{20} 3.90 (NH_2), pK_2^{20} 11.10 (SH).** It is recrystallised from hot H_2O and dried at 100° to constant weight. [Brown *J Appl Chem (London)* **9** 203 *1959*, DOI: 10.1002/jctb.5010090402; Russell et al. *J Am Chem*

Soc **71** 2279 1949, DOI: 10.1021/ja01175a001.] It is used in transcription and translation studies [Rachwitz & Scheit *Eur J Biochem* **72** 191 *1977,* DOI:10.1111/j.1432-1033.1977.tb11239.x].

Thioflavine T [2-(4-dimethylaminophenyl)-3,6-dimethylbenzothiazolium chloride] *[2390-54-7]* **$C_{17}H_{19}ClN_2S$, M 318.9, pK^{25} 2.7.** Crystallise the chloride from *benzene/EtOH (1:1). Used for staining and quantifying amyloid protein aggregates [LeVine *Methods in Enzymology* **309** 274 *1999*, DOI:10.1016/S0076-6879(99)09020-5; Alavez et al *Nature* **472** 226 *2011,* DOI:10.1038/nature09873]. [*Beilstein* **27** III/IV 5052.]

1-Thioflavone (2-phenylthiochromen-4-one) *[784-62-3]* **$C_{15}H_{10}OS$, M 238.3, m 129-130°.** This yellow solid is purified by passage through a silica gel column, eluting with *C_6H_6/Me_6CO, evaporating and crystallising the residue from EtOH. The ***sulfoxide*** *[65373-82-2]* has **m 133-135°**, and the ***sulfone*** *[22810-82-2]* has **m 136.5-137°** (from EtOH). The ***dimethylhydrazone*** has **m 111-113°** (from BuOH). It forms easily hydrolysable salts. [Nakazumi et al. *J Heterocycl Chem* **21** 193 *1984*, DOI: 10.1002/jhet.5570210138; Chen et al. *J Org Chem* **51** 3282 *1986*, DOI: 10.1021/jo00367a007; Van Allan & Reynolds *J Heterocycl Chem* **8** 803 *1971*, DOI: 10.1002/jhet.5570080523; *Beilstein* **17** I 204, **17** III/IV 5420, **17/10** V 560.]

6-Thioguanine *[154-42-7]* **$C_5H_5N_5S$, M 167.2, m >300°, pK$_1^{23}$ 8.2 (SH), pK$_2^{23}$ 11.6 (acidic, 9-NH).** It crystallises from H_2O as needles. It has UV with λ_{max} at 258 and 347nm (H_2O, pH 1) and 242, 270 and 322nm (H_2O, pH 11). [Elion & Hitchings *J Am Chem Soc* **77** 1676 *1955*, DOI: 10.1021/ja01611a082; Fox et al. *J Am Chem Soc* **80** 1669 *1958*, DOI: 10.1021/ja01540a041.] It is an antineoplastic agent [Kataoka et al. *Cancer Res* **44** 519 *1984*, http://cancerres.aacrjournals.org/content/44/2/519]. [*Beilstein* **26** III/IV 3926.]

Thioindigo *[522-75-8]* **$C_{16}H_8O_2S_2$, M 296.2, m >280°, 280°, 359°,** Adsorb it on silica gel from CCl_4/*benzene (3:1), elute with *benzene, evaporate, crystallise the residue from $CHCl_3$ and dry it at 60-65° [Wyman & Brode *J Am Chem Soc* **73** 1487 *1951*, DOI: 10.1021/ja01148a023; this paper also gives details of purification of other thioindigo dyes]. [*Beilstein* **19** H 137, **19** I 690, **19** II 192, **19** III/IV 2091.]

Thiomorpholine (tetrahydro-*2H*-1,4-thiazine) *[123-90-0]* **C_4H_9NS, M 103.2, b 110°/100mm, 169°/atm, d$_4^{20}$ 1.026, n$_D^{20}$ 1.540, pK^{25} 9.00.** Purify it by vacuum distillation. The ***hydrochloride*** *[5967-90-8]* has **m 179°** (from isoPrOH or EtOH/Et_2O/HCl), and the ***picrolonate***, C_4H_9NS. $C_{10}H_8N_4O_5$, **m 242°(dec)** forms orange prisms from EtOH. [Davies *J Chem Soc* 297 *1920*, DOI: 10.1039/CT9201700297; *Beilstein* **2** III/IV 636.]

Thionine (3,7-diaminophenothiazine, Lauth's violet) *[135-59-1, 581-64-6 (HCl), 78338-22-4 (acetate)]* **$C_{12}H_9N_3S_2$, M 263.7, ε_{590} 6.2 x 10^4 M^{-1} cm^{-1}, pK^{15} 6.9.** The standard biological stain is usually highly pure. It can be crystallised from water or 50% EtOH, then chromatographed on alumina using $CHCl_3$ as eluent [Shepp et al. *J Phys Chem* **66** 2563 *1962*, DOI: 10.1021/j100818a055]. Dry it overnight at 100° and store it in a vacuum. The ***hydrochloride*** can be recrystallised from 50% EtOH or dilute HCl and aqueous *n*-butanol. Purify it also by column chromatography and washed with $CHCl_3$ and acetone. Dry it *in vacuo* at room temperature. Thionine derivatives are useful drugs for the treatment of Alzheimer and related diseases. [Synth and spectra: Pereteanu & Muller *Org Biomol Chem* **11** 5127 *2013*, DOI: 10.1039/C3OB40815A; *Beilstein* **27** H 391, **27** I 412, **27** II 447, **27** III/IV 5149.]

Thiooxine hydrochloride (8-mercaptoquinoline hydrochloride) *[34006-16-1]* **C_9H_7NS. HCl, M 197.7, m 165° (dec), 170-175° (dec), pK$_1^{25}$ 2.16, pK$_2^{25}$ 8.38.** It forms yellow crystals from EtOH. It has pKa^{20} values of 2.05 and 8.29 in H_2O. The salt is more stable than thiooxine. [UV: Albert & Barlin *J Chem Soc* 2384 *1959*,DOI: 10.1039/JR9590002384.] [*Beilstein* **21** H 99, **21** III/IV 1197, **21/3** V 30.]

Thiophene *[110-02-1]* **C_4H_4S, M 84.1, m -38.5°, b 84.2°/760mm, 20°/60mm, 46.5°/200mm, d$_4^{20}$ 1.525, n$_D^{20}$ 1.52890, n$_D^{30}$ 1.5223.** The simplest purification procedure is to dry thiophene with solid KOH, or reflux it with sodium, and fractionally distil it through a glass-helices-packed column. More extensive treatments include an initial wash with aqueous HCl, then water, drying with $CaSO_4$ or KOH, and passage through columns of activated silica gel or alumina. Fawcett and Rasmussen [*J Am Chem Soc* **67** 1705 *1945*, DOI: 10.1021/ja01226a026] washed thiophene successively with 7M HCl, 4M NaOH, and distilled water, dried with $CaCl_2$ and fractionally distilled it. *Benzene was removed by fractional crystallisation by partial freezing, and the thiophene was degassed and sealed in Pyrex flasks. [Also a method is described for recovering the thio-

phene from the *benzene-enriched portion.] [Phillips *Org Synth* Coll Vol **2** 578 *1943*, DOI: 10.15227/orgsyn.012.0072; *Beilstein* **17** H 29, **17** I 17, **17** II 35, **17** III/IV 234, **17/1** V 297.]

Thiophene-2-acetic acid *[1918-77-0]* **$C_6H_6O_2S$, M 142.2, m 63-64°, 76°, b 160°/22mm, pK^{25} 3.89, pK^{25} 6.43 [$MeO(CH_2)_2OH$-H_2O/80:20].** Crystallise the acid from ligroin, hexane and/or distil it in a vacuum. The ***acid* chloride** *[39098-97-0]* **C_6H_5ClOS, M 160.6, d^{25} 1.303/ml, n_D^{20} 1.551,** has **b 105-106°/22mm, 130-135°/90mm.** The ***amide*** has **m 148°** (from H_2O or petroleum ether). [*Beilstein* **18** III/IV 4062, **18/6** V 207.]
Thiophene-3-acetic acid *[6964-21-2]* has **m 73-76°, 79-80°, pK_{Est} ~3.1.** Crystallise the acid from ligroin or H_2O. [*Beilstein* **18** III/IV 4066.]

2-Thiophenecarboxaldehyde (2-thenaldehyde) *[98-03-3]* **C_5H_4OS, M 112.2, b 75-77°/11mm, 106°/30mm, 198°/756mm, d_4^{20} 1.593, n_D^{20} 1.222.** Wash it with 50% HCl and distil it under reduced pressure just before use. It has UV with λ_{max} 234nm (hexane). The ***Z*-oxime** has **m 144°, 136-138°** and **142°** (H_2O). [*Beilstein* **17** H 285, **17** I 148, **17** II 313, **17** III/IV 4477, **17/9** V 349.]
3-Thiophenecarboxaldehyde **(3-thenaldehyde)** *[498-62-4]* has **m -30°, b 80-81°/14mm, 194-196°/760mm, d^{25} 1.28, n_D^{20} 1.52660.** Prepared by the reaction of 2-bromomethylthiophen and hexamine to give the respective hexaminium bromide (m 150°, dec), when heated with H_2O the aldehyde distils with steam. The distillate is acidified (HCl), extracted with Et_2O, dried (Drierite), filtered, evaporated and the residual oil is redistilled (preferably in a vacuum) to provide pure aldehyde [Campaigne et al. *Org Synth* Coll Vol **4** 918 *1963*, DOI: 10.15227/orgsyn.033.0093].

Thiophene-2-carboxylic acid *[527-72-0]* **$C_5H_4O_2S$, M 128.2, m 125-127°, 128.5°, 129-130°, b 260°/atm, pK^{25} 3.59.** Crystallise the acid from water and dry it in a vacuum. The ***acid chloride*** *[5271-67-0]* has **b 206-208°/atm,** and the ***amide*** *[5813-89-8]* has **m 181°**(from H_2O) and pK^{25} 10.54 (50% aqueous dioxane). [*Beilstein* **18** H 289, **18** I 438, **18** II 269, **18** III/IV 4011, **18/6** V 158.]
Thiophene-3-carboxylic acid *[88-31-1]* has **m 136-141°, 137-138°, 138-139°, pK^{25} 6.23(4.11).** Obtained by the oxidation of the above 3-aldehyde with AgO, the acid is purified by recrystallisation from water and is dried in a vacuum. [Campaigne & LeSuer *Org Synth* Coll Vol **4** 919 *1963*, DOI: 10.15227/orgsyn.033.0094; *Beilstein* **18** H 292, **18** III/IV 4053, **18/6** V 199.] The ***amide*** *[51640-47-0]* has **m 179-180°** (from H_2O, also 181-184°) [*Beilstein* **18** III/IV 4056].

Thiophene-2,5-dicarboxylic acid (2,5-dicarboxythiophene) *[4282-31-9]* **$C_6H_4O_4S$, M 172.2, m 332-333°(sealed capillary), 358.5-359.5°(corrected, sealed tube), 360°, $pK_{Est(1)}$ ~3.3, $pK_{Est(2)}$ ~7.4.** It can be precipitated from alkaline solution with acid, filtered and recrystallised from H_2O, dried and sublimed at 0.0001 mm. Its ***mono-methyl ester*** crystallises from aqueous MeOH (**m 187-190°, $pK_{Est(1)}$ ~3.2)** or petroleum ether (**m 192°**), and sublimes in a vacuum unchanged. With diazomethane/Et_2O it provides the ***di-methyl ester*** (**m 148.5-149.5°**; **m's 146-147°** and **152°** were also reported) which crystallises from MeOH or 1:1 aqueous MeOH in flattened needles, and sublimes at 80-95° in high vacuum. This ester has λ_{max}(logε) at 275(4.27) in EtOH. [Hartough & Kosak *J Am Chem Soc* **69** 1012 *1947*, DOI: 10.1021/ja01197a010; Birkinshaw & Chaplen *Biochem J* **60** 255 *1955*, DOI: 10.1042/bj0600255; Griffing & Salisbury *J Am Chem Soc* **70** 3416 *1948*, DOI: 10.1021/ja01190a056; *Beilstein* **18** H 330, **18** III/IV 4496.]
Thiophene-2,5-dicarbonyl dichloride **[2,5-bis(chlorocarbonyl)thiophene]** *[3857-36-1]* **$C_6H_2Cl_2O_2S$, M 209.1,** has **m 43-47°, 45-46°, b 102-103°/2mm, 150-152°/11mm.** Purify it by distillation in a vacuum; or if discoloured, then heat it with $SOCl_2$ or oxalyl chloride, and distil it in a vacuum. It solidifies on cooling, and can be recrystallised from *C_6H_6/heptane. It provides the ***di-phenyl ester*** (**m 136-137°**) when treated with phenol at 200° or phenol/pyridine at 100°, followed by adding to cold H_2O, filtering, drying, and recrystallising from EtOH [Griffing & Salisbury *J Am Chem Soc* **70** 3416 *1948*, DOI: 10.1021/ja01190a056]. A useful building block for synthesising chiral bis-oxazoline ligands for Cu- and Ru- catalyzed asymmetric cyclopropanations [Gao et al. *Synth Commun* **35** 2665 *2005*, DOI:10.1080/00397910500213948; Gao et al. *Tetrahedron Lett* **45** 5649 *2004*, DOI: 10.1016/j.tetlet.2004.05.120]. [*Beilstein* **18** H 330, **18** III/IV 4496.]

Thiopyronine (2,7-dimethylaminothiaxanthene chloride hydrochloride) *[2412-14-8]* **$C_{17}H_{19}ClN_2S$, M 318.9, λ_{max} 564nm (ε 78,500) H_2O, pK_{Est} ~ 7.** Purify it as the hydrochloride by recrystallisation from hydrochloric acid forming needles, **m 245°** (**dec**), and UV with λ_{max} at 564nm (ε 78,500, H_2O). [Fanghanel et

al. *J Phys Chem* **91** 3700 *1987*, DOI: 10.1021/j100297a048; *Beilstein* **18** H 596, **18** III/IV 7291.] It has photodynamic effects on cell growth, colony formation and RNA repair synthesis in *Saccharomyces* mutants with DNA repair deficiency [Roth et al. *Photochem Photobiol* **59(S1)** 627 *1994*, DOI: 10.1111/j.1751-1097.1994.tb08229.x].

Thiothienoyltrifluoroacetone [1-(2-thienyl)-4,4,4-trifluorobutan-3-one-1-thione] *[4552-64-1]* **$C_8H_5F_3OS_2$, M 228.2, m 61-62°, 64.5-65°, 73-74°, 74°.** It is easily oxidised and has to be purified before use. This is achieved by recrystallisation from *benzene or by dissolution in petroleum ether, extraction into 1M NaOH solution, acidification of the aqueous phase with 1-6M HCl solution, back extraction into petroleum ether and final evaporation of the solvent. The purity can be checked by TLC. It is stored in ampoules under nitrogen at 0° in the dark. It forms red crystals from petroleum ether (b 55-65°) . Its IR has ν_{max} at 815m(C-S, C-H), 1260m(C-S), 1570sh(C=C) and 1612s(C=O)cm^{-1}. It yields a chocholate brown complex of **$Ni[C_8H_5F_3OS_2]_2$** which has **m 237°**. [Müller & Rother *Anal Chim Acta* **66** 49 *1973*, DOI:10.1016/S0003-2670(00)89466-0; Chaston et al. *Aust J Chem* **18** 673 *1965*, DOI:10.1071/CH9650673.]

2-Thiouracil *[141-90-2]* **$C_4H_4N_2OS$, M 128.2, m 240°(dec), 315°(dec), pK_1^{25} 7.75, pK_2^{25} 12.7.** Crystallise 2-thiouracil from water or EtOH. [*Beilstein* **24** H 323, **24** I 315, **24** II 171, **24** III/IV 1237.]

9*H*-Thioxanthene-9-one (thioxanthone, thionanthone) *[492-22-8]* **$C_{13}H_8OS$, M 212.3, m 200-202°, 209°, 210-213°, 212-214°, b 371-373°/712mm.** It forms yellow needles from $CHCl_3$ or EtOH and sublimes *in vacuo*. It is soluble in CS_2, hot AcOH, and dissolves in concentrated H_2SO_4 to give a yellow colour with green fluorescence in VIS light. The ***sulfone*** has **m 187°** (from EtOH), and the ***hydrazone*** has **m 115°** (yellow leaflets from EtOH/*C_6H_6). The ***oxime*** has **m 194-196°** (from petroleum ether). [Szmant et al. *J Org Chem* **18** 745 *1953*, DOI: 10.1021/jo01134a022; Ullmann et al. *Chem Ber* **49** 2487 *1916*, DOI: 10.1002/cber.191604902110; NMR: Sharpless et al. *Org Magn Res* **6** 115 *1974*, DOI: 10.1002/mrc.1270060213; *Beilstein* **17** H 357, **17** I 191, **17** III/IV 5302, **17/10** V 437.]

Thymine (5-methylpyrimidin-2,4-dione, 5-methyluracil) *[65-71-4]* **$C_5H_6N_2O_2$, M 126.1, m 326°(dec), 335-337°(dec), pK_1^{25} 9.90 (9.82) pK_2^{25} >13.0.** Crystallise thymine from EtOAc, 10% aqueous EtOH or water. It has **m** 318-320° after sublimation at 200°/12mm. Purify it by preparative (2mm thick) TLC plates of silica gel, eluting with ethyl acetate/isopropanol/water (75:16:9, v/v; R_F 0.75). The desired spot is located with a uv lamp, cut the band from the plate, place it in MeOH, shake and filter it through a millipore filter, then evaporate. It is an DNA building block. [Infante et al. *JCS Faraday Trans 1* **68** 1586 *1973*, DOI: 10.1039/F19736901586; *Beilstein* **24** H 353, **24** I 330, **24** II 183, **24** III/IV 1292.]

Tinuvin P (2-[2*H*-benzotriazol-2-yl]-*p*-cresol) *[2440-22-4, 50936-05-5]* **$C_{13}H_{11}N_3O$, M 225.3, m 125.5-129.5°, 128-132°, 131-133°, b 225°/10mm, $pK_{Est(1)}$~1.6 (N protonation), $pK_{Est(2)}$~ 8 (phenolic OH).** Recrystallise it from *n*-heptane or Me_2CO/pentane. It is a UV absorber of light (UVA) in screens and a stabiliser in plastics. [Woessner et al. *J Phys Chem* **89** 3629 *1985*, DOI: 10.1021/j100263a013.]

Toluidine Blue O *[93-31-9]* **$C_{15}H_{16}N_3S^+$ Cl^-, M 305.8, CI 52040, λ_{max} 626nm, pK^{25} 7.5.** Crystallise this blue cationic dibenzothiazine dye from hot water (18ml/g) by adding one and a half volume of alcohol and chilling on ice. Dry it at 100° in an oven for 8-10 hours. [Merrill & Spencer *J Am Chem Soc* **70** 3683 *1948*, DOI: 10.1021/ja01191a043; *Beilstein* **27** I 417, **27** II 454, **27** III/IV 5161.] Used for selectively staining of pre-malignant lesions (in dysplasia).

1,5,7-Triazabicyclo[4.4.0]dec-5-ene (TBD, 1,3,4,6,7,8-hexahydro-2*H*-pyrimido[1,2-a]-pyrimidine) *[5807-14-7]* **$C_7H_{13}N_3$, M 139.2, m 125-130°, pK^{25} ~ 16** It crystallises from Et_2O but readily forms white crystals of the carbonate. It is a strong base (see pK, i.e. about 100 times more basic than tetramethylguanidine). The ***picrate*** has **m 220.5-222°** (from EtOH). It forms the ***5-nitro*** derivative **m 145-160°** that gives a ***5-nitro nitrate salt* m 100-101°** (from EtOH/Et_2O) and a ***5-nitro picrate* m 144-145°** (from H_2O) [McKay & Kreling *Can J Chem* **35** 1438 *1957*, DOI: 10.1139/v57-189; Schwesinger *Chimia* **39** 369 *1985*, Hilpert et al. *J Chem Soc, Chem Commun* 1401 *1983*, DOI: 10.1039/C39830001401; Kampfen & Eschenmoser *Helv Chim Acta* **72** 185 *1989*, DOI: 10.1002/hlca.19890720202]. [*Beilstein* **26** III/IV 60.]

1,2,4(1*H*)-Triazole *[288-88-0]* **$C_2H_3N_3$, M 69.1, m 119-121°, 121°, b 260°//760mm, pK_1^{25} 2.27 (basic), pK_2^{25} 10.26 (acidic).** Crystallise 1,2,4-triazole from EtOH, H_2O, EtOAc (**m 120.5-121°**), or EtOH/*C_6H_6. The ***hydrochloride*** has **m 170°**, and the ***picrate*** has **m 163-164°** (from H_2O or $CHCl_3$). [Barszcz et al. *JCS Dalton Trans* 2025 *1986*, DOI: 10.1039/DT9860002025]. [*Beilstein* **26** H 13, **26** II 6, **26** III/IV 35.]

Tricycloquinazoline *[195-84-6]* **$C_{21}H_{12}N_4$, M 230.4, m 322-323°.** Crystallise it repeatedly from toluene, xylene or these solvents mixed with *C_6H_6. It can also be crystallised from $CHCl_3$ or cymene (**m 308-310°**), followed by sublimation at 210°/0.15-0.3 Torr in subdued light. [*Beilstein* **26** III/IV 1932.] It has carcinogenic properties [Balwin et al. *International J Cancer* **3** 244 *1968*, DOI: 10.1002/ijc.2910030209].

Trifluoperazine dihydrochloride (10-[3-{4-methyl-1-piperazinyl}propyl]-2-trifluoro-methyl-phenothiazine 2HCl) *[440-17-5]* **$C_{21}H_{24}F_3N_3S$. 2HCl, M 480.4, m 240-243°, 242-243°, pK_1 3.9, pK_2 8.1.** Recrystallise the salt from absolute EtOH, filter the crystals, dry them *in vacuo* and store them in tightly stoppered bottles because it is ***hygroscopic***. It is soluble in H_2O but insoluble in *C_6H_6, Et_2O and alkaline aqueous solution. It has UV with λ_{max} at 258 and 307.5nm (log ε 4.50 and 3.50) in EtOH (neutral species). [Craig et al. *J Org Chem* **22** 709 *1957*, DOI: 10.1021/jo01357a618.] It is a calmodulin inhibitor [Levin & Weiss *J Pharmacol Exptl Ther* **208** 454 *1979*, PMID: 34709] and is a psychotropic agent [Fowler *Arzneim.-Forsch* **27** 866 *1977*]. [*Beilstein* **27** III/IV 1353.]

Trigonelline (1-methylnicotinic acid zwitterion) *[535-83-1]* **$C_7H_7NO_2$, M 137.1, m 218°(dec), 230-233°, pK_1^{25} 2.10.** Crystallise trigonelline (as ***monohydrate***) from aqueous EtOH, then dry it at 100°. It also crystallises from H_2O as the monohydrate with **m 230-233°(dec)**. It has been crystallised from EtOH with **m 214-215°(dec)**. The ***hydrochloride*** *[6138-41-6]* **M 173.6** has **m 258-259°(dec)** (from EtOH) [Smissman & Hite *J Am Chem Soc* **81** 1201 *1959*, DOI: 10.1021/ja01514a047]. The ***picrate*** crystallises from EtOH with **m 204-206°**. [Green & Tong *J Am Chem Soc* **78** 4896 *1956*, DOI: 10.1021/ja01600a023; Kosower & Patton *J Org Chem* **26** 1319 *1961*, DOI: 10.1021/jo01063a623; *Beilstein* **22** I 504, **22** II 35, **22** III/IV 462, **22/2** V 143.]

4',5,7-Trihydroxyflavone (apigenin) *[520-36-5]* **$C_{15}H_{10}O_5$, M 270.2, m 296-298°, 300-305°, 345-350° (pK's 7—10, for phenolic OH).** Crystallise it from aqueous pyridine or aqueous EtOH. It dyes wool yellow when mixed with Cr ions. [*Beilstein* **18** H 181, **18** I 396, **18** II 178, **18** III/IV 2682, **18/4** V 574.]

2,2,5-Trimethyl-1,3-dioxane-4,6-dione (Methyl Meldrum's Acid, methylmalonic acid cyclic isopropylidene ester) *[3709-18-0]* **$C_7H_{10}O_4$, M 158.2, m 111-114°, 113-114°, 115°, pK^{25} 4.77.** This 'acid' is synthesised and purified in the same was as ***Meldrum's acid*** *[2033-24-1]*, except that malonic acid is replaced by methylmalonic acid, in 58% yield. [Pihlaja & Seilo *Acta Chim Scand* **22** 3053 *1968*, DOI: 10.3891/acta.chem.scand.22-3053; Davidson & Bernhard *J Am Chem Soc* **70** 3426 *1948*, DOI: 10.1021/ja01190a060]. Its ^{1}H NMR ($CDCl_3$, TMS) has δ at 1.77 (m, isopropylidene Me, J = 0.6Hz), 1.85 (m, isopropylidene Me, J = 0.6Hz), 1.52 (d, 5-Me, J = 7Hz) and 3.81 (q, 5-H, J = 7.0Hz) ppm [Schuster & Schuster *Tetrahedron* **25** 199 *1969*, DOI: 10.1016/S0040-4020(01)99472-4], and the proportion of ***enol-form*** is apparently not seriously altered by the polarity of the solvent, i.e. MeOH (55.7%), EtOH (51.2%), $CDCl_3$ (60.8%) and *C_6H_6 (58.9%) [Kabachnik et al. *Tetrahedron* **1** 317 *1967*, DOI: 10.1016/S0040-4020(01)99472-4]. The un- and acid-catalysed aqueous hydrolysis has been studied in detail with the 5,5-dimethyl-dione (not described here) hydrolysing slightly faster then the 5-methyl-4,6-dione (described here) and the unmethylated acid [Meldrum's acid,] because, unlike the 5,5-dimethyl-4,6-dione, the latter two can enolise [Pihlaja & Seilo *Acta Chim Scand* **22** 3053 *1968,* DOI: 10.3891/acta.chem.scand.22-3053; *Beilstein* **19** III/IV 1928, **19/5** V 11.]

2,2,6-Trimethyl-4*H*-1,3-dioxin-4-one (diketene acetone adduct) *[5394-63-8]* **$C_7H_{10}O_3$, M 142.2, m 12-13°, b 40°/0.03mm, 65-67°/2mm, 275°/atm, d_4^{20} 1.0879, n_D^{20} 1.4678.** The reactions of this dioxinone are very similar to those of diketene and it acts as a β-keto-ester synthon. Its purity can be easily assessed by ^{1}H NMR spectroscopy as it has only three characteristic peaks (see below). Purify it by fractional distillation, preferably under a vacuum. It is a pleasant smelling liquid that is quite stable in the **absence** of alkali. It is slightly soluble in H_2O that becomes faintly acidic, it gives a red colour with $FeCl_3$, and it rapidly reduces alkaline permanganate in alcoholic solution. It is readily prepared by refluxing a mixture of dry acetone (100ml), diketene (100ml, 109g, 1.3moles, see *[674-82-8]* **toxic**) and *p*-toluenesulfonic acid (0.5g, amount is critical) for 3 hours when the odour of diketene disappears. Excess of acetone is distilled off first followed by the ***adduct***

(168g, 1.18moles, 91% based on diketene). This procedure should be carried out in an efficient fume cupboard as diketene is **TOXIC**. [Carroll & Bader *J Am Chem Soc* **75** 5400 *1953*, DOI: 10.1021/ja01117a076; Naylor (uses $ZnCl_2$ as catalyst) *J Chem Soc* 244 *1945*, DOI: 10.1039/JR9450000244; Dehmlow & Shamout (using quaternary ammonium salts as catalysts) *Justus Liebigs Ann Chem* 1753 *1982*, DOI: 10.1002/jlac.198219820917.] The structure of the ***adduct*** has been determined with certainty [Bader et al. *J Org Chem* **21** 821 *1956*, DOI: 10.1021/jo01113a619]. Its FT-IR (film) has ν_{max} at 1738.7, 1640.0, 1392.8, 1272.6, 1205.3, 1031.5, 901.2, 805.1 and 548.3 cm^{-1}; the ^1H NMR ($CDCl_3$, TMS) has δ at 1.69 [s, 6H, gem $(CH_3)_2$], 2.00 (s, but d at very high resolution with J ~1 Hz, 3H, allyl CH_3) and 5.21 (s, but q at very high resolution with J ~1 Hz, 1H, vinyl H); and the ^{13}C NMR ($CDCl_3$) has δ at 168.65, 161.06, 106.32, 93.81, 25.02 and 19.92. Labeling experiments with $(CD_3)_2CO$ showed that isoprenyl acetoacetate may be the key intermediate in the synthesis [Hyatt *J Org Chem* **49** 5102 *1984*, DOI: 10.1021/jo00200a017]. In addition to reacting as a diketene reagent, it has been functionalised, e.g. to 6-bromomethyl-2,2-dimethyl-4*H*-1,3-dioxin-4-one and 6-methylene-4-diethylphosphoryl-2,2-dimethyl-1,3-dioxinane, for the synthesis of natural products such as **ikarugamycin** and **tirandamycin** [Boeckman & Thomas *J Org Chem* **47** 2823 *1982*, DOI: 10.1021/jo00135a041]. [*Beilstein* **19** IV 1604]

1',3',3'-Trimethyl-6-nitrospiro(2*H*-benzopyran-2,2'-indoline) *[1498-88-0]* **$C_{19}H_{18}N_2O_3$, M 322.4, m 178°, 179.5°, 180°.** This photochromic dye crystallises from absolute EtOH [Hinnen et al. *Bull Soc Chim Fr* 2066 *1968*, Ramesh & Labes *J Am Chem Soc* **109** 3228 *1987*, DOI: 10.1021/ja00245a008; Berman et al. *J Am Chem Soc* **81** 5605 *1959*, DOI: 10.1021/ja01530a021]. [*Beilstein* **27** III/IV 1460.]

2,2,4-Trimethyl-6-phenyl-1,2-dihydroquinoline *[3562-69-4]* **$C_{18}H_{19}N$, M 249.3, m 102°, b 394°/atm.** It is the principal ingredient in Santoflex (a synthetic polymer stabiliser). Crystallise it three times from absolute EtOH. It is a glucocorticoid receptor agonist. The ***1-phenylcarbamoyl*** derivative has **m 148-149.6°** (from EtOH). [Hively et al. *Anal Chem* **27** 100 *1955*, DOI: 10.1021/ac60097a029; *Beilstein* **20** III/IV 4116.]

2,4,6-Trimethylpyridine (sym-collidine) *[108-75-8]* **$C_8H_{11}N$, M 121.2, m -46°, -43°, b 10°/2.7mm, 36-37°/2mm, 60.7°/13mm, 65°/31mm, 170.4°/760mm, 175-178°/atm, d_4^{25} 0.9100, n_D^{20} 1.4939, 1.4981, n_D^{25} 1.4959, pK^{25} 6.69(7.45).** Commercial samples may be grossly impure. Likely contaminants include 3,5-dimethylpyridine, 2,3,6-trimethylpyridine and water. Brown, Johnson and Podall [*J Am Chem Soc* **76** 5556 *1954*, DOI: 10.1021/ja01650a085] fractionally distilled 2,4,6-trimethylpyridine under reduced pressure through a 40cm Vigreux column and added to 430ml of the distillate slowly, with cooling to 0°, 45g of BF_3-diethyl etherate. The mixture was again distilled, and an equal volume of dry *benzene was added to the distillate. Dry HCl was passed into the solution, which was kept cold in an ice-bath, and the hydrochloride was filtered off. It was recrystallised from absolute EtOH (1.5ml/g) to **m 286-287°**[**m 256°**(sealed tube), also **m 293-294°** subliming slowly]. The ***free base*** was regenerated by treatment with aqueous NaOH, then extracted with *benzene, dried ($MgSO_4$) and distilled under reduced pressure. Sisler et al. [*J Am Chem Soc* **75** 446 *1953*, DOI: 10.1021/ja01098a055] precipitated trimethylpyridine as its phosphate salt from a solution of the base in MeOH by adding 85% H_3PO_4, shaking and cooling. The ***free base*** was then regenerated as above. Garrett and Smythe [*J Chem Soc* 763 *1903*, DOI: 10.1039/CT9038300763] purified the trimethylpyridine *via* the ***$HgCl_2$ complex***. It is more soluble in cold than hot H_2O [the solubility is 20.8% at 6°, 3.5% at 20°, 1.8% at 100°]. ***Alternatively***, purify it by dissolving it in $CHCl_3$, adding solid K_2CO_3 and Drierite, filtering and fractionally distilling through an 8in helix-packed column. ***The alkali metals, Na, Li or Cs should NOT be used for drying pyridine, and pyridine derivatives, as they form coloured pyridine radical anions leading to bipyridyls.*** [see Schmulbach et al. *J Am Chem Soc* **90** 6600 *1968*, DOI: 10.1021/ja01026a006]. The ***sulfate*** has **m 205°**, and the ***picrate*** (from hot H_2O) has **m 155-156°**. [Frank & Meikle *J Am Chem Soc* **72** 4184 *1950*, DOI: 10.1021/ja01165a097; *Beilstein* **20** H 250, **20** I 87, **20** II 164, **20** III/IV 2810, **20/6** V 93.]

1,3,7-Trimethyluric acid *[5415-44-1]* **$C_8H_{10}N_4O_3$, M 210.2, m 345°(dec), pK^{25} 6.0.** Crystallise it from water and dry it at 100° in a vacuum. It has UV with λ_{max} at 289nm (pH 2.5). [*Beilstein* **26** III/IV 2623.]
1,3,9-Trimethyluric acid *[7464-93-9]* has **m 340°(dec), 347°, pK^{20} 9.39.** Crystallise it from water and dry it at 100° in a vacuum. [*Beilstein* **26** H 530, **26** II 301, **26** III/IV 2623.]

1,7,9-Trimethyluric acid *[55441-82-2]* **$C_8H_{10}N_4O_3$, M 210.2, m 316-318°, 345°, pK_{Est} ~9.0.** Crystallise the uric acid from water or EtOH, and sublime it *in vacuo*. [*Beilstein* **26** H 530, **26** II 302, **26** III/IV 2623.]

3,7,9-Trimethyluric acid *[55441-72-0]* **$C_8H_{10}N_4O_3$, M 210.2, m 373-375°(dec), pK^{20} 9.39.** Crystallise the uric acid from water and dry it at 100° in a vacuum. It has UV with λ_{max} at 294nm (pH 2.5). [Bergmann & Dikstein *J Am Chem Soc* **77** 691 *1955*, DOI: 10.1021/ja01608a044; *Beilstein* **26** H 530, **26** I 156, **26** II 301, **26** III/IV 2623.]

1,3,5-Trioxane (metaformaldehyde) *[110-88-3]* **$C_3H_6O_3$, M 90.1, m 59-62°, 64°, b 114.5°/759mm.** Crystallise 1,3,4-trioxane from sodium-dried diethyl ether or water, and dry it over $CaCl_2$. It can also be purified by zone refining. Used as a source of formaldehyde. [*Beilstein* **19** II 392, **19** III/IV 4710, **19/9** V 103.]

Trioxsalen (2,5,9-trimethyl-7*H*-furo[3,2-*g*]benzopyran-7-one) *[3902-71-4]* **$C_{14}H_{12}O_3$, M 228.2, m 229-231°, 233-235°, 234.5-235°.** Purify trioxsalen by recrystallisation from $CHCl_3$. If too impure, it is fractionally crystallised from $CHCl_3$/petroleum ether (b 30-60°) using Norit, and finally crystallised from $CHCl_3$ alone to give colourless prisms, **m 234.5-235°**. It is a photosensitiser so it should be stored in the dark. [UV: Kaufmann *J Org Chem* **26** 117 *1961*, DOI: 10.1021/jo01060a028.] Used as a photochemical crosslinker of DNA and used to study nucleic acid structure and function [Higuchi et al. *Nucleic Acids Symposium Series (2004)* **49** 331, DOI: 10.1093/nass/49.1.331]. [*Beilstein* **19/4** V 472.]

2,3,5-Triphenyltetrazolium chloride (TTC, TTZ) *[298-96-4]* **$C_{19}H_{15}ClN_4$, M 334.8, m 243°(dec).** Crystallise TTZ from EtOH or $CHCl_3$, and dry it at 105°. Reagent used to distinguish between α-ketols and simple aldehydes, and used as a seed germination indicator. [*Beilstein* **26** H 363, **26** II 216, **26** III/IV 1774.]

Tripyridyl triazine [TPTZ, 2,4,6-tri(2-pyridyl)-*s*-triazine] *[3682-35-7]* **$C_{18}H_{12}N_6$, M 312.3, m 245-248°, 247-249°, 248-250°.** Purify it by repeated crystallisation from aqueous EtOH. It is a reagent for the determination of Fe(II) and total Fe [Collins et al. *Anal Chem* **31** 1862 *1959*, DOI: 10.1021/ac60155a056]. [*Beilstein* **26** III/IV 4192.]

1,1,1-Tris(acetyloxy)-1,1-dihydro-1,2-benzoiodoxol-3-(1*H*)-one (Dess-Martin periodinane, DMP) *[87413-09-0]* **$C_{13}H_{13}IO_8$, M 424.1, m 130-133°, 133-134° (dec).** DMP is essentially the acetylated form of IBX (see above) that renders the latter more soluble in organic solvents. Unlike IBX, it is not explosive on melting or upon hard impact. However, it is subject to hydrolysis in the presence of moisture that may give rise to explosive impurities. It is important that it should be stored in a dry atmosphere and that care should be taken when using it. The original Dess-Martin preparation [Dess & Martin *J Am Chem Soc* **113** 7277 *1991*, DOI: 10.1021/ja00019a027] has been improved and is reported here. ***1-Hydroxy-1,2-benziodoxol-3(1H)-one*** (100g, 360mmol, see IBX *[61717-82-6]*) is added to Ac_2O (400ml, ~4mol) and $TsOH.H_2O$ (0.5g), and stirred under N_2 at 80° for 2 hours, then cooled in an ice-water bath. The white solid that separates in the cold mixture is filtered off onto a fritted glass funnel, rinsed with anhydrous Et_2O (5 x 50ml), and the crystalline solid (138g, 91%, m 134°) is rapidly transferred to an argon filled amber-glass bottle and stored in a freezer. When exposed to light for several weeks some decomposition occurs so it should be kept away from light. [Ireland & Liu *J Org Chem* **58** 2899 1993, DOI: 10.1021/jo00062a040.] Its IR (CH_2Cl_2) has ν_{max} at 1726.9 (s) and 1707.5 cm^{-1}; the ^1H NMR ($CDCl_3$, TMS) has δ at 2.01 (s, 6H, COC*H*$_3$), 2.33 (s, 3H, COC*H*$_3$), 7.80 (t, 1H, J_{HH} = 7.3 and 8.5 Hz) and 8.07 (t, 1H, J_{HH} = 7.3 and 8.5 Hz) (C-4 and C-5), 8.29 (d, 1H, J_{HH} = 8.5 Hz) and 8.31 (d, 1H, J_{HH} = 8.5 Hz) (C-3 and C-6); and the ^{13}C NMR ($CDCl_3$) has δ at 20.29 (2 CO*C*H$_3$), 20.43 (1 CO*C*H$_3$), 126.01 (C-2), 126.51, 131.79, 133.81, 135.76, 142.36 (C-1), 166.08 (endocyclic C=O), 173.96 (1 acetate C=O), 175.66 and (2 acetate C=O's). A 0.3M solution of DMP in CH_2Cl_2 is available commercially.

DMP is an extremely useful reagent for the oxidation of primary and secondary alcohols to aldehydes and ketones to completion, without further oxidation to the acids, within ~2 hours at 20°; allylic and benzylic alcohols require ~30 minutes. The reaction is increased rapidly on addition of an alcohol. Furan rings or sulfides and vinyl ethers are unreactive. Geraniol is oxidised to geranial without rearrangement to nerol, and it oxidises *N*-benzylbenzamide to benzaldehyde. The reagent is usually added in an appropriate anhydrous solvent (e.g. $CHCl_3$, CH_2Cl_2, MeCN etc) followed by the substrate. Workup can be by adding Et_2O followed by aqueous NaOH which decomposes the reagent to iodobenzoate, or for base-sensitive substrates $NaHCO_3$ and sodium thiosulfate ($Na_2S_2O_3$) are added, which also remove iodine. A pyridine buffer can be used to keep near-neutral conditions throughout the entire oxidation followed by a thiosulfate work up procedure. [see Dess & Martin *J Am Chem Soc* **113** 7277 *1991*, DOI: 10.1021/ja00019a027 and papers cited in this reference] In the peptide field, substances like *N*-Fmoc phenylglycinol are oxidised to *N*-Fmoc phenylglycinal almost quantita-

tively in water-saturated CH_2Cl_2 with this reagent [Myers et al. *Tetrahedron Lett* **41** 1359 *2000*, DOI:10.1016/S0040-4039(99)02293-5].

1,3,5-Trithiane (thioformaldehyde trimer) *[291-21-4]* **$C_3H_6S_3$, M 138.3, m 216-218°(dec), 215-220°(dec).** Crystallise it from AcOH or toluene, after Soxhlet extraction with toluene (30g/300ml) [*Beilstein* **19** III/IV 4711, **19/9** V 105.]

3-Tropanol (Tropine) *[120-29-6]* **$C_8H_{15}NO$, M 141.2, m 63°, 64-66°, b 229°/760mm, pK^{15} 3.80.** Distil 3-tropanol in steam and crystallise it from Et_2O or toluene/petroleum ether. It is soluble in H_2O, EtOH, $CHCl_3$, and sublimes at 60°/0.1mm. ***Hygroscopic***. A 0.05M solution in H_2O has a pH of 11.5, and its solubility in H_2O is 0.1g/ml. The ***hydrochloride*** has **m 280°** (from EtOH/Et_2O). [*Beilstein* **21** II 17, **21** III/IV 168, **21/1** V 219.]

Tryptamine [3-(2-aminoethyl)indole)] *[61-54-1]* **$C_{10}H_{12}N_2$, M 160.1, m 113-116°, 116°, 118°, pK_1^{25} -6.31 (aqueous H_2SO_4, diprotonation), $pK_{Est(2)}$~4.9, pK_3^{25} 16.60 (acidic indole NH).** Crystallise tryptamine from *benzene, Et_2O (**m 114°**) or petroleum ether (**m 118°**). It has UV with λ_{max} at 222, 276, 282 and 291nm (EtOH) and 226, 275, 281 and 290nm (HCl). It is vasoactive agent, and a neuromodulator. [*Beilstein* **22** II 346, **22** III/IV 4319, **22/10** V 45.]
Tryptamine hydrochloride *[343-94-2]* **$C_{10}H_{12}N_2$. HCl, M 196.7,** has **m 248°, 252-253°.** Crystallise the salt from EtOH/water, EtOH/Et_2O or EtOH/EtOAc. See previous entry for UV. [*Beilstein* **22** II 347, **22** III/IV 4319, **22/10** V 46.]

Tryptophol [3-(2-hydroxyethyl)indole] *[526-55-6]* **$C_{10}H_{11}NO$, M 161.2, m 56-59°, 59°, b 174°/2mm.** Crystallise it from diethyl ether/petroleum ether, *C_6H_6, *C_6H_6/petroleum ether. The ***picrate*** has **m 100-101°** (from *C_6H_6). [*Beilstein* **21** I 218, **21** II 49, **21** III/IV 788, **21/3** V 61.]

Umbelliferone (7-hydroxycoumarin) *[93-35-6]* **$C_9H_6O_3$, M 162.2, m 225-228°, 230-233°, pK_{Est} ~8.0.** It crystallises from water (**m** 232-232.2°) or EtOH (**m** 232°). It sublimes at 160°/0.001mm. Fluorescence: Em $_{max}$ 452nm/Exc $_{max}$ 325nm in 50% EtOH. [*Beilstein* **18** H 27, **18** I 306, **18** II 16, **18** III/IV 294, **18/1** V 386.]

Uracil (pyrimidine-2,4(1*H*)-dione) *[66-22-8]* **$C_4H_4N_2O_2$, M 122.1, m 335°(dec), pK_1^{25} 9.43, pK_2^{25} 13.3-14.2.** Uracil crystallises from water (**m 339-341°**) and **m 338°** after sublimation in high vacuum. Its solubility in H_2O at 20° is 1g/300ml. [*Beilstein* **24** H 312, **24** I 312, **24** II 169, **24** III/IV 1193.]

Uramil (5-aminobarbituric acid) *[118-78-5]* **$C_4H_5N_3O_3$, M 143.1, m 310-312°, 320°, >400°(dec), $pK_{Est(1)}$~3.9, $pK_{Est(2)}$~8.0, $pK_{Est(3)}$~12.5.** It crystallises from water. It has also been purified by dissolving it in aqueous ammonia and precipitating it by dropwise addition of formic acid. The solid is collected and dried in a vacuum at 100°. [Hartman & Sheppard *Org Synth* Coll Vol **2** 617 *1943*, DOI: 10.15227/orgsyn.012.0084; *Beilstein* **25** H 492, **25** I 704, **25** III/IV 4228.]

Uric acid (2,6,8-trihydroxypurine) *[69-93-2]* **$C_5H_4N_4O_3$, M 168.1, m >300° (dec) pK_1 5.75, pK_2 10.3.** Crystallise uric acid from hot distilled H_2O (the solubility in H_2O is 1part/39,000parts at 18° and 1part/2,000parts at 100°). It is best purified by dissolving in an alkaline solution and acidifying with dilute HCl and drying it at 100° in a vacuum. [Bergmann & Dikstein *J Am Chem Soc* **77** 691 *1955* DOI: 10.1021/ja01608a044; Lister *Purines Part II, Fused Pyrimidines* Brown Ed, Wiley-Interscience pp256-257 *1971*, ISBN 0-471-38205-1, *Beilstein* **26** H 513, **26** I 151, **26** II 293, **26** III/IV 2619.]

β-Uridine (uracil-1-β-D-ribofuranoside) *[58-96-8]* **$C_9H_{12}N_2O_6$, M 244.2, m 163-167°, 165°, $[\alpha]_D^{20}$ +10.0 (c 1.6, H_2O), pK^{25} 9.51 (9.25).** Crystallise β-uridine from aqueous 75% MeOH or EtOH (**m** 165-166°). [*Beilstein* **24** III/IV 1202.]

Urocanic acid (4-imidazolylacrylic acid) *[104-98-3]* **$C_6H_6N_2O_2$, M 138.1, m 225°, 226-228°, $pK_{Est(1)}$~2.5, $pK_{Est(2)}$~6, $pK_{Est(3)}$~11.** Crystallise the acid from water and dry it at 100°. The ***trans-isomer*** *[3465-72-3]* has **m 225°** (**229-230°, 230-231°** or **231°(dec**, from H_2O) and pK_1 3.5 and pK_2 5.6; and the ***picrate*** has **m 225°(dec**,

from H_2O). The ***cis-isomer*** *[7699-35-6]* has **m 175-176°** (**178-179°** or **180-184° dec**, from H_2O) and pK_1 3.0 and pK_2 6.7, and the ***picrate*** has **m 204°** (from H_2O). [*Beilstein* **25** H 124, **25** I 536, **25** II 121, **25** III/IV 786.]

δ-Valerolactam (2-piperidone) *[675-20-7]* **C_5H_9NO, M 99.1, m 38.5-39.5°, 39-40°, 40°, b 81-82°/0.1mm, 136-137°/15mm, 256°/atm, pK^{25} 0.75 (in AcOH).** Purify it by repeated fractional distillation. [Conley *J Org Chem* **23** 1330 *1958*, DOI: 10.1021/jo01103a023; Reppe et al. *Justus Liebigs Ann Chem* **596** 158 198 *1955*, DOI: 10.1002/jlac.19555960109; IR: Huisgen et al. *Chem Ber* **90** 1437 *1957*, DOI: 10.1002/cber.19570900808.] The ***hydrochloride*** *[5174-67-4]* has **m 183-184°** (from isoPrOH or EtOH/Et_2O) [Hurd et al. *J Org Chem* **17** 865 *1952*, DOI: 10.1021/jo01140a013], and the ***oxime*** has **m 122.5°** (from petroleum ether) [Behringer & Meier *Justus Liebigs Ann Chem* **607** 67 *1957*, DOI: 10.1002/jlac.19576070109]. The ***N-benzoyl derivative*** *[4252-56-6]* has **m 115°** (from $CHCl_3$/petroleum ether), the ***N-methyl derivative*** *[931-20-4]* is a water soluble hygroscopic liquid with **b 115°/14mm**, and the ***N-methyl hydrochloride*** *[87243-73-0]* crystallises from from EtOH/Et_2O with **m 115°**. The ***picrate*** has **m 92-93°**. [*Beilstein* **21/6** V 396.]

δ-Valerolactone (tetrahydro-2*H*-pyran-2-one) *[542-28-9]* **$C_5H_8O_2$, M 100.1, m -13°, -12°, b 88°/4mm, 97°/10mm, 124°/24mm, 145-146°/40mm, 229-229.5°/atm, d_4^{20} 1.1081, n_D^{20} 1.4568.** Purify the δ-lactone by repeated fractional distillation. Its IR has ν_{max} at 1750 (in CS_2), 1732 (in $CHCl_3$), 1748 (in CCl_4) and 1733 (in MeOH) cm^{-1} [Huisgen & Ott *Tetrahedron* **6** 253 *1959*, DOI:10.1016/0040-4020(59)80006-5; Linstead & Rydon *J Chem Soc* 580 *1933*, DOI: 10.1039/JR9330000580; Jones et al. *Can J Chem* **37** 2007 *1959*, DOI: 10.1139/v59-293]. [*Beilstein* **17** H 235, **17** II 287, **17** III/IV 4169, **17/9** V 17.]

γ-Valerolactone **(± 4,5-dihydro-5-methyl-2(3*H*)-furanone)** *[108-29-2]* has **m -37°, -36°, -31°, b 82-85°/10mm, 102-103°/28mm, 125.3°/68mm, 136°/100mm, 205.75-206.25°/ 754mm, d_4^{20} 1.072, n_D^{20} 1.4322.** Purify the γ-lactone by repeated fractional distillation [Boorman & Linstead *J Chem Soc* 577, 580 *1933*, DOI: 10.1039/JR9330000577]. Its IR has ν_{max} at 1790 (CS_2), 1775 ($CHCl_3$) cm^{-1} [Jones et al. *Can J Chem* **37** 2007 *1959*, DOI: 0.1139/v59-293]. The ***BF_3-complex*** distils at **110-111°/20mm** [Reppe et al. *Justus Liebigs Ann Chem* **596** 179 *1955*, DOI: 10.1002/jlac.19555960109]. It is characterised by conversion to γ-hydroxy-*n*-valeramide on treatment with NH_3, which has **m 51.5-52°** (by slow evaporation of a $CHCl_3$ solution). [*Beilstein* **17** H 235, **17** I 131, **17** II 288, **17** III/IV 4176, **17/9** V 24.]

(±)-Vinclozolin [3-(3,5-dichlorophenyl)-5-methyl-5-vinyloxazolidine-2,4-dione] *[50471-44-8]* **$C_{12}H_9Cl_2NO_3$, M 286.1, m 108°.** Crystallise this fungicide (controlling plant diseases) from Me_2CO/H_2O. Its solubility at 20° (w/w%) is 44 (Me_2CO), 32 ($CHCl_3$), 25 (EtOAc) and 10 (H_2O). It irritates the eyes and skin. [**GP** 2,207,576 *1973*, *Chem Abstr* **79** 137120 *1973*.]

***N*-Vinylcaprolactam** *[2235-00-9]* **$C_8H_{13}NO$, M 139.2, m 35-38°(polym), b 95-95.5°/4mm, 128°/21mm, d_4^{20} 1.0287, n_D^{20} 1.5133.** Distil it under vacuum and with 0.0015% of 4-*tert*-butylcatechol as stabiliser. [*Beilstein* **21** III/IV 3207.]

***N*-Vinylcarbazole** *[1484-13-5]* **$C_{14}H_{11}N$, M 193.3,** has **m 60-65°, 66°, b 154-155°/3mm.** Crystallise *N*-vinylcarbazole repeatedly from MeOH in amber glassware. It sublimes in a vacuum. [*Beilstein* **20** II 282, **20** III/IV 3830, **20/8** V 19.]

Vinylene carbonate (1,3-diaxol-2-one) *[872-36-6]* **$C_3H_2O_3$, M 86.1, m 19-22°, 22°, b 76-78°/37mm, 165°/~760mm.** Purify it by zone melting, or distillation, and stabilise it with 0.5% of 2,6-di-*tert*-butyl-*p*-cresol. [*Beilstein* **19** III/IV 1597, **19/4** V 72.]

2-Vinylpyridine monomer *[100-69-6]* **C_7H_7N, M 105.1, b 79-82°/29mm, d 0.974, n 1.550, pK^{25} 4.92(4.98).** Steam distil it, then dry it with $MgSO_4$ and distil it in a vacuum. Stabilise it with 0.1w/w% of *p*-tert-butylcatechol if not used immediately. [*Beilstein* **20** H 256, **20** III/IV 2884, **20/6** V 211.]

4-Vinylpyridine monomer *[100-43-6]* has **b 40-41°/1.4mm, 54°/5mm, 58-61°/12mm, 68°/18mm, 79°/33mm, d_4^{20} 0.9836, n_D^{20} 1.5486, pK^{25} 5.62.** Purify the monomer by fractional distillation under a good vacuum and in a N_2 atmosphere; store it in sealed ampoules under N_2, and keep it in the dark at -20°. Stabilise it with 0.1w/w% of *p*-tert-butylcatechol if not used immediately. The ***picrate*** has **m 175-176°**. [UV: Coleman & Fuoss *J Am Chem Soc* **77** 5472 *1955*, DOI: 10.1021/ja01626a006; Overberger et al. *J Polymer Sci* **27** 381 *1958*, DOI: 10.1002/pol.1958.1202711529; Petro & Smyth *J Am Chem Soc* **79** 6142 *1957*, DOI: 10.1021/ja01580a010.] It

is used for alkylating SH groups in peptides [Anderson & Friedman *Can J Biochem* **49** 1042 *1971*, DOI: 10.1139/o71-152; Cavins & Friedman *Anal Biochem* **35** 489 *1970*, DOI:10.1016/0003-2697(70)90211-3]. [*Beilstein* **20** II 170, **20** III/IV 2887, **20/6** V 213.]

Viologen (4,4'-dipyridyl dihydrochloride) *[27926-72-3]* **$C_{10}H_{10}Cl_2N_2$, M 229.1, m 278° (also reported m 302-306°, >300°, with sublimation), pK_1^{20} 3.17, pK_2^{20} 4.82.** Purify viologen by precipitation on adding excess of acetone to a concentrated solution of it in aqueous MeOH. It has also been recrystallised several times from MeOH or *iso*-propanol and dried at 70° under vacuum for 24 hours [Prasad et al. *J Am Chem Soc* **108** 5135 *1986*, DOI: 10.1021/ja00277a017], and recrystallised three times from MeOH/isopropanol [Stramel & Thomas *JCS Faraday Trans 2* **82** 799 *1986*, DOI: 10.1039/F29868200799; Michaelis & Hill *J Am Chem Soc* **55** 1481 *1933*, DOI: 10.1021/ja01331a027; Tilford et al. *J Am Chem Soc* **70** 4001 *1948*, DOI: 10.1021/ja01192a010]. [*Beilstein* **23** I 49.]

Visnagin (4-methoxy-7-methyl-5*H*-furo[3,2-g][1]benzopyran-5-one) *[82-57-5]* **$C_{13}H_{10}O_4$, M 230.2, m 140-142°, 142-145°.** Crystallise visnagin from water. It is soluble in $CHCl_3$ but slightly soluble in EtOH. [Aneja et al. *Tetrahedron* **3** 230 *1958*, DOI: 10.1016/0040-4020(58)80018-6; *Beilstein* **19** III/IV 2640.]

9*H*-Xanthene (dibenzopyran) *[92-83-1]* **$C_{13}H_{10}O$, M 182.2, m 100.5°, 101-102.5°, b 310-312°/760mm.** Crystallise dibenzopyran from *benzene, MeOH or EtOH. [*Beilstein* **17** II 72, **17** III/IV 614, **17/2** V 252.]

Xanthine (2,6-dihydroxypurine, purine-2,6(1*H*,3*H*)dione) *[69-89-6]* **$C_5H_4N_4O_2$, M 152.1, pK_1 0.8 [protonation of imidazole 7(9)NH], pK_2 7.44 [monoanion 1(3)NH], pK_3 11.12 [dianion 1,3-N^{2-}].** The ***monohydrate*** separates in a microcrystalline form on slow acidification with acetic acid of a solution of xanthine in dilute NaOH. It is also precipitated by addition of concentrated NH_3 to its solution in hot 2N HCl (charcoal). After washing with H_2O and EtOH, it is dehydrated by heating above 125°. Its solubility in H_2O is 1 in 14,000 parts at 16° and 1 in 1,500 parts of boiling H_2O, and separates as plates . It has no **m**, but the ***perchlorate*** has **m 262-264°** [Lister *Purines Part II, Fused Pyrimidines* Brown Ed, Wiley-Interscience pp 252-253 *1971*, ISBN 0-471-38205-1]. [*Beilstein* **26** H 447, **26** I 131, **26** II 260, **26** III/IV 2327.]

9-Xanthone (9-xanthenone) *[90-47-1]* **$C_{13}H_8O_2$, M 196.2, m 172-174°, 175.6-175.4°, b 349-350°/730mm.** Crystallise xanthone from EtOH (25ml/g) and dry at 100°. It has also been recrystallised from *n*-hexane (3x) and sublimed *in vacuo*. [Saltiel et al. *J Am Chem Soc* **108** 2674 *1986*, DOI: 10.1021/ja00270a028]. [*Beilstein* **17/10** V 430.] ***9-Xanthydrol* (9-hydroxyxanthenone)** *[90-46-0]* **$C_{13}H_{10}O_2$, M 198.2, m 122-123°, 123-124°, 124-126°, 127-128°.** Crystallise xanthydrol from EtOH and dry at 40-50°. [*Beilstein* **17** III 1602, **17/4** V 502.]

Xanthosine ($2H_2O$) [9-(β-D-ribosyl)purin-2,6(1*H*,3*H*)-dione] *[5968-90-1]* **$C_{10}H_{12}N_4O_6$, M 320.3, $[\alpha]_D^{20}$ -53 (c 8, 0.3M NaOH), pK_1^{25} <2.5, pK_2^{25} 5.67, pK_3^{25} 12.85.** It crystallises from EtOH (anhydrous) or water (as dihydrate). [Howard et al. *J Chem Soc* 232 *1949*, DOI: 10.1039/JR9490000232; *Beilstein* **26** III/IV 2428.]

Xanthurenic acid (5,8-dihydroxyquinoline-2-carboxylic acid) *[59-00-7]* **$C_{10}H_7NO_4$, M 205.2, m 286°, 290-295°(dec), 297-298°(dec), $pK_{Est(1)}$~ 1.5, $pK_{Est(2)}$~ 4.9, $pK_{Est(3)}$~ 9.8.** It is precipitated by the addition of 2N formic acid to its solution in hot 2M ammonia (charcoal). The solid is filtered off, dried in a vacuum at ~80° in the dark. Its UV (H_2O) has λ_{max} nm (ε $M^{-1}cm^{-1}$) at 243 (30,000) and 342 (6,500). The ***methyl ester*** has **m 262°** (from MeOH). It forms Cu^{2+}, Zn^{2+}, Fe^{2+} and Fe^{3+} salts. [*Beilstein* **22** III/IV 2513.]

Yohimbine (Rauwolscine) *[146-48-5]* **$C_{13}H_{10}O_2$, M 354.5, 235-237°(dec), 278°(dec), $[\alpha]_D^{20}$ +55.6 (c 2, EtOH), pK_1^{22} 3.0, pK_2^{22} 7.45.** Crystallise this *Rauwolfia* alkaloid ester from EtOH or aqueous EtOH (needles), and dry *in vacuo* to remove EtOH. Soluble in MeOH, $CHCl_3$, warm *C_6H_6, poorly soluble in Et_2O and H_2O. UV (MeOH): λ_{max} nm(logε) at 226(4.56), 280(3.88) and 291(380). The ***hydrochloride*** *[45-19-0]* **m 302°(dec)** (EtOH plates) **$[\alpha]_D^{20}$ +105° (H_2O)**, is sol. in H_2O (83%) and EtOH (0.25%). [Wenkert et al. *J Am Chem Soc* **101** 5370 *1979*, DOI: 10.1021/ja00512a043; *Beilstein* **25** III/IV 1234.] It is a 5-HT_{1A} serotonin receptor agonist and α_2-adrenoceptor antagonist. δ-Yohimbine is *ajmalicine [483-04-5]* and γ-yohimbine is *ajmaline [4360-12-7]*.

MISCELLANEOUS As, B, P, Si, S, Se and Te COMPOUNDS.

This section contains miscellaneous organic compounds of As, B, P, Si, S, Se, Te, and ***ammonium and metal salts of their acids, and salts of their bases.*** See other sections and chapters for further entries of sulfur, phosphorous and silicon compounds; and for sulfur heterocyclic compounds see section on 'Heterocyclic Compounds' in this Chapter.

Acetonyltriphenylphosphonium chloride *[1235-21-8]* **$C_{21}H_{20}ClOP$, M 354.8, m 237-238°, 243-245°, 244-246°(dec), 248-252°.** Recrystallise it from $CHCl_3$/*C_6H_6/petroleum ether (b 60-80°) or by dissolving it in $CHCl_3$ and pouring it into dry Et_2O. It has UV(EtOH) with λ_{max} nm(ε) at 255(3,600), 262(3,700), 268(4,000) and 275(3,100). The ***iodide salt*** crystallises from H_2O and has **m 207-209°**. [Ramirez & Dershowitz *J Org Chem* **22** 41 *1957*, DOI: 10.1021/jo01352a010.] It is an **IRRITANT** and is ***hygroscopic***. When shaken with a 10% aqueous solution of Na_2CO_3 (8 hours) it gives ***acetylmethylene triphenyl phosphorane*** *[1439-36-7]* $C_{21}H_{19}OP$, M 318.4, which is recrystallised from MeOH/H_2O, and after drying at 70°/0.1mm has **m 205-206°** (**207°**). It has UV with λ_{max} nm(ε) at 268 (6600), 275 (6500) and 288 (5700), and its IR has ν_{max} at 1529(s), 1470(m), 1425(s), 1374(m), 1105(s) and 978(s) (cm^{-1}). [Ramirez & Dershowitz *J Org Chem* **22** 41, 44 *1957*, DOI: 10.1021/jo01352a010; *Beilstein* **16** H 761, **16** II 373.]

3*R*,4*R*,1'*R*-4-Acetoxy-3-[1-(*tert*-butylmethylsilyloxy)ethyl]-2-azetinone *[76855-69-1]* **$C_{13}H_{25}NO_4Si$, M 287.4, m 107-108°, $[\alpha]_D^{20}$ +55 (c 0.5, toluene), $[\alpha]_D^{20}$ +53.7 (c 1.04, $CHCl_3$).** Purify it by chromatography on silica gel (3 x 14cm) for 50g of ester using 20% EtOAc in *n*-hexane. The eluate is evaporated, and the residue is recrystallised from hexane (white fluffy crystals). Avoid breathing it in and contact with eyes. [Leanza et al. *Tetrahedron* **39** 2505 *1983*, DOI: 10.1016/S0040-4020(01)92144-1.]

N*-Acetyl-4-hydroxy-*m*-arsanilic acid (Acetarsol, Stovarsol, 3-acetamido-4-hydroxyphenylarsonic acid)** *[97-44-9]* **$C_8H_{10}AsO_5$, M 275.1, m 240-250°, pK_1 3.73, pK_2 7.9, pK_3 9.3.** It crystallises from water in colourless prisms. It decomposes slowly on prolonged boiling in H_2O or dilute alkalis. The ***N-propionyl derivative recrystallises from H_2O with **m 228-229°(dec)**. [Raiziss & Fisher *J Am Chem Soc* **48** 1323 *1926*, DOI: 10.1021/ja01416a030; Hewitt & King *J Chem Soc* 817 *1926*, DOI: 10.1039/JR9262900817; *Beilstein* **16** I 491, **16** II 521, **16** III 1129.] The drug is an anti-infective used in suppositories [Chen et al. *Int J STD AIDS* **10** 277 *1999*, DOI: 10.1258/0956462991913943].

Alizarin Red S (3,4-dihydroxy-9,10-dioxo-2-anthracene sulfonic acid, Na salt. H_2O, Alizarin sulfonate sodium salt, Alizarin carmine) *[130-22-3]* **$C_{14}H_{22}NaO_7S$, M 342.3, decomposes on heating, CI 58005, pK_1^{25} <1, pK_2^{25} 5.49, pK_3^{25} 10.85 (11.01).** Commercial samples contain large amounts of sodium and potassium chlorides and sulfates. It is purified by passing through a Sephadex G-10 column (size exclusion column), followed by elution with water, then 50% aqueous EtOH [King & Pruden *Analyst (London)* **93** 601 *1968*, DOI: 10.1039/AN9689300601]. Finally dissolve it in EtOH and precipitate it with Et_2O several times [Sacconi *J Phys Chem* ***54*** 829 *1950*, DOI: 10.1021/j150480a012; polarography: Furman & Stone *J Am Chem Soc* **70** 3055 *1948*, DOI: 10.1021/ja01189a064]. A 1% aqueous solution is used as an indicator (purple at pH 5.2 and yellow at pH 7.7), is a reagent for Al and Ca, and is used for microscopic staining [*Beilstein* **11** IV 683.]

Allyl trimethylsilane (2-propenyltrimethylsilane) *[762-72-1]* **$C_6H_{14}Si$, M 114.3, b 82°/atm, 83.0-84.5°/atm, 84-88°/atm, 85.5-86.0°/atm, d_4^{20} 0.713, n_D^{20} 1.405.** Fractionate it through an efficient column at atmospheric pressure. If impure, dissolve it in THF, shake it with H_2O (2x), dry (Na_2SO_4), filter and fractionate it. [Cudlin & Chvalovský *Coll Czech Chem Commun* **27** 1658 *1962*, DOI: org/10.1135/cccc19621658; *Beilstein* **4** IV 3927.]

2-Amino-4-sulfobenzoic acid *[98-43-1]* **$C_7H_7NO_5S$, M 217.1, m** (decomp on heating), **d^{25} 1.709g/cm³, n_D^{20} 1.661, $pK_{Est(1)}$ < 0.0, $pK_{Est(2)}$ ~1.0, $pK_{Est(3)}$ ~4.2.** It was prepared by dissolving toluene in the smallest possible volume of fuming H_2SO_4 (care) then diluted with cold H_2O, and neutralised with $CaCO_3$ then evaporated to a small volume. A solution of $KMnO_4$ is added, the mixture is diluted, heated until colourless, filtered, and saturated with HCl. $BaCl_2$ solution is added to precipitate the barium salt which is collected, dried and treated with the calculated amount of H_2SO_4 to precipitate $BaSO_4$, which is filtered off. Evaporation of the filtrate gave

2-nitro-4-sulfobenzoic acid *[552-23-8]* which is soluble in H_2O but crytallises from a small volume of it as short prisms of the ***hydrate***, **m 130-131°**. It forms Ba, Cu, Ka, Ca and Mg salts readily. The ***potassium 2-nitro-4-sulfobenzoate*** *[5344-48-9]*, prepared by neutralising the acid and evaporating to crystallise it, was reduced with excess of ammonium sulfide, evaporating, filtering and acidifying with HCl, whereby the ***aminosulfobenzoic acid*** separates and is recrystallised from hot H_2O. [Hart *Am Chem J* **2** 42–44 p 44 *1880*, DOI: 10.1021/ja02132a600; Love & Kormendy *J Org Chem* **27** 2177 *1962*, DOI: 10.1021/jo01053a068; Dorssen & Holleman *Recl Trav Chim Pays-Bas* **29** 368 *1910,* DOI: 10.1002/recl.19100291004; Holleman *Recl Trav Chim Pays-Bas* **24** 194 *1905*, DOI: 10.1002/recl.19050240602; Gless et al. US Pat 556560 15 Oct *1996* to Zeneca].
4-Amino-2-sulfobenzoic acid *[527-76-4]* has **m** (decomp on heating), **d ^{25} 1.7g/cm^3, n $^{20}_{D}$ 1.662, $pK_{Est(1)} < 0.0$, $pK_{Est(2)} \sim 1.0$, $pK_{Est(3)} \sim 4.2$.** It was prepared by sulfonating *o*-nitrotoluene to form 2-nitrotoluene-4-sulfonic acid, followed by oxidation with $KMnO_4$ to 2-nitro-4-sulfobenzoic acid then reduction with ammonium sulfide. Crystallise the aminosulfobenzoic acid from H_2O (solubility is 0.3% at 25°). It forms a ***monohydrate***, is insoluble in EtOH and Et_2O, and forms insoluble Ag and Ba salts. [Hart *Am Chem J* **2** 42–44 p 44 *1880*, DOI: 10.1021/ja02132a600; Love & Kormendy *J Org Chem* **27** 2177 *1962*, DOI: 10.1021/jo01053a068; Dorssen & Holleman *Recl Trav Chim Pays-Bas* **29** 368 *1910,* DOI: 10.1002/recl.19100291004; Holleman *Recl Trav Chim Pays-Bas* **24** 194 *1905*, DOI: 10.1002/recl.19050240602; *Beistein* **14** H 877, **14** I 769, **14** IV 2834; *Beilstein* **19** I 356, **19** III/IV 1641 for 4-NO_2.]

Ammonium dodecylsulfate (ammonium laurylsulfate) *[2235-54-3]* **$C_{12}H_{29}NO_4S$, M 283.4.** Recrystallise it first from 90% EtOH and then twice from absolute EtOH, and finally dry it in a vacuum. It is an anionic high-foam surfactant detergent available also as a 30% solution in H_2O (d^{25} 1.01g/l). [*Beilstein* **1** III 1786.]

Ammonium tetraphenylborate *[14637-34-4]* **$C_{24}H_{24}BN$, M 337.3, m *ca* 220°(dec).** Dissolve it in aqueous Me_2CO and allow crystallisation to proceed slowly; otherwise very small crystals are formed. No trace of Me_2CO is left in the crystals after drying at 120° [Davies & Staveley *Trans Faraday Soc* **53** 19 *1957*, DOI: 10.1039/TF9575300019]. Also, the salt can be precipitated from a dilute AcOH solution of sodium tetraphenylborane in the presence of NH_4^+ ions. After standing for 5 minutes, the precipitate is filtered off onto a sintered porcelain crucible, washed with very dilute AcOH and dried at room temperature for at least 24 hours [Wendlandt *Anal Chem* **28** 1001 *1956*, DOI: 10.1021/ac60114a021]. *Alternatively*, a solution of sodium tetraphenylborane (5% excess) in H_2O is added to NH_4Cl solution. After 5 minutes the precipitate is collected, washed several times with H_2O and recrystallised from aqueous Me_2CO. [Howick & Pflaum *Analyt Chim Acta* **19** 342 *1958*, DOI: 10.1016/S0003-2670(00)88173-8; *Beilstein* **16** IV 1625.] A precipitating agent for some inorganic and organometallic compounds (e.g. of Ni, Pd and Pt).

9-Anthraceneboronic acid *[100622-34-2]* **$C_{14}H_{11}BO_2$, M 222.0, m 214-216°, 203-250°.** Crystallise the boronic acid from dilute HCl (**m 180-184°**). The ***disodium salt*** has **m 209-213°**. [*Beilstein* **16** IV 1679.]

Anthraquinone Blue B (Acid Blue 45, 1,5-diamino-4,8-dihydroxy-9,10-anthraquinone-3,7-disulfonic acid di-Na salt) *[2861-02-1]* **$C_{14}H_{10}N_2NaO_{10}S_2$, M 474.3, m >300°, CI 63010, λ_{max} 595nm, $pK_{Est(1)} \sim < 0$, $pK_{Est(2)} \sim 2$, $pK_{Est(3)} \sim 9$.** Purify it by salting out an aqueous solution three times with sodium acetate, followed by repeated extraction with EtOH. Useful dye for Nylon. [McGrew & Schneider *J Am Chem Soc* **72** 2547 *1950*, DOI: 10.1021/ ja01162a059; *Beilstein* **14** H 706, 725].

Anthraquinone Blue RXO *[4403-89-8]* **M 445.5, CI 1076.** Purify the dye by salting out an aqueous solution three times with sodium acetate, followed by repeated extraction with EtOH. Useful dye for Nylon. [McGrew & Schneider *J Am Chem Soc* **72** 2547 *1950*, DOI: 10.1021/ja01162a059]. [*Beilstein* **14** H 706, 725.]

Anthraquinone Green G [Acid Green 25, Alizarin Cyanine Green F, 1,4-bis-(4-methyl-2-sulfophenyl-1-amino)-9,10-anthraquinone di-Na salt] *[4403-90-1 Na salt, 86923-71-9 diNa salt]* **$C_{28}H_{22}N_2NaO_8S_2$, M 624.6, m 235-238°, CI 61570, λ_{max} 642nm, $pK^{25} > 0$.** Purify it by salting out three times from an aqueous solution with sodium acetate, followed by repeated extraction with EtOH [McGrew & Schneider *J Am Chem Soc* **72** 2547 *1950*, DOI: 10.1021/ja01162a059]. It is a green powder that is slightly soluble in Me_2CO, EtOH and pyridine. It is soluble in concentrated H_2SO_4 to give a blue solution that becomes turquoise in colour upon dilution. [UV: Allen et al. *J Org Chem* **7** 63 *1942*, DOI: 10.1021/jo01195a009; *Beilstein* **14** H 725.]

9,10-Anthraquinone-2,6-disulfonic acid (disodium salt) *[853-68-9]* **$C_{14}H_6Na_2O_8S_2$, M 412.3, m >325°, pK_{Est} ~<0 (for SO_3H).** Crystallise it three times from water, in the dark [Moore et al. *JCS Faraday Trans 2* **82** 745 *1986*, DOI: 10.1039/F29868200745]. Its solubility in H_2O at ~25° is 1%. [*Beilstein* **11** IV 673.]

***o*-Arsanilic acid** *[2045-00-3]* **$C_6H_8AsNO_3$, M 217.0, m 145-150°, 153°, 154-155°, pK_1^{22} 3.77 (AsO_3H_2), pK_2^{22} 8.66 (AsO_3H^-).** Crystallise it from water or ethanol/ether. **POISONOUS.** [*Beilstein* **16** I 463.]
***p*-Arsanilic acid** *[98-50-0]* has **m 232°, pK_1^{22} 4.05 (AsO_3H_2), pK_2^{22} 8.66 (AsO_3H^-).** Crystallise it from water or ethanol/ether. **POISONOUS.** [*Beilstein* **16** I 466.]

Arsenazo I [Neothorin, Uranon, 3(2-arsonophenylazo)-4,5-dihydroxy-2,7-naphthalenedisulfonic acid tri Na salt] *[520-10-5, 66019-20-3]* **$C_{16}H_{10}AsN_2Na_3O_{11}S_2$, M 614.3, m >300°, ε 2.6 x 10^4 at 500nm, pH 8.0, pK_1 0.6(0.8), pK_2 3.52, pK_3 2.97(AsO_3H_2), pK_4 8.20(AsO_3H^-), pK_5 9.98(OH), pK_6 15.0.** A saturated aqueous solution of the free acid is slowly added to an equal volume of concentrated HCl. The orange precipitate is filtered off, washed with acetonitrile and dried for 1-2 hours at 110° [Fritz & Bradford *Anal Chem* **30** 1021 *1958*, DOI: 10.1021/ac60138a002]. It is then titrated with NaOH to form the di or tri Na salt as set out below. It has been used to titrate Ca and Mg (pH 10, violet/red-orange); and rare earths (pH 5.5-6.5, violet/red-orange), also Th^{4+} and U^{4+} (pH 1.7-3.0, violet/orange) and Y (pH 5.5-6.5, violet/red-orange) [Fritz et al. *Anal Chem* **30** 1111 *1958*, DOI: 10.1021/ac60138a032].
Arsenazo III **[3,6-bis(2-arsonophenylazo)-4,5-dihydroxy-2,7-naphthalenedisulfonic acid di Na salt]** *[62337-00-2 Na salt, 1668-00-4 acid]* **$C_{22}H_{18}As_2N_4O_{14}S_2$, M 776.4 (acid),** has **m >320°, λ_{max} 350nm, pK_1 -2.7, pK_2 -2.7, pK_3 0.6, pK_4 0.8, pK_5 1.6, pK_6 3.4, pK_7 6.27, pK_8 9.05, pK_9 11.98, pK_{10} 15.1.** Contaminants include monoazo derivatives, starting materials for synthesis and by-products. It is partially purified by precipitation of the dye from aqueous alkali on addition of HCl. More thorough purification is achieved by taking a 2g sample in 15-25ml of 5% aqueous NH_3 and filter. Add 10ml HCl (1:1) to the filtrate to precipitate the dye. Repeat the procedure and dissolve the solid dye (0.5g) in 7ml of a 1:1:1 mixture of *n*-propanol/880 NH_3/water at 50°. After cooling, filter the solution and chromatograph the filtrate through a cellulose column using a 3:1:1 mixture of *n*-propanol/880 NH_3/water as eluent. Collect the blue band and evaporate it to 10-15ml below 80°, then add 10ml of concentrated HCl to precipitate pure Arsenazo III. Wash it with EtOH and dry it in air [Borak et al. *Talanta* **17** 215 *1970*, DOI: 10.1016/0039-9140(70)80069-8]. The sodium salt is then obtained by dissolving it in the equivalent amount of dilute NaOH and freeze-drying. The purity of the dye can be checked by paper chromatography using M HCl as eluent. It is used for the spectrophotometric estimation of Th, U, Zr, rare earths, Cd and Zn [Michaylova & Yuroukova *Anal Chim Acta* **68** 73 *1974*, DOI: 10.1016/S0003-2670(01)85147-3.]

Benzaldehyde-2-sulfonic acid sodium salt

[1008-72-6] **$C_7H_5NaO_4S$, M 208.2, m decomposes on heating.** It forms white prisms or plates by extracting with boiling EtOH, filtering, evaporating to dryness and recrystallising the Na salt from a small volume of H_2O. The ***N*-phenylhydrazone sodium salt** recrystallises from H_2O with **m 174.5°**. [Gnehm & Schüle *Justus Liebigs Ann Chem* **299** 347 *1898*, DOI: 10.1002/jlac.18982990212; *Beilstein* **11** IV 652.]

Benzeneselenenyl bromide (phenylselenenyl bromide) *[34837-55-3]* **C_6H_5BrSe, M 236.0, m 58-62°, 60°, 62°, b 107-108°/15mm, 134°/35mm.** Distil it in a vacuum, recrystallise it from petroleum ether, $CHCl_3$ (EtOH free), or Et_2O (cooling mixture) to give dark red or orange crystals. These sublime at 25°/0.001mm and are soluble in hexane, CH_2Cl_2, Et_2O and THF. [Behaghel et al. *Chem Ber* **65** 812 *1932*, DOI: 10.1002/cber.19320650525; Pitteloud & Petrzilka *Helv Chim Acta* **62** 1319 *1979*, DOI: 10.1002/hlca.19790620445]. [*Beilstein* **6** III 1111.] **HIGHLY TOXIC.**

Benzeneselenenyl chloride (benzeneselenyl chloride, phenylselenenyl chloride) *[5707-04-0]* **C_6H_5ClSe, M 191.5, m 59-60°, 64-65°, b 92°/5mm, 120°/20mm.** Purify it by distillation in a vacuum, and recrystallisation (orange needles) from hexane [Foster *J Am Chem Soc* **55** 822 *1933*, DOI: 10.1021/ja01329a063; Foster et al. *Recl Trav Chim Pays-Bas* **53** 405, 408 *1934*, DOI: 10.1002/recl.19340530504; Behaghel & Seibert *Chem Ber* **66** 708 *1933*, DOI: 10.1002/cber.19330660520]. [*Beilstein* **6** III 1110.] **HIGHLY TOXIC.**

Benzeneseleninic acid *[6996-92-5]* **$C_6H_6O_2Se$, M 189.1, m 121-124°, 122-124°, b 114.4°/760mm, pK^{25} 4.70.** Add 10% excess of 15M NH_3 to the solid acid and stir until the solid dissolves, filter, decolorise with charcoal (2x, Norite) and acidify by slow addition of 6M HCl, filter the solid off and wash it with H_2O. Dissolve the acid in the minimum volume of MeOH, and this solution is added dropwise to boiling H_2O until cloudiness appears. At this point add 25% more boiling H_2O, filter hot (decolorise if necessary) and cool rapidly, with scratching, to 0°. After 30 minutes the solid is filtered off and recrystallised as before but with very slow cooling. The colourless needles are filtered off and dried in a vacuum desiccator ($CaCl_2$) before the melting point is measured [McCullough & Gould *J Am Chem Soc* **71** 674 *1949*, DOI: 10.1021/ja01170a083]. The ***HNO_3 complex*** has **m 112°**. [*Beilstein* **11** H 422, **11** I 110, **11** III 716.] **TOXIC** solid.
Benzeneseleninic anhydride *[17697-12-0]* **$C_{12}H_{10}O_3Se_2$, M 360.1,** has **m 124-126°, 164-165°, 165-170°, 170-173°**. When the anhydride is recrystallised from $*C_6H_6$ it has **m 124-126°**, but when this is heated at 140°/1 hour in a vacuum or at 90°/2 hours it has **m 164-165°** and gives a solid **m 124-126°** when then recrystallised from $*C_6H_6$. Both depress the melting point of the acid $PhSeO_2H$. If the low melting anhydride is dissolved in $*C_6H_6$ and seeded with the high melting anhydride, the high melting anhydride crystallises out. It readily absorbs H_2O to form the acid ($PhSeO_2H$, **m 122-124°**). Because of this, the commercial anhydride could contain up to 30% of the acid. It is best purified by converting to the ***HNO_3 complex*** (**m 112°**) and heating this *in vacuo* at 120°/72 hours to give the anhydride as a white powder **m 164-165°**. *Alternatively*, heat the anhydride *in vacuo* at 120°/72 hours until the IR shows no OH band. [Ayrey et al. *J Chem Soc* 2089 *1962*, DOI: 10.1039/JR9620002089; Barton et al. *JCS Perkin Trans 1* 567 *1977*, DOI: 10.1039/P19770000567; *Beilstein* **11** H 422, **11** I 110, **11** III 716, **11** IV 708.] **TOXIC** solid.

Benzeneselenol (phenylselenol, selenophenol) *[645-96-5]* **C_6H_6Se, M 157.1, b 57-59°/8mm, 71-72°/18mm, 84-86°/25mm, d_4^{20} 1.480, n_D^{20} 1.616.** Dissolve it in aqueous N NaOH, acidify this with concentrated HCl and extract with Et_2O, dry over $CaCl_2$, filter, evaporate on a steam bath and distil the residue from a Claisen flask or through a short column collecting the middle fraction, and seal immediately in a glass vial, otherwise the colourless liquid becomes yellow. The alkali insoluble materials consist of ***diphenylselenide*** (**b 167°/16mm**) and ***diphenyldiselenide***, **m 63°** (from EtOH). **TOXIC**, use rubber gloves. It has a foul odour. [Foster *Org Synth* Coll Vol **3** 771 *1955*, DOI: 10.152227/orgsyn.024.0089; *Beilstein* **6** III 1104, 1110, **6** IV 1777.] The anion is a strong nucleophile [Sonoda in *Encyclopedia of Reagents for Organic Synthesis* (ed. L. Paquette) J. Wiley & Sons, NY 2005, DOI:10.1002/047084289X.rb018].

Benzeneselenonic acid (benzeneselenoic acid) *[39254-48-3]* **$C_6H_6O_3Se$, M 205.1, m 64°, pK^{25} 4.79.** It has been prepared by reaction of $*C_6H_6$ with SeO_3 in liquid SO_2, and isolated in good yield *via* its barium salt. Purify it by dissolving in H_2O and passing through a strong cation exchange resin (H^+ form). Evaporate the effluent under reduced pressure and dry the residue in a high vacuum to give colourless hygroscopic crystals [Dostál et al. *Z Chem* **6** 153 *1966*, DOI: 10.1002/zfch.19660060413; and IR: Dostál et al. *Chem Ber* **104** 2044 *1971*, DOI: 10.1002/cber.19711040704]. [*Beilstein* **11** H 422, **11** I 111.]

Benzenestibonic acid *[535-46-6]* **$C_6H_7O_3Sb$, M 248.9, m >285°(dec).** It crystallises from acetic acid (minute white crystals), or from EtOH/$CHCl_3$ mixture on addition of water (large diamond-shaped glistening crystals). It is insoluble in H_2O, slightly soluble in EtOH, soluble in Me_2CO, warm $CHCl_3$ and amyl acetate. It has also been purified by dissolving it in aqueous Na_2CO_3, filtering, then acidifiying with dilute H_2SO_4 which precipitates the stibonic acid as a fine white powder. When moist it has a characteristic, not unpleasant, odour. [Schmidt *Justus Liebigs Ann Chem* **421** 174 *1920*, DOI: 10.1002/jlac.19204210204; May *J Chem Soc* **101** 1033 *1912*, DOI: 10.1039/CT9120101033.]

m-**Benzenedisulfonic acid** *[98-48-6]* **$C_6H_6O_6S_2$, M 238.2, pK_{Est} <0.** Free it from H_2SO_4 by conversion to the calcium or barium salts (using $Ca(OH)_2$ or $Ba(OH)_2$, and filtering). The calcium salt is then converted to the potassium salt, using K_2CO_3. Both the potassium and the barium salts are recrystallised from H_2O, and the acid is regenerated by passing through the H^+ form of a strong cation exchange resin. The acid is recrystallised twice from conductivity water and dried over $CaCl_2$ at 25°. [Atkinson et al. *J Am Chem Soc* **83** 1570 *1961*, DOI: 10.1021/ja01468a008.] It has also been crystallised from Et_2O and dried in a vacuum oven. The ***S-benzylisothiuronium salt*** has **m 214.3°** (from EtOH/H_2O). [*Beilstein* **11** IV 553.] It is best kept as the ***di-***

***disodium salt*, *[831-59-4]* M 180.2, $C_6H_4O_6S_2Na_2$,** which decomposes on heating [*Beilstein* **11** H 199, **11** I 48, **11** II 213, **11** III 453.]
m-***Benzenedisulfonyl chloride*** *[585-47-7]* **$C_6H_4Cl_2O_2S_2$, M 275.1,** has **m 59-60°, 63°.** Crystallise it from $CHCl_3$ (EtOH free, by passing through an alumina column) or *C_6H_6/petroleum ether and dry it in a 20mm vacuum. [*Beilstein* **11** IV 553.]

Benzene-1,2-dithiol (1,2-dimercaptobenzene) *[17534-15-5]* **$C_6H_6S_2$, M 142.2, m 24-25°, 27-28°, b 119-120°/17mm, pK$_{Est(1)}$ ~6.1, pK $_{Est(2)}$ ~9.5.** Likely impurities are the oxidation products, the disulfides which could be polymeric. Dissolve it in aqueous NaOH until the solution is alkaline. Extract with Et_2O and discard the extract. Acidify with cold HCl (diluted 1:1 by volume with H_2O) to Congo Red paper under N_2 and extract it three times with Et_2O. Dry the Et_2O with Na_2SO_4, filter, evaporate and distil the residue under reduced pressure in an atmosphere of N_2. The distillate solidifies on cooling. [UV: Dewar et al. *J Chem Soc* 3076 *1958*, DOI: 10.1039/JR9580003076; Adams & Ferretti *J Am Chem Soc* **81** 4939 *1959*, DOI: 10.1021/ja01527a045; Ferretti *Org Synth* Coll Vol **5** 419 *1973*, DOI: 10.15227/orgsyn.042.0054; *Beilstein* **6** IV 5651.]
Benzene-1,3-dithiol **(1,3-dimercaptobenzene)** *[626-04-0]* has **m 24-25°, 27-28°, b 62°/0.2mm, 128-129°/16mm, 244°/atm, 245°/atm, d^{25} 1.236, pK$_{Est(1)}$ ~6.0, pK $_{Est(2)}$ ~8.0.** Purification is as for the preceding 1,2-isomer. [*Beilstein* **6** IV 5705.]

Benzenesulfinic acid *[618-41-7]* **$C_6H_6O_2S$, M 142.2, m 84°, pK^{25} 2.16(2.74).** The acid is purified by dissolving the Na salt in H_2O, acidifying to Congo Red paper with HCl and adding a concentrated solution of $FeCl_3$ whereby Fe sulfinate precipitates. Collect the salt, wash it with a little H_2O, drain, suspend it in H_2O and add a slight excess of 1.5M aqueous NaOH. The $Fe(OH)_3$ precipitates, it is filtered off, the sulfinic acid in the aqueous solution is extracted with Et_2O, the extract is dried (Na_2SO_4) and evaporated to give colourless crystals of benzenesulfinic acid **m 84°** which are stored under N_2 in the dark, as it slowly oxidises in air to the sulfonic acid. [*Beilstein* **11** H 2, 26, **11** I 3, **11** II 3, **11** III 3, **11** IV 3.] ***Sodium benzenesulfinate*** *[873-55-2]* **$C_6H_5O_2SNa$, M 164.2,** prepared from the acid with one equivalent of NaOH has **m ~300°**. [*Beilstein* **11** IV 3.]

Benzenesulfonic acid *[anhydrous 98-11-3; monohydrate 26158-00-9]* **$C_6H_6O_3S$, M 158.2, m 43-44°, 50-55°(anhydrous), 65-66°, pK^{25} -2.7, 0.70, (2.53?)** Purify benzenesulfonic acid by dissolving it in a small volume of distilled H_2O and stirring with slightly less than the theoretical amount of $BaCO_3$. When effervescence is complete and the solution is still acidic, filter off the insoluble ***barium benzenesulfonate***. The salt is collected and dried to constant weight *in vacuo*, then suspended in H_2O and stirred with a little less than the equivalent (half mol.) of sulfuric acid. The insoluble $BaSO_4$ (containing a little barium benzenesulfonate) is filtered off and the filtrate containing the ***free acid*** is evaporated in a high vacuum. The oily residue will eventually crystallise when completely anhydrous. A 32% commercial acid is allowed to fractionally crystallise at room temperature over P_2O_5 in a vacuum desiccator giving fine colourless deliquescent plates **m 52.5°**. The anhydrous crystalline acid is deliquescent and should be stored over anhydrous Na_2SO_4 in the dark, and should be used in subdued sunlight as it darkens under sunlight. The main impurity is Fe which readily separates as the Fe salt in the early fractions [Taylor & Vincent *J Chem Soc* 3218 *1952*, DOI: 10.1039/JR9520003218]. The ***S-benzylisothiuronium salt*** has **m 148°** (from EtOH/H_2O). It is a strong acid, and an IRRITANT to the skin and eyes. [See Adams & Marvel *Org Synth* Coll Vol **1** 84 *1941*, DOI: 10.15227/orgsyn.001.0021; Michael & Adair *Chem Ber* **10** 583 *1877*, DOI: 10.1002/cber.187701001162; *Beilstein* **11** IV 27.]
Benzenesulfonyl chloride *[98-09-9]* **$C_6H_5ClO_2S$, M 176.6,** has **m 14.5°, b 120°/10mm, 177°/100mm, 251.2°/760mm(dec), d_4^{20} 1.384.** Distil the sulfonyl chloride, preferably under a vacuum, then treat it with 3mole % each of toluene and $AlCl_3$, and allow it to stand overnight. The sulfonyl chloride is distilled off at 1mm pressure and then carefully fractionally distilled at 10mm in an all-glass column. [Adams & Marvel *Org Synth* Coll Vol **I** 84 *1941*, DOI: 10.15227/orgsyn.001.0021; Jensen & Brown *J Am Chem Soc* **80** 4042 *1958*, DOI: 10.1021/ja01548a055; *Beilstein* **11** IV 49.] It is reactive and **TOXIC, handle with gloves.** With concentrated aqueous NH_3 it is converted into ***benzenesulfonamide*** *[98-10-2]* **C_6H_7NOS, M157.2,** with **m 153°** after recrystallisation from H_2O or aqueous EtOH. [*Beilstein* **11** IV 50.] ***Benzenesulfonyl hydrazide*** **(Porofor, BSH)** *[98-09-9]* **$C_6H_8N_2O_2S$, M 172.2,** has **m 101-103°, 103-104° (with evolution of N_2).** The hydrazide separates out when benzenesulfonyl chloride is treated with aqueous hydrazine and cooling. It crystallises from H_2O or aqueous EtOH. [*Beilstein* **11** IV 94.]

Benzenesulfonic anhydride *[512-35-6]* **$C_{12}H_{20}O_5S_2$, M 298.3,** has **m 88-91°.** Crystallise the anhydride from Et_2O (**m** 88.5-91.5°), $CHCl_3$ or chlorobenzene (**m 90-92°**). Store it dry. [Field *J Am Chem Soc* **74** 394 *1952*, DOI: 10.1021/ja01122a032; *Beilstein* **11** H 3, **11** I 11, **11** II 23, **11** III 50, **11** IV 50.]

Benzopurpurin 4B {3,3'-[(3,3'-dimethyl[1,1'-biphenyl]-4,4'-diyl)bis(azo)]bis[4-amino-1-naphthalene-sulfonic acid] di-Na salt, Direct red 2} *[992-59-6]* **$C_{34}H_{26}N_6Na_2O_6S_2$, M 724.7, decomposes without melting, λ_{max} 500nm, CI 23500, pK^{25} <0**. It crystallises from H_2O, is soluble in EtOH, Me_2CO, $EtOCH_2CH_2OH$, insoluble in other organic solvents, and soluble in aqueous NaOH or H_2SO_4. It is a biological stain that is violet at pH 1.2 and red at pH 4.0 and is used for detecting Al, Mg, Hg, Au and U. Used also for dying rayon and cotton. [*Beilstein* **16** H 411, **16** II 224, **16** III 474, **16** IV 601.]

Benzotriazol-1-yloxytris(dimethylamino)phosphonium hexafluorophosphate (BOP, Castro's Reagent) *[56602-33-6]* **$C_{12}H_{22}F_6N_6OP_2$, M 442.3, m > 130°(dec), 147-149°(dec).** Dissolve it in CH_2Cl_2, dry ($MgSO_4$), filter, concentrate it under a vacuum, then add dry Et_2O and filter off the first crop. Add CH_2Cl_2 to the filtrate and concentrate again to obtain a second crop. The solid is washed with dry Et_2O and dried in a vacuum. Also recrystallise it from dry Me_2CO/Et_2O and check the purity by NMR. Store it in the dark. [Castro et al. *Synthesis* 751 *1976*, DOI: 10.1055/s-002-1666; Nguyen et al *JCS Perkin Trans I* 1915 *1987*, DOI: 10.1039/P19870001915; Coste et al. *Tetrahedron Lett* **36** 4253 *1995*, DOI: 10.1016/0040-4039(95)00736-V.]

S-Benzylisothiuronium chloride *[538-28-3]* **$C_8H_{11}ClN_2S$, M 202.7, two forms, m 146-148° and 172-174°, pK_{Est} ~9.8 (free base).** This useful compound which forms characteristic salts with carboxylic, sulfinic and sulfonic acids is prepared from benzyl chloride (126g) and thiourea (76g) in EtOH (200ml), whereby a vigorous reaction occurs to form a homogeneous solution which is boiled for half an hour. On cooling, the chloride salt forms a crystalline magma which is filtered off and recrystallised from EtOH, or a mixture of equal volumes of concentrated HCl and H_2O. Crystallise the chloride from 0.2M HCl (2ml/g) or EtOH and it dry in air. It is ***dimorphic***. When the lower melting form is dissolved in EtOH and seeded with crystals of the higher melting form, the higher melting form crystallises out. However, the same characteristic carboxylic, sulfinic and sulfonic isothiuronium salts are formed whichever crystals are used. The procedure for preparing the salts for characterisation of organic acids is as follows: To a strong solution of the Na or K salt of the organic acid in aqueous EtOH or H_2O is added, rapidly with stirring, a slight excess of a 15% solution of S-benzylthiuronium chloride in hot EtOH. On cooling, the desired S-benzylthiuronium salt crystallises out of solution in a highly pure state. It can be recrystallised from EtOH. In a few cases the solution has to be evaporated in order to obtain crystals. This can happen with weak carboxylic acids where the salts readily hydrolyse. To avoid this, the solutions need to be as concentrated as possible, or better avoid the presence of H_2O in the solvent. This does not occur with strong acids that include the sulfinic and sulfonic acids. Careless manipulation of salts of very weak acids, e.g. repeated recrystallisation, leads to hydrolysis where the free base decomposes to form benzylmercaptan which results in a noxious odour. [Donleavy *J Am Chem Soc* **58** 1004 *1936*, DOI: 10.1021/ja01297a048; *Beilstein* **6** III 1600.]

Benzyl mercaptan *[100-53-8]* **C_7H_8S, M 124.2, b 70.5-70.7°/9.5mm, 194-195°/atm, d_4^{20} 1.058, n_D^{20} 1.5761, pK^{25} 9.43.** Purify benzyl mercaptan *via* the ***mercury salt*** [see Kern *J Am Chem Soc* **75** 1865 *1953*, DOI: 10.1021/ja01104a025], which crystallises from *benzene as needles (**m 121°**), and then dissolve it in $CHCl_3$. Pass H_2S gas through the solution to regenerate the mercaptan. The HgS that precipitates is filtered off and washed thoroughly with $CHCl_3$. The filtrate and washings are evaporated to remove $CHCl_3$; then the residue is fractionally distilled under reduced pressure. Store under N_2 as it oxidises in air to form ***dibenzyl disulfide***. [Mackle & McClean, *Trans Faraday Soc* **58** 895 *1962*, DOI: 10.1039/TF9625800895]. [*Beilstein* **6** IV 2632.]

Benzyl Orange [4-(4-benzylaminophenylazo)benzenesulfonic acid potassium salt] *[589-02-6 K-salt, 36402-77-4 Na-salt]* **$C_{19}H_{16}N_3KO_3S$, M 405.5, $pK_{Est(1)}$~<0, $pK_{Est(2)}$~3.8.** Crystallise it from H_2O.

Benzyltriphenylphosphonium chloride *[1100-88-5]* **$C_{25}H_{22}ClP$, M 388.9, m 280° (sintering), 287-288°, 337°.** Wash it with Et_2O and crystallise it from EtOH (six-sided plates). It is ***hygroscopic*** and forms crystals with one molecule of H_2O. [Michaelis et al. *Justus Liebigs Ann Chem* **229** 320 *1885*, DOI: 10.1002/jlac.18852290304; Kröhnke *Chem Ber* **83** 295 *1950*, DOI: 10.1002/cber.19500830318; *Beilstein* **16** IV

994.]

Biphenyl-2-yl diphenyl phosphate *[132-29-6]* **$C_{24}H_{19}O_4P$, M 402.4, b 280-290º/9mm, 494.4 ±24º/760mm, d $^{25}_{25}$ 1.184, n $^{25}_{D}$ 1.5925.** Distil the ester in a vacuum, then percolate it through an alumina column. Pass the ester through a packed column maintained at 150º to remove residual traces of volatile materials by a counter-current stream of nitrogen at reduced pressure. [Dobry & Keller *J Phys Chem* **61** 1448 *1957*, DOI: 10.1021/j150556a052; *Beilstein* **6** III 3295, **6** IV 4585.]

Bis(*p-tert*-butylphenyl)phenyl phosphate *[115-87-7]* **$C_{26}H_{31}O_4P$, M 438.5, b 281º/5.5mm, d $^{25}_{4}$ 1.108, n $^{25}_{D}$ 1.5412.** Purify as for biphenyl-2-yl diphenyl phosphate (above). [*Beilstein* **6** III 1871, **6** IV 3310.]

Bis(2-chlorophenyl) phenyl phosphate *[597-80-8]* **$C_{18}H_{13}Cl_2O_4P$, M 395.2, b 254º/4mm, n $^{25}_{D}$ 1.5767**. Purify as for biphenyl-2-yl diphenyl phosphate (above). [Fox et al. *J Phys Chem* **59** 1097 *1955*, DOI: 10.1021/j150532a027; *Beilstein* **6** III 680, **6** IV 807.]

Bis(2-ethylhexyl) 2-ethylhexyl phosphonate *[25103-23-5, 126-63-6, 1300-52-3]* **$C_{24}H_{51}O_3P$, M 418.6, b 479.1 ±14º/760mm, d 0.9 ±0.1g/cm^3, n $^{25}_{D}$ 1.4473.** Purify it by stirring a 0.4M solution in *benzene with an equal volume of 6M HCl at *ca* 60º for 8 hours. The *benzene layer is then shaken successively with equal volumes of water (twice), aqueous 5% Na_2CO_3 (three times), and water (eight times), followed by evaporation of the *benzene and distillation of the residue under reduced pressure at room temperature (using a rotating evacuated flask). It should be stored dry and in the dark [Peppard et al. *J Inorg Nucl Chem* **24** 1387 *1962*, DOI: 10.1016/0022-1902(62)80147-X]. Distil it in a vacuum, then percolate it through an alumina column before finally passing it through a packed column maintained at 150º where residual traces of volatile materials are removed by a counter-current stream of N_2 under reduced pressure [Dobry & Keller *J Phys Chem* **61** 1448 *1957*, DOI: 10.1021/j150556a052].

Bis(2-ethylhexyl) phosphoric acid ('diisooctyl' phosphate) *[298-07-7, 27215-10-7]* **$C_{16}H_{35}O_4P$, M 322.4, m -60º, -50º, b 209º/10mm, 393º/760mm, d $^{20}_{4}$ 0.965, pK_{Est} ~1.7.** Contaminants of commercial samples include the monoester, polyphosphates, pyrophosphate, 2-ethylhexanol and metal impurities. Dissolve the acid in *n*-hexane to give an 0.8M solution. Wash this with an equal volume of M HNO_3, then with saturated $(NH_4)_2CO_3$ solution, with 3M HNO_3, and twice with water [Petrow & Allen *Anal Chem* **33** 1303 *1961*, DOI: 10.1021/ac60178a004]. Similarly, the impure sodium salt, after scrubbing with petroleum ether, is acidified with HCl and the free organic acid is extracted into petroleum ether and purified as above [Peppard et al. *J Inorg Nucl Chem* **7** 231 *1958*, DOI: 10.1016/0022-1902(58)80075-5], or as described by Stewart & Crandall [*J Am Chem Soc* **73** 1377 *1951*, DOI: 10.1021/ja01147a533]. It can be purified *via* its copper salt [McDowell et al. *J Inorg Nucl Chem* **38** 2127 *1976*, DOI: 10.1016/0022-1902(76)80486-1]. [*Beilstein* **1** IV 1796.] It can be used as a solvent for the exctraction of uranium and rare earth metals [Sato *Hydrometallurgy* **22** 121 *1989*: DOI: 10.1016/0304-386X(89)90045-5], and similarly it can be used for extracting Fe, but it must be in the reduced form Fe^{2+}.

Bis-(4-fluoro-3-nitrophenyl) sulfone *[312-30-1]* **$C_{12}H_6F_2N_2O_6S$, M 344.3, m 193-194º.** Recrystallise the sulfone from Me_2CO and H_2O (5:1). It should give a yellow colour in aqueous base. [Zahn & Zuber *Chem Ber* **86** 172 *1953*, DOI: 10.1002/cber.19530860209; *Beilstein* **6** IV 172.]

2,4-Bis(methylthio)-1,3,2λ^5,4λ^5-dithiadiphosphetane-2,4-dithione (Davy's reagent methyl) *[82737-61-9]* **$C_2H_6P_2S_6$, M 284.4, m 160º, b 382.5º/760mm, d 1.69g/cm^3.** It crystallises from *C_6H_6 in yellow plates or from hot trichlorobenzene. The low melting point reported in the literature (112º with gradual softening at 68-102º) has been attributed to the presence of elemental sulfur in the crystals. It has a **foul odour** and is a ***suspected carcinogen***. [Yousif et al. *Tetrahedron* **40** 2663 *1984*, DOI: 10.1016/S0040-4020(01)96883-8; Scott et al. *J Org Chem* **22** 789 *1957*, DOI: 10.1021/jo01358a019.]

Bis-(phenylsulfonyl)imide (dibenzenedisulfimide) *[2618-96-4]* **$C_{12}H_{11}NO_4S_2$, M 297.4, m 157-158º.** Obtained by adding slowly a 1:1 solution of benzenesulfonyl chloride (2.2 mol) in Me_2CO to a 4% solution of NH_4Cl (1 mol) with stirring followed, at 0º, by addition of 10N aqueous NaOH until the pH rises to 8, and the

temperature is allowed to rise to 25°. Acetone was distilled off, and ***diphenylsulfinimide sodium salt*** separated [~90% yield, **m 327-329°** (also **314-316°** reported); and was recrystallised from H_2O in needles, and dried at 100°]. It can similarly be prepared from benzenesulfonamide by reaction with benzenesulfonyl chloride in the presence of NaOH. The ***free imide*** is obtained on acidification, extraction into Et_2O, and finally crystallised as white crystals from Et_2O. It readily forms stable recrystallisable salts with a variety of amines, amino acids and esters, as well as a variety of heterocyclic compounds and alkaloids; and used as a method for purifying these compounds (see Tables 1 to 5 in Chapter 2). The ***L-glutamic acid di-tert-butyl ester dibenzenesulfimide salt*** *[16874-06-9]* has m 139-141°, $[\alpha]_D^{20}$ +12 (c 2, MeOH); the ***glycine tert-butyl ester dibenzenesulfimide salt*** *[77284-30-1]* has m 154-157°; the ***L-aspartic acid di-tert-butyl ester dibenzenesulfimide salt*** *[70534-48-4]* has m 150-155°, $[\alpha]_D^{20}$ +6.6 (c 2, pyridine); and the ***L-proline tert-butyl ester dibenzenesulfimide salt*** *[83283-35-6]* and are available commercially. ***Bis-(4-chlorobenzenesulfonyl)imide sodium salt*** crystallises as white needles from H_2O, which on drying at 100°, have **m 298°** (also **297-300°, >360°, dec**). The ***free imide*** is obtained on acidification, and crystallises from H_2O (**m 207-208°**) or from *C_6H_6 (**m 206-207°**). [Runge et al. *Chem Ber* **88** 533 *1955*, DOI: 10.1002/cber.19550880414; Runge et al. *Chem Ber* **86** 1571 *1953*, DOI: 10.1002/cber.19530861216; Runge & Pfeiffer *Chem Ber* **90** 1757 *1957*, DOI: 10.1002/ cber.19570900910; Helferich & Grünert *Chem Ber* **73** 1131 *1940*, DOI: 10.1002/cber.19400731019; Helferich & Flechig *Chem Ber* **75** 532 *1942*, DOI: 10.1002/cber.19420750514; *Beilstein* **11** H 49, **11** IV 85, 122.] ***Dibenzenesulfonimide*** is soluble in alkaline solution, used in electroplating, and a primary brightner instead of saccharin with better leveling ability, and with lower consumption than saccharin. [See Tables 1 to 5 in Chapter 2.]

Bismuthiol I (2,5-dimercapto-1,3,4-thiadiazole) potassium salt *[4628-94-8]* **$C_2H_2N_2S_3$, M 226.4, m 274-276°(dec), 275-276°(dec), ~294°(dec), $pK_{Est(1)}$~4.1.** Usually contaminated with disulfide. Purify it by recrystallisation from EtOH (yellow needles). ***Bismuthiol I*** *[1072-71-5]* $C_2K_2N_2S_3$, M 150.3, is the ***free acid*** and has **m 165°(dec)** (**m 162°** and **168°** also reported), $pK_{Est(1)}$ ~4.5. This reagent has been used for the spectroscopic detection of Bi, Cu, Pb and Sb, and forms complexes with Pd and Pt. [Busch *Chem Ber* **27** 2507 *1894*, DOI: 10.1002/cber.189402702251; Najumdar & Chakrabarty *Anal Chim Acta* **19** 372 *1958*, DOI: 10.1016/S0003-2670(00)88179-9; Mura et al. *Inorg Chim Acta* **97** 45 *1985*, DOI: 10.1016/S0020-1693(00)87988-8; *Beilstein* **27** H 677, **27** IV 7725.]

Bis-(2-nitrophenyl) disulfide *[1155-00-6]* **$C_{12}H_8N_2O_4S_2$, M 308.3, m 192-195°, 195°, 194-197°, 198-199°.** Purify the disulfide by recrystallisation from glacial AcOH or from *C_6H_6 and the yellow needles are dried in an oven at 100° until the odour of the solvent is absent. It is sparingly soluble in EtOH and Me_2CO. It is used for the preparation of ***orthanilic acid***, see below. [Bogert & Stull *Org Synth* Coll Vol **1** 220 *1941*, DOI: 10.15227/orgsyn.008.0064; Bauer & Cymerman *J Chem Soc* 3433 *1949*, DOI: 10.1039/JR9490003433; *Beilstein* **6** IV 1672.]

Bis[4-(1,1,3,3-tetramethylbutyl)phenyl]phosphate calcium salt (Selectophore) *[40835-97-0]* **$C_{56}H_{84}CaO_8P_2$, M 987.3.** The Ca diester salt is washed with H_2O (x3) and MeOH (x3) alternately and dried in a vacuum oven at 50°. If the Ca salt is contaminated with much Ca salt of the ***monoester***, then it (10g) isconverted to the ***free acid*** by adding 6N HCl (*ca* 10 volumes) and Et_2O (> 50 volumes) is added to it and stirred vigorously to form the free acids. When no white precipitate remains (*ca* 5 minutes), the Et_2O is separated, washed with H_2O (2x > 50 ml) and dried by filtering through a bed of anhydrous Na_2SO_4 (11 x 5 cm) which is then washed with Et_2O (2x >50 ml). Evaporation gives an oil (TLC R_F 0.81 for diester and 0.50 for monoester). The oil is dissolved in *benzene (*ca* 25ml) and extracted with ethane-1,2-diol (25ml, 10x). After ten washings, a small sample of the *benzene layer is washed twice with H_2O to remove the diol and showed that it is pure ***bis-[4-(1,1,3,3-tetramethylbutyl)-phenyl]phosphoric acid*** by TLC, i.e. no monophosphate. To form the ***Ca salt***, the oil is dissolved in MeOH and to it is added the equivalent amount of $CaCl_2$ together with aqueous NaOH to keep the pH >10. The resulting white precipitate is collected, washed alternately with 3 batches of H_2O and MeOH and dried in a vacuum oven at 50°. [Craggs et al. *J Inorg Nucl Chem* **40** 1483 *1978*, DOI: 10.1016/0022-1902(78)80455-2; Morton et al. *Anal Biochem* **157** 345 *1986*, DOI: 10.1016/0003-2697(86)90636-6.] It has been used as a component of a polyaniline Ca-selective conducting electrode membrane [Lindfors & Ivaska *Analyt Chim Acta* **437** 171 *2001*, DOI: 10.1016/S0003-2670(01)00996-5].

2,4-Bis(*p*-tolylthio)-1,3,2λ^5,4λ^5-dithiadiphosphetane-2,4-dithione (Heimgartner's reagent or Davy's rea-

gent *p*-tolyl) *[114234-09-2]* **$C_{14}H_{14}P_2S_6$, M 436.6, m 175-176°(dec).** Recrystallise it from toluene (light yellow solid), wash it with Et_2O and dry *in vacuo*. It has IR (KBr) with ν_{max} at 3420w, 1597w, 1488w, 1387w, 1183w, 1020w, 941w, 811s and 684s cm-1; and MS has *m/e* at 218 (10%, $M^+/2$). [Wipf et al. *Helv Chim Acta* **70** 1001 *1987*, DOI: 10.1002/hlca.19870700412.]

***N,O*-Bis(trimethylsilyl)acetamide (BSA)** *[10416-59-8]* **$C_8H_{21}NOSi_2$, M 203.4, b 71-73°/35mm, d_4^{20} 0.836, n_D^{20} 1.4150.** Fractionate it through a spinning band column and collect liquid **b 71-73°/35mm**, and not higher because the main impurity $MeCONHSiMe_3$ distils at **b 105-107°/35mm**. It is used for derivatising alcohols and sugars [Klebe et al. *J Am Chem Soc* **88** 3390 *1966*, DOI: 10.1021/ja00966a038; see Blau, Karl; J. M. Halket *Handbook of Derivatives for Chromatography* (2nd ed.). John Wiley & Sons *1993*, ISBN 0-471-92699-X; Matsuo et al. *Carbohydr Res* **241** 209 *1993*, DOI: 10.1016/0008-6215(93)80107-P; Johnson *Carbohydr Res* **237** 313 *1992*, DOI: 10.1016/S0008-6215(92)84254-P]. It is **FLAMMABLE** and **TOXIC**.

Bis(trimethylsilyl)acetylene (BTMSA) *[14630-40-1]* **$C_8H_{18}Si_2$, M 170.4, m 24-24.5°, 26°, b 134-136°/atm.** Dissolve it in petroleum ether and wash it with ice-cold dilute HCl. The petroleum ether extract is dried ($MgSO_4$), evaporated and fractionated at 760mm. Its solubility in H_2O is 31mg/L at ~25°. [Walton & Waugh *J Organomet Chem* **37** 45 *1972*, DOI: 10.1016/S0022-328X(00)89260-8; *Beilstein* **4** IV 3950.]

Bis(trimethylsilyl) selenide *[4099-46-1]* **$C_6H_{18}SeSi_2$, M 225.3, m -7°, b 31°/2mm, 45-46°/5.3mm, 176°/atm, d^{25} 0.9010g/cm^3.** Purify by redistillation at high vacuum preferably in an inert atmosphere. Prepare it as follows: Under a dry inert (argon) atmosphere containing 1M $Li(Et)_3BH$ in THF (105ml, 0.105mol) and cooled in an ice bath, is added selenium shot (3.95g, 0.0500mol). The mixture is slowly warmed to ~25°, with stirring during 2 hours, then cooled to ice-bath temperature and Me_3SiCl (12.6g, 0.117mol, see *[75-77-4]* below) is added all at once. The mixture is stirred for 2 hours at ~25°, the low boiling volatiles are removed at low vacuum, then the product is distilled at higher vacuum to give the colourless selenide [10.6g, 95%, **b 45-46°/5.3mm**, ^{1}H NMR ($CDCl_3$) one peak at δ 0.50]. Store at -35° in a drybox. [Detty & Seidler *J Org Chem* **47** 1354 *1982*, DOI: 10.1021/jo00346a041; see also Steigerwald et al. *J Am Chem Soc* **110** 3046 *1988*, DOI: 10.1021/ja00218a008.]
It is a colourless, air sensitive liquid with a strong odour, readily hydrolysed by moist air to give highly toxic H_2Se, so work under an efficient fume cupboard. Store under argon or N_2 at -20°, at which temperature it is a solid. It slowly deposits amorphous Se which is red in colour. Destroy the pot residue in an inert atmosphere after treating with cold MeOH. Any gases that escape should be absorbed in an aqueous alkaline solution. [*Osawa & Sonoda 15 APR 2001 e-EUROS Encyclopedia of reagents in organic synthesis*, DOI: 10.1002/047084289X.rb221.]

Bis(trimethylsilyl) sulfide (hexamethyldisilathiane) *[3385-94-2]* **$C_6H_{18}SSi_2$, M 178.5, b 65-67°/16mm, 162.5-163.5°/750mm, 164°/760mm, d_4^{20} 0.85, n_D^{20} 1.4598.** Dissolve it in petroleum ether (b *ca* 40°), remove the solvent and distil it. Redistil it under atmospheric pressure of dry N_2. It is collected as a colourless liquid which solidifies to a white solid in Dry-ice. On standing for several days it turns yellow possibly due to liberation of sulfur. Store it below 4° under dry N_2. It is prepared by adding Ag_2S (37g, 0.15mol) to Me_3SiI (40g, 0.2mol, see *16029-98-4* below) and heating under reflux for 14 hours when the temperature rises to 150°. Distil off the liquid from the solid and redistil to give the disilathiane (13g, 73%). The boiling time depended on the quality of the Ag_2S. [Eaborn *J Chem Soc* 3077 *1950*, DOI: 10.1039/JR9500003077; *Beilstein* **4** IV 4033; Fieser **8** 240, **15** 165.] *Alternatively*, sulfur (0.64g, 0.02mol) is added to 1M $Li(Et)_3BH$ in THF (40ml, 0.04mol) with cooling in an ice bath. The mixture is then stirred for 0.5 hour at ~25° and Me_3SiCl (4.32g, 0.04mol, see *75-77-4* below) is added slowly as an exothermic reaction ensues, the mixture is stirred for 2 hours at ~25°. The low boiling volatiles are removed (at 30-40°/20mm), and the disilathiane (2.9g, 83%) is distilled off. Store it at -35° in a drybox. [Detty & Seidler *J Org Chem* **47** 1354 *1982*, DOI: 10.1021/jo00346a041.]

Bis(trimethylsilyl) telluride *[4551-16-0]* **$C_6H_{18}TeSi_2$, M 274.0, m 13.5°, b 74°/11mm.** Purify by fractional distillation (or bulb transfer) at reduced pressures under red light to minimise photochemical decomposition, also observed after 24 hours in dark storage at -20° under argon. It is prepared freshly from Te shot (3.56g, 0.0279mol) and 1M $Li(Et)_3BH$ (58ml, 0.058mol) as described for the preceding Se compound. After 8 hours the mixture turned purple with a chalky white suspension. The flask is wrapped in foil, Me_3SiCl (7.00g, 0.0648mol, see *75-77-4* below) is added, stirred at ~25° for 6 hours, the volatiles are then removed (at 30-40°/20mm), and

then distilled to give the telluride (4.07g, 53%, **b** 49-51°/2.5mm, orange-brown liquid) which is collected in a foil-wrapped receiving flask to minimise exposure to light. Store it as a solid at -20° under Ar in the dark, or at -35° in a drybox also in the dark. [Detty & Seidler *J Org Chem* **47** 1354 *1982*, DOI: 10.1021/jo00346a041; for reactions with acyl halides to form C-C bonds see Severengiz et al. [*Angew Chem Int Ed* **24** 1041 *1985*, DOI: 10.1002/anie.198510411], and Severengiz & du Mont [*JCS Chem Commun* 820 *1987*, DOI: 10.1039/C39870000820].
The more stable ***bis(tert-butyldimethylsilyl) telluride*** *[80594-86-1]* **$C_{12}H_{30}TeSi_2$, M 358.1, m 46-49°, b 90-95°/5.5mm**, is prepared from Te shot (3.56g, 0.0279mol), 1M $Li(Et)_3BH$ (58ml, 0.058mol), and *tert*-butylchlorodimethylsilane (9.74g, 0.0580mol, *18162-48-6 below*) in a similar way. The product (7.77g, 79%) is isolated as a white solid after initial distillation as a colourless oil. It has ^1H NMR ($CDCl_3$) δ 1.00 (s, 9 H), 0.57 (s, 6 H). It is stable for several weeks at -20° under Ar in sealed flasks in the dark, but when stored at ~25° under red light it is noticeably decomposed after several days. [Detty & Seidler *J Org Chem* **47** 1354 *1982*, DOI: 10.1021/jo00346a041.]

9-Borabicyclo[3.3.1]nonane (9BBN) ***[monomer*** *280-64-8]* ***[dimer*** *21205-91-4 or 70658-61-6]* ***[1:1 coordination compound with tetrahydrofuran*** *76422-63-4]* **$C_8H_{15}B$, M 122.0 (monomer), 244.0 (dimer), m 141-143° (monomer), 150-152°, 154-155° (dimer), b 195°/12mm.** It is available as the solid dimer or in tetrahydrofuran solution. The solid is relatively stable and can be purified by distillation in a vacuum (as dimer) and by recrystallisation from tetrahydrofuran (solubility at room temperature is 9.5%, 0.78M), filter off the solid under N_2, wash it with dry pentane and dry it *in vacuo* at *ca* 100°. The solid is a *dimer* (IR 1567cm^{-1}), stable in air (for *ca* 2 months), and can be heated for 24 hours at 200° in an inert atmosphere without loss of hydride activity. It is a *dimer* in tetrahydrofuran solution also (IR 1567cm^{-1}). It is sensitive to H_2O and air (O_2) in solution. Its concentration in solution can be determined by reaction with MeOH and measuring the volume of H_2 liberated, or it can be oxidised to ***cis-cyclooctane-1,5-diol*** (**m 73.5-74.5°**). [IR: Knights & Brown *J Am Chem Soc* **90** 5280 *1968*, DOI: 10.1021/ja01021a046; Brown et al. *J Am Chem Soc* **96** 7765 *1974*, DOI: 10.1021/ja00832a025; Brown et al. *J Org Chem* **41** 1778 *1976*, DOI: 10.1021/jo00872a025; Brown & Chen *J Org Chem* **46** 3978 *1981*, DOI: 10.1021/jo00333a009; Fieser **2** 31, **3** 24, **10** 48, **15** 43, **17**, 49.]

Borane pyridine complex *[110-51-0]* **C_5H_8BN, M 92.9, m 8-10°, 10-11°, b 86°/7mm, 100-101°/12mm, d_4^{20} 0.785.** Dissolve it in Et_2O and wash it with H_2O in which it is insoluble. Evaporate the Et_2O and distil the residual oil to give better than 99.8% purity. Its vapour pressure is less than 0.1mm at room temperature. [Taylor et al. *J Am Chem Soc* **77** 1506 *1955*, DOI: 10.1021/ja01611a031; *Beilstein* **20** IV 2235.]

(+)-3-Bromocamphor-10-sulfonic acid hydrate *[67999-30-8]* **$C_{10}H_{15}BrO_4S.xH_2O$ M 329.2,** has **m 119-121°**, **$[\alpha]_D^{20}$ +98.3 (c 1, H_2O), pK ~0.** Crystallise the acid from water. [For '***Methods of optical resolution***' see Boyle *Quart Rev Chem Soc* **25** 323 *1971*, DOI: 10.1039/QR9712500323; UV: Lowry & Owen *J Chem Soc* 606 1926, DOI: 10.1039/JR9262900606; *Beilstein* **11** II 181, **11** III 592.]

Bromocresol Green (3',3",5',5"-tetrabromo-*m*-cresolsulfonephthalein) *[76-60-8]* **$C_{21}H_{14}Br_4O_5S$, M 698.0, m 218-219°(dec), 225°(dec), pK^{25} 4.51.** Crystallise the dye from glacial acetic acid or dissolve it in aqueous 5% $NaHCO_3$ solution and precipitate it from the hot solution by dropwise addition of aqueous HCl. Repeat this until the UV/VIS-extinction does not increase at λ_{max} 423nm. It is an indicator: at pH 3.81 (yellow) and pH 5.4 (blue-green). [*Beilstein* **19/3** V 460.]
Bromocresol Purple **(5',5"-dibromo-*o*-cresolsulfonephthalein)** *[115-40-2]* **$C_{21}H_{16}Br_2O_5S$, M 540.2,** has **m 241-242°(dec), pK_1 -2.15, pK_2 6.3.** Dissolve the dye in aqueous 5% $NaHCO_3$ solution and precipitate it from a hot solution by dropwise addition of aqueous HCl. Repeat this until the UV/VIS-extinction does not increase at λ_{max} 419nm. It can also be recrystallised from *benzene. It is an indicator: at pH 5.2 (yellow) and pH 6.8 (purple). [*Beilstein* **19/3** V 460.]
Bromophenol Blue **(3,3',5,5'-tetrabromophenolsulfonephthalein, sultone form)** *[115-39-9]* **$C_{19}H_{10}Br_4O_5S$, M 670.0,** has **m 270-271°(dec), 273°(dec), 279°(dec), λ_{max} 422nm, pK^{25} 3.62 (acidic).** Crystallise the dye from *C_6H_6 or Me_2CO/AcOH, and dry it in air. It is an indicator: at pH 3.0 it is yellow and is purple at pH 4.6. For indicator use: Dissolve indicator (0.1g) in of 0.02M NaOH (7.45ml) and dilute with H_2O (750ml). [*Beilstein* **19/3** V 458.] ***Bromophenol Blue solution (sodium salt,*** 0.04wt% in H_2O***)*** *[62625-28-9]* **$C_{19}H_9Br_4NaO_5S$, M 691.9, λ_{max} 422nm,** is available commercially. [*Beilstein* **19** 649.]
Bromopyrogallol Red **(5,5'-dibromopyrogallolsulfonephthalein)** *[16574-43-9]* **$C_{19}H_{10}Br_2O_8S$, M 558.2 (576.2 for free sulfonic acid),** has **m 300°, λ_{max} 538nm (ε 54,500 H_2O pH 5.6-7.5), pK_1 2.9, pK_2 4.39, pK_3 9.15, pK_4 11.72.** Crystallise the dye from 50% EtOH, or aqueous alkaline solution followed by acidification. It is a metal chromic indicator. [Suk *Coll Czech Chem Commun* **31** 3127 *1966*, DOI: org/10.1135/cccc19663127; *Beilstein* **19/10** V 226].

Bromosulfalein (phenoltetrabromophthalein 3',3'-disulfonic acid disodium salt) *[71-67-0]* **$C_{20}H_8Br_4O_{10}S_2$. 2Na, M 838.0.** Purify it by TLC on silica Gel G (Merck 250μ particle size) in two solvent

systems (BuOH/AcOH/H_2O 30:7.5:12.5 v/v, and BuOH/propionic acid/H_2O 30:20:7.5 v/v). When the solvent reaches a height of ~10cm, the plate is removed, dried in air and developed with NH_3 vapour giving blue-coloured spots. Also, the dye can be chromatographed on MN Silica Gel with *t*-BuOH/H_2O/*n*-BuOH (32:10:5 v/v) as eluent and visualised with a dilute KOH (or NaOH if the Na salt is required) spray. The product corresponding to bromosulfalein is scraped off and eluted with H_2O, filtered and evaporated to dryness in a vacuum. It is then dissolved in H_2O, filtered through Sephadex G-25 and evaporated to dryness. [UV and IR identification: Barbier & DeVeerdt *J Pharm Sci* **57** 819 *1968*, DOI: 10.1002/jps.2600570521; NMR: Kato et al. *Chem Pharm Bull Jpn* **20** 581 *1972*, DOI: 10.1016/0003-2697(77)90512-7; McGuire et al. *Anal Biochem* **83** 75 *1977*, DOI: 10.1016/0003-2697(77)90512-7; *Beilstein* **18/9** V 461.]

Bromothymol Blue **(3',3"-dibromothymolsulfonephthalein)** *[76-59-5]* **$C_{27}H_{28}Br_2O_5S$, M 624.4,** has **m 201-203°, pK_1 -0.66, pK_2 6.99.** Dissolve the dye in aqueous 5% $NaHCO_3$ solution and precipitate it from the hot solution by dropwise addition of aqueous HCl. Repeat this until the extinction at λ_{max} 420 nm does not increase. It is an indicator [prepared by dissolving it (0.1g) in 50% aqueous EtOH (100ml)]: aqueous solutions are yellow at pH 6.0, and blue at pH 7.6. [*Beilstein* **19/3** V 461.]

Dry it in a vacuum desiccator over $CaCl_2$. It has also been recrystallised twice from propan-2-ol. [Kilpatrick *J Am Chem Soc* **71** 2607 *1949*, DOI: 10.1021/ja01176a003; Nichol *J Am Chem Soc* **72** 2367 *1950*, DOI: 10.1021/ja01162a006; Koller & Hawkridge *J Am Chem Soc* **107** 7412 *1985*, DOI: 10.1021/ja00311a032; *Beilstein* **4** H 610, **4** I 567, **4** II 993, **4** III 1818, **4** IV 3681.]

Cadion [1-(4-nitrophenyl)-3-(4-phenylazophenyl)-triazene] *[5392-67-6]* **$C_{18}H_{14}N_6O_2$, M 346.3, m 189°(dec).** Commercial cadion is purified by recrystallisation from 95% EtOH and is dried *in vacuo*. It is stable in 0.2 N KOH (in 20% aqueous EtOH) at 25°. It is a sensitive reagent for Cd, and the Cd complex has λ_{max} (EtOH) 475nm. [Chavanne & Geronimi *Anal Chim Acta* **19** 377 *1958*, DOI: 10.1016/S0003-2670(00)88180-5; *Beilstein* **16** III 664.]

(*1R*)-(-)Camphor-10-sulfonic acid *[35963-20-3]* **$C_{10}H_{16}O_4S$, M 232.3, m 197.4-198°(dec), 197-198°, [α] $_D^{20}$ -20.7 (c 5.4, H_2O), pK_{Est} ~ -1.** It forms prisms from AcOH or EtOAc, and is deliquescent in moist air. Store it in tightly stoppered bottles. The **(*1R*)-(-)- *NH_4 salt*** *[82509-30-6]* **$C_{10}H_{19}NO_4S$, M 249.3,** forms needles from H_2O with **m ~250°(dec)** and [α] $_D^{22}$ -18.4, [α] $_D^{16}$ -20.5 (c 5, H_2O)**.** [Burgess & Lowry *J Chem Soc* **127** 271 *1925*, DOI: 10.1039/CT9252700271; Marsi et al. *J Am Chem Soc* **78** 3063 *1956*, DOI: 10.1021/ja01594a032]. The ***RS-acid*** *[5872-08-2]* recrystallises from AcOH. [60g of (±)-acid in 60ml of AcOH at 105° gave 40g of crystals has **m** 202-203°]. The ***1R-(-) acid*** has been obtained by the optical resolution of the *RS*-acid as follows: To a warm solution of the (±)-acid (50.0g, 0.215 mole) in H_2O (500 mL) is added *l*-brucine powder (83.6g, 0.215 mole) in small portions. After 24 hour at 25° the salt [56.8g, [α] $_D^{24}$ -16.1 (c 5.4, H_2O)]. By a process of fractional crystallisation the more soluble fairly pure ***(-)-brucine (-)-camphorsulfonate*** (12.5g, [α] $_D^{24}$ -29.3) can be obtained. The salt is then dissolved in warm H_2O (195 mL), treated with $Ba(OH)_2.8H_2O$ (3.25g, 0.01 mole),

the precipitated mixture is kept at ~100° for 2 hours, then filtered to remove the insoluble brucine (7.09g, 90%). The filtrate is treated with 0.50 M H_2SO_4, the precipitated Ba SO_4 is is filtered off and the filtrate is evaporated to dryness *in vacuo*. The yellow-brown residue is extracted with hot anhydrous *C_6H_6 (4 x 24 mL) and the extract, on refrigeration, gave colourless crystals (3.35g) of ***R-sulfonic acid***, **m 197.4-198°(dec),** $[\alpha]_D^{24}$ -18.52 (c 5.4, H_2O); a further 0.37g can be recovered from the mother liquor. ***Silver (1R)-(-)camphor-10-sulfonate*** is readily obtained by adding freshly prepared hydrated silver oxide [from $AgNO_3$ (22.2g, 0.129 mole) in H_2O (40 mL) basified with NaOH (6.0g, 0.15 mole), filtered and washed well with H_2O] to the sulfonic acid (28.0g, 0.12 mole) in H_2O (200 mL), stirred for several minutes, unreacted Ag_2O is filtered off, and the filtrate is evaporated to dryness which provided the ***silver salt*** (32.0g, 79%). The ***ethylamine salt***, **$C_{10}H_{16}O_3S.C_2H_7N$**, has **m 160-161°** (from Et_2O/EtOH). [Marsi et al *J Am Chem Soc* **78** 3063 *1956*, DOI: 10.1021/ja01594a032; Bartlett & Knox *Org Synth* **45** 12 *1965*, DOI: 10.15227/orgsyn.045.0012; *Beilstein* **11** II 182, **11** III 584, **11** IV 642.]

(*1S*)-(+)Camphor-10-sulfonic acid *[3144-16-9]* **$C_{10}H_{16}O_4S$, M 232.3, m 193°(dec), 197-198°, $[\alpha]_{546}^{20}$ +27.5 (c 10, H_2O), $[\alpha]_D^{20}$ +43.5 (c 4.3, EtOH), pK_{Est} ~ -1.** Crystallise the acid from ethyl acetate and dry it under vacuum (deliquescent). The ***(±)-acid chloride*** *[4552-50-5]* has **m 85°** (**66-68°**)[Bartlett & Knox *Org Synth* **45** 14 *1965*, DOI: 10.15227/orgsyn.045.0014]. They are characterised as their ***amides*** (by reaction with NH_4OH/0-10°/1hr then 25°/4hr and extraction into CH_2Cl_2 and evaporation) [*S* +, 60933-63-3; and *R* -, 72597-34-3], **$C_{10}H_{17}NO_3S$, M 231.3,** which form prisms from EtOH with **m 132°**, and $[\alpha]_D^{20}$ + and -22 and (c 1, MeOH). On repeated recrystallisation from EtOH the ***anilides*** have **m 120.5-121°**, and $[\alpha]_D^{25}$ +76 or -76 (c 1, $CHCl_3$). [Read & Storey *J Chem Soc* 2761 *1930*, DOI: 10.1039/JR9300002761; Sutherland & Shriner *J Am Chem Soc* **58** 62 *1936*, DOI: 10.1021/ja01292a019; Halterman et al. *J Am Chem Soc* **109** 8105 *1987*, DOI: 10.1021/ ja00260a037; Bartlett & Knox *Org Synth* **45** 55 *1945*, DOI: 10.15227/orgsyn.045.0055; Coll Vol **5** 196 *1973*, DOI: 10.15227/orgsyn.045.0014; Towson et al. *Org Synth* Coll Vol **8** 104 *1993*, DOI: 10.15227/orgsyn.069.0158; and *Beilstein* **11** IV 650.]

(4-Carbamylphenylarsylenedithio)diacetic acid (Arsenamide) *[531-72-6]* **$C_{11}H_{12}NO_5S_2As$, M 377.3, m 158-162°, 168-169°, pK 4.0.** Recrystallise it from H_2O (1.7g/25ml, containing a small amount of thiolacetic acid), MeOH or EtOH. It is insoluble in *iso*-PrOH. The ***disodium salt*** is obtained by titrating with NaOH to pH 7-8. [Maren *J Am Chem Soc* **68** 1864, *1946*, DOI: 10.1021/ja01213a504; Gough & King *J Chem Soc* 669 *1930*, DOI: 10.1039/JR9300000669.] It has chemotherapeutic activity against *filaria* and *trichomonas*, and is used in the treatment of heart worm in dogs.

Catecholborane (1,3,2-Benzodioxaborole) *[274-07-7]* **$C_6H_5O_2B$, M 119.2, b 50°/50mm, 66°/80mm, 76-77°/100mm, 88°/165mm, d_4^{20} 1.125, n_D^{20} 1.507 (also available as a 1.0M solution in THF or toluene).** It is a moisture-sensitive flammable liquid which is purified by distillation in a vacuum under a N_2 atmosphere and stored under N_2 at 0-4°. It liberates H_2 when added to H_2O or MeOH. A solution in THF, after 25 hours at 25°, has residual hydride of 95% (under N_2) and 80% (under air) [Brown & Gupta *J Am Chem Soc* **97** 5249 *1975*, DOI: 10.1021/ja00851a038].

Calconcarboxylic acid [3-hydroxy-4-(2-hydroxy-4-sulfo-1-naphthylazo)naphthalene-2-carboxylic acid] *[3737-95-9]* **$C_{21}H_{14}N_2O_7S$, M 428.4, m 300°, λ_{max} 560nm, pK_1 1.2, pK_2 3.8, pK_3 9.26, pK_4 13.14.** Purify it *via* its ***p-toluidinium salt***, *viz*: dissolve the dye in warm 20% aqueous MeOH, treat with an equivalent of *p*-toluidine and cool to precipitate the salt. Finally recrystallise the acid from hot water. [Itoh & Ueno *Analyst (London* **95** 583 *1970*, DOI: 10.1039/AN9709500583.] It complexes with Ca^{2+} in presence of Mg^{2+} and other metal ions. It it is thus used as an indicator for titrations of Ca^{2+}, which when EDTA is added, is unaffected by the presence of Mg^{2+} and other metal ions which are masked. [Patton & Reeder *Anal Chem* **28** 1026 *1956*,

DOI: 10.1021/ac60114a029; Prentoe & Prentoe *Analyst* **106** 227 *1981*, DOI: 10.1039/AN9810600227.]

Calmagite [1-(1-hydroxy-4-methyl-2-phenylazo)-2-hydroxynaphthalene-4-sulfonic acid] *[3147-14-6]* **$C_{17}H_{14}N_2O_5S$, M 358.4, m 300°, pK_1 8.1, pK_2 12.4.** A crude dye is extracted with anhydrous diethyl ether and forms red crystals from Me_2CO. It gives a red colour in H_2O at pH 7—9 and a blue colour at pH 9—11 which turns red on addition of Ca^{2+} or Mg^{2+} ions. [Lindstrom & Diehl *Anal Chem* **32** 1123 *1960*, DOI: 10.1021/ac60165a022]. Complexes with Ca, Mg and Th, and is used as an indicator for titrating Ca or Mg ions with EDTA.

Chloramine-T (*N*-chloro-*p*-toluenesulfonamide sodium salt) $3H_2O$ *[7080-50-4]* **$C_7H_7ClNNaO_2S.3H_2O$, M 281.7, m 168-170°(dec).** Recrystallise it from hot water (2ml/g). Dry it in a desiccator over $CaCl_2$ where it loses water. Protect it from sunlight. It is used for the detection of bromate and halogens, and Co, Cr, Fe, Hg, Mn, Ni and Sb ions. [Campbell & Johnson *Chem Rev* **78** 65 *1978*, DOI: 10.1021/cr60311a005; Bremner *Synthetic Reagents* **6** 9 *1985*, Chattaway **87** 145 *1905*, DOI: 10.1039/CT9058700145; for selective oxidation of methionine see Trout *Anal Biochem* **93** 419 *1979*, DOI: 10.1016/S0003-2697(79)80173-6; Inglis *J Soc Chem Ind* **37** 288 1918, DOI: 10.1002/jctb.5000371401; *Beilstein* **11** H 107, **11** I 29, **11** II 62, **11** III 300, **2** IV 457.]

Chlorazol Sky Blue FF {Chicago Sky Blue 6B, Direct Blue 1, 6,6'-[(3,3'-dimethoxy[1,1'-biphenyl]-4,4'-diyl)bis(azo)bis(4-amino-5-hydroxy-1,3-naphthylenedisulfonic acid) tetra-Na salt *[2610-05-1]* **$C_{34}H_{24}N_6Na_4O_{16}S_4$, M 996.9, m >300°(dec).** Free it from other electrolytes by adding aqueous sodium acetate to a boiling solution of the dye in distilled water. After standing, the salted-out dye is filtered on a Büchner funnel, the process being repeated several times. Finally, the precipitated dye is boiled several times with absolute EtOH to wash out any sodium acetate, then dried (as the sodium salt) at 105°. [McGregor et al. *Trans Faraday Soc* **58** 1045 *1962*, DOI: 10.1039/TF9625801045; *Beilstein* **16** I 346, **16** II 259.]

4-Chlorobenzenesulfonic acid *[98-66-8]* **$C_6H_5ClO_3S$, M 192.6, m 67°, b 149°/22mm, $pK^{25} < 0$.** It is prepared by the sulfonation of chlorobenzene with Oleum and recrystallises from H_2O as a ***hydrate***. The ***anhydrous*** acid is obtained on distillation, preferably under reduced pressure. [Cook & Cook *J Am Pharm Assoc* **38** 239 *1949*, DOI: 10.1002/jps.3030380503; *Beilstein* **11** H 63.]
4-Chlorobenzenesulfonyl chloride *[98-60-2]* **$C_6H_4Cl_2O_2S$, M 211.1,** has **m 53°, b 141°/15mm.** Crystallise it from ether in powdered Dry-ice, after the solution has been washed with 10% NaOH until colourless and dried (Na_2SO_4). Distil it *in vacuo* and store it in the absence of H_2O. **IRRITANT**. [*Beilstein* **11** IV 114.] ***4-Chlorobenzenesulfonamide*** *[98-64-6]* **$C_6H_6ClNO_2S$, M 191.6, m 144°,** is obtained by reaction of the sulfonyl chloride with aqueous 088 NH_3 and crystallised from H_2O. [*Beilstein* **11** IV 115.]

S-4-Chlorobenzylisothiuronium chloride *[544-47-8]* **$C_8H_{10}ClN_2S$, M 237.1, m 177-178°, and 197°, 201-203°, pK_{Est} ~9.6 (free base).** Crystallise the salt from concentrated HCl by addition of water (1:1). Dry it in a vacuum over P_2O_5. Also crystallise it from EtOH, wash the crystals with EtOH, then Et_2O to give the lower melting form **m 177-178°**. By evaporating the filtrate and washings to a quarter of the volume and adding an equal volume of Et_2O the higher melting form **m 201-203°** is obtained. [Harvey & Jensen *J Org Chem* **28** 470 *1963*, DOI: 10.1021/jo01037a047; *Beilstein* **6** III 1639, **6** IV 2778.] Its preparation and use as a reagent for characterising acids by forming salts which are best recrystallised from dioxane is described by Dewey and Sperry [*J Am Chem Soc* **61** 3251 *1939*, DOI: 10.1021/ja01267a005]. Both forms provide the same derivatives.

Chlorodicyclohexylphosphine [Cy_2PCl] *[16523-54-9]* **$C_{12}H_{22}ClP$, M 232.7, b 132-138°/3mm, 165°/12mm, 173-174°/17mm, 182-183°/23mm, d_4^{25} 1.054, n_D^{20} 1.533.** Cy_2PCl can be obtained as a colourless oil from cyclohexyldichloro-phosphine and cyclohexylmagnesium chloride, also from dicyclohexyldiethylamino-phosphine and HCl in the presence of NH_4Cl in petroleum ether (b 70-90°) followed by fractional distillation. *Alternatively*, reaction of cyclohexylmagnesium chloride (from 12.6g of Mg and 62g of cyclohexyl chloride) in Et_2O (250ml) and PCl_3 (35g) in Et_2O (300ml) under N_2 followed by fractional distillation gives (22g, 37.2%) of Cy_2PCl. [Issleib & Seidel *Chem Ber* **92** 2681 *1959*, DOI: 10.1002/cber.19590921102; *Beilstein* **16** IV 968.]

Chlorodiphenylphosphine (diphenylphosphinous chloride) *[1079-66-9]* **$C_{12}H_{10}ClP$, M 220.6, m 15-16°, b 124-126°/0.6mm, 174°/5mm, 320°/atm, d_4^{20} 1.229, n_D^{20} 1.636.** This air-sensitive, pale yellow **lachrymatory**

liquid is purified by careful fractional distillation and discarding the lower boiling fraction which contains the main impurity $PhPCl_2$ (**b** 48-51°/0.7mm), and checking for impurities by NMR. [Weinberg *J Org Chem* **40** 3586 *1975*, DOI: 10.1021/jo00912a027; Horner et al. *Chem Ber* **94** 2122 *1961*, DOI: 10.1002/cber.19610940826.]

Chlorodi(*o*-tolyl)phosphine *[36042-94-1]* **$C_{14}H_{14}ClP$, M 248.7, m 36-37°, b 120-122°/0.03mm, 146-147°/1.1mm.** It is purified by fractional distillation in a vacuum (**b 179-183°/7mm, 253-257°/15mm**) and the distillate solidifies (**m 36°**, also reported is **m 37°**). [Weinberg *J Org Chem*. **40** 3586 *1975*, DOI: 10.1021/jo00912a027; McEwen et al. *J Am Chem Soc* **100** 7304 *1978*, DOI: 10.1021/ja00491a030; *Beilstein* **16** H 769, **16** IV 970 *for chlorodi(p-tolyl)phosphine*.]

(Chloromethyl)dimethylvinylsilane *[16709-86-7]* **$C_5H_{11}ClSi$, M 134.7, b 121-122°/760mm, 122-126°/atm, d $_4^{25}$ 0.908, n $_D^{20}$ 1.440.** Distil the silane in a vacuum, but if it is suspect then dissolve it in Et_2O, shake it with saturated aqueous NH_4Cl, dry the Et_2O layer (anhydrous Na_2SO_4), filter, evaporate and fractionate in a vacuum. [Altamura et al. *J Org Chem* **60** 8403 *1995*, DOI: 10.1021/jo00131a015.]

Chloromethyl phenyl sulfide *[7205-91-6]* **C_7H_7ClS, M 158.7, b 63°/0.1mm, 98°/12mm, 113-115°/20mm, d $_4^{20}$ 1.184, n $_D^{20}$ 1.5950.** Dissolve the sulfide in CH_2Cl_2 or CCl_4 and dry it ($CaCl_2$), or pass it through a tube of $CaCl_2$ and distil it using a fractionating column. ***Harmful** vapours*. It gives the ***sulfone*** *[7205-98-3]* **$C_7H_7ClO_2S$, M 190.7,** which has **b 130°/1mm** and **m 53°** (from EtOH) on oxidation with permonophthalic acid. [*Beilstein* **6** IV 1507.] [Böhme et al. *Justus Liebigs Ann Chem* **563** 54 64 *1949*, DOI: 10.1002/jlac.19495630107.] [*Beilstein* **6** III 1002.] The ***sulfoxide*** *[7205-94-9]* **C_7H_7ClOS, M 174.7,** has **b 109-111°/0.011mm**, is a useful reagent for the synthesis of alkyl sulfoxides [Hojo et al. *Synthesis* 789 *1977*, DOI: 10.1055/s-1977-24581], and can be used as a thiol ester acyl anion equivalent [More & Wimple *J Org Chem* **43** 2713 *1978*, DOI: 10.1021/jo00407a040].

Chloromethylphosphonic acid dichloride *[1983-26-2]* **CH_2Cl_3OP, M 167.4, b 50°/0.5mm, 52-53(59)°/2mm, 63-65°/3mm, 78-79°/10mm, 87-88°/15mm, 102-103°/30mm, d $_4^{20}$ 1.638, n $_D^{20}$ 1.4971.** It is fractionally distilled using a short Claisen column and redistilled. The ***aniline salt*** has **m 199-201°**. The ^{31}P NMR has a single peak at -38±2 ppm from 85% H_3PO_4. [Kinnear & Perren *J Chem Soc* 3437 *1952*, DOI: 10.1039/JR9520003437; NMR: van Wazer et al. *J Am Chem Soc* **78** 5715 *1956*, McConnell et al. *J Org Chem* **22** 462 *1957*, DOI: 10.1021/jo01355a619; *Beilstein* **1** III 2593, **1** IV 3068.]

2-Chloro-2-oxo-1,3,2-dioxaphospholane *[6609-64-9]* **$C_2H_4ClO_3P$, M 142.5, m 12°, 14°, 12-14°, b 89-91°/0.8mm, 88-89°/2mm, 303°/760mm, d $_4^{20}$ 1.549, n $_D^{20}$ 1.448.** It should be distilled under high vacuum as some polymerisation occurs at atmospheric pressure. It has IR bands at 3012, 2933, 1477, 1366, 1325, 1040, 924 and 858 cm^{-1}. It is hydrolysed to $HOCH_2CH_2OPO_3H_2$ in 30 minutes in H_2O at 100° [IR: Cox & Westheimer *J Am Chem Soc* **80** 5441 *1958*, DOI: 10.1021/ja01553a031]. [*Beilstein* **1** IV 2419.]

Chlorophenol Red (3,3'-dichlorophenolsulfonephthalein) *[4430-20-0]* **$C_{19}H_{12}Cl_2O_5S$, M 423.3, m dec on heating, λ_{max} 573nm, pK^{25} 5.96.** Crystallise the dye from glacial acetic acid. It is an indicator which is yellow at pH 4.8 and violet at pH 6.7. [*Beilstein* **19/3** V 458.]

2-Chlorophenyl diphenyl phosphate *[115-85-5]* **$C_{18}H_{14}ClO_4P$, M 360.7, b 236°/4mm, 413.9°/760mm, n $_D^{25}$ 1.5707.** Purify it by vacuum distillation, percolate it through a column of alumina, then pass it through a packed column maintained by a countercurrent stream of N_2 at reduced pressure [Dobry & Keller *J Phys Chem* **61** 1448 *1957*, DOI: 10.1021/j150556a052].

Chlorosulfonic (chlorosulfuric) acid *[7790-94-5]* **$HClO_3S$, M 116.5, m -80°, b 60-64°/2-4mm, 74-75°/19mm, 151-152°/750mm, 151°/760mm, d $_4^{20}$ 1.753, n $_D^{25}$ 1.4929, pK^{25} -5.9 (aqueous H_2SO_4).** Distil it in an all-glass apparatus, taking the fraction boiling at 156-158°/atm, or under reduced pressure. The colourless to pale yellow distillate has a pungent odour, fumes in air and reacts **EXPLOSIVELY** with water [Kaplan et al. *Inorg Synth* **4** 52 *1953*, DOI: 10.1002/9780470132357.ch17; Cremlyn *Chlorosulfonic acid: A Versatile Reagent*, Royal Society of Chemistry UK, 2002, 308 pp, ISBN 0854044981]. **LACHRYMATORY, CORROSIVE, attacks the eyes and skin, wear gloves and face shield, work in an efficient fume cupboard.**

Chlorotriphenylsilane (TPSCl, triphenylchlorosilane) *[76-86-8]* **$C_{18}H_{15}ClSi$, M 294.9, m 90-92°, 91-93°, 91-96°, 94-95°, 97-99°, b 156°/1mm, 161°/0.6mm, 188-189°/3mm.** Likely impurities are tetraphenylsilane, small amounts of hexaphenyldisiloxane and traces of triphenylsilanol. Purify it by distillation at low pressure, then crystallise it from EtOH-free $CHCl_3$, and from petroleum ether (b 30-60°) or hexane by cooling in a Dry-ice/acetone bath. It is moisture sensitive. [Allen & Modena *J Chem Soc* 3671 *1957*, DOI: 10.1039/JR9570003671; Curran et al. *J Am Chem Soc* **72** 4471 *1950*, DOI: 10.1021/ja01166a038; Speier & Zimmerman *J Am Chem Soc* **77** 6395 *1955*, DOI: 10.1021/ja01628a110; Thomas & Rochow *J Am Chem Soc* **79** 1843 *1957,* DOI: 10.1021/ja01565a021; *Beilstein* **16** IV 1484.]

Chromeazurol S (Mordant Blue 29) *[1667-99-8]* **$C_{23}H_{13}Cl_2Na_3O_9S$, M 605.3, λ_{max} 540nm, ε 7.80 x 10^4 (10M HCl), CI 43825, pK_1^{25} <0, pK_2^{25} 2.25, pK_3^{25} 4.88, pK_4^{25} 11.75.** The crude ***phenolic triphenylmethanecarboxysulfonic acid tri-Na salt*** (40g) is dissolved in water (250ml) and filtered. Then concentrated HCl (50ml) is added to the filtrate, with stirring. The precipitate is filtered off, washed with HCl (2M) and dried. It is redissolved in water (250ml), and precipitation is repeated twice more in a water bath at 70°. It is dried under vacuum over solid KOH (first), then P_2O_5 [Martynov et al. *Zh Analyt Khim* **32** 519 *1977*]. It has also been purified by paper chromatography using *n*-butanol, acetic acid and water (7:3:1). First and second spots were extracted. It chelates Al and Be. It is used also for estimating fluoride. [*Beilstein* **11** IV 707.]

Congo Red (4B) {Cosmos Red, Cotton Red B, 3,3,'-[(1,1'-biphenyl)-4,4'-diylbis(azo)]bis[4-amino-1-napthaleneulfonic acid] disodium salt} *[573-58-0]* **$C_{32}H_{22}N_6Na_2O_6S_2$, M 696.7,** m **>360°, λ_{max} 488nm (E $^{1\%}_{cm}$ 595) at pH 7.3, pK_2^{28} 4.19.** Crystallise the dye from aqueous EtOH (1:3), and dry it in air. Its colour is yellow-red in H_2O and orange in EtOH. It is a useful biological stain. [*Beilstein* **6** I 342.]

Copper (I) thiophenolate *[1192-40-1]* **C_6H_5CuS, M 172.7, m *ca* 280°, pK_1^{25} 6.62 (for PhS^-).** The Cu salt can be extracted from a thimble (Soxhlet) with boiling MeOH. It is a green-brown powder that gives a yellow-green solution in pyridine. Wash it with EtOH and dry it in a vacuum. It can be precipitated from a pyridine solution by adding H_2O, collecting the precipitate, washing it with EtOH and drying in a vacuum. [Posner et al. *Synthesis* 662 *1974*, DOI: 10.1055/s-1974-23397; Krebs et al. *Chem Ber* **90** 425 DOI: 10.1002/cber.19570900321; *1957*, *Beilstein* **6** IV 1465.] It is a useful reagent for preparing Cu-*N*-heterocyclic carbenes [Cisnetti et al. *Tetrahedron Lett* **51** 5226 *2010*, DOI: 10.1016/j.tetlet.2010.07.124].

o-**Cresol Red [*o*-cresolphthalein, 3,4-benz-5,5-bis-(4-hydroxy-2-methylphenyl)-1(3*H*)-oxa-2-thiole 2,2-dioxide]** *[1733-12-6]* **$C_{21}H_{18}O_5S$, M 382.4, m 290°(dec), λ_{max} 367nm** and **570nm, pK_1^{25} 1.26, pK_2^{25} 8.18.** Crystallise the reddish-brown powder from glacial acetic acid. Dry it in air. *Alternatively*, dissolve it in aqueous 5% $NaHCO_3$ solution and precipitate it from a hot solution by dropwise addition of aqueous HCl. Repeat the procedure until the UV maxima do not increase. It is an acid-base indicatior volumetric analysis with two colour changes *viz:* pH range 1.8—2.0 from Orange (acid) to Yellow, and at pH range 7.0—8.8 from Yellow to Violet (alkaline) (cf: pK values). [*Beilstein* **19** IV 1133.] The ***sodium salt*** *[62625-29-0]* **$C_{21}H_{17}NaO_5S$, M 404.4, λ_{max} 425nm,** has **m 250°(dec).**

Cupferron ammonium salt (*N*-nitroso-*N*-phenylhydroxylamine ammonium salt) *[135-20-6]* **$C_6H_9N_3O_2$, M 155.2, m 150-155°(dec), 162.5-163.5°, 163-164°, pK^{25} 4.16 (free base).** Recrystallise it twice from EtOH after treatment with Norite and finally once with EtOH. The crystals are washed with diethyl ether and air dried, then stored in the dark over solid ammonium carbonate. A standard solution (*ca* 0.05M prepared in air-free H_2O) is prepared daily from this material for analytical work and is essentially 100% pure. [Olsen & Elving *Anal Chem* **26** 1747 *1954*, DOI: 10.1021/ac60095a017.] It can also be washed with Et_2O, dried and stored as stated. In a sealed, dark container it can be stored for at least 12 months without deterioration. The UV has λ_{max} at 260nm ($CHCl_3$). [Marvel *Org Synth* Coll Vol **1** 177 *1941*, DOI: 10.15227/orgsyn.004.0019; Elving & Olson *J Am Chem Soc* **78** 4206 *1956*, DOI: 10.1021/ja01598a006; *Beilstein* **16** IV 891.] *Possible* **CARCINOGEN.**

Cupric trifluoromethylsulfonate (copper II triflate) *[34946-82-2]* **$C_2CuF_6O_6S_2$, M 361.7, m >300°, pK^{25} <-3.0 (for triflic acid).** Dissolve it in MeCN, add dry Et_2O until cloudy and cool at -20° in a freezer. The light blue precipitate is collected and dried in a vacuum oven at 130°/20mm for 8 hours. It has λ_{max} at 737nm (ε 22.4 M^1cm^{-1}) in AcOH. [Jenkins & Kochi *J Am Chem Soc* **94** 843 *1972*, DOI: 10.1021/ja00758a024; Salomon &

Kochi *J Am Chem Soc* **95** 3300 *1973*, DOI: 10.1021/ja00791a038]. It was prepared from $CuCO_3$ in MeCN and CF_3CO_2H, and the ***blue salt*** has also been dried in a vessel at 0.1Torr by heating with a Fischer burner [Andrist et al. *J Org Chem* **43** 3422 *1978*, DOI: 10.1021/jo00411a047]. It has been dried at 110-120°/5mm for 1 hour before use and forms a ****benzene complex*** which should be handled in a dry box because it is air sensitive [Kobayashi et al. *Chem Pharm Bull Jpn* **28** 262 *1980*, DOI: org/10.1248/cpb.28.262; Salomon & Kochi *J Am Chem Soc* **95** 3300 *1973*, DOI: 10.1021/ja00791a038]. [*Beilstein* **3** IV 34.]

Cuprous (I) bromide dimethylsulfide complex *[54678-23-8]* **C_2H_6BrCuS, M 205.6, m *ca* 135°(dec).** Purify it by recrystallisation in the presence of Me_2S. A solution of the complex (1.02g) in Me_2S (5ml) is slowly diluted with hexane (20ml), and the pure colourless prisms of the complex (0.96g) separate and are collected and dried, **m 124-129°(dec)**. The complex is insoluble in hexane, Et_2O, Me_2CO, $CHCl_3$ and CCl_4. It dissolves in DMF and DMSO, but the solution becomes hot and green indicating decomposition. It dissolves in $*C_6H_6$, Et_2O, MeOH and $CHCl_3$ if excess of Me_2S is added and a colourless solution is obtained. [House et al. *J Org Chem* **40** 1460 *1975*, DOI: 10.1021/jo00898a019.] Prior to use, the complex is dissolved in Me_2S and evaporated to dryness in the weighed reaction flask [Bourgain-Commerçon et al. *J Organomet Chem* **228** 321 *1982*, DOI: 10.1016/S0022-328X(00)84333-8]. If this reagent is to assist in methylations with MeMgBr (e.g. of fullerenes) it is always best to make a fresh preparation. CuBr (25g) is washed with MeOH (4 x 50ml) to remove coloured impurities and dried *in vacuo* for 1 hour. This white green-tinged CuBr is dissolved in Me_2S (60ml, redistilled b 38°, **use efficient fume cupboard**) and insoluble impurities are filtered off. Hexane (200ml) is added and the precipitated light-sensitive white crystalline complex is filtered off and washed with hexane (5 times) under suction and N_2. It should be dried under a stream of dry N_2, and should not be kept or stored under some pressure as it will lose the some of the disulfide ligand and its efficiency. [Wuts *Synth Commun* **2** 139 *1981*, DOI: 10.1080/00397918108064294; Matsuo et al. *Org Synth* **83** 80, *2006*, DOI: 10.15227/ orgsyn.083.0080.]

Cuprous iodide trimethylphosphite *[34836-53-8]* **$C_3H_9CuIO_3P$, M 314.5,** has **m 175-177°, 192-193°.** Cuprous iodide dissolves in a $*C_6H_6$ solution containing trimethylphosphite to form the ***complex***. The ***complex*** crystallises from $*C_6H_6$ or petroleum ether. [Arbusoff *Chem Ber* **38** 1171 *1905*, DOI: 10.1002/cber.190503801212; Nishizawa *Bull Chem Soc Jpn* **34** 1170, 1177 *1961*, DOI: org/10.1246/ bcsj.34.1170.] It is useful for preparing Cu-enolates [Ziegler & Fang *J Org Chem* **46** 825 *1981*, DOI: 10.1021/jo00317a042] and for the alkylation of trimethylsilylvinyl aluminates [Ziegler & Mikami *Tetrahedron Lett* **25** 131 *1984*, DOI: 10.1016/S0040-4039(00)99821-6].

Cyclohexyl mercaptan (cyclohexane thiol) *[1569-69-3]* **$C_6H_{12}S$, M 116.2, b 38-39°/12mm, 57°/23mm, 90°/100mm, 157°/763mm, d_4^{20} 0.949, n_D^{20} 1.493, pK_{Est} ~10.8.** Possible impurities are the sulfide and the disulfide. Purify the thiol by conversion to the Na salt by dissolving it in 10% aqueous NaOH, extract the sulfide and disulfide with Et_2O, and then acidify the aqueous solution (with cooling and under N_2) with HCl, extract with Et_2O, dry over $MgSO_4$, evaporate and distil it in a vacuum (**b** 41°/12mm). The ***sulfide*** has **b 74°/0.2mm**, $n_D^{18.5}$ 1.5162 and the ***disulfide*** has **b 110-112°/0.2mm**, $n_D^{18.5}$ 1.5557. The ***Hg-mercaptide*** has **m 77-78°** (needles from EtOH). [Naylor *J Chem Soc* 1532 *1947*, DOI: 10.1039/JR9470001532; *Beilstein* **6** H 8, **6** I 6, **6** II 14, **6** III 46, **6** IV 72.]

Decaborane (14) ($B_{10}H_{14}$) *[17702-41-9]* **$B_{10}H_{14}$, M 122.2, m 99.6-99.7°, 99.7-100°, b 100°/19mm, 213°/atm, d_4^{25} 0.94.** Purify decaborane by vacuum sublimation at 80°/0.1mm, followed by crystallisation from methylcyclohexane, CH_2Cl_2, or dry olefin-free-*n*-pentane, the solvent being subsequently removed by storing the crystals in a vacuum desiccator containing $CaCl_2$, and is stable at ~25° indefinitely. It is soluble in H_2O but is slowly decomposed to give H_2. It is soluble in alkali, and on acidification it liberates H_2. **TOXIC, excessive exposure causes headache, dizziness, muscle spasma and nausea.** [Greenwood in *Comprehensive Chemistry (Ed Bailar et al.)* Pergamon Press Vol **1** pp 818-837 *1973*.]

4,4-Diaminodiphenyl sulfide (4,4'-thioaniline) *[139-65-1]* **$C_{12}H_{12}S$, M 216.3, m 108-109°, pK^{20} 2.28 (1:1 EtOH/H_2O).** It separates as needles from EtOH and is a **possible mutagen**. The free base is used for the detection of NO_3^- ions. The ***diacetate*** crystallises from aqueous AcOH with **m 182°** and the ***sulfoxide***, *[119-59-5]* **m 184°**, forms prisms from EtOH or H_2O. [Fuson & Melamed *J Org Chem* **13** 690 I1948, DOI: 10.1021/

jo01163a012; *Beilstein* **13** III 1246, **13**, IV 1306.]

Di-*n*-amyl *n*-amylphosphonate *[6418-56-0]* **$C_{15}H_{33}O_3P$, M 292.4, b 150-151°/2mm, n_D^{20} 1.4378.** Purify it by three crystallisations of its ***uranyl nitrate complex*** from hexane (see *tributyl phosphate*). It extracts Zr^{2+} from NaCl solutions.

Dibenzyl disulfide *[150-60-7]* **$C_{14}H_{14}S_2$, M 246.4, m 69°, 71-72°, 74-75°, b 142-148°/0.05-0.1mm, 210-216°/18mm.** Crystallise the disulfide from EtOH (**m 77°**), petroleum ether or CS_2 (**m** 72°) or distil it. The $AgNO_3$ complex has **m 103°.** [*Beilstein* **6** H 465, **6** I 229, **6** II 437, **6** III 1635, **6** IV 2760.] It is a rubber antioxidant.
Dibenzyl sulfide *[538-74-9]* **$C_{14}H_{14}S$, M 214.3,** has **m 44°, 47°, 48.5°, 50°.** Crystallise the sulfide from EtOH/water (10:1), or repeatedly from Et_2O. It has also been purified by chromatography on Al_2O_3 (pentane as eluent), then recrystallised from EtOH [Kice & Bowers *J Am Chem Soc* **84** 2390 *1962*, DOI: 10.1021/ja00871a023]. Dry in a vacuum at 30° over P_2O_5, fuse under N_2 and re-dry. [*Beilstein* **6** IV 2649.]

Di-*n*-butyl boron triflate (di-*n*-butylboryl trifluoromethanesulfonate) *[60669-69-4]* **$C_9H_{18}BF_3O_3S$, M 274.1, b 37°/0.12mm, 60°/2mm, pK^{25} <-3.0 (for triflic acid).** Distil it in a vacuum under argon and store it under argon. It should be used within 2 weeks of purchase or after redistillation. Use a short path distillation system. It has IR bands in CCl_4 with ν_{max} at 1405, 1380, 1320, 1200 and 1550cm^{-1}, and ^{13}C NMR ($CDCl_3$) with δ at 118.1, 25.1, 21.5 and 13.6. [Gage & Evans *Org Synth* **68** 83 *1990*, DOI: 10.15227/orgsyn.068.0083; Evans et al. *J Am Chem Soc* **103**, 3099 *1981*, DOI: 10.1021/ja00401a031.] **TOXIC.**

Di-*n*-butyl *n*-butylphosphonate *[78-46-6]* **$C_8H_{18}O_3P$, M 250.3, b 150-151°/10mm, 160-162°/20mm, b 283°/atm, d^{25} 0.946, n^{25} 1.4302.** Purify by three recrystallisations of its compound with ***uranyl nitrate***, fromhexane. For method, see *tributyl phosphate*. It has been used as an extraction solvent. [*Beilstein* **4** III 1782.]

Di-*n*-butyl cyclohexylphosphonate *[1085-92-3]* **$C_{14}H_{25}O_3P$, M 272.3.** The compound with ***uranyl nitrate*** is recrystallised three times from hexane. For method see *tributyl phosphate*.

Di-*tert*-butyl dichlorosilane (DTBCl_2) *[18395-90-9]* **$C_8H_{18}Cl_2Si$, M 213.2, m -15°, b 190°/729mm, 195-197°/atm, d_4^{20} 1.01, n_D^{20} 1.457.** Purify it by fractional distillation. It is a colourless liquid with a pleasant odour and does not fume in moist air, but does ***not*** titrate quantitatively with excess of dilute alkali. [Tyler et al. *J Am Chem Soc* **70** 2876 *1948*, DOI: 10.1021/ja01189a012.]

Di-*tert*-butylphosphine *[819-19-2]* **$C_8H_{19}P$, M 146.2, m -1°, b 34-35°/2mm, 38-40°/13mm, 165°/760mm, d_4^{25} 0.951, pK_{Est} ~8.7.** It is prepared by reaction of *tert*-butylmagnesium bromide with PCl_3 in the presence of $LiAlH_4$, and purified by distillation in a vacuum. *Alternatively*, the intermediate ***di*-tert-*butylchlorophosphine*** *[13716-10-4]* is reduced separately and the product is purified by fractional distillation *in vacuo*. [Hoffmann & Schellenbeck *Chem Ber* **99** 1134 *1966*, DOI: 10.1002/cber.19660990408; Hoffmann & Schellenbeck *Chem Ber* **100** 692 *1967*, DOI: 10.1002/cber.19671000241; Crofts et al. *J Chem Soc C* 332 *1970*, DOI: 10.1039/J39700000332.] **Flammable and pyrophoric.**

Di-*tert*-butyl silyl bis(trifluoromethanesulfonate) *[85272-31-7]* **$C_{10}H_{18}F_6O_6S_2Si$, M 440.5, b 73.5-74.5°/0.35mm, d_4^{20} 1.36, n_D^{20} 1.398, (see pK for triflic acid).** Purify it by fractional distillation at high vacuum. It is a pale yellow liquid that should be stored under argon. It is less reactive than the diisopropyl analogue. The presence of the intermediate monochloro compound can be detected by ^1H NMR, ($CHCl_3$): ***tert-Bu$_2$Si(OTf)$_2$*** [δ 1.25s], but impurities have δ 1.12s for ***tert-Bu$_2$Si(H)OTf*** and δ 1.19s for ***tert-Bu$_2$HSi(Cl)OTf.*** [Corey & Hopkins *Tetrahedron Lett* **23** 4871 *1982*, DOI: 10.1016/S0040-4039(00)85735-4; Deslongchamps *Aldrichimica Acta* **17** 72 *1984*.] Used as a protecting group (Mukaiyama) reagent for e.g. 1,3-diols [Kimura et al. *Synlett* 2379 *2006*, DOI: 10.1055/s-002-5130; Hillaert & Van Calenberg *Org Lett* **7** 5769 *2005*, DOI: 10.1021/ol052335x]. **TOXIC.**

Dichloramine-T (*N,N*-dichloro-*p*-toluenesulfonamide) *[473-34-7]* **$C_7H_7Cl_2NO_2S$, M 240.1, m 83°.**

Crystallise it from petroleum ether (b 60-80°) or $CHCl_3$/petroleum ether. Dry it in air <55° and store in the dark. It is soluble in $CHCl_3$ (~1:1), $*C_6H_6$ (~1:1) and CCl_4 (~1:2.5). It is a *germicide* and *antibacterial* as it readily liberates chlorine, and it should not smell strongly of chlorine; otherwise it should be purified. *Alternatively*, dissolve ~15g of reagent in 75ml of hot acetic acid and precipitate it by addition of 37ml of N/10 bleaching powder solution (NaOCl), filter off, wash it with a dilute solution of the latter, dry it as above (**m 78-84°**) and recrystallise it. Excessive drying, 'Sharp drying', will decompose it. [Orton & Bradfield *J Chem Soc* 986 *1927*, DOI: 10.1039/JR9270000986; Krauss & Crede *J Am Chem Soc* **39** 2720 *1917*, DOI: 10.1021/ja02257a024; Soper *J Chem Soc* 1899 *1924*, DOI: 10.1039/CT9242501899; see also ***chloramine-T*** (***monochloramine T Na salt***) in this Chapter.] [*Beilstein* **11** H I07, **11** I 27, **11** II 63, **11** III 301.]

2,6-Dichlorophenol-indophenol sodium salt ($2H_2O$) (DCPIP, DCIP) *[620-45-1]* **$C_{12}H_6Cl_2NNaO_2$. xH_2O, M 326.1, ε 2.1 x 10^4 at 600nm and pH 8, pK^{30} 5.7 (oxidised form), pK_1^{30} 7.0, pK_2^{30} 10.1 (reduced form).** Dissolve the green powder in 0.001M phosphate buffer, pH 7.5 (*alternatively*, about 2g of the dye is dissolved in 80ml of M HCl), and extracted into diethyl ether. The extract is washed with water, extracted with aqueous 2% $NaHCO_3$, and the ***sodium salt*** of the dye is precipitated by adding NaCl (30g/100ml of $NaHCO_3$ solution), then filtered off, washed with dilute NaCl solution and dried. It is ***blue*** in the oxidised form with λ_{max} at 605nm at pH ~8, but turns ***red*** in aqueous acidic solution. [Hiromi et al. *Anal Biochem* **101** 421 *1980*, DOI: 10.1016/0003-2697(77)90512-7.] It has been used for the determination of vitamin C in fruits by capillary zone electrophoresis [Chiari et al. *J Chromatogr* **645** 179 *1993*, DOI: 10.1016/0021-9673(93)80637-N]. The ***acetate*** *[24857-20-3]* **M 310.1** has **m 101-103°** (from Et_2O/petroleum ether) and **99.5-100.5°** (from Et_2O). [*Beilstein* **13** IV 1078-1079.]

Dicyclopentylphosphine *[39864-68-1]* **$C_{10}H_{19}P$, M 170.2, b 76-78°/0.8mm, d_4^{25} 0.933, pK_{Est} ~4.5.** Purify dicyclopentylphosphine by distillation in a vacuum in a stream of N_2 or Ar as it is air sensitive and must be stored in an inert atmosphere. [cf. Neidergall & Langenfeld *Chem Ber* **95** 64 *1962*, DOI: 10.1002/cber.19620950114; *Beilstein* **16** IV 947 *for dicyclohexyl-phosphine*.]

O,O*-Diethyl-*S*-2-diethylaminoethyl phosphorothiolate** *[78-53-5]* **$C_{10}H_{24}NO_3PS$, M 269.3, m 98-99°, b 110°/0.2mm.** Recrystallise it from isopropanol/diethyl ether. It is a very **toxic nerve agent** (similar to **Sarin** which is ***iso*-Pr-OP(=O)MeF**, *[107-44-8]* **$C_4H_{10}FO_2PS$, M 140.1, m -57°, b 56°/16mm, 147°/atm**), too dangerous to use in agriculture and is used in warefare. [Ailman & Magee in *Organo Phosphorus Compound* (Kosolapoff & Maier eds) Wiley Vol **7** pp 487-871 *1976*.] For the systematic behaviour of the ***free base and its salts see Metcalf et al. *J Economic Entomology* (ed. J.T. Trumble) pp 205-210 *1957*, DOI: http://dx.doi.org/10.1093/jee/50.2.205]. **TAKE EXTREME CARE as with very toxic insecticides, use with protective clothing in an efficient fume cupboard.**

Diethylmethylsilane *[760-32-7]* **$C_5H_{14}Si$, M 102.3, b 78.4°/760mm, 77.2-77.6°/atm, d_4^{20} 0.71, n_D^{20} 1.3984.** Fractionally distil it through a *ca* 20-plate column, and the fraction boiling within a range of less than 0.5° is collected. It is a **flammable** and **irritant** liquid. [Price *J Am Chem Soc* **69** 2600 *1947*, DOI: 10.1021/ja01203a010; *Beilstein* **4** III 1847, **4** IV 3894]

***N,N*-Diethyltrimethylsilylamine** *[996-50-9]* **$C_7H_{19}NSi$, M 145.3, m -10°, b 33°/26mm, 126.8-127.1°/738mm, 126.1-126.4°, 126.3°/760mm, d_4^{20} 0.763, n_D^{20} 1.411.** Fractionate it through a 2ft vacuum-jacketed column containing Helipak packing with a reflux ratio of 10:1. [Sauer & Hasek *J Am Chem Soc* **68** 241 *1946*, DOI: 10.1021/ja01206a028; Langer et al. *J Org Chem* **23** 50 *1958*, DOI: 10.1021/jo01095a017; Rühlmann *J Prakt Chem* **9** 315 *1959*, DOI: 10.1002/prac.19590090514; *Beilstein* **4** IV 4010.]

Diethyl trimethylsilyl phosphite *[13716-45-5]* **$C_7H_{19}O_3PSi$, M 210.3, b 61°/10mm, 66°/15mm, d_4^{20} 0.9476, n_D^{20} 1.4113.** Fractionate it under reduced pressure and has ^{31}PMR: δ_P -128ppm relative to H_3PO_4. It is useful for preparing ketones from aldehydes *via* α-trimethylsilyloxy-phosphonates [Sekine et al. *Bull Chem Soc Jpn* **55** 224 *1982*, DOI: org/10.1246/bcsj.55.224; Sekine et al. *J Org Chem* **46** 2097 *1981*, DOI: 10.1021/jo00323a024; Evans et al. *J Am Chem Soc* **100** 3467 *1978*, DOI: 10.1021/ja00479a031.]

Dihexadecyl phosphate (DHP) *[2197-63-9]* **$C_{32}H_{67}O_4P$, M 546.9, m 74-75°, 75°, pK_{Est} ~1.2.** Recrystallise it from MeOH. Solutions of DHP were made in $CHCl_3$ or CH_2Cl_2 for making vesicles. It has been used for making surfactant vesicles in studies of the viscosity-dependent variations of the fluorescence yield ϕ_F and the polarity induced shift of the emission band maximum $\lambda_{F(max)}$ of a derivative of a **[*p*-(dialkylamino)benzylidene]malononitrile** *[74677-08-0]* fluorescence probe. [Luka *J Am Chem Soc* **106** 4386 *1984*, DOI: 10.1021/ja00328a016]. [*Beilstein* **1** IV 1880.] It forms vesicles with $Ru(bpy)_3^{2+}$ adsorbed on the outer and the inner surface of the vesicles whose absorption spectra are different [Tricot et al. *Aust J Chem* **38** 527 *1985*, DOI:10.1071/CH9850527].

1,2-Dihydroxybenzene-3,5-disulfonic acid, di-Na salt (TIRON) *[149-45-1]* **$C_6H_4Na_2O_8S_2$, M 332.2, ε 6.9 x 10^4 at 260nm, pH 10.8, pK_1 and pK_2 <2 (for SO_3^-), pK_3 7.7, pK_4 12.6 (for OHs of disulfonate dianion).** Recrystallise it from water [French & Adams *Analyst* **99** 551 *1974*, DOI: 10.1039/AN9749900551]. It is an indicator colour reagent for Fe, Mn, Ti and Mo ions, and complexes with Al, Cd, Co, Co, Fe (III), Mn, Pd, UO_2^{2+}, VO^{2+} and Zn. [*Beilstein* **11** IV 630.]

(±)-Diisooctyl phenylphosphonate (bis[2-ethylhexyl] phenylphosphonate) *[49637-59-4]* **$C_{22}H_{39}O_3P$, M 382.5, b 204-207°/4mm, d_4^{20} 0.970, n_D^{25} 1.4780.** Distil it in a vacuum, percolate it through a column of alumina, then pass it through a packed column maintained at 150° to remove residual traces of volatile materials in a countercurrent stream of N_2 under reduced pressure [Dobry & Keller *J Phys Chem* **61** 1448 *1957*, DOI: 10.1021/j150556a052]. [*Beilstein* **16** III 884.]

Diisopropyl chlorosilane (chlorodiisopropylsilane) *[2227-29-4]* **$C_6H_{14}ClSi$, M 150.7, b 59°/8mm, 80°/10mm, 200°/738mm, d_4^{20} 0.9008, n_D^{20} 1.4518**. Impurities can be readily detected by ^1H NMR spectroscopy. Purify it by fractional distillation [Gilman & Clark *J Am Chem Soc* **69** 1499 *1947*, DOI: 10.1021/ja01198a071; Allen et al. *J Chem Soc* 3668 *1957*, DOI: 10.1039/JR9570003668].

Dilongifolyl borane *[77882-24-7]* **$C_{30}H_{51}B$, M 422.6, m 169-172°**. Wash it with dry Et_2O and dry it in a vacuum under N_2. It has **m** 160-161° in a sealed evacuated capillary. It is sparingly soluble in pentane, tetrahydrofuran, carbon tetrachloride, dichloromethane, and chloroform, but the suspended material is capable of causing asymmetric hydroboration. Disappearance of solid indicates that the reaction has proceeded. [Jadhav & Brown *J Org Chem* **46** 2988 *1981*, DOI: 10.1021/jo00327a036; Herold et al. *Helv Chim Acta* **66** 744 *1983*, DOI: 10.1002/hlca.19830660304.]

4,4'-Dimethoxythiobenzophenone *[958-80-5]* **$C_{15}H_{14}O_2S$, M 258.3, m 120°**. Recrystallise the thioketone from a mixture of cyclohexane/dichloromethane (4:1) or EtOH (**m** 119°). [Bergmann & Wagenberg *Chem Ber* **63** 2585*1930*, DOI: 10.1002/cber.19300630934; *Beilstein* **8** H 319, **8** II 355, **8** III 2658, **8** IV 2457.]

4-*N*,*N*'-Dimethylaminoazobenzene-4'-isothiocyanate {DABITC, 4-[(4-isocyanatophenyl)-azo]-*N*,*N*'-dimethylaniline} *[7612-98-8]* **$C_{15}H_{14}N_4S$, M 282.4, m 167° to 171°, 170-171°, pK_{Est}~ 2.5.** Crystallise DABITC by dissolving 1g in 150ml of boiling Me_2CO, filtering hot and allowing to cool at -20° overnight, collecting the solid and drying it in a vacuum. Solutions of it in pyridine should be used immediately, otherwise they decompose. It is soluble in dioxane (20mg/ml) to give a **red** solution. It is moisture sensitive and is used for microsequencing of peptides and proteins. [Chang *Methods Enzymol* **91** 79, 455 *1983*, DOI: 10.1016/S0076-6879(83)91012-1, DOI: 10.1016/S0076-6879(83)91043-1.] **IRRITANT.**

Dimethyldichlorosilane *[75-78-5]* **$C_2H_6Cl_2Si$, M 129.1, m -75.5°, b 68.5-68.7°/750mm, 70.5°/760mm, d_4^{20} 1.0885, n_D^{20} 1.4108.** Other impurities are chlorinated silanes and methylsilanes. Fractionate it through a 3/8in diameter 7ft Stedman column rated at 100 theoretical plates at almost total reflux. See purification of $MeSiCl_2$ *[75-54-7]* Solutions in heptane, CH_3CCl_3 or, 1-chloronaphthalene are used for the silanisation of glassware and pipettes. [Sauer & Hadsell *J Am Chem Soc* **70** 3590 *1948,* DOI: 10.1021/ja01191a014; *Beilstein* **4** IV 4110.]

2,6-Dimethyl-1,10-phenanthrolinedisulfonic acid, di-Na salt (H_2O) (bathocuproine-disulfonic acid di-Na salt) *[52698-84-7]* **$C_{26}H_{20}N_2Na_2O_6S_2$, xH_2O, M 564.5, m ~300°, pK_{Est}~0 (for free acid).** Inorganic salts and some coloured species can be removed by dissolving the crude material in the minimum volume of water

and precipitating by adding EtOH. The purified reagent can be obtained by careful evaporation of the filtrate. Recrystallise it from EtOH and dry it in a vacuum at room temperature in the dark. The reagent is used for the analytical determination of Cu and Cu-protein complexes. [Lorenzo et al. *J Electroanalyt Chem* **356** 43 *1993*, DOI: 10.1016/0022-0728(93)80509-G; Watkins et al. *Microchem J* **16** 14 *1971*, DOI: 10.1016/0026-265X(71)90077-4; cf. Matsushita et al. *Clin Chim Acta* **216** 103 *1993*, DOI: 10.1016/0009-8981(93)90143-R.]

Dimethylphenylsilyl chloride (DMPSCl, chlorodimethylphenylsilane, phenyl dimethyl chlorosilane) *[768-33-2]* **M 170.7, b 79°/15mm, 85-87°/32mm, 196°/760mm, d $_4^{20}$ 1.017, n $_D^{20}$ 1.509.** Fractionate it through a 1.5 x 18inch column packed with stainless steel helices, or a spinning band column. [Daudt & Hyde *J Am Chem Soc* **74** 386 *1952*, DOI: 10.1021/ja01122a029; Lewis *J Am Chem Soc* **70** 1115 *1948*, DOI: 10.1021/ja01183a073; Eaborn *J Chem Soc* 494 *1953*, DOI: 10.1039/JR9530000494.] It is used for standardising MeLi or MeMgBr that form Me_3PhSi which is estimated by GC. [Maienthal et al. *J Am Chem Soc* **76** 6392 *1954*, DOI: 10.1021/ja01653a043; House & Respess *J Organomet Chem* **4** 95 *1965*, DOI: 10.1016/S0022-328X(00)82372-4; *Beilstein* **16** IV 1475.] **TOXIC** and **MOISTURE SENSITIVE**.

Dimethyl thiophosphonate (dimethyl hydrogen phosphonothiolate) *[5930-72-3]* **M 126.1, b 53-53.5°/16.5mm, 56-59°/9mm, 59°/16mm, d $_4^{25}$ 1.1892, n $_D^{20}$ 1.4768.** Fractionally distil the ester in a stream of dry N_2 or Ar at as high a vacuum as possible. Store in a sealed ampoule under argon as it has a foul odour. The IR (film) has ν_{max} at ~800 cm^{-1} (12.6 μ, P-S). [IR: McIvor et al. *Canad J Chem* **34** 1611 *1956*, DOI: 10.1139/v56-211; McIvor et al. *Canad J Chem* **36** 820 *1958*, DOI: 10.1139/v58-121; Tongcharoensirikul et al. *J Org Chem* **69** 2322 *2004*, DOI: 10.1021/jo035707t; *Beilstein* **1** IV 1258.]

2,4-Dinitrobenzenesulfenyl chloride (Kharasch reagent) *[528-76-7]* **$C_6H_3ClN_2O_4S$, M 234.6, m 94-95°, 96°.** Crystallise the yellow sulfenyl chloride from CCl_4. It is a useful protective group [Review: Kharasch et al. *Chem Rev* **39** 269 *1946*]. [Kharasch & Langford *Org Synth* Coll Vol **5** 474 *1973*, DOI: 10.15227/orgsyn.044.0047; *Beilstein* **6** II 316.]

2,4-Dinitrobenzenesulfonyl chloride *[1656-44-6]* **$C_6H_3ClN_2O_6S$, M 266.6, m 101° to 103°, 102°.** Crystallise the sulfonyl chloride from *benzene or *benzene/petroleum ether. Useful reagent for the Eschenmoser α,β-cleavage of α,β-epoxyketones which involves conformational control of halolactonisation [Corey & Sachdev *J Org Chem* **40** 579 *1975*, DOI: 10.1021/jo00893a008]. [*Beilstein* **11** H 78, **11** IV 214.]

Di-*n*-octyl phenylphosphonate (DOPP) *[1754-47-8]* **$C_{22}H_{39}O_3P$, M 382.5, b 207°/4mm, 219-220°/0.7mm, d $_4^{20}$ 932, n^{25} 1.4780.** Purify it as described for diisooctyl phenylphosphonate and distil under high vacuum. [*Beilstein* **16** IV 1069.] It is used in ion-based potentiometric sensors for the flow-injection determination of promethazine hydrochloride in pharmaceutical formulations and human urine [Hassan et al. *Sensors (Basel)* **11** 1028 *2011*, DOI: 10.3390/s110101028].

(1,3-Dioxalan-2-ylmethyl)triphenylphosphonium bromide *[52509-14-5]* **$C_{22}H_{22}BrO_2P$, M 429.3, m 198-193°, 191.5-193°, 193-195°.** Wash the crystals with Et_2O, dry them in a vacuum and recrystallise them from CH_2Cl_2/dry Et_2O to give prisms with **m 172-174°**, which is raised to **191.5-193°** on drying at 56°/0.5mm. [Cresp et al. *JCS Perkin Trans 1* 37 *1974*, DOI: 10.1039/P19740000037.]

Diphenyl disulfide (phenyl disulfide) *[882-33-7]* **$C_{12}H_{10}S_2$, M 218.3, m 58° to 60°, 60.5°.** Crystallise the orange coloured disulfide from MeOH. [Alberti et al. *J Am Chem Soc* **108** 3024 *1986*]. Also crystallise it repeatedly from hot Et_2O, then dry it in a vacuum at 30° over P_2O_5, fuse it under N_2 and re-dry it; the whole procedure being repeated, with a final drying under a vacuum for 24 hours. *Alternatively*, recrystallise it from hexane/EtOH solution. [Burkey & Griller *J Am Chem Soc* **107** 246 *1985*, DOI: 10.1021/ja00287a044; *Beilstein* **6** H 323, **6** IV 1560.]

Diphenyldiselenide *[1666-13-3]* **$C_{12}H_{10}Se_2$, M 312.1, m 59-61°, 61°, 62-64°.** Crystallise it twice from hexane [Kice & Purkiss *J Org Chem* **52** 3448 *1987*, DOI: 10.1021/jo00391a054]. [*Beilstein* **6** IV 1781.]

Diphenyl hydrogen phosphate (diphenyl phosphate) *[838-85-7]* **$C_{12}H_{11}O_4P$, M 250.2, m 62-70°, 66°, 67.5°, 69°, 66-70°, 99.5°, pK^{20} 0.26.** Crystallise it from $CHCl_3$/petroleum ether. [Cherbuliez in *Organo Phosphorus Compounds* (Kosolapoff & Maier eds) Wiley Vol **6** pp 211-577 *1973*, *Beilstein* **6** IV 714.]

4,7-Diphenyl-1,10-phenanthrolinedisulfonic acid, di-Na salt $3H_2O$ (bathophenanthroline-disulfonic acid di-Na salt) *[52746-49-3]* **$C_{24}H_{14}N_2Na_2O_6S_2$, M 590.6, m 300°, pK_{Est}~0 (for free acid).** Dissolve the crude sample in the minimum volume of water and add EtOH to precipitate the contaminants. Carefully evaporate the filtrate to obtain pure material. It forms a **dark red complex** with Fe^{2+} with λ_{max} 535nm (ε 2.23 x $10^4 mol^{-1} cm^{-1}$) [Imasaka et al. *Anal Chim Acta* **115** 407 *1980*, DOI: 10.1016/S0003-2670(01)93187-3]. It is prepared by sulfonating ***bathophenanthroline*** **{(4,7-diphenyl-1,10-phenanthroline)** *[1662-01-7]* **$C_{24}H_{16}N_2$, M 332.4, m 218-220°, pKa 4.67, green colour}**, with $ClSO_3H$: to 100g of bathophenanthroline is added 0.5ml of Fe free $ClSO_3H$ and heated over a flame for 30 seconds (**CARE**). Cool and carefully add 10ml of pure distilled H_2O and warm on a water bath with stirring till all solid dissolves. A stock solution is made by diluting 3ml of this reagent to 100ml with 45% aqueous NaOAc, filter off the solid and store in a dark bottle. In this way it is stable for several months. [Landers & Zak *Am J Clinical Pathology* **29** 590 *1958*, PMID: 13533371.]

Diphenylphosphinic acid *[1707-03-5]* **$C_{12}H_{11}O_2P$, M 218.2, m 193-195°, 194-195°, pK^{20} 1.72.** Recrystallise it from 95% EtOH and dry it under vacuum at room temperature. Its solubility in 0.1N aqueous NaOH is 5g/100ml at ~25°. [see Kosolapoff *Organophosphorus Compounds* J Wiley, NY, *1950*, Kosolapoff and Maier *Organic Phosphorus Compounds* Wiley-Interscience, NY, *1972-1976*, *Beilstein* **16** IV 1036.]

Diphenyl phosphorazidate (DPPA, diphenyl phosphoryl azide, phosphoric acid diphenyl ester azide) *[26386-88-9]* **$C_{12}H_{10}N_3O_3P$, M 275.2, b 134-136°/0.2mm, 157°/0.17mm, d_4^{25} 1.277, n_D^{20} 1.551.** This azide, a **nitrene source**, is prepared by stirring a mixture of diphenyl phosphorochloridate (56.8g, 210mmol, freshly distilled at 165-168°/5mm, see *[2524-64-3]*), sodium azide (16.3g, 250mmol) and anhydrous Me_2CO (300ml, dried over K_2CO_3 and freshly distilled) in a dry atmosphere at 20-25° for 21 hours. The ***lachrymatory*** mixture is filtered in a fume cupboard, and the filtrate is concentrated in vacuum. The residue is purified by distillation through a short Vigreux column keeping the bath temperature below 200° to avoid decomposition of the ***azidate***, and collecting the fraction with b 134-136°/0.2mm (49-52g, 84-89%). It is a colourless non-explosive oil which can be stored for long periods if it is protected from moisture and light. It has IR (neat) with ν_{max} at 3060 (w, C-H), 2170 (s, $-N_3$), 1590 (m), 1490 (s, arene C=C), 1270 (m, P=O) and 960 (s, P-O-aryl) cm^{-1}; and the ^1H NMR ($CDCl_3$) has δ at 7.0-7.3 (br s, aryl-H). [Shioiri & Yamada *Org Synth* Coll Vol **7** 206 *1990*, DOI: 10.15227/orgsyn.062.0187.] It is a *useful activating agent* and a versatile reagent in organic synthesis (Cremlyn *Aust J Chem* **26** 1591 *1973*, DOI:10.1071/CH9731591; see also references cited in *Org Synth* Coll Vol **7** 206 *1990*, DOI: 10.15227/orgsyn.062.0187; above). It is commercially available on a 100-200 mesh, 1% cross-linked polydivinylbenzene support and bound (*via para* linkage) through one of its phenyl rings (**PS-DPPA**, 1.0-1.5mmol/g N_3 loading). **TOXIC.**

Diphenyl phosphoro chloridate (diphenyl phosphoryl chloride) *[2524-64-3]* **$C_{12}H_{10}ClO_3P$, M 268.6, b 141°/1mm, 194°/13mm, 314-316/272mm, d_4^{30} 1.2960, n_D^{35} 1.5490.** Fractionally distil it in a good vacuum; better use a spinning band column. [Walsh *J Am Chem Soc* **81** 3023 *1959*, DOI: 10.1021/ja01521a028; IR: Bellamy & Beecher *J Chem Soc* 475 *1952*, DOI: 10.1039/JR9520000475; *Beilstein* **6** IV 737.] Used for phosphorylating OH groups, e.g. of serines [Mora et al. *Tetrahedron Lett* **34** 2461 *1963*, DOI: 10.1016/S0040-4039(00)60441-0] and of pyranoses [Sabesam & Neira *Carbohydr Res* **223** 169 *1992*, DOI: 10.1016/0008-6215(92)80015-S]. **TOXIC, do not inhale vapours.**

Diphenylsilane *[775-12-2]* **$C_{12}H_{12}Si$, M 184.1, b 75-76°/0.5mm, 95-95°/13mm, 113-114°/9mm, 124-126°/11mm, 134-135°/16mm, 235.9-238.5°/760mm, d_4^{20} 1.0027, n_D^{20} 1.5802.** Dissolve it in Et_2O, mix slowly with ice-cold 10% AcOH. The Et_2O layer is then shaken with H_2O until the washings are neutral to litmus. Dry over Na_2SO_4, evaporate the Et_2O and distil the residual oil under reduced pressure using a Claisen flask with the take-off head modified into a short column. Ph_2SiH_2 boils at 257°/760mm, but it cannot be distilled at this temperature because exposure to **air leads to flashing**, decomposition and formation of silica. It is a colourless, odourless oil, miscible with organic solvents but not H_2O. A possible impurity is ***Ph_3SiH*** which has **m 43-45°**

and would be found in the residue. [West & Rochow *J Org Chem* **18** 303 *1953*, DOI: 10.1021/jo01131a012; Benkeser et al. *J Am Chem Soc* **74** 648 *1952*, DOI: 10.1021/ja01123a019; Gilman & Zuech *J Am Chem Soc* **81** 5925 *1959*, DOI: 10.1021/ja01531a021; *Beilstein* **16** IV 1366.]

Diphenylsilanediol *[947-42-2]* **$C_{12}H_{12}O_2Si$, M 216.1, m 148°(dec), 150°(dec).** Recrystallise it from $CHCl_3$/methyl ethyl ketone. The diol can act as an anticonvulsant like ***phenytoin*** (5,5-diphenylimidazolidine-2,4-dione, ***Dilantin***) *[57-41-0]* $C_{15}H_{12}N_2O_2$, M 252.3, m 293-295°, Fawcett et al. *Can J Chem* **55** 3631 *1977*, DOI: 10.1139/v77-510]. [*Beilstein* **16** IV 1523.]

Diphenyl sulfide *[139-66-2]* **$C_{12}H_{10}S$, M 186.3, m -40°, b 145°/8mm, 296°/atm, d_4^{20} 1.114, n_D^{20} 1.6327.** Wash the sulfide with aqueous 5% NaOH, then water. Dry it with $CaCl_2$, then with sodium. The sodium is filtered off, and the diphenyl sulfide is distilled under reduced pressure. [*Beilstein* **2** H 299, **6** IV 1488.]
Diphenyl sulfone *[127-63-9]* **$C_{12}H_{10}SO_2$, M 218.3,** has **m 123°, 125°, 129°, b 378-379°/atm.** Crystallise the sulfone from diethyl ether. Soluble in hot H_2O. It has been purified by zone melting. [*Beilstein* **6** H 300, **6** IV 1490.] Poisonous to insect eggs and spiders.

***sym*-Diphenylthiourea (thiocarbanilide)** *[102-08-9]* **$C_{13}H_{12}N_2S$, M 228.3, m 152°, 153°, 154°, 155°.** Crystallise the thiourea from boiling EtOH by adding hot water and allowing to cool. [*Beilstein* **12** H 394, **12** IV 810.] It is a rubber vulcaniser.

Diphenyl *p*-tolyl phosphate *[26444-49-5]* **$C_{19}H_{17}O_4P$, M 340.3, m 18-29°, b 156-158°/0.002mm, 235-255°/760mm, d 1.20, n_D^{25} 1.5758.** Distil it in a vacuum, then percolate it through a column of alumina. Finally, pass it through a packed column maintained at 150° to remove traces of volatile impurities in a countercurrent stream of nitrogen under reduced pressure. [Dobry & Keller *J Phys Chem* **61** 1448 *1947*, DOI: 10.1021/j150556a052; *Beilstein* **6** IV 2130.]

Disodium 4,5(1,8)-dihydroxynaphthalene-2,7(3,6)-disulfonate $2H_2O$ (Chromotropic acid di-Na salt) *[5808-22-0]* **$C_{10}H_6Na_2O_8S_2$. $2H_2O$, M 400.3, m >300°, pK_1 0.61(SO_3^-), pK_2 0.7(SO_3^-), pK_3 5.45(OH), pK_4 15.5(OH).** Recrystallise it from H_2O or H_2O by adding EtOH. It complexes with Ag, ClO_3^-, Cr, Hg, NO_2^-, NO_3^- and Ti. [*Beilstein* **11** H 72, **11** I 307, **11** II 174, **11** III 174, **11** IV 576.]

Disodium ethylenebis(dithiocarbamate) (Nabam) *[142-59-6]* **$C_4H_6Na_2S_4$, M 256.3, m 195-198°, d^{20} 1.14, pK_{Est} ~ 3.0.** It crystallises (as ***hexahydrate***) from aqueous ethanol. It is a fungicide, a skin irritant, a potential carcinogen and a hepatic microsomal monoxygenase inhibitor in rats [Périquet & Derache *Toxicol Eur Res* **3** 285 *1981*, PMID: 7330871]. [*Beilstein* **4** III 149, **4** IV 234.]

Disodium-β-glycerophosphate *[819-83-0 ($4H_2O$), 13408-09-8 ($5H_2O$)]* **$C_3H_7Na_2O_6P$. xH_2O, M 216.0 (anhydr), m 96-98°, 102-104°, pK_2^{25} 6.66 (free acid).** Crystallise it from water (solubility at ~20° is 0.1g/ml) in which it forms various hydrates. [Attwood et al. *Biochem J* **253** 387 *1988*, DOI: 10.1042/bj253038; *Beilstein* **1** I 275, **1** IV 2766.] It is a tonic agent and used in the treatment of hyperphosphatemia.

Disodium naphthalene-1,5-disulfonate *[1655-29-4]* **$C_{10}H_6Na_2O_6S_2$, M 332.3, pK_{Est} ~0.** Recrystallise it from aqueous acetone. It darkens at high temperatures. [Okahata et al. *J Am Chem Soc* **108** 2863 *1986*, DOI: 10.1021/ja00271a013; *Beilstein* **11** IV 561.]

Disodium *p*-nitrophenylphosphate ($6H_2O$) (pNPP) *[4264-83-9]* **$C_6H_4NNa_2O_6P$. $6H_2O$, M 371.1** Dissolve it in hot aqueous MeOH, filter and precipitate it by adding Me_2CO. Wash the solid with Me_2CO and repeat the purification. Aqueous MeOH and Et_2O can also be used as solvents. The white fibrous crystals contain less than 1% of free *p* -nitrophenol. It is a substrate for the determination of acid and alkaline phosphatases where it produces the soluble yellow end product (*p*-nitrophenol) that can be read off spectrophotometrically at 405nm. The pNPP enzymic reaction may be stopped with 3N NaOH, and its concentration is read at 405nm. [Assay: Axelrod *J Biol Chem* **167** 57 *1947*, http://www.jbc.org/content/167/1/57.] [*Beilstein* **6** IV 1327.]

Disodium phenylphosphate ($2H_2O$) *[3279-54-7, 66778-08-3 ($2H_2O$)]* **$C_6H_5Na_2O_4P$. $2H_2O$, M 254.1, pK_1^{25}**

1.46, pK_2^{25} 6.29 [for $PhPO(OH)_2$]. Dissolve it in a minimum amount of methanol, filtering off any insoluble residue of inorganic phosphate, then precipitate it by adding an equal volume of Et_2O. Wash the solid with Et_2O and dry it in a vacuum [Tsuboi *Biochim Biophys Acta* **8** 173 *1952*, DOI: 10.1016/0006-3002(52)90027-9]. Store it in a sealed container at 2-8° as it is ***hygroscopic***. Its solubility in H_2O at ~20° is 0.1g/ml. [*Beilstein* **6** IV 708.]

Dithizone (diphenylthiocarbazone) *[60-10-6]* **$C_{13}H_{12}N_4S$, M 256.3, m 168°(dec), ratio of $\varepsilon_{620nm}/\varepsilon_{450nm}$ should be ≥1.65, ε_{620} 3.4 x 10^4 ($CHCl_3$), pK_2 4.6.** The crude dithizone is dissolved in CCl_4 to give a concentrated solution. This is filtered through a sintered glass funnel and shaken with 0.8M aqueous ammonia to extract ***dithizonate ion***. The aqueous layer is washed with several portions of CCl_4 to remove undesirable materials. The aqueous layer is acidified with dilute H_2SO_4 to precipitate pure ***dithizone***. This is dried in a vacuum. When only small amounts of dithizone are required, purification by paper chromatography is convenient. [Cooper & Hibbits *J Am Chem Soc* **75** 5084 *1933*, DOI: 10.1021/ja01116a054.] Instead of CCl_4, $CHCl_3$ can be used, and the final extract, after washing with water, can be evaporated in air at 40-50° and dried in a desiccator. It complexes with Cd, Hg, Ni and Zn. [*Beilstein* **16** H 26, **16** IV 18.]

Di-*p*-tolyl phenylphosphonate *[94548-75-1]* **$C_{20}H_{19}O_3P$, M 338.3, n_D^{25} 1.5758.** Purify as described under diisooctyl phenylphosphonate.

Di-*p*-tolyl sulfone *[599-66-6]* **$C_{14}H_{14}O_2S$, M 246.3, m 158-159°, 160°, 163.5°, b 405°/760mm.** Crystallise the sulfone repeatedly from Et_2O or EtOH. It has been purified by zone melting. [*Beilstein* **6** H 419, **6** II 395, **6** III 1405, **6** IV 2174.]

1,3-Divinyl-1,1,3,3-tetramethyldisiloxane *[2627-95-4]* **$C_8H_{18}OSi_2$, M 186.4, m -100°, -99°, -99.7°, b 128-129°/atm, 139°/760mm, 139-140°/760mm, d_4^{20} 0.811, n_D^{20} 1.4122.** Dissolve it in Et_2O, wash it with H_2O, dry it over $CaCl_2$, evaporate the solvent and distil the residue. It is an **IRRITANT**. [Kantor et al. *J Am Chem Soc* **77** 1685 *1955*, DOI: 10.1021/ja01611a090; Bažant & Matoušek *Coll Czech Chem Commun* **24** 3758 *1959*, DOI: org/10.1135/cccc19593758; *Beilstein* **4** IV 4080.]

Eriochrome Black T

[3-hydroxy-7-nitro-4-(1-hydroxy-2-naphthylazo)naphthalene-1-sulfonic acid Na salt] *[1787-61-7]* **$C_{20}H_{12}N_3NaO_7S$, M 461.4, $A^{\%}_{1cm}(\lambda_{max})$ 656(620nm) at pH 10, using the dimethylammonium salt, pK_2^{25} 5.81, pK_3^{25} 11.55.** The sodium salt (200g) is converted to the ***free acid*** by stirring with 500ml of 1.5M HCl, and, after several minutes, the slurry is filtered on a sintered-glass funnel. The process is repeated and the material is air dried after washing with acid. It is then extracted with *benzene for 12 hours in a Soxhlet extractor, the *benzene solution is evaporated and the residue is air dried. A further desalting with 1.5M HCl (1L) is followed by crystallisation from dimethylformamide (in which it is very soluble) by forming a saturated solution at the boiling point, and allowing to cool slowly. The crystalline dimethylammonium salt so obtained is washed with *benzene and treated repeatedly with dilute HCl to give the insoluble ***free acid*** which, after air drying, is dissolved in alcohol, filtered and evaporated. The final material is air dried, then dried in a vacuum desiccator over $Mg(ClO_4)_2$. The purified acid is converted to the dimethylammonium salt with Me_2NH. [Diehl & Lindstrom *Anal Chem* **31** 414 *1959*, DOI: 10.1021/ac60147a026]. It is an indicator in the complexometry of alkaline earth metals. [*Beilstein* **16** IV 429.]

Eriochrome Blue Black B **(Mordant Black, 3, 3-hydroxy-4-(1-hydroxy-2-naphthylazo)-naphthalene-1-sulfonic acid Na salt]** *[3564-14-5]* **$C_{20}H_{13}N_2NaO_5S$, M 416.4,** has **pK_2^{25} 7.0, pK_3^{25} 13,5.** Free it from metallic impurities by three precipitations from aqueous solution by addition of HCl. The precipitated dye is dried at 60° under vacuum and converted into the Na salt with the calculated amount of alkali. It is an indicator in the complexometry of Al, Fe and Zr. [*Beilstein* **16** III 319.]

Eriochrome Blue Black R **(Palatine Chrome Black 6BN, Mordant Black 17, 3-hydroxy-4-(2-hydroxy-1-naphthylazo)naphthalene-1-sulfonic acid Na salt]** *[2538-85-4]* **$C_{20}H_{13}N_2NaO_5S$, M 416.4,** has **pK_2^{25} 7.0, pK_3^{25} 13.5.** Free it from metallic impurities by three precipitations from aqueous solution by addition of HCl. The precipitated dye is dried at 60° under vacuum and converted into the Na salt with the calculated amount of alkali. It is an indicator in the complexometry of Al, Fe and Zr. [*Beilstein* **16** H 297, **16** IV 428.]

Ethoxycarbonylmethylene triphenylphosphonium bromide *[1530-45-6]* **$C_{22}H_{22}BrO_2P$, M 429.3, m 145-**

150°, 155-155.5°, 158°(dec), pKa 8.95-9.2 (deprotonation). Wash it with petroleum ether (b 40-50°) and recrystallise it from $CHCl_3/Et_2O$; and dry it in a high vacuum at 65°. Its solubility at ~20° in H_2O is 100g/L, in EtOH it is 350g/L, in $CHCl_3$ it is 550g/L, but it is insoluble in THF (<10g/L). [Isler et al. *Helv Chim Acta* **40** 1242 *1957*, DOI: 10.1002/hlca.19570400515; Wittig & Haag *Chem Ber* **88** 1654, 1664 *1955*, DOI: 10.1002/cber.19550881110.] [*Beilstein* **16** IV 980.] **IRRITANT.**

(Ethoxycarbonylmethylene)triphenylphosphorane **[ethyl (triphenylphosphoranylidene)-acetate]** *[1099-45-2]* **$C_{22}H_{21}O_2P$, M 348.4,** has **m 116-117°, 128-130°.** Crystallise it by dissolving it in AcOH and adding petroleum ether (b 40-50°) to give colourless plates. Its UV has λ_{max} ($A^{1\%}_{1mm}$) at 222nm (865) and 268nm (116). Its solubility at ~20° in EtOH is 4.2g/10ml, in THF it is 1.3g/10ml, in $CHCl_3$ it is 2.9g/10ml, but it is insoluble in H_2O (<0.05g/10ml). [Isler et al. *Helv Chim Acta* **40** 1242 *1957*, DOI: 10.1002/hlca.19570400515; *Beilstein* **16** IV 977.]

Ethylarsonic acid *[507-32-4]* **$C_2H_7AsO_3$, M 154.0, m 94-95°, 99.5°, pK_1 4.72 ($As(OH)O^-$), pK_2 8.00 [AsO_2^{2-}].** Crystallise it from ethanol. Also it dissolves in excess EtOH, filter off the insoluble matter (salts?), evaporate the filtrate to dryness and recrystallise the residue from small volumes of EtOH or H_2O. [Quick & Adams *J Am Chem Soc* **44** 805 *1922*, DOI: 10.1021/ja01425a014; Banks et al. *J Am Chem Soc* **69** 927 *1947*, DOI: 10.1021/ja01196a057; *Beilstein* **4** H 614, **4** II 997, **4** III 1823, **4** IV 3682.]

Ethylene di(*p*-toluenesulfonate) (ethylene glycol ditosylate) *[6315-52-2]* **$C_{16}H_{18}O_6S_2$, M 370.44, m 124-127°, m 126-127°, m 128°.** It is prepared when ethylene glycol (0.5mole) and *p*-toluenesulfonyl chloride (1.0mole) are stirred in Me_2CO (100ml) in the presence of 25% aqueous NaOH (175ml, 44g, 1.1mole) at 2-10° for ~4 hours. Excess of ice-water is added, the solid is filtered off, washed with large volumes of H_2O, dried *in vacuo* and recrystallised from dry $*C_6H_6$ (absolute EtOH has also been used) to give the ***di-tosylate*** (**m 128°**) in 76% yield [Drahowzal & Klamann *Monatsh Chem* **82** 452 *1951*, DOI: 10.1007/BF00900841]. *Alternatively*, ethylene glycol (0.25mole), *p*-toluenesulfonyl chloride (0.52mole) in dry pyridine (80g, 1mole) are stirred gently at -10° to -4° for 2 hours then treated with excess of ice-water as above to give the ***diester*** in 87.3% yield [Drahowzal & Klamann *Monatsh Chem* **82** 460 *1951*, DOI: 10.1007/BF00900842]. The latter method is superior as there is no H_2O in the reaction medium. **Note** that attempts to prepare the ***mono-p-tosylate ester*** using equimolar amounts of glycol and sulfonyl chloride always produced the ***diester*** which crystallised as white plates (**m 126°**) from hot EtOH [Butler et al. *J Am Chem Soc* **57** 575 *1935*, DOI: 10.1021/ja01306a057]. [*Beilstein* **11** II 296, **11** III 225, **11** IV 290.]

S,S'-Ethylene di(*p*-toluenethiosulfonate) (ethylene dithiotosylate) *[2225-23-2]* **$C_{16}H_{18}O_4S_4$, M 402.5, m 75-76°.** This reagent is the lower homologue of ***1,3-trimethylene di(thiotosylate)*** *[3866-79-3]*, and is made from potassium thiotosylate (45g, 0.20 mole, see below *[28519-50-8]*) and 1,2-dibromoethane (18.8g, 0.1 mole) in EtOH (200ml, containing 10-20mg of KI to activate the dibromide) by refluxing, with stirring in the dark under a N_2 atmosphere, for 8 hours. The solvent is evaporated *in vacuo*, and the white solid residue is washed, by decantation, with a mixture of EtOH (80ml) and H_2O (150ml), and then with H_2O (3 x 50ml), and recrystallised from EtOH (~150ml) to provide the crude thioester (28.7g) with m 72-75°. The ***pure thioester*** (24g, 60%), **m 75-76°**, is obtained as white crystals after three recrystallisations from EtOAc/EtOH; and its ^1H NMR ($CDCl_3$, TMS) has δ at 2.47 (s, 6H, $2CH_3$), 3.31 (s, 4H, CH_2CH_2), 7.48 (d, *J* = 9Hz, 4H, Aromatic H) and 7.97 (d, *J* = 9Hz, 4H, Aromatic H). [Woodward et al. *Org Synth* Coll Vol **6** 1016 *1988*, DOI: 10.15227/orgsyn.054.0033.] Like the trimethylene homologue below it can form 1,3-dithiolanes with activated methylene groups and carbonyl compounds. [*Beilstein* **11** II 71.]

Ethynyl *p*-tolylsulfone (tosylacetylene) *[13894-21-8]* **$C_9H_8O_2S$, M 180.2, m 65-67°, 73-74°.** Recrystallise the sulfone from petroleum ether, $*C_6H_6$ or EtOH (**m** 66°), and dry it in a vacuum. [te et al. *J Am Chem Soc* **107** 686 *1985*, DOI: 10.1021/ja00289a024; *Beilstein* **6** III 1397, **6** IV 2160.]

Ethyl Orange (sodium 4,4'-diethylaminophenylazobenzenesulfonate) $C_{16}H_{18}NaN_3O_3S$, *[62758-12-7, 13545-67-0 free acid]* **M 355.4, pK_{Est} ~ 3.8 .** Recrystallise it twice from water. It is an indicator with a visual transition interval from red to orange in the pH region 3.0—4.8 with λ_{max} at 474nm. [*Beilstein* **16** IV 511.]

Ethyl trimethylsilylacetate (ETSA) *[4071-88-9]* **$C_7H_{16}O_2Si$, M 160.3, b 75.5°/42mm, 157°/730mm, 156-158°/760mm, d_4^{20} 0.8762, n_D^{20} 1.4149.** Purify it by distilling *ca* 10g of reagent through a 15cm, Vigreux column and then redistilling it through a 21cm glass helices-packed column [Hance & Hauser *J Am Chem Soc* **75** 994 *1953*, DOI: 10.1021/ja01100a511]. *Alternatively*, dissolve it in Et_2O, wash with H_2O, dilute Na_2CO_3, dry over Na_2CO_3, evaporate Et_2O, and distil it through a column of 15 theoretical plates. [Gold et al. *J Am Chem Soc* **70** 2874 *1948*, DOI: 10.1021/ja01100a511; *Beilstein* **4** IV 3974.]

Ethyl 3-(trimethylsilyl)propionate *[17728-88-0]* **$C_8H_{18}O_2Si$, M 174.3, b 93°/40mm, 178°-180°/atm, d_4^{20} 0.8763, n_D^{20} 1.4198.** Dissolve it in Et_2O, wash this with H_2O, dilute Na_2CO_3, dry (Na_2SO_4), evaporate Et_2O and fractionally distil. It is a starting material for the synthesis of ***2-(TMS-methyl)allylic alcohols*** and related compounds [Vedejs et al. *J Org Chem* **47** 1534 *1982*, DOI: 10.1021/jo00347a034; Nishitani & Yamakawa *Tetrahedron Lett* **28** 655 *1987*, DOI: 10.1016/S0040-4039(00)95805-2]. [Sommer & Marans *J Am Chem Soc* **72** 1935 *1950*, DOI: 10.1021/ja01161a021; *Beilstein* **4** IV 3975.]

Ethyl triphenylphosphonium bromide *[1530-32-1]* **$C_{20}H_{20}BrP$, M 371.3, m 203-205°**. Recrystallise it from H_2O and dry it in a high vacuum at 100°. Its IR has bands at 1449, 1431 and 997cm^{-1}. [Wittig & Wittenberg *Justus Liebigs Ann Chem* **606** 1 *1957*, DOI: 10.1002/jlac.19576060102; Bergmann & Dusza *J Org Chem* **23** 1245 *1958,* DOI: 10.1021/jo01103a002; *Beilstein* **16** IV 982.] It is a useful phase transfer catalyst, is *hygroscopic* and should stored in a dry atmosphere.

Ethynyl trimethylsilane *[1066-54-2]* **M 98.2, b 53°/atm, 52.5°/atm, d_4^{20} 0.71, n_D^{20} 1.3871.** Distil it through an efficient column. The IR has bands at ν_{max} 2041 (C≡C) and 3289 (≡C-H) cm^{-1}. [Kröhnke & Gross *Chem Ber* **92** 22 *1959*, DOI: 10.1002/cber.19590920105; *Beilstein* **4** IV 3937.] A suitable substrate for Ni-catalysed cross-coupling with benzonitriles [Penney & Miller *Tetrahedron Lett* **45** 4989 *2004*, DOI: 10.1016/j.tetlet.2004.02.163], and used in the *microwave assisted* 1,3-dipolar cycloaddition reactions for preparing pyrazoles [Zrinski et al. *Heterocycles* **68** 1961 *2006*, DOI: 10.3987/COM-06-10803].

4-Fluorophenyl isothiocyanate *[1544-68-9]* **C_7H_4FNS, M 153.2, m 24-26°, 26-27°, b 66°/2mm, 215°/atm, 228°/760mm, n_D^{20} 1.6116.** A likely impurity is the symmetrical thiourea. Dissolve the isothiocyanate in dry $CHCl_3$, filter and distil the residue in a vacuum. It can also be steam distilled, the oily layer is separated, dried over $CaCl_2$ and distilled *in vacuo*. ***Bis-(4-fluorophenyl)thiourea*** has **m 145°** (from aqueous EtOH). [Browne & Dyson *J Chem Soc* 3285 *1931*, DOI: 10.1039/JR9310003285; Buu Hoi et al. *J Chem Soc* 1573 *1955*, DOI: 10.1039/JR9550001573; Dains et al. *Org Synth* Coll Vol **1** 447 *1941*, DOI: 10.15227/orgsyn.006.0072].

Fluorotrimethylsilane (trimethylsilyl fluoride, TMSF) *[420-56-4]* **C_3H_9FSi, M 92.2, m -74°, b 16°/760mm, 16-18°/760mm, 19°/730mm, d^0 0.793.** It is a **FLAMMABLE** gas that is purified by fractional distillation through a column at low temperature and with the exclusion of air. Preferably work in a vacuum line. [Booth & Suttle *J Am Chem Soc* **68** 2658 *1946*, DOI: 10.1021/ja01216a072; Reid & Wilkins *J Chem Soc* 4029 *1955*, DOI: 10.1039/JR9550004029; *Beilstein* **4** IV 4007.]

Hexaethyldisiloxane *[924-49-0]* **$C_{12}H_{30}OSi_2$, M 246.5, b 114-115°/16mm, 235.5°/760mm, d_4^{20} 0.8443, n_D^{20} 1.4330**. Distil in a vacuum, but it can be distilled at atmospheric pressure without decomposition. It is characterised by completely dissolving in concentrated H_2SO_4. [Eaborn *J Chem Soc* 3077 *1950*, DOI: 10.1039/JR9500003077; *Beilstein* **4** IV 4055.] Used in the facile silylation of carboxylic acids to trimethylsilyl carboxylates in 74-97% yields [Matsumoto et al. *Chem Lett* 1475 *1980*, DOI: 10.1246/cl.1980.1475].

2,2,4,4,6,6-Hexamethylcyclotrisilazane *[1009-93-4]* **$C_6H_{21}N_3Si_3$, M 219.6, m -10°, b 81-82°/19mm, 111-112°/85mm, 188°/756mm, d_4^{20} 0.9196, n_D^{20} 1.448.** Purify it by fractional distillation at atmospheric pressure until the temperature reaches 200°. It is ***moisture sensitive***. The residue in the flask can be distilled (**b** 225°/756mm) and is mostly octamethylcyclo-tetrasilazane which can be crystallised from petroleum ether (**m**

97°). [Brewer & Haber *J Am Chem Soc* **70** 3888 *1948*, DOI: 10.1021/ja01191a106; *Beilstein* **4** III 1887.]

2,2,4,4,6,6-Hexamethylcyclotrisiloxane *[541-05-9]* **$C_6H_{18}O_3Si_3$, M 222.4, m 50-64°, 64.5°, 64-66°, b 131°/760mm, 134°/760mm.** The cyclotrisiloxane is purified by stirring the molten compound with finely ground CaH_2 for 12 hours, filtered hot and sublimed under high vacuum. The sublimed ***monomer*** is then dissolved in dry $*C_6H_6$, treated with PS^-Li^+ (polystyrene lithium salt) for further purification. The $*C_6H_6$ solution is filtered, evaporated to dryness and the residue is sublimed under high vacuum again. A stock solution of the ***siloxane*** in $*C_6H_6$ can be used for further work [Bellas et al. *Macromolecules* **33** 6993 *2000*, DOI: 10.1021/ma000635i]. [*Beilstein* **4** IV 4123.]

Hexamethyldisilane *[1450-14-2]* **$C_6H_{18}Si_2$, M 164.4, m 9-12°, 12-13°, 13.5°, b 113.1°/750mm, 112-114°/760mm, d_4^{20} 0.7272, n_D^{20} 1.4229.** The most likely impurity is ***trimethylchlorosilane*** (cf. boiling point). Wash it with H_2O, cold concentrated H_2SO_4, H_2O again, then aqueous $NaHCO_3$, dry over $CaSO_4$ and fractionate at atmospheric pressure. [Brown & Fowles *J Chem Soc* 2811 *1958*, DOI: 10.1039/JR9580002811.] A grossly impure sample (25% impurities) was purified by repeated spinning band distillation. This lowered the impurity level to 500 ppm. The main impurity was identified as ***1-hydroxypentamethyldisilane***. The Si-Si bond is cleaved by strong nucleophiles and electrophiles. [Hiyama & Kuroboshi, '*Hexamethyldisilane*' in Encyclopedia of Reagents for Organic Synthesis, 2001 John Wiley & Sons. DOI:10.1002/047084289X.rh015; *Beilstein* **4** IV 4277.] Used in low pressure chemical deposition of silicon carbide thin films [Chiu & Hsu *Thin Solid Films* **252** 13 *1994,* DOI: 10.1016/0040-6090(94)90818-4]. **IRRITANT and FLAMMABLE.**

Hexamethyldisilazane [HMDS, $(Me_3Si)_2NH$) *[999-97-3]* **$C_6H_{19}NSi_2$, M 161.4, m -80°, -78°, b 125-125.6°/atm, 126°/760mm, d_4^{20} 0.7747, n_D^{20} 1.407.** A possible impurity is ***Me_3SiCl***. Wash it well with petroleum ether and fractionate it through a vacuum jacketed column packed with Helipac using a reflux ratio of 10:1. [Langer et al. *J Org Chem* **23** 50 *1958*, DOI: 10.1021/jo01095a017; Osthoff & Kantor 'Organosilazane Compounds' *Inorg Synth* **5** 5 *1957*, DOI: 10.1002/9780470132364.ch16. ISBN 978-0-470-13236-4; *Beilstein* **4** IV 4014.] It forms a ***lithium salt***, $(Me_3Si)_2NLi$ *[4039-32-1]*, which is soluble in THF and hexane; and ~ 1M solutions in these solvents are available commercially. **IRRITANT and FLAMMABLE**.

Hexamethyldisiloxane (HMDSO) *[107-46-0]* **$C_6H_{19}OSi_2$, M 162.4, m -59°, b 99.4°/760mm, 100.4°/764mm, 101°/764mm, d_4^{20} 0.7633, n_D^{20} 1.3777.** Fractionally distil through a column packed with glass helices with *ca* 15 theoretical plates. It is highly **flammable** and is an **irritant**. [Mills & McKenzie *J Am Chem Soc* **76** 2672 *1954*, DOI: 10.1021/ja01639a020; Csakvari et al. *J Organometal Chem* **107** 287 *1976*, DOI: 10.1016/S0022-328X(00)91519-5; *Beilstein* **4** IV 4018.] It is also a commercially available NMR reference standard, as a 25% solution in $*C_6H_6$-d_6.

Hexamethylphosphoric triamide (HMPA) *[680-31-9]* **$C_6H_{18}N_3OP$, M 179.2, m 7.2°, b 68-70°/1mm, 230-232°/740mm, 235°/760mm, d_4^{20} 1.024, n_D^{20} 1.460.** The industrial synthesis is usually by treatment of $POCl_3$ with excess of dimethylamine in isopropyl ether. Impurities are water, dimethylamine and its hydrochloride. It is purified by refluxing over BaO or CaO at about 4mm pressure in an atmosphere of nitrogen for several hours, then distilled from sodium at the same pressure. The middle fraction (**b *ca* 90°**) is collected, refluxed over sodium under reduced pressure under nitrogen and distilled. It is kept in the dark under nitrogen, and stored in solid CO_2. It can also be stored over 4A molecular sieves. ***Alternatively***, it is distilled under vacuum from CaH_2 at 60° and is crystallised twice in a cold room at 0°, seeding the liquid with crystals obtained by cooling in liquid nitrogen. After about two-thirds are frozen, the remaining liquid is drained off [Fujinaga et al. *Pure Appl Chem* **44** 115 *1975*, DOI: 10.1351/pac197544010115]. For tests of purity see Fujinaga et al. in *Purification of Solvents*, Coetzee Ed., Pergamon Press, Oxford, 1982. For efficiency of desiccants in drying HMPA see Burfield and Smithers [*J Org Chem* **43** 3966 *1978*, DOI: 10.1021/jo00414a038; and Sammes et al. *JCS Perkin Trans 1* 281 *1986*, DOI: 10.1039/P19860000281]. [*Beilstein* **4** IV 284.] Useful aprotic solvent. **CARCINOGEN.**

Hexamethylphosphorous triamide [HMPT, tris(dimethylamino)phosphine] *[1608-26-0]* **$C_6H_{18}N_3P$, M 163.2, m -44°, b 49-51°/12mm, 162-164°/atm, 176.2-178.9°/760mm, d_4^{20} 0.989, n_D^{20} 1.4636.** It may contain more than 1% of phosphoric triamide. The yellow oil is first distilled at atmospheric pressure, then under

reduced pressure and stored under N_2. ^{1}H NMR ($CDCl_3$, 300MHz): δ 2.48 (d, *J* 9.1Hz, 18*H*) ppm; ^{31}P NMR ($CDCl_3$, 162MHz, H_3PO_4, 40%): δ 122 ppm. It is air sensitive, **TOXIC**, *and should not be inhaled*. It is absorbed through the skin. [Mark *Org Synth* Coll Vol **5** 602 *1973*, DOI: 10.15227/orgsyn.046.0042; Harvey & Schneider in *e-EROS Encyclopedia of Reagents for Organic Synthesis* on line 22 APR 2013, DOI: 10.1002/047084289X.rh022.pub2; *Beilstein* **4** IV 274.]

Hydroquinone-2-sulfonic acid K salt *[21799-87-1]* **$C_6H_5KO_5S$, M 228.3, m 250°(dec), $pK_{Est(1)}$~1, $pK_{Est(2)}$~8.5, $pK_{Est(3)}$~11.** Recrystallise it from water or EtOH. [*Beilstein* **11** I 70, **11** II 170, **11** III 570.]

Hydroxynaphthol Blue tri-Na salt [1-(2-hydroxy-4-sulfo-1-naphthylazo)-2-naphthol-3,6-disulfonic acid tri-Na salt) *[63451-35-4 for di-Na salt, 165660-27-5 for tri-Na salt]* **$C_{20}H_{11}N_2Na_3O_{11}S_3$, M 620.5, m dec on heating, pK_{Est} <0.** The crude material is treated with hot EtOH to remove soluble impurities, then dissolve in 20% aqueous MeOH and chromatographed on a cellulose powder column with propanol/EtOH/water (5:5:4) as eluent. The upper of three zones are eluted to give the pure dye that is precipitated as the ***monosodium salt trihydrate*** by adding concentrated HCl to the concentrated eluate [Ito & Ueno *Analyst* **95** 583 *1970*, DOI: 10.1039/ AN9709500583]. It can be converted to the ***trisodium salt*** by adding the calculated amount of alkali. The synthetic dye is a Ca indicator with λ_{max} at 650m, where in the pH range 12—13 the solution of the indicator is red-pink in the presence of Ca^{2+} and deep blue in the presence of excess of EDTA.

6-Hydroxy-2-naphthyl disulfide *[6088-51-3]* **$C_{20}H_{14}O_2S_2$, M 350.5, m 221-222°, 226-227°, pK_{Est} ~9.0.** It crystallises as leaflets from AcOH and is slightly soluble in EtOH, and AcOH, but is soluble in $^*C_6H_6$ and in alkalies to give a yellow solution. [Zincke & Dereser *Chem Ber* **51** 352 *1918*, DOI: 10.1002/ cber.19180510137.] The ***acetyl derivative*** has **m 198-200°** (from AcOH or dioxane/MeOH), and the ***diacetyl derivative*** has **m 167-168°** (from AcOH). A small amount of impure disulfide can be purified by dissolving it in a small volume of Me_2CO and adding a large volume of toluene, filtering rapidly and concentrating to one-third of its volume. The hot toluene solution is filtered rapidly from any tarry residue, and crystals separate on cooling. Recrystallisation from hot acetic acid gives crystals with **m 220-223°** [Barrett & Seligman *Science* **116** 323 *1952*, DOI: 10.1126/science.116.3013.323]. Store at -20°. **[***Beilstein* **6** I 481.]

Hydroxy(tosyloxy)iodobenzene [phenyl(hydroxyl)tosyloxyiodine, hydroxy(4-methylbenzenesulfonato-O)-phenyliodine, Koser's reagent] *[27126-76-7]* **$C_{13}H_{13}IO_4S$, M 392.2, m 131° to 137°, 134-136°, 135-138°, 134-136°, 136-138.5°.** Possible impurities are tosic acid (removed by washing with Me_2CO) and acetic acid (removed by washing with Et_2O). It is purified by dissolving in the minimum volume of MeOH, adding Et_2O to cloud point and setting aside for the prisms to separate [Koser & Wettach *J Org Chem* **42** 1476 *1977*, DOI: 10.1021/jo00428a052; NMR: Koser et al. *J Org Chem* **41** 3609 *1976*, DOI: 10.1021/jo00884a028]. It has also been crystallised from CH_2Cl_2 (needles, **m 140-142°**) [Neiland & Karele *J Org Chem, USSR (Engl Transl)* **6** 889 *1970*]. Store in a refrigerator. It is a useful oxidant in organic synthesis [Kumar *Synlett* 2764 *2007*, DOI: 10.1055/s-2007-991080].

Indigocarmine (2[1,3-dihydro-3-oxo-5-sulfo-2*H*-indol-2-ylidene]-2,3-dihydro-3-oxo-1*H*-indole-5-sulfonic acid di-Na salt), Acid Blue 74, Indigo-5,5'-disulfonic acid di-Na salt) *[860-22-0]* **$C_{16}H_8N_2Na_2O_8S_2$, M 466.4, pK_1^{20} 2.8, pK_2^{20} 12.3.** Its solubility in H_2O is 1g/100ml at 25°. It has been purified by dissolving in H_2O, filtering and adding EtOH to cause the salt to separate. Wash the solid with EtOH, Et_2O and dry *in vacuo*. Biological Stain. [Vörlander & Schubart *Chem Ber* **34** 1860 *1901*, DOI: 10.1002/cber.19010340290; UV: Smit et al. *Anal Chem* **27** 1159 *1955,* DOI: 10.1021/ac60103a035; Preisler et al. *J Am Chem Soc* **81** 1991 *1959*, DOI: 10.1021/ja01517a051; *Beilstein* **25** IV 1975.]

Iodomethyl trimethylsilane *[4206-67-1]* **$C_4H_{11}ISi$, M 214.1, b 139.5°/744mm, d_4^{20} 1.44, n_D^{25} 1.4917.** If slightly violet in colour, wash it with aqueous 1% sodium metabisulfite, H_2O, dry it (Na_2SO_4), and fractionally distil it at 760mm. [Whitmore & Sommer *J Am Chem Soc* **68** 481 *1946*, DOI: 10.1021/ja01207a036.]

Iodotrimethylsilane (trimethylsilyl iodide, TMSI) *[16029-98-4]* **C_3H_9ISi, M 200.1, b 106.8°/742mm, 107.5°/760mm, d_4^{20} 1.470.** Add a little antimony powder and fractionate with this powder in the still. Stabilise

the distillate with 1% wt of Cu powder and store away from light. It is prepared by adding I_2 (124g, 0.49mol) in ~20g portions to trimethylphenylsilane (75g, 0.5ml, see *3385-94-2* below) containing aluminium iodide (1g) and refluxing after each addition until the I_2 is consumed. Further AlI_3 (1g) is added after ~60g of I_2 are used, and boiling continued (total 2 hours) when all I_2 is consumed. ***Me$_3$SiI*** (94g, 94%) is collected by fractionation as stated above. [Eaborn *J Chem Soc* 3077 *1950*, DOI: 10.1039/JR9500003077; review *A versatile organic reagent* see Olah & Narang *Tetrahedron* **38** 2225 *1982*, DOI: 10.1016/0040-4020(82)87002-6; *Beilstein* **4** IV 4009.] It has also been obtained from ***bis(trimethylsilyl) selenide*** (1.0g, 7.4mmol, 4099-46-1, *via* syringe) which is added to a solution of I_2 (1.14, 4.5mmol) in *m*-xylene (1ml) under argon causing a mild exothermic reaction. ***Me$_3$SiI*** (1.6g, 94%) is distilled onto a Cu wire (colourless liquid, b 106-107°/atm). The residue in the pot when washed with Et_2O and dried was pure Se (0.35g, 100%). Store at -35° in a drybox in the dark. [Detty & Seidler *J Org Chem* **47** 1354 *1982*, DOI: 10.1021/jo00346a041.]

Isopropyldimethyl chlorosilane *[3634-56-8]* **$C_5H_{13}ClSi$, M 136.7, b 109.8-110.0°/738mm, d_4^{20} 0.88, n_D^{20} 1.4158.** Probable impurity is Me_3SiCl (**b** 56.9°/783mm) which can be removed by efficient fractional distillation. [Sommer et al. *J Am Chem Soc* **76** 801 *1954*, DOI: 10.1021/ja01632a050; *Beilstein* **4** IV 4067.]

N*-Isopropylidene-*N′*-2-nitrobenzenesulfonyl hydrazine (IPNBSH, isopropylidenehydrazide *o*-nitrobenzenesulfonic acid)** *[6655-27-2]* **$C_9H_{11}N_3O_4S$, M 257.3, m 132-135°, 139-140°.** IPNSBH is more stable than ***NBSH (*vide infra*) from which it is readily prepared by dissolving it (1.14g, 1 equivalent) in Me_2CO (8ml) at 0°, and after 30 minutes the solvent is removed *in vacuo*, the residue is re-dissolved in Me_2CO (4ml), and added slowly into 150ml of hexanes. The fine powder is filtered off, rinsed with hexanes (2 x 5ml) and dried *in vacuo* to give ***IPNBSH*** as a white solid (1.20g, 89%; TLC has R_F 0.7, 66% EtOAc in hexanes). Its FTIR (thin film) has ν_{max} at 1177s, 1347m, 1375s, 1551s, 3264s cm^{-1}; its ^1H NMR [400MHz, $CDCl_3$, 20°] has δ at 8.30-8.28 (m, 1H), 7.87-7.85 (m, 2H), 7.79-7.77 (m, 2H), 1.96 (s, 3H), 1.92 (s, 3H), and its ^{13}C NMR [500MHz, $CDCl_3$, 20°] has δ at 158.9, 134.2, 133.5, 132.9.2, 132.0, 125.4, 25.5, 17.2. ***IPNBSH*** promotes the same reactions as ***NBSH*** except that it is more stable. A solution of 0.02M ***IPNBSH*** in DMSO is undecomposed at 50° during 30 minutes, whereas *NBSH* is 60% decomposed, and at is stable at 75° or 100° for 30 minutes so it can be stored at room temperature for several months without deterioration; all the same store it under argon (as it is possibly flammable), and use gloves due to its **toxicity**. It is a reagent used for allylic transposition, debromination and reduction of alcohols in the presence of DEAD and Ph_3P. [Movassaghi et al. *Angew Chem Int Ed* **45** 5859 *2006*, DOI: 10.1002/anie.200602011; Movassaghi & Ahmad *J. Org. Chem.* **72** 1838 *2007*, DOI: 10.1021/jo062325p].

N-Lauroyl-*N*-methyltaurine sodium salt

(sodium *N*-decanoyl-*N*-methy-2-aminoethane sulfonate) *[4337-75-1]* **$C_{15}H_{30}NNaO_4S$, M 344.5, pK_{Est} ~1.5.** It is prepared from methyldecanoate (at 180° under N_2) or decanoyl chloride and sodium *N*-methylethane sulfonate and purified by dissolving it in H_2O and precipitating by addition of Et_2O. It decomposes on heating. It is a useful surfactant detergent [Desseigne & Mathian *Mém Services Chim Etat Paris* **31** 359 *1944*, cf. *Chem Abstr* **41** 705 *1947*.]

Lawesson's Reagent [LR, 2,4-bis(4-methoxyphenyl)1,3,2,4-dithiadiphosphetane 2,4-disulfide, *p*-methoxyphenylthiophosphonic acid cyclic di(thioanhydride)] *[19172-47-5]* **$C_{14}H_{14}O_2P_2S_4$, M 404.5, m 228-229.5° (sintering at 215°), 228-230°.** The reagent has been washed with anisole or C_6H_6* and dried in a vacuum over paraffin wax and P_2O_5, and heated above room temperature. It does not lose the solvents completely (possibly due to formation of clathrates). It loses anisole on heating at ~230°. Analytically pure reagent was obtained by recrystallisation from *o*-dichlorobenzene, washing the crystals with C_6H_6* and drying *in vacuo* at 150°. It is extremely ***moisture sensitive***, liberating H_2S, and should be stored in sealed containers, and preferably weighed in a dry-box. Its molecular weight is consistent with the formula $(C_7H_7OPS_2)_2$ but slowly polymerises in solution at ~80-85°. ***Polymerisation*** is more rapid in polar than non-polar solvents. It is a very useful ***thiating reagent*** particularly for converting hydroxy to thiol substituents. [Nishio *JCS Perkin Trans I* 1113 *1993*, DOI: 10.1039/P19930001113; Nair et al. *Tetrahedron Lett* **47** 9329 *2006*, DOI: 10.1016/j.tetlet.2006.10.115; *Beilstein* **16** IV 1113.]

Lead diethyldithiocarbamate *[17549-30-3]* **$C_{10}H_{20}N_2PbS_4$, M 503.7, pK_1^{25} 3.36 (for *N,N*-diethyldithio-**

carbamate), decomposes on heating liberating toxic fumes. Wash it with H_2O and dry it at 60-70°, or dissolve it in the minimum volume of $CHCl_3$ and add the same volume of EtOH. Collect the solid that separates and dry it as before. *Alternatively*, recrystallise it by slow evaporation of a $CHCl_3$ solution at 70-80°. Filter the crystals, wash them with H_2O until all Pb^{2+} ions are eluted (check by adding chromate) and then dry it at 60-70° for at least 10 hours. [Lo et al. *Analyt Chem* **49** 1146 *1977*, DOI: 10.1021/ac50016a021.] It is **POISONOUS**.

Lissamine Green B {1-[bis-(4,4'-dimethylaminophenyl)methyl]-2-hydroxynaphthalene-3,6-disulfonic acid sodium salt, Acid Green 50, Wool Green S} *[3087-16-9]* **$C_{27}H_{25}N_2NaO_7S_2$, M 576.6, m >200°(dec), CI 44090, λ_{max} 633nm.** Crystallise it from EtOH/water (1:1, v/v). It is a food additive that can be used in mint sauce, desserts, sweets, ice creams and tinned peas, but has been prohibited in several countries. **Irritant**. [*Beilstein* **14** II 574.]

Lissapol C (mainly sodium salt of 9-octadecene-1-sulfate) *[2425-51-6]* **$C_{18}H_{36}NaO_4S$, M 387.6.** Reflux the salt with 95% EtOH, then filter to remove insoluble inorganic electrolytes. The alcoholic solution is then concentrated, and the residue is poured into dry acetone. The precipitate is filtered off, washed in acetone and dried under vacuum. It is an anionic surfactant detergent, and the effect of NaCl or non-ionic surfactants, e.g. polyethylene glycol (PEG), on its CMC (critical micellar concentration) has been investigated. [Biswas & Mukerji *J Phys Chem* **64** 1 *1960*, DOI: 10.1021/j100830a001].
Lissapol LS* (mainly sodium salt of anisidine sulfate)** *[28903-20-0].** Reflux the salt with 95% EtOH, then filter to remove insoluble inorganic electrolytes. The alcoholic solution is then concentrated, and the residue is poured into dry acetone. The precipitate is filtered off, washed in acetone and dried under vacuum. It is an anionic surfactant detergent, and the effect of NaCl or non-ionic surfactants, e.g. polyethylene glycol (PEG), on its CMC (critical micellar concentration) has been investigated. [Biswas & Mukerji *J Phys Chem* **64** 1 *1960*, DOI: 10.1021/j100830a001].

Lithium dodecylsulfate *[2044-56-6]* **$C_{12}H_{25}LiO_4S$, M 272.3.** Recrystallise this detergent twice from absolute EtOH and dry it under vacuum. Critical Micellar Concentration (CMC) in H_2O is 8.77 x 10^{-3}M (7-10mM at 20-25°). It is an anionic detergent that can be used instead of SDS for electrophoresis at low temperatures. [Mukerjee et al. *J Phys Chem* **71** 4166 *1967*, DOI: 10.1021/j100872a702; Mysels & Dulin *J Colloid Sci* **10** 461 *1955*, DOI: 10.1016/0095-8522(55)90064-7; *Beilstein* **1** IV 1847.]

Lithium trimethylsilanolate (trimethylsilanol Li salt) *[2004-14-0]* **C_3H_9LiOSi, M 96.1, m 120°(dec in air).** Wash it with Et_2O and petroleum ether. It sublimes at 180°/1mm as fine transparent needles. [Tatlock & Rochow *J Org Chem* **17** 1555 *1952*, DOI: 10.1021/jo50012a001; *Beilstein* **4** IV 3992.] Suspected **CARCINOGEN**.

Magnesium dodecylsulfate *[3097-08-3]* **$C_{12}H_{25}MgO_4S$, M 555.1.** Recrystallise it three times from EtOH and dry it in a vacuum. [*Beilstein* **1** I 1788, **1** IV 1849.]

Magnesium trifluoromethanesulfonate *[60871-83-2]* **$(CF_3SO_3)_2Mg$, M 322.4, m >300°.** Wash it with CH_2Cl_2 and dry it at 125°/2 hour and 3mmHg. An efficient catalyst for preparing dithioketals under mild conditions [Corey & Shimoji *Tetrahedron Lett* **24** 169 *1983*, DOI: 10.1016/S0040-4039(00)81357-X]. [*Beilstein* **3** IV 34.]

Manganous ethylenebis(dithiocarbamate) (Maneb) *[12427-38-2]* **$C_4H_6MnN_4S_4$ (monomer), M 293.3, pK_{Est} ~ 3.0 (for −NCSSH).** Crystallise this agriculture fungicide from EtOH. [Pease & Holt *J Agric Food Chem* **25** 561 *1977*, DOI: 10.1021/jf60211a043.] It is soluble in $CHCl_3$. It is a skin **irritant**. [*Beilstein* **4** III 149, **4** IV 234.]

1*R*,2*S*,5*R*-Menthyl phosphorochloridite (*l*-MenOPCl_2) *[95456-31-8]* **$C_{10}H_{19}Cl_2PO$, M 257.1, b 110-112°/260Pa, (62°/150mm also reported).** MenOPCl_2 is prepared by adding a solution of ***(1R,2S,5R)(-)-menthol*** (78g, 0.50mol) in CH_2Cl_2 (50ml, or THF) dropwise to a solution of PCl_3 (137.5g, 1.0mol) in CH_2Cl_2 (50ml, or THF) during 30 minutes. The mixture is stirred for 1 hour under a N_2 atmosphere, the volatiles are

removed at ~25°/100mm, and pure ***MenOPCl$_2$*** distilled at ~62°/150mm quantitatively. It has ^{1}H NMR (400MHz, C_6D_6, TMS) with δ at 0.64 (m, 1H, H-4), 0.77 (m, 10H, H-3, H-8, H-9, H-10), 1.15 (M, 3H, H-2, H-5, H-6), 1.44 (m, 2H, H-3, H-4), 1.98 (M, 1H, H-7), 2.30 (M, 1H, H-6), 4.40 (m, 1H, H-1); the ^{13}C{^{1}H} NMR (100MHz, C_6D_6, TMS) with δ at 16.1 (s, C-8), 21.2 (s, C-9), 22.0 (s, C-10), 22.8 (s, C-3), 25.1 (s, C-7), 31.4 (s, C-5), 33.8 (s, C-4), 43.3 (s, C-6), 48.7 (s, C-2), 83.5 (d, $^2J_{PC}$ = 9.8Hz, C-1); and the ^{31}P NMR (121.4MHz, THF, external ref 85% H_3PO_4) with δ at 175.6 or (at 162MHz, C_6D_6) with δ at 176.1 (d, $^3J_{PH}$ = 13.5Hz). This ***resolving agent*** (generally used successfully in solution without strict purification) is stable for weeks under inert atmosphere, but is very sensitive to moisture. [Brunel & Buono *J Org Chem* **58** 7313 *1993*, DOI: 10.1021/jo00077a072; Totland et al. *Macromolecules* **29** 6114 *1996*, DOI: 10.1021/ma960351r]. Note that Hey-Hawkins and co-workers found that a 5 molar excess of PCl_3 in a solvent-free system gave 98% of ***menthyl phosphorodi-chloridite*** **(*l*-MenOPCl$_2$)**, **b 110-112°/260Pa**; but when a 1:0.5 ratio of menthol to PCl_3 was used a 65% yield of ***bis-menthyl phosphorochloridite*** [(*l*-MenO)$_2$PCl)], **m 53-55°, b 130°/0.4Pa**, was obtained [Hey-Hawkins et al. *Eur J Inorg Chem* 2776 *2009*, DOI: 10.1002/ejic.200900304].

2-Mercaptopyridine *N*-oxide sodium salt (pyridinethione or pyrithione sodium salt) *[3811-73-2]* **C_5H_4NOS, M 149.1, m ~250°(dec), pK_1 -1.95, pK_2 4.65.** When recrystallised from water, it assayed as 98.7% pure based on $AgNO_3$ titration [Krivis et al. *Anal Chem* **35** 966 *1963*, DOI: 10.1021/ac60201a013; see also Oliveri-Vigh & Karageozian *Anal Chem* **48** 1001 *1976*, DOI: 10.1021/ac60371a021; and Barton & Crich *JCS Perkin Trans 1* 1603, 1613 *1986*, DOI: 10.1039/P19860001603; Reactions: Crich *Aldrichimica Acta* **20** 35 *1987*; derived free radicals: Ingold et al. *Tetrahedron Lett* **29** 917 *1988*, DOI: 10.1016/S0040-4039(00)82481-8]. [*Beilstein* **21/7** V 151.]

Metanilic acid (3-aminobenzenesulfonic acid) *[121-47-1]* **$C_6H_7NO_3S$, M 173.2, m <300°(dec), 301-306°(sesquehydrate, dec), pK_1^{25} <1, pK_2^{25} 3.74.** Crystallise the acid from water (as the ***hydrate***, solubility is ~2.4w/v% at 15°), under CO_2 in a semi-darkened room. The solution is ***photosensitive***. Dry it over 90% H_2SO_4 in a vacuum desiccator. The solubility in H_2O of the ***anhydrous*** amino acid is ~0.9w/v% at 0° and ~7w/v% at ~90°. The ***sodium salt***, crystallises from H_2O, and decomposes above 300°. [*Beilstein* **14** H 688, **14** IV 2640.]

Metanil Yellow (3[{4-phenylamino}phenylazo]-benzenesulfonic acid) *[587-98-4]* **$C_{18}H_{14}N_3NaO_3S$, M 375.4, pK_{Est} <0.** It can be salted out from water three times with sodium acetate, then repeatedly extracted with EtOH [McGrew & Schneider *J Am Chem Soc* **72** 2547 *1950*, DOI: 10.1021/ja01162a059]. It is an indicator (2 drops of a 0.1% aqueous solution in 10ml H_2O) in the pH range of 1.5 (red) to 2.7 (yellow) with λ_{max} at 414nm. [*Beilstein* **16** II 168.]

(Methoxycarbonylmethyl)triphenylphosphorane [methyl (triphenylphosphoranylidene)-acetate] *[2605-67-6]* **M 334.4, m 162-163°, 168-172°, 169-171°**. Crystallise this ***phosphorus ylide*** by dissolving in it AcOH and adding petroleum ether (b 40-50°) to give colourless plates which are dried at 50°/water-pump vacuum. Its UV has λ_{max} ($A^{1\%}_{1mm}$) at 222nm (908) and 268nm (125) [Isler et al. *Helv Chim Acta* **40** 1242 *1957*, DOI: 10.1002/hlca.19570400515]. [Fieser **1** 112; *Beilstein* **16** IV 977.] It is a useful two-carbon homologation **Wittig reagent** for conversion of aldehydes to the respective α,β-unsaturated esters as in the synthesis of (-)-mellein and (+)-ramulosin [Islam et al. *Tetrahedron* **63** 1074 *2007*, DOI: 10.1016/j.tet.2006.11.068] and in the efficient preparation of pyrazoles *via* cascade reactions of *N*- and *P*- containing ylides with methyl diazoacetate/Et_3N [Tomilov et al. *Tetrahedron Lett* **48** 883 *2007*, DOI: 10.1016/ j.tetlet.2006.11.133].

Methoxycarbonylmethyltriphenylphosphonium bromide *[1779-58-4]* **$C_{21}H_{20}BrO_2P$, M 415.3, m 163°, 165-170°(dec).** Wash it with petroleum ether (b 40-50°), recrystallise it from $CHCl_3$/Et_2O and dry it at high vacuum at 65°. [Isler et al. *Helv Chim Acta* **40** 1242 *1957*, DOI: 10.1002/hlca.19570400515; Wittig & Haag *Chem Ber* **88** 1654, 1664 *1955*, DOI: 10.1002/cber.19550881110; *Beilstein* **16** IV 988.]

Methoxymethyl trimethylsilane (trimethylsilylmethyl methyl ether) *[14704-14-4]* **$C_5H_{14}OSi$, M 118.3, b 83°/740mm, d_4^{25} 0.758, n_D^{25} 1.3878.** It forms an azeotrope with MeOH (**b** 60°). If it contains MeOH (check IR for bands above 3000cm^{-1}), then wash with H_2O and fractionate. A possible impurity could be ***chloromethyl trimethylsilane*** (**b 97°/740mm**). [Speier *J Am Chem Soc* **70** 4142 *1948*, DOI: 10.1021/ja01192a049; *Beilstein* **4**

III 1844.] It is an **IRRITATING FLAMMABLE** liquid.

1-Methoxy-2-methyl-1-trimethylsiloxypropene (dimethyl ketene methyl trimethylsilyl acetal) *[31469-15-5]* **$C_8H_{18}O_2Si$, M 174.3, b 35-36°/15mm, 140-142°/atm, d_4^{20} 0.858, n_D^{20} 1.4150.** Add Et_2O, wash with cold H_2O, dry (Na_2SO_4), filter, evaporate Et_2O, and distil the oily residue in a vacuum. It is moisture sensitive. [Ainsworth et al. *J Organometal Chem* **46** 59 *1972*, DOI: 10.1016/S0022-328X(00)90475-3.]

***trans*-1-Methoxy-3-(trimethylsilyloxy)-1,3-butadiene (Danishefsky's diene)** *[54125-02-9]* **$C_8H_{16}O_2Si$, M 172.3, b 68-69°/14mm, 70-72°/16mm, d_4^{20} 0.885, n_D^{20} 1.4540.** It may contain up to 1% of the precursor 4-methoxybut-4-ene-2-one. It is easily purified by distilling through a Vigreux column in a vacuum and taking the middle fraction. [Danishefsky & Kitihara *J Am Chem Soc* **96** 7807 *1974*, DOI: 10.1021/ja00832a031; Danishefsky *Acc Chem Res* **14** 400 *1981*, DOI: 10.1021/ar00072a006.] A useful electron rich functionalised Diels-Alder diene [Teyssot et al. *J Org Chem* **72** 2364 *2007*, DOI: 10.1021/jo062186b; Dai et al. *J Am Chem Soc* **129** 645 *2007*; DOI: 10.1021/ja065762u].

Methylarsonic acid *[124-58-3]* **CH_5AsO_3, M 139.97, m 159.8°, 161°, b 393°/atm, pK_1^{25} 4.58, pK_2^{25} 7.82 [$As(OH)_2$].** Recrystallise this herbicide from Me_2CO or absolute EtOH (white plates; its solubility is 28g/100ml EtOH). Inhalation causes coughing and soreness of throat — **TOXIC**. [Quick & Adams *J Am Chem Soc* **44** 805 *1922*, DOI: 10.1021/ja01425a014; *Beilstein* **4** H 613, **4** I 577, **4** II 996, **4** III 1822, **4** IV 3682.]

Methyl dichlorosilane (dichloro methylsilane) *[75-54-7]* **CH_4Cl_2Si, M 115.0, m -93°, -92.5°, b 41°/748mm, 40.9°/760mm, 40-45°/atm, d_{27}^{27} 1.105.** Impurities are generally other chloromethyl silanes. Distil it through a conventional Stedman column of 20 theoretical plates or more. It should be protected from H_2O by storing over P_2O_5. [Stock & Somieski *Chem Ber* **52** 695 *1919*, DOI: 10.1002/cber.19190520410; Sauer et al. *J Am Chem Soc* **68** 962 *1946*, DOI: 10.1021/ja01210a014; *Beilstein* **4** IV 4096.]

N*-Methyl-*N*-nitroso-*p*-toluenesulfonamide (Diazald)** *[80-11-5]* **$C_8H_{10}N_2O_3S$, M 214.2, m 58°, 61-62°. 62°.** Crystallise diazald from *benzene by addition of petroleum ether and store it in a refrigerator. It is soluble in most organic solvents including Et_2O, and liberates ***diazomethane on treatment with alkali. Store it in the cold. It remains active for many months if it is kept in a stoppered bottle in a cold room below 10°. [de Boer & Backer *Org Synth* **34** 96 1954, DOI: 10.15227/orgsyn.034.0096; *Org Synth* Coll Vol **4** 250 *1963*, DOI: 10.15227/orgsyn.036.0016; *Beilstein* **11** I 29.] Reagent for the preparation of ***diazomethane***. It has also found use in the ***nitrosation*** of molybdenum and tungsten complexes [Legzdins et al. *Organometallics* **12** 1029 *1993*, DOI: 10.1021/om00028a017], and in ***kinetic studies*** of Diazald with ***amines*** [Garcia-Rio et al. *JCS Perkin 2* 29 *1993*, DOI: 10.1039/P29930000029] and ***carbanions*** [Leis et al. *JCS Perkin 2* 1233 *1993*, DOI: 10.1039/P29930001233].

Methyl Orange (sodium 4,4'-dimethylaminophenylazobenzenesulfonate, Orange III) *[547-58-0]* **$C_{14}H_{14}N_3NsO_3S$, M 327.3, pK_1^{25} 3.56, pK_2^{25} 6.49.** Recrystallise the orange-yellow powder twice from hot water (solubility at ~20° is 0.2w/w%), then wash it with a little EtOH followed by diethyl ether. It is an acid-base indicator (few drops of 0.1% aqueous solution): pH 3.1 (red) and pH 4.4 (yellow). [*Beilstein* **16** IV 510.]

Methylphenyl dichlorosilane (dichloro methyl phenylsilane) *[149-74-6]* **$C_7H_8Cl_2Si$, M 191.1, b 114-115°/50mm, 202-205°/atm, 205-206°/760mm, d_4^{20} 1.173, n_D^{20} 1.519.** Purify it by fractionation using an efficient column. It hydrolyses *ca* ten times more slowly than methyltrichlorosilane and *ca* sixty times more slowly than phenyltrichlorosilane. [Shaffer & Flanigen *J Phys Chem* **61** 1591 *1957*, DOI: 10.1021/j150558a004; *Beilstein* **16** III 1211, **16** IV 1517.]

Methylphosphonic acid *[993-13-5]* **CH_5O_3P, M 96.0, m 104-106°, 106°, 105-107°, 108°, 108.5°, pK_1^{25} 2.12, pK_2^{25} 7.29**. If it tests for Cl^-, then add H_2O and evaporate to dryness, repeat several times till free from Cl^-. The residue solidifies to a wax-like solid. *Alternatively*, dissolve the acid in the minimum volume of H_2O, add charcoal, warm, filter and evaporate to dryness in a vacuum over P_2O_5. [Crofts & Kosolapoff *J Am Chem Soc* **75** 3379 *1953*, DOI: 10.1021/ja01110a024.] The ***di-Na salt*** is prepared from 24g of acid in 50ml of dry EtOH, and a solution of 23g Na dissolved in 400ml EtOH is added. A white precipitate is formed, but the mixture is

refluxed for 30 minutes to complete the reaction. Filter off the solid and recrystallise it from 50% EtOH. Dry the crystals in a vacuum desiccator. [Thompson *J Chem Soc* 3292 *1952*, DOI: 10.1039/JR9520003292; *Beilstein* **4** IV 3498.]

Methylphosphonic dichloride *[676-97-1]* **CH_3Cl_2OP, M 132.9, m 33°, 33-37°, b 53-54°/10mm, 64-67°/20.5mm, 86°/44mm, 162°/760mm, d_4^{40} 1.4382.** Fractionally redistil it until the purity as checked by hydrolysis and acidimetry for Cl^- is correct and the distillate should solidify on cooling. [Kinnear & Perren *J Chem Soc* 3437 *1952*, DOI: 10.1039/JR9520003437; Crofts & Kosolapoff *J Am Chem Soc* **75** 3379 *1952*, DOI: 10.1021/ja01110a024; for IR see McIvor et al. *Can J Chem* **34** 1611 *1956*, DOI: 10.1139/v56-211; Svara, Weferling & Hofmann *Phosphorus Compounds, Organic*, in *Ullmann's Encyclopedia of Industrial Chemistry*, Wiley-VCH, Weinheim, 2008; DOI: 10.1002/14356007.a19_545; L. Maier, *Organic Phosphorus Compounds, 90.l 'A convenient one-step synthesis of alkyl- and arylphosphonyl dichlorides'* in *Phosphorus, Sulfur, and Silicon and the Related Elements* **47** (3-4) 465–470 *1990*, DOI: 10.1080/ 10426509008038002; *Beilstein* **4** IV 3509.] **TOXIC**

Methyl Thymol Blue, sodium salt {MTB, 3,3'-bis[*N,N'*-di(carboxymethyl)amino]thymolsulfonephthalein sodium salt} *[1945-77-3]* **$C_{37}H_{44}N_2O_{13}S$, M 844.8, ε 1.89 x 10^4 at 435nm, pH 5.5, pK_1^{25} 3.0, pK_2^{25} 3.3, pK_3^{25} 3.8, pK_4^{25} 7.4 (pK_4^{25} 7.2), pK_5^{25} 11.5 pK_6^{25} 13.4.** The starting material for synthesis is **Thymol Blue**. Purify it as for **Xylenol Orange** *[1611-35-4]*, see entry below in this Chapter. [Tereshin et al. *J Anal Chem USSR (Engl Trans)* **20** 1138 *1965*, Körbl & Kakáč *Coll Czech Chem Commun* **23** 889 *1958*, DOI: org/10.1135/ cccc19580889; *Beilstein* **19/8** V 619.]

Methyl 4-toluenesulfonate *[80-48-8]* **$C_8H_{10}O_3S$, M 186.2, m 25-28°, 28°, b 144.6-145.2°/5mm, 168-170°/13mm, d_4^{20} 1.23, n_D^{20} 1.5172.** The ester is purified by distillation *in vacuo* and can be crystallised from petroleum ether or Et_2O/petroleum ether at low temperature. It is a powerful **methylating agent**, is **TOXIC** and is a **skin irritant**, so it is better to purify it by repeated distillation. [IR: Schreiber *Anal Chem* **21** 1168 *1949*, DOI: 10.1021/ac60034a005; Buehler et al. *J Org Chem* **02** 167 *1937*, DOI: 10.1021/jo01225a004; Roos et al. *Org Synth* Coll Vol **1** 145 *1941*, DOI: 10.15227/orgsyn.009.0028; *Beilstein* **11** IV 247.]

Methyl trichlorosilane *[75-79-6]* **CH_3Cl_3Si, M 149.5, b 13,7°/101mm, 64.3°/710.8mm, 65.5°/745mm, 66.1°/atm, d_4^{20} 1.263, n_D^{20} 1.4110.** If not very pure, distil it before use. The purity is checked by ^{29}Si NMR (δ in MeCN is 13.14 ppm with respect to Me_4Si). Possible contaminants are other silanes which can be removed by fractional distillation through a Stedman column of >72 theoretical plates with total reflux and 0.35% take-off. This apparatus should be under N_2 gas at a rate of 12 bubbles/minute fed into the line using an Hg manometer to control the pressure. It is sensitive to H_2O. [Gilliam et al. *J Am Chem Soc* **73** 4252 *1951*, DOI: 10.1021/ja01153a064; Olah et al. *J Org Chem* **48** 3667 *1983*, DOI: 10.1021/jo00169a010; *Beilstein* **4** IV 4212.]

Methyl triethoxysilane *[2031-67-6]* **$C_7H_{18}O_3Si$, M 178.31, b 142-144.5°/742mm, 141°/765mm, 141.5°/775mm, d_4^{20} 0.8911, n_D^{20} 1.3820.** Purify by fractionating it repeatedly in a stream of N_2 through a 3' Heligrid packed Todd column. It is hydrolysed by H_2O and yields cyclic polysiloxanes on hydrolysis in the presence of acid in $*C_6H_6$. [McBee et al. *J Am Chem Soc* **77** 1292 *1955*, DOI: 10.1021/ja01610a066; Sprung & Guenther *J Am Chem Soc* **77** 3990 *1955*, DOI: 10.1021/ja01620a013; *Beilstein* **4** IV 4204.]
Methyl trimethoxysilane *[1185-55-3]* **$C_4H_{12}O_3Si$, M 136.2,** has **b 102°/760mm, 102-104°/atm, d_4^{20} 1.3687, n_D^{20} 1.3711.** Likely impurities are **1,3-dimethyltetramethoxy disiloxane** (**b 31°/1mm**) and cyclic polysiloxanes, see previous entry methyl triethoxysilane. It hydrolyses in both aqueous acidic and basic solutions. [Tamborski & Post *J Org Chem* **17** 1400 *1952*, DOI: 10.1021/jo50010a022; Seyferth & Rochow *J Org Chem* **20** 250 *1955*, DOI: 10.1021/jo01120a016; *Beilstein* **4** IV 4203.]

***N*-Methyl-*N*-trimethylsilylacetamide** *[7449-74-3]* **$C_6H_{15}NOSi$, M 145.3, b 48-49°/11mm, 84°/13mm, 105-107°/35mm (solid at room temperature), 159-161°/atm, d_4^{20} 0.90, n_D^{20} 1.4379.** A likely impurity is $Et_3N.HCl$ which can be detected by its odour. If it is completely soluble in $*C_6H_6$, then redistil; otherwise dissolve it in this solvent, filter and evaporate first in a vacuum at 12mm, then fractionate; all operations should be carried out in a dry N_2 atmosphere. [Klebe et al. *J Am Chem Soc* **88** 3390 *1966*, DOI: 10.1021/ja00966a038; Ried & Suarez-Rivero *Chem Ber* **96** 1475 *1963*, DOI: 10.1002/cber.19630960544; *Beilstein* **4** IV 4011.]

Methyl trimethylsilylacetate *[2916-76-9]* **$C_6H_{14}O_2Si$, M 146.3, b 38-39°/13mm, 65-68°/50mm, d_4^{20} 0.89.** Dissolve it in Et_2O, shake with 1M HCl, wash with H_2O, aqueous saturated $NaHCO_3$, H_2O again, and dry it (a precipitate may be formed in the $NaHCO_3$ solution and should be drawn off and discarded). The solvent is distilled off, and the residue is fractionated through a good column. The IR ($CHCl_3$) has ν_{max} at 1728cm^{-1}. [Fessenden & Fessenden *J Org Chem* **32** 3535 *1967*, DOI: 10.1021/jo01286a054; Matsuda et al. *J Org Chem* **45** 237 *1980*, DOI: 10.1021/jo01290a006; *Beilstein* **4** III 1855, **4** IV 3974 for Et ester.]

Methyl (±)-2-(trimethylsilyl)propionate *[55453-09-3]* **$C_7H_{16}O_2Si$, M 160.3, m 32°, b 142.3 ±13°/760mm, 155-157°/atm, d_4^{20} 0.89.** Dissolve it in Et_2O, wash it with aqueous $NaHCO_3$, H_2O, 0.1M HCl, H_2O again, dry ($MgSO_4$), evaporate and distil it. [Emde & Simchen *Synthesis* 867 1977, DOI: 10.1055/s-1977-24611; Oppolzer et al. *Tetrahedron* **39** 3695 *1983*, DOI: 10.1016/S0040-4020(01)88608-7; Crimmin et al. *JCS Perkin Trans 1* 541 *1985*, DOI: 10.1039/P19850000541.]

N*-Methyl-*N*-trimethylsilyl trifluoroacetamide** *[24589-78-4]* **$C_6H_{12}F_3NOSi$, M 199.3, m 98-100°, b 78-79°/130mm, 131-132°/atm.** Fractionate the amide through a 40mm Vigreux column. Usually it contains *ca* 1% of methyl trifluoroacetamide and 1% of other impurities which can be removed by gas chromatography or fractionating using a spinning band column. It is ***moisture sensitive, store appropriately. [Donike *J Chromatogr* **42** 103 *1969*, DOI: 10.1016/S0021-9673(01)80592-6; Donike *J Chromatogr* **103** 91 *1975*, DOI: 10.1016/S0021-9673(00)83805-4; *Beilstein* **4** IV 4011.]

Methyl triphenoxyphosphonium iodide (triphenylphosphite methiodide) *[17579-99-6]* **$C_{19}H_{18}IO_3P$, M 452.2, m 114°** (sealed tube), **146°**. Gently heat the impure iodide with good grade Me_2CO. The saturated solution obtained is decanted rapidly from undissolved salt and treated with an equal volume of dry Et_2O. The iodide separates as flat needles which are collected by centrifugation, washed several times with dry Et_2O, and dried in a vacuum over P_2O_5. For this recrystallisation, it is essential to minimise the time of contact with Me_2CO, and to work rapidly and with rigorous exclusion of moisture. If the crude material is to be used, it should be stored under dry Et_2O, and dried and weighed *in vacuo* immediately before use. [Landauer & Rydon *J Chem Soc* 2224 *1953*, DOI: 10.1039/JR9530002224; for NMR data see: Hudson et al. *JCS Perkin Trans 1* 982 *1974*, DOI: 10.1039/P19740000982; *Beilstein* **6** IV 704.]

Methyl triphenylphosphonium bromide *[1779-49-3]* **$C_{19}H_{18}BrP$, M 357.2, m 229-230°(corr), 227-229°, 230-233°, 231-234°, 233°.** If the solid is sticky, wash it with $*C_6H_6$ and dry it in a vacuum over P_2O_5. [Marvel & Gall *J Org Chem* **24** 1494 *1959*, DOI: 10.1021/jo01092a026; *Chem Ber* **87** 1318 *1954*, Milas & Priesing *J Am Chem Soc* **79** 6295 *1957*, DOI: 10.1021/ja01580a049; Wittig & Schöllkopf *Org Synth* **40** 66 *1960,* DOI: 10.1002/cber.19540870919.] The ***iodide***, on recrystallisation from H_2O, has **m 187.5-188.5°** [Mann et al. *J Chem Soc* 1130 *1953*, DOI: 10.1039/JR9530001130; Wittig & Geissler *Justus Liebigs Ann Chem* **580** 44 *1953*, DOI: 10.1002/jlac.19535800107]. [*Beilstein* **16** IV 981.]

Methyl vinyl dichlorosilane (dichloro methyl vinyl silane) *[124-70-9]* **$C_3H_6Cl_2Si$, M 141.1, b 43-45.5°/11-11.5mm, 91°/742mm, 92.5°/743.2mm, 92.5-93°/atm, d_4^{20} 1.0917, n_D^{20} 1.444.** Likely impurities are dichloromethyl-silane, butadienyl-dichloromethylsilane. Fractionate the silane through a column packed with metal filings (20 theoretical plates) at atmospheric or better under reduced pressure. [Shostakovsky et al. *Izv Akad Nauk SSSR Ser Khim* **6** 1474 *1957*, DOI: 10.1007/BF01169751; Mironov & Petrov *Izv Akad Nauk SSSR Ser Khim* **7** 767 *1958*, DOI: 10.1007/BF00917295; *Beilstein* **4** III 1894, **4** IV 4184.]

Milling Red SWB {1-[4-[4-[4-toluenesulfonyloxy]phenylazo](3,3'dimethyl-1,1'-biphenyl)-4'-azo]-2-hydroxynaphthalene-6,8-disulfonic acid di-Na salt, Acid Red 114} *[6459-94-5]* **$C_{37}H_{28}N_4Na_2O_{10}S_3$, M 830.8, m dec >250°, CI 23635, λ_{max} ~514nm.** Salt out three times with sodium acetate, then repeatedly extract it with EtOH and dry the solid in air. [McGrew & Schneider *J Am Chem Soc* **72** 2547 *1950*, DOI: 10.1021/ja01162a059; *Beilstein* **16** II 140.] This textile Dye can also be used for staining epithelial intracellular bridges [Bredrick *Stain Technology* **39** 33 *1964*, DOI: 10.3109/10520296409061205]

***Milling Yellow G* {5-chloro-2-[3-methyl-4-[[4-(methylphenyl)sulfonyloxyhenyl]diazenyl]-5-oxo-4*H*-pyrazil-1-yl]benzenesulfonic acid Na-salt, Acid yellow 40}** *[6372-96-9, 51569-18-7, 88529-27-5]* **$C_{23}H_{18}ClN_4$**

$Na_2O_7S_2$, M 582.0, CI 642, decomposes on heating. Salted out three times with sodium acetate, then repeatedly extracted with EtOH. [McGrew & Schneider *J Am Chem Soc* **72** 2547 *1950*, DOI: 10.1021/ja01162a059; *Beilstein* **16** II 125.] See also **Solochrome Violet R** [2092-55-9] below.

Naphthalene Scarlet Red 4R [1-(4-sulfonaphthalene-1-azo)-2-hydroxynaphthalene-6,8-disulfonic acid tri-Na salt, New Coccine, Ponceau 4R, Acid Red 18] *[2611-82-7]* **$C_{20}H_{11}N_2Na_3O_{10}S_3$, M 604.5, m>250°(dec), CI 16255, λ_{max} 350nm and 506nm.** Dissolve the dye in the minimum quantity of boiling water, filter and enough EtOH is added to precipitate *ca* 80% of the dye. This process is repeated until a solution of the dye in aqueous 20% pyridine has a constant extinction coefficient. [*Beilstein* **16** I 306.]

Naphthalene-1,4-disulfonic acid *[92-41-1]* **$C_{10}H_8O_6S_2$, M 288.2, pK_{Est} <0.** Crystallise the acid from concentrated HCl. The ***disulfonamide*** has **m** 273° (from EtOH). [*Beilstein* **11** II 119, **11** III 463.]
***Naphthalene-1,5-disulfonic acid tetrahydrate* (Armstrong's acid)** *[81-04-9 (anhydrous), 211366-30-2 (4 H_2O)]* **$C_{10}H_8O_6S_2$, M 288.3, 360.4 (4 H_2O),** has **m 240-245° (anhydrous), d 1.704, pK_{Est} <0.** Crystallise the acid from concentrated HCl. It is soluble in EtOH and H_2O, but insoluble in Et_2O. [Lynch & Scanlan *Ind Eng Chem* **19** 1010 *1927*, DOI: 10.1021/ie50213a018; *Beilstein* **11** H 212.]

Naphthalene-1-sulfonic acid *[85-47-2]* **$C_{10}H_8O_3S$, M 208.2, m (hydrates) 97° to 79°, ($2H_2O$) 90°, (anhydrous) 139-140°, pK^{20} -0.17.** Crystallise the acid from concentrated HCl and twice from H_2O. The ***S-benzylisothiuronium salt*** has **m 137°** (from aqueous EtOH). [*Beilstein* **11** H 155, **11** III 383, **11** IV 521.]
Naphthalene-1-sulfonyl chloride *[85-46-1]* **$C_{10}H_7ClO_2S$, M 226.7,** has **m 64-67°, 68°, b 147.5°/0.9mm, 194-195°/13mm.** If the IR indicates the presence of OH, then treat it with an equal weight of PCl_5 and heat it at *ca* 100° for 2 hours, cool and pour onto ice + H_2O, stir well and filter off the solid. Wash the solid with cold H_2O and dry the solid in a vacuum desiccator over P_2O_5 + solid KOH. Extract the solid with petroleum ether (b 40-60°), filter off any insoluble solid and cool. Collect the crystalline sulfonyl chloride and recrystallise it from dry Et_2O, petroleum ether or *C_6H_6/petroleum ether. If large quantities are available, then it can be distilled under high vacuum. [Fierz & Weissenbach *Helv Chim Acta* **3** 312 *1920*, DOI: 10.1002/hlca.19200030130.] The ***sulfonamide*** crystallises from EtOH (**m 150.5°**) or H_2O (**m 153°**). [*Beilstein* **11** H 175, **11** II 93, **11** IV 383.]
Naphthalene-2-sulfonic acid *[120-18-3]* **$C_{10}H_8O_3S$, M 208.2,** has **m 91° (anhydrous), 124-125° (anhydrous) pK_{Est} <1.** Crystallise the acid from concentrated HCl. The ***S-benzylisothiuronium salt*** has **m** 192° (from aqueous EtOH). [Berger **8** 432 *1954*, *Beilstein* **11** H 171, **11** IV 527.]
Naphthalene-2-sulfonyl chloride *[93-11-8]* **$C_{10}H_7ClO_2S$, M 226.7,** has **m 74-76°, 78°, 79°, 83°, b 147.7°/0.6mm, 201°/13mm.** Distil the chloride in a vacuum and/or recrystallise it (twice) from *benzene/petroleum ether (1:1 v/v). Purify it as the ***1-sulfonyl chloride*** above. [Fierz & Weissenbach *Helv Chim Acta* **3** 2312 *1920*, DOI: 10.1002/hlca.19200030130.] The ***sulfonamide*** *[1576-47-2]* **$C_{10}H_9NO_2S$,** M 207.3, has **m 217°** (from EtOH, **215°** to **219°** also reported). [*Beilstein* **11** III 399, **11** IV 529.]

Naphthionic acid (4-aminonaphthalene-1-sulfonic acid, Piria's acid) *[84-86-6]* **$C_{10}H_9NO_3S$, M 223.3, m > 300°(dec), d_4^{25} 1.673, pK^{25} 2.68.** It crystallises from H_2O as needles of the ***0.5 hydrate***. Its solubility in H_2O varies from 0.03w/v% at 0° to 0.22w/v% at 100°. Salt solutions fluoresce strongly blue. The ***S-benzylisothiuronium salt*** has **m 195°** (from aqueous EtOH). [*Beilstein* **14** IV 2793.]

Naphthol Yellow S (citronin A, Food Yellow 1, flavianic acid sodium salt, 8-hydroxy-5,7-dinitro-2-naphthalene sulfonic acid disodium salt) *[846-70-8]* **$C_{10}H_4N_2Na_2O_8S$, M 358.2, CI 10316, decomposes on heating.** This dye is a water-soluble greenish yellow powder. The ***free sulfonic acid*** can be recrystallised from dilute HCl (**m 150°**) or AcOH/EtOAc (**m 148-149.5°**). The disodium salt is then obtained by dissolving the acid in two equivalents of aqueous NaOH and evaporating to dryness, and drying the residue in a vacuum desiccator. The ***sodium salt*** can be recrystallised from the minimum volume of H_2O or from EtOH [Dermer & Dermer *J Am Chem Soc* **61** 3302 *1939*, DOI: 10.1021/ja01267a019]. It is a food colouring matter that has been banned by many countries [see https://www.sigmaaldrich.com/content/dam/sigma-aldrich/docs/Fluka/Brochure/1/food_color_additives.pdf]. [*Beilstein* **11** III 542.]

1,2-Naphthoquinone-4-sulfonic acid sodium salt (Folin's reagent, 3,4-dihydro-3,4-dioxo-1-naphthlene

sulfonic acid sodium salt) *[521-24-4]* **$C_{10}H_5NaO_5S$, M 260.2, m 289°(dec), pK_{Est} <0.** It forms yellow crystals from aqueous EtOH and should be dried at 80° *in vacuo*. Its solubility in H_2O is 5%, and it is moderately soluble in Me_2CO, slightly soluble in EtOH but mostly insoluble in other organic solvents. It is a reagent for the detection and determination of amines, amino acids, peptides and proteins. Aqueous solutions of it fade in the presence of light, but addition of HCl slows down this process. [Folin (and Wu) *J Biol Chem* **51** 377 *1922*, http://www.jbc.org/content/167/1/57; Martin & Fieser *Org Synth* Coll Vol **3** 633 *1955*, DOI: 10.15227/orgsyn.021.0091; ***estimation*** of amino acid nitrogen in blood: Danielson *J Biol Chem* **101** 505 *1933*, http://www.jbc.org/content/101/2/505.] UV ***estimation*** of amines: Rosenblatt et al. *Anal Chem* **27** 1290 *1955*, DOI: 10.1021/ac60104a024]. [*Beilstein* **11** IV 668.]

2-Naphthylamine-1-sulfonic acid (Tobias acid) *[81-16-3]* **$C_{10}H_9NO_3S$, M 223.3, m >200°(dec), pK_1^{25} <1, pK_2^{25} 2.35 (NH_2).** Crystallise the acid under nitrogen from boiling water and dry it in a steam oven [Bryson *Trans Faraday Soc* **47** 522, 527 *1951*, DOI: 10.1039/TF9514700522]. [*Beilstein* **14** III 2240, **14** IV 2792.]
5-Naphthylamine-1-sulfonic acid **(Laurent's acid)** *[84-89-9]* **$C_{10}H_9NO_3S$, M 223.3,** has **m >200°(dec), $pK_{Est(1)}$<1, pK_2^{25} 3.69 (NH_2).** Crystallise the acid under nitrogen from boiling water (solubility is 0.1w/v% at <10°) and dry it in a steam oven [Bryson *Trans Faraday Soc* **47** 522, 527 *1951*, DOI: 10.1039/TF9514700522]. [*Beilstein* **14** IV 2800.]
2-Naphthylamine-6-sulfonic acid **(Broenner's acid)** *[93-00-5]* **$C_{10}H_9NO_3S$, M 223.3,** has **m >200°(dec), pK^{25} 3.74.** Crystallise the acid from a large volume of hot water. The ***diethylamine salt*** has **m 190.5-192°** (from EtOH/*iso*BuOH), and the ***S-benzylisothiuronium salt*** has **m 330°** (from *n*BuOH). [*Beilstein* **14** H 760, **14** II 463, **14** III 2249, **14** IV 2804.]

1-Naphthyl thiourea (ANTU) *[86-88-4]* **$C_{11}H_{10}N_2S$, M 202.2, m 197.8°, 198°.** Crystallise ANTU from EtOH as colourless prisms. [*Beilstein* **12** III 2941, **12** IV 3086.] It is a rodenticide and fairly toxic.

2-Nitrobenzenesulfenyl chloride (NPS-Cl) *[7669-54-7]* **$C_6H_4ClNO_2S$, M 189.6, m 70° to 75°, 73-74.5°, 74.5-75°, 74-76°.** Recrystallise it from CCl_4 (2ml/g), filter off the solution at 5° (recovery 75%). It has also been recrystallised from petroleum ether (b 40-60°), dried rapidly at 50° and stored in a brown glass bottle, sealed well and stored away from moisture. [Hubacher *Org Synth* Coll Vol **2** 455 *1943*, DOI: 10.15227/orgsyn.015.0045; Ito et al. *Chem Pharm Bull Jpn* **26** 296 *1978*, *Beilstein* **6** I 157.]

2-Nitrobenzenesulfonyl chloride *[1694-92-4]* **$C_6H_4ClNO_4S$, M 221.6, m 63-67°, 68-69°, 69.5-69.7°, b 350.6°/760mm, d 1.606.** It is prepared by the oxidation of di-*o*-nitrophenyldisulfide with Cl_2 [Wertheim *Org Synth* Coll Vol **2** 471 *1943*, DOI: 10.15227/orgsyn.015.0055] or from *o*-nitrobenzenesulfonic acid and PCl_5, then pouring into H_2O, washing the solid with H_2O, drying it *in vacuo* and recrystallising it from petrol, Et_2O/petrol, petroleum ether/CCl_4 or petroleum ether. With ammonia it is converted to the ***sulfonamide*** *[5455-59-4]* **M 202.1, m 193°,** which forms needles from hot aqueous EtOH; and with phenol/pyridine or Na_2CO_3, the ***phenyl ester*****, m 57°,** is obtained which crystallises from EtOH. The ***sulfonylazide***, **m 71-73°**, separates as needles from petroleum ether [Leffler & Tsuno *J Org Chem* **28** 902 *1963*, DOI: 10.1021/jo01039a004]. [*Beilstein* **11** H 67, **11** I 20, **11** II 32, **11** III 114, **11** IV 174.]
3-Nitrobenzenesulfonyl chloride *[121-51-7]* has **m 61-62°, 63.9-64.2°.** It can be prepared from *m*-nitrobenzenesulfonic acid and PCl_5 as for the isomer above and crystallised from petroleum ether/CCl_4 or petroleum ether in needles. With ammonia it is converted to the ***sulfonamide*** *[121-52-8]* **M 202.1, m 167-168°,** which forms needles from hot aqueous EtOH and is a moderately strong base with **pK^{20} 9.20**. With phenol/pyridine or Na_2CO_3, the ***phenyl ester*****, m 94°,** is obtained which crystallises from acetic acid. [Gilbert *Synthesis* 315 *1977*, DOI: 10.1055/s-1977-24376; *Beilstein* **11** H 69, **11** I 21, **11** II 33, **11** III 126, **11** IV 182.]
4-Nitrobenzenesulfonyl chloride **(Nosyl chloride)** *[98-74-8]* has **m 66-70°, 78-80°, 80°, b 143-144°/1.5mm, 180-181°/17mm.** It is prepared in the same way as for the *m*-isomer above from ***p-nitro-benzenesulfonic acid***, and is purified by vacuum distillation and/or by recrystallisation from petroleum ether or Et_2O/petroleum ether. With ammonia it is converted to the ***sulfonamide*** *[6325-93-5]* **M 202.1, m 179-180°,** which forms prisms from hot aqueous EtOH and is a moderately strong base with **pK^{20} 9.14**. [Prinsen et al. *Recl Trav Chim Pays-Bas* **84** 24 *1965*, DOI: 10.1002/recl.19650840104; *Beilstein* **11** H 72, **11** I 21, **11** II 34, **11** III 136, **11** IV 192.] It is highly efficient in solid phase peptide synthesis when using ***N-nosyl-α-amino acids*** [Leggio et al. *Tetrahedron* **63** 8164 *2007*, DOI: 10.1016/j.tet.2007.05.121.]

2-Nitrobenzenesulfonylhydrazine (NBSH) *[606-26-8, 6655-77-2]* **$C_6H_7N_3O_4S$, M 217.2, m 100-101°, 101° (dec).** NBSH is unstable unless handled properly. If the material is suspect, it is preferable to prepare freshly thus: hydrazine monohydrate (12.1ml, 2.5 equivalents) is added to a solution of *o*-nitrobenzenesulfonyl chloride (22.2g, 1 equivalent) in dry THF (100ml) at -30° under argon whereby the solution became brown, white N_2H_4.HCl deposited, and after 30 minutes TLC (2/1, EtOAc/hexanes) indicating that all the sulfonyl chloride was used up. EtOAc (200ml, at 23°) is added to the cold mixture and washed repeatedly with ice-cold 10% aqueous NaCl (5 x 150ml, contact time with each wash should not be <1 minute; the use of just distilled H_2O results in much lower yields). The organic layer is washed, dried (Na_2SO_4 at 0°), then added slowly to a stirred solution of hexanes (1.2L) at 23° during 5 minutes. The off-white NBSH that precipitates within 10 minutes is isolated by vacuum filtration, the solid is washed with hexanes (2 x 50ml, 23°) and dried at 23°/<1.5mm for 14 hours to provide ***pure NBSH*** as an off-white powder (17.6g, 81%; TLC has R_F 0.19, EtOAc/hexanes 2/1). Store it at ~0-5° under argon, and use gloves due to its **toxicity**. Its IR (EtOAc) has ν_{max} at 1165, 1352, 1547, 3400—3100 cm^{-1} and its ^1H NMR [300MHz, CD_3CN] has δ: 8.17-8.03 (1H, m), 7.91-7.78 (3H, m), 5.97 (1H, bs), 3.90 (2H, bs); and its ^{13}C NMR [75MHz, CD_3CN] has δ: 149.4, 135.5, 133.4, 133.2, 130.8 and 125.8. [Meyers et al. *J Org Chem* **62** 7507 *1997*, DOI: 10.1021/jo9710137; Dann & Davies *J Chem Soc* 1050 *1929*, DOI: 10.1039/JR9290001050; for use in the **Mitsunobu reaction** see: Hughes *Org React* **42** 335 *1992*, DOI: 10.1002/0471264180.or042.02.]
NBSH is a **versatile reagent** for synthesising allenes from propargyl alcohols [Meyers & Zheng *J Am Chem Soc* **118** 4492 *1996*], for reductive transposition of allylic alcohols [Myers & Zheng *Tetrahedron Lett* **37** 4841 *1996*, DOI: 10.1016/0040-4039(96)00965-3], and for deoxygenation of unhindered alcohols; each of which proceeds by **Mitsunobu displacement** of an alcohol with **NBSH** followed by *in situ* elimination of *o*-nitrobenzoylsulfinic acid to produce mono-alkyl diazene intermediates under mild reaction conditions, i.e. neutral pH and less than 23°, particularly useful with substrates that have sensitive substituents. [Mitsunobu *Synthesis* 1 *1981*, DOI: 10.1055/s-1981-29317; Hughes *Org React* **42** 335 *1992*.] For the success of these reactions it is imperative that the reagent is as pure as possible. Solutions of NBSH in THF that are pale yellow are still suitable for these applications.

2-Nitrophenol-4-arsonic acid (Roxarsone, 4-hydroxy-3-nitrophenylarsonic acid) *[121-19-7]* **$C_6H_6AsNO_6$, M 263.0, m >300°, $pK_{Est(1)}$~ 4.4 As(O)-(OH)-(O^-), $pK_{Est(2)}$~ 7.4 (phenolic OH), $pK_{Est(3)}$~ 7.7 (As(O)-2(O^-).** It crystallises from water and is used for the spectroscopic detection of Zn. Used in poultry feed premixes. [*Beilstein* **16** II 468, **16** III 1073, **16** IV 1188.]

1-Nitroso-2-naphthol-3,6-disulfonic acid, di-Na salt, hydrate (Nitroso-R-salt) *[525-05-3]* **$C_{10}H_5NNa_2O_8S_2$, M 377.3, m >300°, $pK_{Est(1)}$<0 (SO_3^-), pK_2 7.13 (OH).** Purify the salt by dissolution in aqueous alkali and precipitation by addition of HCl to give the ***free acid*** which is isolated, and dissolved in minimum volume of hot H_2O containing 2 equivalents of NaOH (solubility of di-Na salt at ~20° is 2.5w/w%), and cooled to give golden-yellow fan-shaped crystals. It complexes with Cd ($log\beta_{11}$ 3.2, $log\beta_{12}$ 5.6), Cu ($log\beta_{11}$ 8.5, $log\beta_{12}$ 14.6), La ($log\beta_{11}$ 4.4, $log\beta_{12}$ 7.8, $log\beta_{13}$ 11.2), Ni ($log\beta_{11}$ 6.9, $log\beta_{12}$ 12.4), Pb ($log\beta_{11}$ 4.6, $log\beta_{12}$ 7.4), Pd ($logK_{12}$ 8.8), Y ($log\beta_{11}$ 4.5, $log\beta_{12}$ 7.8, $log\beta_{13}$ 11.3), is used for the ***spectrophotometric determination*** of Co, Fe, K, Ag, Ba, Cu (colour change pH 4-7, gold/green), Ni (colour change pH 3, yellow/green), and Pb. [Oka & Miyamoto *J Chem Soc Jpn* (Pure Chem Sectn) **76** 672 *1955* (*Chem Abstr* 11882 *1956I*), *Beilstein* **11** IV 669.]
2-Nitroso-1-naphthol-4-sulfonic acid **($3H_2O$)** *[3682-32-4]* **$C_{10}H_7NO_5S$, M 316.3,** has **m 140-145°(dec), 142-146°(dec), pK_{Est} ~6.3 (OH).** Crystallise the acid from dilute HCl solution. The crystals are dried over $CaCl_2$ in a vacuum desiccator. It has also been purified by dissolution in aqueous alkali and precipitation by addition of water. It is a reagent for cobalt. [*Beilstein* **11** H 331, **11** II 189, **11** III 621, **11** IV 668.]

2-Nitro-4-sulfobenzoic acid *[552-23-8]* **$C_7H_5NO_7S$, M 247.1, m 111°, d ^{25} 1.8g/cm^3, n $^{20}_D$ 1.643, pK_{Est} ~1.65.** It is prepared by sulfonating 2-nitrotoluene to 2-nitro-4-toluenesulfonic acid which is oxidised with $KMnO_4$ [Hart *Am J* **1** 352 *1879-1880*]. ***Alternatively***, boil under reflux a solution of 2-nitro-4-toluenesulfonic acid (2.0g, 8.4mmol) in NaOCl (20ml, 32.2mmol) for 1 hour, cool to room temperature, filter, acidify the filtrate with concentrated HCl (dropwise, CARE), filter off the solid and dry it *in vacuo* (92% yield) [Gless et al. to Zeneca Ltd, Pat US5565608 A, expired 19 Dec *2000*]. Recrystallise the acid from dilute HCl (needles) and dry it *in vacuo*. It is stable in air but is *hygroscopic* in moist air. It is a standard in acid-base titrations. [*Beilstein* **11** III 685.]

Nuclear Fast Red (1-amino-2,4-dihydroxy-5,10-anthraquinone-3-sulfonic acid Na Salt) *[6409-77-4]* **$C_{14}H_8NNaO_7S$, M 357.3, m >290°(dec), λ_{max} 518nm.** A solution of 5g of the dye in 250ml of warm 50% EtOH is cooled to 15° for 36 hours, then filtered on a Büchner funnel, washed with EtOH until the washings are colourless, then with 100ml of Et_2O and dried over P_2O_5 *in vacuo*. It is a biological stain that is also used for the estimation of Ca. [Kingsley & Robnett *Anal Chem* **33** 552 *1961*, DOI: 10.1021/ac60172a020.]

n*-Octadecylphosphonic acid (ODPA)** *[4724-74-4]* **$C_{18}H_{38}O_3P$, M 334.5, m 95-98°, 98.5-99°, 98-100°, 100°, 100-101°, b ~463°/760mm (predicted), d_4^{25} ~1.0g/ml, n_D^{20} 1.444, pK_{Est} ~2.65.** The acid is best prepared by reaction of sodium dibutylphosphite [$NaPO(n\text{-}BuO)_2$] and *n*-octadecylbromide followed by hydrolysis of the dibutyl *n*-octadecylphosphonate formed. Thus, under N_2, Na (1.15g, 0.05 mole) is suspended in dry hexane, or heptane, (150ml) and refluxed gently while dibutylphosphite (9.7g, 0.05 mole) is added dropwise over 30 minutes. The boiling is continued until the Na completely dissolves (*ca* 4-5 hours) then *n*-octadecylbromide (0.05 mole) is added during 1 hour and gently refluxed for 5-6 hours while NaBr separated. The mixture is cooled, H_2O is added, the organic layer is collected, evaporated under reduced pressure (at room temperature when all the solvent is removed) and the residual oil (phosphonate ester) is distilled *in vacuo* (fractionating apparatus) to give **di-*n*-butyl *n*-octadecylphosphonate** (>80% yield, **b 248-250°/2mm,** d_4^{25} 0.9037, n_D^{25} 1.4499). The ester is hydrolysed by boiling under reflux with concentrated HCl (~75ml) overnight, then distilled from an oil bath whereby *n*-butanol and *n*-butylchloride and about half the volume of excess acid are distilled off, and cooled. The ***phosphonic acid that crystallises as crust is collected, dried and recrystallised from hexane or heptane (clusters of flat needles similar to naphthalene) and dried *in vacuo* over solid KOH and has **m 98.5-99°** (80-85% yield). [Kosolapoff *J Am Chem Soc* **67** 1180 *1945*, DOI: 10.1021/ja01223a045; see also Griffin & Wells *J Org Chem* **24** 2049 *1959*, DOI: 10.1021/jo01094a624.]
Alternatively, the phosphonic acid (100g) is dissolved in EtOH (150ml) by heating and stirring, and when clear, hexane (1L, total) is added slowly, set aside overnight then in a refrigerator for 6 hours and the crystals are collected by filtration. The crystals are stirred at 100° under vacuum to remove entrapped EtOH, toluene (300ml) is added slowly to the hot solid while stirring, heat is removed to give a white suspension, and the solid **ODPA** is collected at room temperature and dried to constant weight *in vacuo* (~24 hors, yield ~75g). $\{^1H\}^{31}P$ NMR (162MHz, MeOH-d_4) δ 29.1. [Owen et al. *J Am Chem Soc* **130** 12279 *2008*, DOI:10.1021/ja804414f]. At 10^{-3}mol/L in Milli Q H_2O, ODPA molecules behave as free species as shown by ^1H NMR [Hauffman et al. *Langmuir*, *24* 13450 *2008*, DOI: 10.1021/la801978a].
ODPA is used for the preparation of thermal paper for receipts, tickets etc, capping nano materials (cf. e.g. CdTe quantum dots in *Nanotechnology* Chapter 7). **IRRITANT,** affects eyes, skin, harmful if ingested.

***n*-Octadecyl trichlorosilane (OTS)** *[112-04-9]* **$C_{18}H_{37}Cl_3Si$, M 387.9, m 20°, 22°, b 160-162°/3mm, 185-199°/2-3mm, 223°/10mm, 280.3-283.2°/760mm, d_4^{30} 0.98, n_D^{20} 1.459.** Purify it by fractional distillation at high vacuum. It is moisture sensitive. [Winstein & Seubold *J Am Chem Soc* **69** 2916-2917 *1947*, DOI: 10.1021/ja01203a513; Barry et al. *J Am Chem Soc* **69** 2916-2916 *1947*, DOI: 10.1021/ja01203a512; *Beilstein* **4** IV 4256.] It has been used for making SAMs (Self-Assembled Monolayers, see Chapter 7) [Kovaks (seminar, 7 May 2013), quantum.esu.edu; Kelkar et al. *Appl Surface Sci* **282** 291 *2013*, DOI: 10.1016/j.apsusc.2013.05.121].

Octamethyl cyclotetrasiloxane *[556-67-2]* **$C_8H_{24}O_4Si_4$, M 296.6, m 17-19°, 17.58°, 18.5°, b 74°/20mm, 176.4°/760mm, $d_4^{29.3}$ 0.9451, n_D^{30} 1.3968.** The solid exists in two forms, **m 16.30°** and **17.65°**. Dry it over CaH_2 and distil it. Further fractionation can be effected by repeated partial freezing and discarding the liquid phase. [Patnode & Wilcock *J Am Chem Soc* **68** 358 *1946*, DOI: 10.1021/ja01207a004; Osthoff & Grubb *J Am Chem Soc* **76** 399 *1954*, DOI: 10.1021/ja01631a025; Hoffman *J Am Chem Soc* **75** 6313 *1953*, DOI: 10.1021/ja01120a515; *Beilstein* **4** IV 4125.]

Octamethyl trisiloxane *[107-51-7]* **$C_8H_{24}O_2Si_3$, M 236.5, m -82°, -80°, b 151.7°/747mm, 153°/760mm.** Distil it twice, the middle fraction from the first distillation is again distilled, and the middle fraction of the second distillation is used. [Patnode & Wilcock *J Am Chem Soc* **68** 358 *1946*, DOI: 10.1021/ja01207a004; Wolcock *J Am Chem Soc* **68** 691 *1946*, DOI: 10.1021/ja01208a050; Thompson *J Chem Soc* 1908 *1953*, DOI: 10.1039/JR9530001908; *Beilstein* **4** IV 4115.]

1-Octanethiol *[111-88-6]* **$C_8H_{18}S$, M 146.3, m -49°, b 77-78°/10m, 197-199°/atm, 199.1°/760mm, 197-200°/760mm, d ^{25} 0.843g/ml, n $_D^{20}$ 1.452, [also available as a 5mM solution in EtOH, d ^{25} 0.781g/ml], pKa 9.97.** 1-Acetylthio-octane [$C_{10}H_{20}OS$, M 188.0, b 116-117°/10m, n $_D^{20}$ 1.4641] prepared by reaction of thiolacetic acid and 1-octene (catalysed by a few milligrams of benzoyl peroxide) [Brown et al. *J Chem Soc* 2123 *1951*, DOI: 10.1039/JR9510002123], is hyrolysed with aqueous ethanolic KOH under N_2 to give ***octane-1-thiol*** in 85% yield, which is purified by distillation at **77-78°/10m**, and is stored under N_2. **The *2,4-dinitrophenylthioether*** has **m 75-76°** after recrystallisation from light petroleum (b 60-80°), and the ***mercuric salt*** forms plates with **m 71-72°** from EOH. [Bateman et al. *J Chem Soc* 2838 *1958*, DOI: 10.1039/JR9580002838.] ***Alternatively***, the thiol can be obtained by stirring a mixture of crude **S-octyl ethylxanthate** (0.1mol) [prepared by boiling under reflux a solution of potassium ethylxanthate (0.15mol, see *[140-89-6]* above) and *n*-octylchloride (0.1mol) in Me_2CO (200ml) for 8 hours}, the precipitated KCl is filtered off, the filtrate is evaporated off under reduced pressure, and the residue is washed with H_2O to remove unreacted K xanthate. The ester is recovered in 90-95% yield as an oil which is dried over anhydrous Na_2SO_4. The crude ester in ethylenediamine (30ml) is heated at 30° for 3 hours under N_2, poured into an ice-water solution of H_2SO_4 and extracted with $*C_6H_6$ (3 x 50ml). The extract is washed with 5% H_2SO_4, dried (Na_2SO_4), filtered, the filtrate is evaporated and the oily thiol is distilled (**b 71-72°/10mm**) under a vacuum in a current of N_2. [Mori & Nakamura *J Org Chem* **34** 4170 *1969*, DOI: 10.1021/jo01264a095.] Store the foul smelling oil in a sealed container under N_2 or argon. Used to prepare functionalise gold nanoparticles, e.g. $Au—SCH_2(CH_2)_6CH_3$ [see MFCD09953506, PubChemID 24884475 in Chapter 7, 'Nanotechnology'], and for other applications in nanotechnology. **IRRITANT**, prevent contact with eyes and skin.

Octaphenyl cyclotetrasiloxane *[546-56-5]* **$C_{48}H_{40}O_4Si_4$, M 793.2, m 200.5°, 201°, 201-202°, 203-204°, b 330-340°/1mm.** Recrystallise it from AcOH, EtOAc, $*C_6H_6$ or $*C_6H_6$/EtOH. It forms two stable isomorphs and both forms, as well as the mixture, melt at **200-201°**. There is a ***metastable*** form which melts at **187-189°**. [Burkhard et al. *J Am Chem Soc* **67** 2174 *1945*, DOI: 10.1021/ja01228a035; Hyde et al. *J Am Chem Soc* **69** 488 *1947*, DOI: 10.1021/ja01195a003; *Beilstein* **16** IV 1530.]

Octyl trichlorosilane *[5283-66-9]* **$C_8H_{17}Cl_3Si$, M 247.7, b 96.5°/10mm, 112°/15mm. 119°/28mm, 233°/731mm, 225-227°/atm, 229°/760mm, d $_4^{20}$ 1.0744, n $_D^{20}$ 1.4453.** Purify the silane by repeated fractionation using a 15-20 theoretical plate glass column packed with glass helices. This can be done more efficiently using a spinning band column. Its purity can be checked by analysing for HCl (*ca* 0.5-1g of sample is dissolved in 25ml of MeOH, diluted with H_2O and the HCl formed by hydrolysis is titrated with standard alkali). It is moisture sensitive. [Whitmore *J Am Chem Soc* **68** 475 *1946*, DOI: 10.1021/ja01207a035; El-Abbady & Anderson *J Am Chem Soc* **80** 1737 *1958*, DOI: 10.1021/ja01540a058; *Beilstein* **4** III 1907, **4** IV 4253]

Orange I [tropaeolin 000 Nr1, 4-(4-hydroxy-1-naphthylazo)benzenesulfonic acid sodium salt] *[523-44-4]* **$C_{16}H_{11}N_2NaO_4S$, M 350.3, m >260°(dec).** Purify the dye by dissolving it in the minimum volume of H_2O, adding, with stirring, a large excess of EtOH. The salt separates as orange needles. It is collected by centrifugation or filtration, washed with absolute EtOH (3x) and Et_2O (2x) in the same way, and dried in a vacuum desiccator over KOH. The ***free acid*** can be recrystallised from EtOH. [Slotta & Franke *Chem Ber* **64** 86 *1931*, DOI: 10.1002/cber.19310640115; *Beilstein* **16** H 275, **16** II 117, **16** IV 410.] The purity can be checked by titration with titanium chloride [Klotz *J Am Chem Soc* **68** 2299 *1946*, DOI: 10.1021/ja01215a051].
Orange II [tropaeolin 000 Nr2, CI Acid Orange 7,* 4-(2-hydroxy-1-naphthylazo)benzenesulfonic acid sodium salt]** *[633-96-5]* **$C_{16}H_{11}N_2NaO_4S$, M 350.3,** has **m 164°(predicted).** Purification is as for Orange I. Its solubility in H_2O is 40g/L at 25°. [Müller et al. *Helv Chim Acta* **35** 2579 *1952*, DOI: 10.1002/hlca.19520350745.] Also purify it by extracting it with a small volume of cold water, then crystallising it by dissolving in boiling water, cooling to *ca* 80°, adding two volumes of EtOH and cooling. When cold, the precipitate is filtered off, washed with a little EtOH and dried in air. It can be salted out from aqueous solution with sodium acetate, then repeatedly extracted with EtOH. Meggy and Sims [*J Chem Soc* 2940 *1956*, DOI: 10.1039/JR9560002940], after crystallising the sodium salt twice from water, dissolved it in cold water (11ml/g) and added concentrated HCl to precipitate the ***acid dye which was separated by centrifugation, redissolved and again precipitated with acid. After washing the precipitate three times with 0.5M acid, it was dried over NaOH, recrystallised twice from absolute EtOH, washed with a little Et_2O, dried over NaOH and stored over concen-

trated H_2SO_4 in the dark. It can then be converted to the ***pure salt*** with the calculated amount of NaOH or Na_2CO_3. [*Beilstein* **16** IV 408.] The purity, like Orange I above, can be checked by titration with titanium chloride [Klotz *J Am Chem Soc* **68** 2299 *1946*, DOI: 10.1021/ja01215a051].

Orange G* (Acid Orange 10, 1-phenylazo-2-naphthol-6,8-disulfonic acid di-Na salt)** *[1936-15-8]* **$C_{16}H_{10}N_2Na_2O_7S_2$, M 452.4,** has **$pK_{Est}$~ 9.** Recrystallise this dye from 75% EtOH, dry it for 3 hours at 110° and keep it in a vacuum desiccator over H_2SO_4. The ***free acid crystallises from EtOH or concentrated HCl in deep red needles with a green reflex. A biological stain for connective tissue, pituitary acidophils, keratin, mucus, and in Flemming's triple stain on paraffin sections of onion root. [Oxidation-reduction potential of azo dyes: Conant & Pratt *J Am Chem Soc* **48** 2468 *1923*, DOI: 10.1021/ja01420a039; Drew & Landquist *J Chem Soc* 292 *1938*, DOI: 10.1039/JR9380000292; *Beilstein* **16** H 301, **16** I 305, **16** II 141, **16** III 327.]

***Orange RO* {acid orange 8, 1,8-[bis(4-*n*-propyl-3-sulfophenyl-1-amino)]anthra-9,10-quinone di-Na salt}** *[5850-86-2]* **$C_{17}H_{13}N_2NaO_4S$, M 364.4, CI 15575,** has **λ_{max} 490nm.** Salt it out three times with sodium acetate, then extract it repeatedly with EtOH and dry it *in vacuo*.

Orthanilic acid (2-aminobenzenesulfonic acid) *[88-21-1]* **$C_6H_7NO_3S$, M 173.2, m >300°(dec), pK^{25} 2.49.** Crystallise orthanilic acid from aqueous solution, containing 20ml of concentrated HCl per L, then recrystallise it from distilled water, and dry it in a vacuum desiccator over Sicapent (**m** 315°). When an aqueous solution is chilled below 13.5°, the hydrated form of the acid is obtained. It is used for the determination of nitrite and nitrate. The ***S-benzylisothiuronium salt*** has **m** 137° (from H_2O). [Wertheim *Org Synth* Coll Vol **2** 471 *1943*, DOI: 10.15227/orgsyn.015.0055; *Beilstein* **14** H 681, **14** I 714, **14** II 429, **14** III 1896, **14** IV 2638.] It promotes the formation of a reverse-turn in peptides, and induces a folded conformation when incorporated into peptides.

Pentafluorophenyl dimethylchlorosilane (Flophemesyl chloride) *[20082-71-7]* **$C_8H_6ClF_5Si$, M 260.7, b 47°/1mm, 89-90°/10mm, d_{20}^{20} 1.4080-1.412, d_4^{30} 1.403, n_D^{20} 1.4460-1.4490.** If it goes turbid on cooling due to separation of some LiCl, then dissolve it in Et_2O, filter and fractionate it in a vacuum. [Morgan & Poole *J Chromatogr* A **89** 225 *1974*, DOI: 10.1016/S0021-9673(01)99397-5; Birkinshaw et al. *J Chromatogr* A **132** 548 *1977*, DOI: 10.1016/S0021-9673(00)82921-0.] A sensitive derivatising reagent in electron capture gas chromatography for analysing steroids and aliphatic alcohols [Poole et al. *J Chromatogr* A **199** 123 *1980*, DOI: 10.1016/S0021-9673(01)91366-4].

Phenol-2,4-disulfonic acid *[96-77-5]* **$C_6H_6O_7S_2$, M 254.2, pK_1 <1, pK_2 <1, pK_3 ~8.3.** Crystallise the acid from EtOH/diethyl ether. [*Beilstein* **11** H 250, **11** I 58, **11** II 139, **6** III 522.] **IRRITANT.**

Phenylarsonic acid (benzenearsonic acid) *[98-05-5]* **$C_6H_7AsO_3$, M 202.0, m 155-158°(dec), 158-162°(dec), pK_1^{25} 3.65, pK_2^{25} 8.77.** Crystallise it from H_2O (3ml/g) between 90° and 0°. *Alternatively*, dissolve 600g of the acid in 500ml of boiling H_2O, add 20g of Norite, filter hot, cool, filter off the crystals and dry them. On heating at ~154-160° it is converted to the ***anhydride***. [Bullard & Dickery *Org Synth* Coll Vol **2** 494 *1943*, DOI: 10.15227/orgsyn.015.0059; for the ***4-nitro derivative*** see Ruddy & Starkey *Org Synth* Coll Vol **3** 665 *1955*, DOI: 10.15227/orgsyn.026.0060; *Beilstein* **16** H 868, **16** I 448, **16** II 457, **16** III 1057, 16 IV 1183.]

N*-Phenyl-bis(trifluoromethanesulfonimide) [ditriflic phenylimide, *N*,*N*-bis(trifluoromethylsulfonyl) aniline]** *[37595-74-7]* **$C_8H_5F_6NO_4S_2$, M 357.3, m 93-94°, 100-102°, 99-105°.** This ditriflic imide is a very ***stable triflating agent. If hydrolysis appears to have occurred, it would be better to prepare anew from purified aniline with 2 mols of redistilled trifluoroacetic anhydride in CH_2Cl_2 at -78°, with 2 mols of Et_3N in order to keep the aniline as the free base and to mop up the free acid formed. It is then evaporated *in vacuo* to give the crystalline reagent. [McMurry & Scott *Tetrahedron Lett* **24** 979 *1983*, DOI: 10.1016/S0040-4039(00)81581-6; Crisp & Scott *Synthesis* 335 *1985*, DOI: 10.1055/s-1985-31204; Hendrickson & Bergeron *Tetrahedron Lett* **14** 4607 *1973*, DOI: 10.1016/S0040-4039(01)87289-0; Mascarenas et al. *Tetrahedron* **47** 3485 *1991*, DOI: 10.1016/S0040-4020(01)86410-3.]

1,4-Phenylene diisothiocyanate (bitoscanate) *[4044-65-9]* **$C_6H_4N_2S_2$, M 192.3, m 129-131°, 130-131°, 132°, 129-133°.** Purify bitoscanate by recrystallisation from AcOH, petroleum ether (b 40-60°), Me_2CO or

aqueous Me_2CO. [van der Kerk et al. *Recl Trav Chim Pays-Bas* **74** 1262 *1955*, DOI: 10.1002/recl.19550741007; Lieber & Slutkin *J Org Chem* **27** 2214 *1962*, DOI: 10.1021/jo01053a509; *Beilstein* **13** IV 174.] It is a CNS and gastrointestinal **toxin** in humans, harmful if swallowed.

Phenylboronic acid (benzeneboronic acid) *[98-80-6]* **$C_6H_7BO_2$, M 121.9, m ~43°, 215-216° (anhydride), 217-220°, 219°, b 265°/atm, pK_1^{25} 8.83.** It recrystallises from H_2O, but it can convert spontaneously to ***benzeneboronic anhydride*** or ***phenylboroxide*** on standing in dry air. A possible impurity is ***dibenzeneborinic*** acid which can be removed by washing with petroleum ether. Heating in an oven at 110°/760mm for 1 hour converts it to the ***anhydride*** **m 214-216°**. Its solubility in H_2O is 1.1% at 0° and 2.5% at 25°, and in EtOH it is 10% (w/v). [Gilman & Moore *J Am Chem Soc* **80** 3609 *1958*, DOI: 10.1021/ja01547a032.] If the acid is required, not the anhydride, the acid (from recrystallisation in H_2O) is dried in a slow stream of air saturated with H_2O. The ***anhydride*** is converted to the acid by recrystallisation from H_2O. The acid gradually dehydrates to the ***anhydride*** if left in air at room temperature with 30-40% relative humidity. The melting point is usually that of the anhydride because the acid dehydrates before it melts [Washburn et al. *Org Synth* Coll Vol **4** 68 *1963*, DOI: 10.15227/orgsyn.039.0003]. [Fieser **1** 833; *Beilstein* **16** IV 1654.] It is a useful component in Stille- [Chan & Mak *Tetrahedron* **50** 2003 *1994*, DOI: 10.1016/S0040-4020(01)85064-X; Gilbert & Wulff *J Am Chem Soc* **116** 7449 *1994*, DOI: 10.1021/ja00095a075] and Suzuki- [Chan & Mak *Tetrahedron* **50** 2003 *1994*, DOI: 10.1016/S0040-4020(01)85064-X; Shapiro & Gomez-Lor *J Org Chem* **59** 5524 *1994*, DOI: 10.1021/jo00098a006; Marck et al. *Tetrahedron Lett* **35** 3277 *1994*, DOI: 10.1016/S0040-4039(00)76884-5] cross coupling reactions, and in Suzuki and Suzuki-Miyaura bi-aryl cross-coupling reactions [Wu et al. *Tetrahedron Lett* **47** 9267 *2006*, DOI: 10.1016/j.tetlet.2006.10.127; Li et al. *Tetrahedron Lett* **47** 9239 *2006*, DOI: 10.1016/ j.tetlet.2006.10.148].

1,2-Phenylenephosphorochloridate (2-chloro-1,3,2-benzodioxaphosphole-2-oxide) *[1499-17-8]* **$C_6H_4ClO_3P$, M 190.5, m 52°, 58-59°, 59-61°, b 80-81°/1-2mm, 118°/10mm, 122°/12mm, 125°/16mm, 155°/33mm.** After distilling it in a vacuum, it sets to a colourless solid. It is soluble in petroleum ether, *benzene and slightly soluble in Et_2O. [Khwaja et al. *J Chem Soc (C)* 2092 *1970*, DOI: 10.1039/ J39700002092; Anschütz & Broeker *Justus Liebigs Ann Chem* **454** 109 *1927*, DOI: 10.1002/jlac.19274540107; Fieser **1** 837; *Beilstein* **6** IV 5602.]

Phenylisothiocyanate (phenyl mustard oil) *[103-72-0]* **C_7H_5NS, M 135.2, m -21°, b 95°/12mm, 117.1°/33mm, 221°/760mm, d_4^{25} 1.1288, $n_D^{23.4}$ 1.64918.** It is insoluble in H_2O, but soluble in Et_2O and EtOH. If impure (due to formation of thiourea), then steam distil it into a receiver containing 5-10ml of N H_2SO_4. Separate the oil, dry over $CaCl_2$ and distil it under vacuum. [Dains et al. *Org Synth* Coll Vol **1** 447 *1941*, DOI: 10.15227/orgsyn.006.0072; *Beilstein* **12** IV 867.] Used for derivatisation.

Phenyl methanesulfonate *[16156-59-5]* **$C_7H_8O_3S$, M 172.1, m 58-61°, 61-62°, 62-63°, b 279°/atm,** Crystallise the sulfonate from MeOH or from H_2O (**m 61.5°**). [*Beilstein* **6** H 176, **6** III 650, **6** IV 689.]

Phenyl methanesulfonyl fluoride (PMSF) *[329-98-6]* **$C_7H_7FO_2S$, M 174.2, m 90-91°, 92-93°**. Purify PMSF by recrystallisation from *C_6H_6, petroleum ether or $CHCl_3$/petroleum ether. [Davies & Dick *J Chem Soc* 483 *1932*, DOI: 10.1039/JR9320000483; cf. Tullock & Coffman *J Org Chem* **25** 2016 *1960*, DOI: 10.1021/jo01081a050.] It is a general **protease inhibitor** (specific for trypsin and chymotrypsin) and is a good substitute for diisopropylphosphorofloridate [Fahrney & Gold *J Am Chem Soc* **85** 997 *1963*, DOI: 10.1021/ja00890a037]. [*Beilstein* **11** III 331.] It is used in the preparation of cell lysates as a protease inhibitor.

Phenylphosphinic acid [benzenephosphinic acid, PhPH(O)(OH)] *[1779-48-2]* **$C_6H_7O_2P$, M 142.1, m 70°, 71°, 83-85°, 86°, pK_1^{25} 1.75**. Crystallise it from H_2O (solubility is 7.7% at 25°). Also purify it by placing the solid in a flask covered with dry Et_2O, and allowed it to stand for 1 day with intermittent shaking. Et_2O is decanted off and the process repeated. After filtration, excess Et_2O is removed in a vacuum. It has also been recrystallised from *C_6H_6. [Michaelis *Justus Liebigs Ann Chem* **181** 265 *1876*, DOI: 10.1002/jlac.18761810302; Banks & Skoog *Anal Chem* **29** 109 *1957*; for ^{31}P NMR of P compounds see Van Wazer et al. *J Am Chem Soc* **78** 5715 *1956*, DOI: 10.1021/ja01603a002; and for deuterium exchange see Reuben et al. *J Am Chem Soc* **85** 3093 *1963*, DOI: 10.1021/ja00903a009; *Beilstein* **16** IV 1033.]

Phenylphosphonic acid *[1571-33-1]* **$C_6H_7O_3P$, M 158.1, m 161°, 163°, 164.5-166°, pK_2^{25} 7.43 (7.07).** It is best to recrystallise it from H_2O by concentrating an aqueous solution to a small volume and allowing it to crystallise. Wash the crystals with ice cold H_2O and dry them in a vacuum desiccator over H_2SO_4. [Lecher et al. *J Am Chem Soc* **76** 1045 *1954*, DOI: 10.1021/ja01633a035]. pK^{25} values in H_2O are 7.07, and in 50% EtOH 8.26. [Jaffé et al. *J Am Chem Soc* **75** 2209 *1953*, DOI: 10.1021/ja01105a054; IR: Daasch & Smith *Anal Chem* **23** 853 *1951*, DOI: 10.1021/ac60054a008; *Beilstein* **16** IV 1068.]
Phenylphosphonic dichloride **(P,P-dichlorophenyl phosphine oxide)** *[824-72-6]* **$C_6H_5Cl_2OP$, M 195.0,** has **m 3°, b 83-84°/1mm, 135-136°/23mm, d_4^{30} 1.977, n_D^{30} 1.5578.** Fractionally distil it using a very efficient or a spinning band column. [Lecher et al. *J Am Chem Soc* **76** 1045 *1954*, DOI: 10.1021/ja01633a035; NMR: Muller et al. *J Am Chem Soc* **78** 3557 *1956*, DOI: 10.1021/ja01596a002; Van Wazer et al. *J Am Chem Soc* **78** 5715 *1956*, DOI: 10.1021/ja01603a002; IR: Daasch & Smith *Anal Chem* **23** 853 *1951*, DOI: 10.1021/ac60054a008; Fieser **1** 846; *Beilstein* **16** IV 1074.]

Phenylphosphonous acid [$PhP(OH)_2$] [tautomer of phenylphosphinic acid – above] *[121-70-0, 1779-48-2]* **$C_6H_7O_2P$, M 142.1, m 71°, pK_{Est} <0, pK^{17} 2.1.** Crystallise it from hot H_2O or $*C_6H_6$. [For deuterium exchange see Reuben et al. *J Am Chem Soc* **85** 3093 *1963*, DOI: 10.1021/ja00903a009; *Beilstein* **16** IV 1033.]
Phenylphosphonous dichloride **(P,P-dichloro phenyl phosphine)** *[644-97-3]* **$C_6H_5Cl_2P$, M 179.0,** has **m -51°, b 68-70°/1mm, 224-226°/atm, d_4^{30} 1.9317, n_D^{35} 1.5962.** Distil it in a vacuum by fractionating through a 20cm column packed with glass helices (better to use a spinning band column) [Buchner & Lockhart *J Am Chem Soc* **73** 755 *1951*, DOI: 10.1021/ja01146a076; NMR: Muller et al. *J Am Chem Soc* ***78*** 3557 *1956*, DOI: 10.1021/ja01596a002; IR: Daasch & Smith *Anal Chem* **23** 853 *1951*, DOI: 10.1021/ac60054a008]. It forms a yellow ***Ni complex: $Ni(C_6H_5Cl_2P)_4$*** **(m 91-92°**, from H_2O) [Quin *J Am Chem Soc* **79** 3681 *1957*, DOI: 10.1021/ja01571a020], and a yellow complex also with ***molybdenum carbonyl: $Mo(CO)_3.(C_6H_5Cl_2P)_3$*** **(m 106-110° dec)** [Abel et al. *J Chem Soc* 2323 *1959*, DOI: 10.1039/JR9590002323]. [*Beilstein* **16** IV 972.]

Phenyl phosphoryl dichloride *[770-12-7]* **$C_6H_5Cl_2O_2P$, M 211.0, m -1°, b 103-104°/2mm, 110-111°/10mm, 130-134°/21mm, 241-243°/atm, d_4^{30} 1.4160, n_D^{30} 1.5216.** Fractionally distil it under as high a vacuum as possible using an efficient fractionating column or a spinning band column. It should be redistilled if the IR is not very satisfactory [IR: Bellamy & Beecher *J Chem Soc* 475 *1952*, DOI: 10.1039/JR9520000475; Orloff et al. *J Am Chem Soc* **80** 727 *1958*, DOI: 10.1021/ja01536a052; for the diNa phenyl phosphate see Freeman & Colver *J Am Chem Soc* **60** 750 *1938*, DOI: 10.1021/ja01271a004]. [*Beilstein* **6** IV 737.] **HARMFUL VAPOURS.**

Phenylsilane ($PhSiH_3$) *[694-53-1]* **C_6H_8Si, M 108.2, b 62°/100mm, 120°/atm, d_4^{25} 0.877, n_D^{20} 1.5125.** It is best prepared by reduction of $PhSiCl_3$ with $LiAlH_4/Et_2O$: stir at room temperture overnight, pour onto crushed ice, extract with Et_2O, dry the extract (Drierite), filter, evaporate and distil the residual oil preferably in a vacuum [Benkeser et al. *J Am Chem Soc* **74** 648 *1952*, DOI: 10.1021/ja01123a019; Koch et al. *Recl Trav Chim Pays-Bas* **114** 206 *1995*, DOI: 10.1002/recl.19951140413; Finholt et al. *J Am Chem Soc* **69** 2692 *1947*, DOI: 10.1021/ja01203a041]. It is a **useful reagent** for deoxygenating phosphine oxides to phosphines, and *will reduced chiral phosphine oxides to chiral phosphines with retention of configuration* [Marsi *J Org Chem* **39** 265 *1974*, DOI: 10.1021/jo00916a041]. It is a reducing agent in radical reactions [Perez et al. *J Org Chem* **52** 5570 *1967*, DOI: 10.1021/jo00234a012], and deoxygenates primary and secondary alcohols *via* their xanthate or thionocarbonate esters (prepared from aryl-OCSCl and an inhibitor, e.g benzoyl peroxide) in 60-100 minutes in >87% yields [Barton et al. *Synlett* 435 *1991*, DOI: 10.1055/s-1991-20755]. [*Beilstein* **16** III 1198, **16** IV 1360.]

1-Phenylthiosemicarbazide *[645-48-7]* **$C_7H_9N_3S$, M 167.2, m 200-201°(dec).** Crystallise it from EtOH. [*Beilstein* **15** IV 183.]
4-Phenylthiosemicarbazide *[5351-69-9]* has **m 138-140°, 140°.** Crystallise it from EtOH. [*Beilstein* **12** IV 827.]

Phenylthio trimethylsilane (trimethyl phenylthio silane) *[4551-15-9]* **$C_9H_{14}SSi$, M 182.4, b 72°/8mm, 95-99°/12mm, d_4^{25} 0.963, d_4^{30} 0.97, n_D^{20} 1.532.** Purification is as for phenyl trimethylsilylmethyl sulfide.

1-Phenyl-2-thiourea *[103-85-5]* **$C_7H_8N_2S$, M 152.1, m 145-150°, 154°.** Crystallise the thiourea from water and dry it at 100° in air. [*Beilstein* **12** IV 804.]

Phenyl 4-toluenesulfonate *[640-60-8]* **$C_{13}H_{12}O_3S$, M 248.3, m 94.5-95.5°, 96°, 95.8-97.8°.** Crystallise the ester from MeOH or glacial acetic acid. [*Beilstein* **11** H 99, **11** II 47, **11** III 200, **6** IV 271.]

Phenyl trimethoxysilane (trimethoxysilyl benzene, PTMOS) *[2996-92-1]* **$C_9H_{14}O_3Si$, M 198.3, m -25°, b 103°/20mm, 130.5-131°/45mm, 210-213°/atm, 233°/atm, d_4^{35} 1.022, n_D^{35} 1.4698.** Fractionate it through an efficient column, but note that it forms an azeotrope with MeOH which is a likely impurity. [Kantor *J Am Chem Soc* **75** 2712 *1953*, DOI: 10.1021/ja01107a048; *Beilstein* **16** IV 1556.] The hydrolysis and polymerisation of PTMOS produces vitreous solids [Jermouni et al. *J Mater Chem* **5** 1203 *1995*, DOI: 10.1039/JM9950501203].

Phenyl trimethylsilylmethyl sulfide [(phenylthiomethyl)trimethylsilane] *[17873-08-4]* **$C_{10}H_{16}SSi$, M 196.4, b 48°/0.04mm, 113-115°/12mm, 158.5°/52mm, d_4^{30} 0.9671, n_D^{30} 1.5380.** If the sample is suspect, then add H_2O, wash it with 10% aqueous NaOH, H_2O again, dry (anhydrous $CaCl_2$) and fractionally distil it through a 2ft column packed with glass helices. [Cooper *J Am Chem Soc* **76** 3713 *1954*, DOI: 10.1021/ja01643a035; *Beilstein* **6** IV 1505.]

Phosphine *[7803-51-2]* **PH_3, M 34.0, m -133°, b -87.5°/760mm, -87.7°/760mm, critical temperature 51.3°, d^{25} 1.5307, pK^{25} ~ -14 (extremely weak base).** Phosphine is a gas with a very strong odour of fish and is **POISONOUS**. The gas is poorly soluble in H_2O (0.26ml/ml at 20°), and ignites spontaneously in air with a luminous glow. It has been prepared in various ways. A convenient preparation is to make aluminium phosphide by mixing 2 parts of Al powder and 1 part of red P on a piece of paper. By igniting the paper, the mixture becomes white-hot resulting in a spongy mass of aluminium phosphide [Hoffman *J Am Chem Soc* **43** 1684 *1921*, DOI: 10.1021/ja01440a035; Bodoux *Bull Soc Chim Fr* **27** (3) 568 *1902*]. This phosphide reacts with cold H_2O to give a steady stream of PH_3. [Use an efficient fume cupboard in these experiments.] Fortunately, the gas is available in metal cylinders, but all due precautions should still be taken. [Klement in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **1** p 525-530 *1963*, Gokhale et al. *Inorg Synth* **9** 56 *1967*, DOI: 10.1002/9780470132401.ch17; for basicity see Henderson & Streuli *J Am Chem Soc* **82** 5791 *1960*, DOI: 10.1021/ja01507a008]. [For further detail see 'Inorganic Compounds' in Chapter 4.]

Polystyrenesulfonic acid sodium salt (-$CH_2CH(C_6H_4SO_3Na)$-) *[25704-18-1]* **M**(average) **~70,000, ~200,000, ~1,000,000.** Purify the polymeric anionic electrolyte by repeated precipitation of the sodium salt from an aqueous solution by MeOH, with subsequent conversion to the ***free acid*** by passage through an Amberlite IR-120 ion-exchange resin. [Kotin & Nagasawa *J Am Chem Soc* **83** 1026 *1961*, DOI: 10.1021/ja01466a003] Recrystallise it from EtOH. *Alternatively*, purify it by passage through cation and anion exchange resins in series (Rexyn 101 cation exchange resin and Rexyn 203 anion exchange resin), then titrated it with NaOH to pH 7. The ***sodium form*** of polystyrenesulfonic acid is precipitated by addition of 2-propanol. Dry it in a vacuum oven at 80° for 24 hours, and finally increasing to 120° before to use. [Kowblansky & Ander *J Phys Chem* **80** 297 *1976*, DOI: 10.1021/j100544a019.]

Pontacyl Carmine 2G (Acid Red 1, Amido Naphthol Red G, Azophloxine, 1-acetamido-8-hydroxy-7-phenylazonaphthalene-3,7-disulfonic acid di-Na salt) *[3734-67-6]* **$C_{18}H_{13}N_3Na_2O_8S_2$, M 509.4, CI 18050, λ_{max} 506 and 532nm.** Salt it out three times with sodium acetate, then repeatedly extract it with EtOH. See below. [McGrew & Schneider *J Am Chem Soc* **72** 2547 *1950*, DOI: 10.1021/ja01162a059.]
Pontacyl Light Yellow GX **[Acid Yellow 17, 1-(2,5-dichloro-4-sulfophenyl]-3-methyl-4-(4-sulfophenylazo)-5-hydroxypyrazole di-Na Salt]** *[6359-98-4]* **$C_{16}H_{10}Cl_2N_4Na_2O_7S_2$, M 551.3, CI 18965,** has **λ_{max} 400nm.** Purify this yellow powder as for Pontacyl Carmine 2G above.

Potassium 4-acetylphenyltrifluoroborate *[252726-24-2]* **$C_8H_7BF_3KO$, M 226.1, m >250°, 290°(dec).** The salt is prepared by adding an aqueous solution of KHF_2 (41ml, 4.5M solution, 185mmol) to a solution of 4-acetylphenylboronic acid (10g, 61mmol) in MeOH (40ml) at ~25°, when a heavy precipitate deposits, but the suspension is stirred for 1 hour at 25° and the solid is filtered off, washed with MeOH and recrystallised from the minimum volume of Me_2CO to provide ***p-AcC_4H_4-BF_3^- K^+*** (12, 87%), **m >250°**. Its ^{1}H NMR [$(CD_3)_3CO$, 500MHz] has δ at 7.74(d, *J* = 7.8Hz, 2H), 7.59 (d, *J* = 7.8Hz, 2H), 2.49 (s, 3H); the ^{13}C NMR [$(CD_3)_3CO$, 125MHz] has δ at 198.1, 134.2, 131.3 (d, *J* = 1.5Hz), 126.2, 26.4; the ^{19}F NMR (DMSO-d_6, 470MHz) has δ at -140.3 (br s); the ^{11}B NMR (DMSO-d_6, 64MHz) has δ at 3.27 (br s), and has the correct elemental analysis

for C and H. It has been used for inserting a **4-acetylphenyl group** into the position of a halogen or triflate group of various arenes and various heterocycles in Pd-catalysed **Suzuki-Miyaura cross-coupling** reactions [Molander & Biolatto *J Org Chem* **68** 4302 *2003*, DOI: 10.1021/jo0342368].

Potassium 3,5-bis(trifluoromethyl)phenyltrifluoroborate *[166328-09-2]* **$C_8H_3BF_9K$, M 320.0, m >250°.** This salt was prepared by the same procedure as the preceding salt in 89% yield and recrystallised from the minimum volume of Me_2CO. Its ^1H NMR (DMSO-d_6, 500MHz) has δ at 7.87(s, 2H), 7.71 (s, 1H), 2.49 (s, 3H); the ^{13}C NMR (DMSO-d_6, 125MHz) has δ at 131.2, 128.1 (q, J = 31Hz), 124.2 (q, J = 272Hz), 118.6 (s); the ^{19}F NMR (DMSO-d_6, 470MHz) has δ at -61.7, -141.6 (br d, J = 71Hz), and the ^{11}B NMR (DMSO-d_6, 64MHz) has δ at 2.57 (br s), and has the correct elemental analysis for C and H. It has been used for inserting a 3,5-bis(trifluoromethyl)phenyl group into the position of a halogen or triflate group of various arenes and various heterocycles in Pd-catalysed **Suzuki-Miyaura cross-coupling** reactions [Molander & Biolatto *J Org Chem* **68** 4302 *2003*, DOI: 10.1021/jo0342368;Vedejs et al. *J Org Chem* **60** 3020 *1995*, DOI: 10.1021/jo00115a016;]

Potassium 2,4-difluorophenyltrifluoroborate *[871231-41-3]* **$C_6H_3BF_5K$, M 220.0, m >300°**. This borate can be prepared by the same procedure as below and applied in similar reactions.
Potassium 2,6-difluorophenyltrifluoroborate *[267006-25-7]* has **m >300°.** This salt was prepared by the same procedure as the preceding bis(trifluoromethyl) salt in 90% yield except that the crystalline precipitate was washed with H_2O then Et_2O and dried at high vacuum in a Schlenk line, and had m >250°. Its ^1H NMR (DMSO-d_6, 500MHz) has δ at 6.66 (m, 2H), 7.10 (m, 1H); the ^{13}C NMR (DMSO-d_6, 125MHz) has δ at 168.7 (dd, J = 242Hz, 18H), 127.5 (t, J = 11Hz), 110.0 (dd, J = 23Hz, 8H), 118.6 (s); the ^{19}F NMR (DMSO-d_6, 470MHz) has δ at -103.7 (q, J = 9.4Hz), -132.6 (qt, J = 43.9Hz); and the ^{11}B NMR (DMSO-d_6, 64MHz) has δ at 2.17 (q, J = 44Hz), and has the correct elemental analysis for C and H. It has been used for inserting a **2,6-difluorophenyl group** into the position of a halogen or triflate group of various arenes and various heterocycles in Pd-catalysed **Suzuki-Miyaura cross-coupling** reactions [Molander & Biolatto *J Org Chem* **68** 4302 *2003*, DOI: 10.1021/jo0342368.]
Potassium 2,6-dimethylphenyltrifluoroborate *[561328-67-4]* **$C_8H_9BF_3KO_2$, M 212.1,** has **m >250°.** This salt was prepared by the same procedure as the preceding difluorophenyl salt in 88% yield, except that the crystalline precipitate was washed with H_2O then Et_2O and dried at high vacuum in a Schlenk line and had m >250°. Its ^1H NMR (acetone-d_6, 500MHz) has δ at 6.83 (t, J = 7.4Hz, 1H), 6.75 (d, J = 7.4Hz, 2H), 2.40 (s, 6H); the ^{13}C NMR (acetone-d_6, 125MHz) has δ at 142.5, 127.7, 125.9, 23.8; the ^{19}F NMR (acetone-d_6, 470MHz) has δ at -132.5 (q, J = 48Hz); and the ^{11}B NMR (acetone-d_6, 64MHz) has δ at 4.94 (br d, J = 49Hz), and has the correct elemental analysis for C and H. It has been used for inserting a **2,6-dimethylphenyl group** into the position of a halogen or triflate group of various arenes and various heterocycles in Pd-catalysed **Suzuki-Miyaura cross-coupling** reactions [Molander & Biolatto *J Org Chem* **68** 4302 *2003*, DOI: 10.1021/jo0342368; cf. Vedejs et al. *J Org Chem* **60** 3020 *1995*, DOI: 10.1021/jo00115a016]. ***Potassium 4-tert-butylphenyltrifluoroborate*** *[423118-47-2]* **$C_{10}H_{13}BF_3K$, M 240.1, m >230°,** can be similarly prepared from 4-*tert*-butylphenylboronic acid and used in Pd catalysed **Suzuki cross-coupling** reactions.

Potassium ethyl xanthate (potassium *O*-ethyl dithiocarbonate, potassium ethyl xanthogenate) *[140-89-6]* **$C_3H_5KOS_2$, M 160.3, m ~210°(dec), > 215°(dec), pK^{25} 2.16 (for $-S^-$).** It forms white to pale yellow crystals, prepared by adding ethanolic KOH dropwise to an ethanolic solution of CS_2 to form the salt which can be coaxed further out of solution by adding Et_2O. Crystallise it from absolute EtOH, ligroin/ethanol or acetone by adding Et_2O. Wash it with ether, then dry it in a desiccator. Its solubility at 56° in EtOH is >1% and in Me_2CO is 8% (the Na salt has 44%), and very high in H_2O at 25°. Dry it *in vacuo*, if it contains H_2O, and store it in a tightly stoppered bottle away from light. [X-ray diffraction identification of xanthate derivatives of alcohols: Warren & Matthews *Anal Chem* **26** 1985 *1954*, DOI: 10.1021/ac60096a041; *Beilstein* **3** H 209, **3** I 84 **3** II 152, **3** III 336, **3** IV 402.]

Potassium 2-furantrifluoroborate *[166328-14-9]* **$C_4H_3BF_3KO$, M 174.0, m 200°(dec), >293-303°.** This salt has been prepared from furan (5.0ml, 68.7mmol, dried over 3Å Molecular Sieves) in dry THF (50ml) which was treated under N_2 with BuLi (42.0ml, 1.64M in pentane, 68.9mmol) and stirred at -5° for 3.5 hours to form ***furyllithium***. The latter was treated with B(*iso*-PrO)$_3$ and allowed to warm to ~25°, quenched with 10% aqueous HCl (~50ml), diluted with Et_2O (50ml) and the organic layer was extracted with 1N NaOH (2 X 50ml). The alk-

aline extracts were combined, acidified to pH 3 with 10% aqueous HCl, and the acid layer was then extracted with Et_2O (3 x 50ml). The combined Et_2O extracts were dried (Na_2SO_4) and evaporated to dryness. The residual 2-furanboronic acid was dissolved in MeOH (200ml) and H_2O (40ml) was treated with 3 equivalents of KHF_2 (16g, 206mmol), refluxed overnight and evaporated to dryness *in vacuo*. The residue was extracted with MeCN (2 x 30ml), filtered and the filtrate was evaporated to dryness, the residue was washed with Et_2O, dried and recrystallised from MeCN/EtOAc to give pure ***2-furan-BF_3^- K^+*** (5.8g, 48%) as yellow crystals. Attempted TLC on Silica Gel with EtOAc caused hydrolysis of the salt to ***2-furylboronic acid***. Its IR (KBr) had bands at ν_{max} 1575 (C=C), 1005 (B-F), 970 (B-F) cm^{-1}, the ^1H NMR (CD_3CN, 200MHz) had δ at 7.44-7.33 (m, 1H), 6.25-6.17 (m, 1H), 6.17-6.10 (m, 1H); and the ^{11}B NMR (CD_3CN, 160MHz) has δ (from $BF_3.OEt_2$, 0 ppm) 1.8 (q, *J* 49Hz) and it had the correct elemental analysis for C and H. It is air stable and has been used successfully in Pd-catalysed **Suzuki-Miyaura cross-coupling** reactions [Vedejs et al. *J Org Chem* **60** 3020 *1995*, DOI: 10.1021/jo00115a016; Molander et al. *J Org Chem* **74** 973 *2009*, DOI: 10.1021/jo802590b].

Potassium isoamyl xanthate (potassium *O*-isoamyl dithiocarbonate) *[928-70-1, 61792-26-5]* **$C_6H_{11}KOS_2$, M 202.4, pK^{25} 1.82 (pK^0 2.8 free acid).** Crystallise it twice from acetone/diethyl ether. Dry it in a desiccator for two days and store it under refrigeration. Its solubility in Me_2CO is 2.3% at 56°. [See potassium ethyl xanthate above for storage. FOR X-ray diffraction identification of xanthate derivatives of alcohols see Warren & Matthews *Anal Chem* **26** 1985 *1954*, DOI: 10.1021/ac60096a041; *Beilstein* **3** III 340, **3** IV 404.]

Potassium 4-methoxyphenyltrifluoroborate *[192863-36-8]* **$C_7H_7BF_3KO$, M 214.0, m >300°.** The salt is prepared by mixing ***4-methoxyphenylboronic acid*** (0.65g, 4.3mmol) and KHF_2 (0.76g, 9.7mmol) in H_2O (1ml) and MeOH (1.8ml) at ~25° for 2 hours and the resulting yellow slurry is extracted into Me_2CO (10ml) and evaporated under a vacuum. The residue is dissolved consecutively in hot Me_2CO and THF, filtered and Et_2O is added to give a yellow solid which is filtered off, washed with Et_2O until free from the yellow colour, and the crystalline material is dried in a Schlenk vacuum line to give ***p-$MeOC_4H_4$-BF_3^- K^+*** (0.83g, 92%). Its ^1H NMR (acetone-d_6, 500MHz) has δ at 7.38 (d, *J* = 8.2Hz, 2H), 7.69 (d, *J* = 8.2Hz, 2H), 3.70 (s, 3H); the ^{13}C NMR (acetone-d_6, 125MHz) has δ at 158.9, 133.5, 112.8, 55.1; the ^{19}F NMR (acetone-d_6, 470MHz) has δ (from $.Cl_3$, 0ppm) at -142.28 (br d, *J* = 66Hz); and the ^{11}B NMR (acetone-d_6, 64MHz) has δ (from $BF_3.OEt_2$, 0ppm) at 4.8 (br s, *J* = 17Hz), and it has the correct elemental analysis for C and H. It is air stable and has been used successfully in Pd-catalysed **Suzuki-Miyaura cross-coupling** reactions [Molander & Biolatto *Org Lett* **4** 1867 *2002*, DOI: 10.1021/ol025845p].

Potassium 3-methoxyphenyltrifluoroborate *[438553-44-7]* has **m >300° and** was prepared in the same manner from ***3-methoxyphenylboronic acid*** in 89% yield and had IR (KBr) with bands at ν_{max} 1241 (? C=C), 987 (B-F) cm^{-1}; the ^1H NMR (acetone-d_6, N, 500MHz) had δ: 7.03 (m, 3H), 6.61 (m, 1H), 3.67 (s, 3H); the ^{13}C NMR (acetone-d_6, 125MHz) had δ at 159.6, 128.2, 124.9, 117.6, 112.0 55.0; the ^{19}F NMR (acetone-d_6, 470MHz) had δ (from $CFCl_3$, 0ppm) at -142.8 (br d, *J* = 66Hz); and the ^{11}B NMR (acetone-d_6, 64MHz) had δ (from $BF_3.OEt_2$, 0ppm) at 4.2 (br s, *J* 43Hz), and it had the correct elemental analysis for C and H [Molander & Biolatto *Org Lett* **4** 1867 *2002*, DOI: 10.1021/ol025845p; cf. Vedejs et al. *J Org Chem* **60** 3020 *1995*, DOI: 10.1021/jo00115a016].

Potassium 2-methoxyphenyltrifluoroborate *[236388-46-8]* has **m >300°** and can be prepared in the same manner from 2-methoxyphenylboronic acid and used successfully in Pd-catalysed **Suzuki-Miyaura cross-coupling** reactions.

Potassium methyltrifluoroborate *[13862-28-7]* **CH_3BF_3K, M 121.94,** has **m 168-183°, 183°.** This salt, which was used successfully in Pd-catalysed **Suzuki-Miyaura cross-coupling** is air stable, more robust and easier to handle than methylboronic acid. It is prepared by adding ***trimethyl boroxine*** (5.14g, 41mmol, 3 equivs, *[823-96-1]*) at room temperature to KHF_2 (19.0g, 243mmol, 6 equivs) in MeCN (200ml), and the mixture is cooled to 0° and stirred for 30 minutes. Then H_2O (4.5ml) is added and after stirring for 3 hours the solvent is evaporated and the resulting solid is dried thoroughly *in vacuo*. The residue is triturated with Me_2CO/MeOH (1:1, 100ml), filtered off, washed with the same mixture of solvents (100ml) and once with Me_2CO/MeOH (1:2, 100ml), and the remaining insoluble white solid is dried at high vacuum in a Schlenk line to give ***$MeBF_3^-$ K^+*** (12.0g, 80%) as a white powder **m 183°**. Its ^1H NMR (D_2O, 500MHz) has δ at -0.15 (s), the ^{13}C NMR (D_2O, 125MHz) has δ at 1.40 to -1.14 (br s), ^{19}F NMR (D_2O, 470MHz) has δ at -132.3 (q, *J* = 64Hz), and ^{11}B NMR (D_2O, 64MHz) has δ at 7.25 (q, *J* = 64Hz). and has the correct elemental analysis for C and H. It has been used for inserting a methyl group in the position of a halogen or triflate group of various arenes. [Molander et al. *J Org Chem* **68** 5534

2003, DOI: 10.1021/jo0343331.]

Potassium nonafluorobutane sulfonate *[29420-49-3]* **$C_4H_9KO_3S$, M 338.2, m >300°.** Wash it with H_2O and dry it *in vacuo*. When the K salt is distilled with 100% H_2SO_4, it gives the ***free acid*** which can be re-distilled (**b 105°/22mm, 210-212°/760mm**) and then converted to the pure K salt. [Gramstad & Haszeldine *J Chem Soc* 2640 *1957*, DOI: 10.1039/JR9570002640; *Beilstein* **2** IV 818.] **IRRITANT.**

Potassium phenol-4-sulfonate (4-hydroxybenzene-1-sulfonic acid K salt) *[30145-40-5]* **$C_6H_5KO_4S$, M 212.3, m >300°.** Crystallise it several times from distilled water at 90°, after treatment with charcoal, and cooling to *ca* 10°. Dry it at 90-100°, *in vacuo*. [*Beilstein* **11** H 55, **11** I 242, **11** II 137, **11** III 498, **11** IV 582.]

Potassium phenyltrifluoroborate *[11042-64-1, 153766-81-5]* **$C_6H_5BF_3K$, M 184.0,** has **m 290°, 296°(dec), 296-301°.** The salt is obtained by adding excess of saturated aqueous KHF_2 (125ml, *ca* 4.5M solution, 563mmol) dropwise to a solution of ***phenylboronic acid*** (20g, 169mmol, *[98-80-6]*) in MeOH (50ml) with vigorous stirring. The precipitate is collected after 15 minutes, washed with cold MeOH and recrystallised from the minimum volume of MeCN and dried *in vacuo* to give ***Ph-BF_3^- K^+*** (25.5g, 82%), m 296°(dec.). Its ^{1}H NMR (CD_3CN, 200MHz) has δ at 7.44-7.41 (m, 2H), 7.22-7.05 (m, 3H); the ^{19}F NMR (CD_3CN, vs $CF_3C_6H_5$, 470MHz) has δ at -79 (1:1:1:1 q, J = 57Hz); and the ^{11}B NMR (CD_3CN, 160MHz) has δ: 4.1 (q, J = 57Hz), and it has the correct elemental analysis for C and H. [Vedejs et al. *J Org Chem* **60** 3020 *1995*, DOI: 10.1021/jo00115a016; Thierig & Umland *Naturwissenschaften* **54** 563 *1967*.] It is air stable and has been used successfully in Pd-catalysed **Suzuki-Miyaura cross-coupling** reactions [Vedejs et al. *J Org Chem* **60** 3020 *1995*, DOI: 10.1021/jo00115a016; Molander & Biolatto *J Org Chem* **68** 4302 *2003*, DOI: 10.1021/jo0342368].

Potassium 2-naphthalene-trifluoroborate *[668984-08-5]* **$C_{10}H_7BF_3K$, *M 234.1, m >300°*** can be prepared in the same manner from ***2-naphthaleneboronic acid*** and used successfully in Pd-catalysed **Suzuki-Miyaura cross-coupling** reactions.

Potassium pyridine-3-trifluoroborate *[561328-69-6]* **$C_5H_4BF_3KN$, M 185.0,** has **m 228-232°.** The 3-pyridine salt is prepared under N_2 from ***3-bromopyridine*** (3.46g, 21.9mmol) and ***triisopropyl borate*** (6.1ml, 26.4mmol) in a mixture of dry toluene (40ml) and dry THF (10ml) at -60° to which is added *n*-BuLi (39ml, 1.6M in hexane, 62mmol) dropwise, the mixture is stirred for 2 hours and allowed to warm to room temperature overnight. This mixture containing the ***pyridine-3-boronic lithium salt*** is cooled to 0° and an aqueous solution of KHF_2 (4.5M, 58mmol) is added dropwise and stirred for 4 hours then the mixture is evaporated to dryness. The residue is dissolved in MeOH, filtered, evaporated to dryness and the residual oil gave a solid (90%) under high vacuum. Its ^{1}H NMR (MeOD-d_3, 500MHz) has δ at 8.57 (br s, 1H), 8.26 (br d, J = 4.6Hz, 1H), 7.90 (d, J = 7.3, 1H), 7.23 (dd, J = 5.5, 6.6Hz, 1H); the ^{13}C NMR (DMSO-d_6, 125MHz) has δ: 153.0, 145.7, 138.8, 122.0; the ^{19}F NMR (DMSO-d_6, 470MHz) has δ: -134.9 (s); and the ^{11}B NMR (MeOD-d_3, 64MHz) has δ: 4.0 (br s). It has been used for inserting a *2,6-dimethylphenyl group* into the position of a halogen or triflate group of various arenes and various heterocycles in Pd-catalysed **Suzuki-Miyaura cross-coupling** reactions [Molander & Biolatto *J Org Chem* **68** 4302 *2003*, DOI: 10.1021/jo0342368; Molander et al. *Org Lett* **12** 5783 *2010*, DOI: 10.1021/ol102717x.]

Potassium tetraphenylborate *[3244-41-5]* **$C_{24}H_{20}BK$, M 358.3,** has **m >300°.** Precipitate it from a solution of KCl acidified with dilute HCl, then crystallise it twice from acetone, wash it thoroughly with water and dry it at 110° [For the amperometric titration-method for determination of K see Findeis & de Vries *Anal Chem* **28** 1899 *1956*, DOI: 10.1021/ac60120a026]. It has also been recrystallised from conductivity water. [*Beilstein* **16** IV 1625.]

Potassium 3-thiophenyltrifluoroborate *[192863-37-9]* **$C_4H_3BF_3KS$, M 190.0,** has **m >260°(dec).** This salt, which was used successfully in Pd-catalysed **Suzuki-Miyaura cross-coupling** is air stable, more robust and easier to handle than 3-thienylboronic acid. ***3-Thiophenylboronic acid*** (4.97g, 26.2mmol) and KHF_2 (5.14g, 65.8mmol) in a Nalgene (polyethylene) bottle (100ml) are stirred vigorously with MeOH (7.5ml) and H_2O (14ml) for 2 hours, and the amber solid formed is set aside at 4° for 2 hours. The solid was collected washed with the minimum of cold MeOH and dissolved in hot Me_2CO filtered, and the filtrate was cooled to 25° and Et_2O was added in portions with stirring, until the supernatant showed no cloudiness. The mixture was set aside at 4° for 1 hour until crystallisation was complete. The crystals were collected washed with a little cold Et_2O and dried *in vacuo* to give ***C_4H_3S-BF_3^- K^+*** (4.68g, 94%). Its ^{1}H NMR [$(CD_3)_3CO$, 500MHz] has δ at 7.20 (s, 1H), 7.14 (m, 2H); the ^{13}C NMR [$(CD_3)_3CO$, 125MHz] has δ at 131.8, 125.2, 122.3; the ^{19}F NMR [$(CD_3)_3CO$, 470MHz] has δ at -139.5 (d, J = 75Hz), and it has the correct elemental analysis for C and H. It has been used

for inserting a ***thiophenyl group*** into the position of a halogen or triflate group of various arenes and various heterocycles. [Molander & Biolatto *J Org Chem* **68** 4302 *2003*, DOI: 10.1021/jo0342368;]. ***Potassium 5-methyl-2-thiophenyltrifluoroborate*** *[871231-40-2]* **$C_5H_5BF_3KS$, *M 204.1, m >220°, >250° (dec also reported)*** can be similarly prepared from ***5-methylthiophenyl-2-boronic acid*** and used in Pd catalysed **Suzuki cross-coupling** reactions.

Potassium trimethylsilanolate **(trimethylsilanol K salt)** *[10519-96-7]* **C_3H_9KOSi, M 128.3,** has **m 131-135° (cubic form), 135-138°, d^{25} 1.11, 125°dec (orthorhombic form).** Recrystallise it from H_2O and dry it at 100°/1-2mm. [Hyde et al. *J Am Chem Soc* **75** 5615 *1953*, DOI: 10.1021/ja01118a042; prepn and hydrolysis, IR: Tatlock & Rochow *J Org Chem* **17** 1555 *1952*, DOI: 10.1021/jo50012a001; *Beilstein* **4** IV 3992.]

Propargyl triphenyl phosphonium bromide *[2091-46-5]* **$C_{21}H_{18}BrP$, M 381.4, m 179°.** It recrystallises from 2-propanol as white plates. It also crystallises from EtOH with **m 156-158°**. Its IR has ν_{max} at 1440, 1110cm^{-1} (P-C str). [Elter & Oediger *Justus Liebigs Ann Chem* **682** 62 *1965*, DOI: 10.1002/jlac.19656820106; Schweizer et al. *J Org Chem* **42** 200 *1977*, DOI: 10.1021/jo00422a003; X-ray crystallography: Steiner *Acta Cryst* **C52** 2263 *1996*, DOI: 10.1107/S0108270196004490].

Propenyloxy trimethylsilane *[1833-53-0]* **$C_6H_{14}OSi$, M 130.3, b 93-95°/atm, d_4^{20} 0.786, n_D^{20} 1.395.** Purify it by fractional distillation using a very efficient column at atmospheric pressure. It usually contains 5% of hexamethyl-disiloxane that boils at 99-101°, but is generally non-reactive and need not be removed. [Hauser & Hance *J Am Chem Soc* **74** 5091 *1952*, DOI: 10.1021/ja01140a029.] It has been distilled under N_2 through a 15cm column packed with glass helices. Fraction **b 99-104°** is further purified by gas chromatography through a Carbowax column (Autoprep A 700) at a column temperature of 87°, and has a retention time of ~9.5 minutes. [Krüger & Rochow *J Organomet Chem* **1** 476 *1964*, DOI: 10.1016/S0022-328X(00)94483-8.]

1-Propenyltrimethylsilane (*cis and trans* mixture) *[17680-01-2]* **$C_6H_{14}Si$, M 114.3, b 85-88°, n_D^{20} 1.4121.** Dissolve ~20g in THF (200ml), shake it with H_2O (2x 300 ml), dry (Na_2SO_4) and fractionate. This is a mixture of *cis* and *trans* isomers which can be separated by gas chromatography on an $AgNO_3$ column [for preparation: see Seyferth & Vaughan *J Organomet Chem* **1** 138 *1963*, DOI: 10.1016/S0022-328X(00)87444-6] at 25° with He as carrier gas at 9 psi. The ***cis-isomer*** has n_D^{25} 1.4105, and the ***trans-isomer*** has n_D^{25} 1.4062. [Seyferth et al. *Pure Appl Chem* **13** 159 *1966*, DOI: 10.1351/pac196613010159.]

1-Propyl-3-(*p*-chlorobenzenesulfonyl) urea *[94-20-2]* **$C_{10}H_{13}ClN_2O_3S$, M 260.7, m 126-128°, 127-129°.** Crystallise the urea from aqueous EtOH. It is soluble in $CHCl_3$ and Me_2CO, slightly soluble in Et_2O and $*C_6H_6$. [*Beilstein* **11** IV 119.]

Propylphosphonic acid (1-propanephosphonic acid) *[4672-38-2]* **$C_3H_9O_3P$, M 124.1, m 71°, 73°, 73.8°, pK_1^{25} 2.49, pK_2^{25} 8.18 (H_2O).** The phosphonic acid is purified by recrystallisation from hexane, heptane or $*C_6H_6$ to give long colourless needles, and is dried *in vacuo* over KOH. It is best prepared from di-*n*-butylphosphite (50mmol), which is converted into its sodium salt in dry hexane (150ml, by stirring under reflux until Na has dissolved, ~3-5 hours), treated with an equivalent of *n*-propylbromide and refluxed gently for 5-6 hours. After cooling, the mixture is washed thoroughly with H_2O, the organic layer is dried by distillation under a vacuum, and the residual ***dibutyl n-propylphosphonate*** is refluxed with 50-70ml of concentrated HCl overnight, and distilled from an oil bath to remove, BuCl and BuOH until *ca* 30ml are left, then carefully evaporated *in vacuo* and the residual solid is recrystallised from $*C_6H_6$ and/or hexane to give ***n-propylphosphonic acid*** (~80% yield) **m 72.5-74.5°**. ***Diethyl propanephosphonate*** *[18812-51-6]* **$C_7H_{17}O_3P$, M 180.2** has **b 88-89°/9mm, 94-96°/12mm, d_4^{25} 1.010, n_D^{20} 1.4172**, and its ^{13}C NMR (25MHz, MeCO d_6, TMS) has δ_C at 61.8 (ester ***C***H_3, $^3J_{P,C-3}$ = 5.9 Hz), 61.3 (ester ***C***H_2, $^2J_{P,C-2}$ = 6.2 Hz), 28.2 (P-***C***H_2, $^1J_{P,C-1}$ = 140.4 Hz), 16.7 (-CH_2-***C***H_2-CH_3, $^2J_{P,C-2}$ = 5.2 Hz) and 15.4 (propane ***C***H_3, $^3J_{P,C-3}$ = 16.2 Hz) ppm [Ernst *Org Mag Res* **9** 35 *1977*, DOI: 10.1002/mrc.1270090108]. [Kosolapoff *J Am Chem Soc* **67** 1180 *1945*, DOI: 10.1021/ ja01223a045; *Beilstein* **4** H 596.]

Propylphosphonic anhydride **(2,4,6-tripropyl-1,3,5,2,4,6-trioxatriphosphorinane-2,4,6-trioxide, T3P)** *[68957-94-8]* **$C_9H_{21}O_6P_3$, M 318.2 (cyclic trimer),** has **b 200°/0.3mm 200-350°/0.01-50mm.** This reagent is prepared by heating *n*-propylphosphonic acid with acetic anhydride at 70-100°, and the polymeric phosphonic acid anhydride intermediate gives the trimeric cyclic anhydride on distilling at 200-350°/0.01-50mm. The an-

hydride is immediately made into 50% w/w solutions in DMF, CH_2Cl_2, EtOAc or BuOAc, which are also commercially available. It was originally used as a **peptide coupling reagent**, but has found many applications which require removal of the elements of water from organic molecules. It allows the synthesis of a variety of heterocyclic compounds, acylation reactions which involves C-C coupling; in the presence of DMSO, alcohols can be oxidised to ketones; and with $NH_2OH.HCl$ and Et_3N in MeCN, TBDMSCl is a selective reagent for hydroxyamidation of carboxylic acids. [Ariel & Llanes *Synlett* 1328 *2007*, DOI: 10.1055/s-2007-980339; Wehner et al. PCT Int. Appl. WO 2005014604 *2005*, *Chem Abstr* **142** 198208 *2005*, Wissmann & Kleiner *Angew Chem Int Ed* **19** 133 *1980*, DOI: 10.1002/anie.198001331; Escher & Bünning *Angew Chem Int Ed* **25** 277 *1986*, DOI: 10.1002/anie.19860277.]

1-Pyrenesulfonic acid *[26651-23-0, 654055-00-2 hydrate]* **$C_{16}H_{10}O_3S$. xH_2O, M 202.2, m 125-129° (hydrate), >350°, pK_{Est} <0.** Crystallise the sulfonic acid from EtOH/H_2O. The ***sulfonyl chloride*** has **m 120°(dec**). [Vollmann et al. *Justus Liebigs Ann Chem* **531** 1 32 *1937,* DOI: 10.1002/jlac.19375310102; and Tietze & Bayer *Justus Liebigs Ann Chem* **540** 189 *1939*, DOI: 10.1002/jlac.19395400113; *Beilstein* **11** H 198, **11** III 448.] The pyrene is a fluorogenic group.
1,3,6,8-Pyrenetetrasulfonic acid *[6528-53-6]* **$C_{16}H_{10}O_{12}S_4$, M 522.5,** has **m >400°, pK_{Est} <0.** Crystallise the tetrasulfonic acid from water. The ***tetra-Na salt*** *[59572-10-0]* M 614.5, crystallises also from H_2O. [Tietze & Bayer *Justus Liebigs Ann Chem* **540** 189 *1939*, DOI: 10.1002/jlac.19395400113; *Beilstein* **11** III 486.]

3-(2-Pyridyl)-5,6-diphenyl-1,2,4-triazine-*p,p'*-disulfonic acid, monosodium salt (H_2O) [Ferrozine] *[63451-29-6]* **$C_{20}H_{13}N_4NaO_6S_2$, M 510.5, m >350°(dec).** Purify it by recrystallisation from water or by dissolving it in the minimum volume of water, followed by addition of EtOH to precipitate the pure salt. It is light sensitive, complexes with Fe and used as a spectrophotometric reagent for Fe [Stookey *Anal Chem* **42** 779 *1970*, DOI: 10.1021/ac60289a016],

Pyrocatechol Violet (tetraphenolictriphenylmethanesulfonic acid Na salt) *[115-41-3]* **$C_{19}H_{14}O_7S$, M 386.4, ε 1.4 x 10^4 at 445nm in acetate buffer pH 5.2-5.4, $pK_{Est(1)}$>0 (SO_3H), $pK_{Est(2)}$~ 9.4, $pK_{Est(3)}$~ 13.** It is recrystallised from glacial acetic acid. It is very ***hygroscopic*** and is a colour indicator standard for metal complex titrations: *viz* metal (pH, colour change, medium): Cd (10, blue/red-purple, NH_3-buff); Cu (5-6.3, blue/yellow, AcOH-buff; 6-7, blue/yellow-green, pyridine; 9.3, blue/purple, NH_3-buff); Fe^{2+} (3-6, blue/yellow, AcOH-buff); Ga (3.8, blue/yellow, AcOH-buff), In (5-6, blue/yellow, AcOH-buff); Mg (10, blue/red-purple, NH_3-buff); Mn (9.3, blue/red-purple, NH_3-buff. hydroxylamine); Ni (8-9.3, blue/red-violet, NH_3-buff); Pb (5.5, blue/yellow, urotropin); Th (2.5-3.5, red/yellow, HNO_3-soln); and Zn (10, blue/red-violet, NH_3-buff). [Bishop *Indicators* pp 127-128, Oxford Pergamon Press *1972*, Library of Congress Catalog Card No 78-171464, ISBN: 0080166172, 9780080166179; Ryba et al. *Coll Czech Chem Commun* **21** 349 *1956*, DOI: org/10.1135/cccc19560349; Cífka et al. *Coll Czech Chem Commun* **21** 1418 *1956*, DOI: org/10.1135/cccc19561418; Ryba et al. *Coll Czech Chem Commun* **23** 71 *1958*, DOI: org/10.1135/cccc19580071; Šír and R. Přibil *Coll Czech Chem Commun* **21** 866 *1956*, DOI: org/10.1135/cccc19560866; *Beilstein* **19/3** V 703.]

Pyrogallol Red (tetraphenolic xanthyliumphenylsulfonate) *[32638-88-3]* **$C_{19}H_{12}O_8S$, M 418.4, m >300°(dec), ε 4.3 x 10^4 at 542nm, pH 7.9-8.6, pK_1 2.71, pK_2 6.60, pK_3 10.41, pK_4 12.16 (5% aqueous EtOH).** It is recrystallised from aqueous alkaline solution (Na_2CO_3 or NaOH) by precipitation on acidification. Filter the dye off and dry it in a vacuum. [Suk *Coll Czech Chem Commun* **31** 3127 *1966*, DOI: 10.1135/cccc19663127; *Beilstein* **19** H 407, **19** II 417, **19** III/IV 599, **19/10** V 226.]

Rose Bengal [Acid Red 94, 4,5,6,7-tetrachloro-2'.4',5',7'-tetraiodofluorescein di-Na or di-K salt] *[di-Na salt 632-69-9]* **$C_{20}H_2Cl_4I_4Na_2O_5$, M 1017.6 (di-Na salt)** *[di-K salt 11121-48-5]* **M 1049.8 (di-K salt).** This biological stain can be purified by chromatography on silica TLC using a 35:65 mix of EtOH/acetone as eluent. It is a biological stain for dead (not healthy) cells and mucous strands; and used for staining corneas and assessment of ocular surface damage [Feenstra et al. *Ophthalmology* **99** 605 *1992*, DOI: 10.1016/S0161-6420(92)31947-5; Doughty *Cont Lens Anterior Eye* **36(6)** 272 *2013*, DOI: 10.1016/j.clae.2013.07.008]. [*Beilstein* **19** II 261, **19** III/IV 2926.]

Selenopyronine (3,6-dimethylaminoselenaxanthene HCl) *[85051-91-8]* **$C_{17}H_{19}N_2Se$. HCl, M 366.8, λ_{max} 571nm (ε 81,000).** Purify by recrystallising it as the ***hydrochloride*** from hydrochloric acid. *Alternatively* recyrstallisation from 10% HBF_4 provides the ***borotetrafluoroborate salt*** *[84835-12-1]*. [Fanghaenel et al. *J Phys Chem* **91** 3700 *1987*, DOI: 10.1021/j100297a048]. [*Beilstein* **18** II 434.]

Selenourea *[630-10-4]* **CH_4N_2Se. M 123.0, m 200°(slow heating), 202-205°, 205-207°(dec), 214-215°(dec), Kofler 235°(dec).** Recrystallise it from the least volume of H_2O using Norite (preferably under N_2) to form colourless needles which are dried over P_2O_5. It is air and light sensitive. It slowly turns moderately dark on storage even below 0°. Authors state that the solid can be kept in a refrigerator for extended periods with no apparent change other than moderate darkening. [For reactions with ketones and I_2 see King & Hlavacek *J Am Chem Soc* **73** 1864 *1951*, DOI: 10.1021/ja01148a529; synthesis: Bacher *Recl Trav Chim Pays-Bas* **62** 580 *1943*, DOI: 10.1002/recl.19430620903; synthesis: Hope *Acta Chem Scand* **18** 1800 *1964*, DOI: 10.3891/acta.chem.scand.18-1800]. The ***Se-methyl iodide*** provides yellow crystals from EtOH/Et_2O with **m 187-188°(dec)**. ***Methyl isoselenourea sulfate*** (from 185g of selenourea and Me_2SO_4/N_2) is dissolved in 1L of hot H_2O (4-5 drops of 18*M* H_2SO_4 are added), and the metallic Se which cleaved off in the initial reaction is removed by filtering through a steam jacketed funnel, and the filtrate is cooled, when the ***sulfate*** (194g) crystallises out. A further amount (42g, total yield 85%, **m 205-207°**) can be obtained by reducing the filtrate to 100ml and adding an equal volume of EtOH. MeSeH is **not** liberated on treatment with NaOH, but a yellow oil separates [Dunbar & Painter *J Am Chem Soc* **69** 1833 *1947,* DOI: 10.1021/ja01199a079]. The ***N,N-dimethyl derivative*** crystallises from H_2O or EtOH as colourless needles which slowly turn pink, then grey on standing, and although slightly soluble in *benzene it can be recrystallised from it and has **m 167-170°(dec)** [Zingaro et al. *J Org Chem* **18** 292 *1953*, DOI: 10.1021/jo01131a010; IR: Jensen & Nielsen *Acta Chem Scand* **20** 597 *1966*, DOI: 10.3891/acta.chem.scand.20-0597; *Beilstein* **3** IV 435.]

Silicon tetraacetate *[562-90-3]* **$C_8H_{12}O_8Si$, M 264.3, m 110-111°, 111-115°, b 148°/5-6mm, pK_1^{25} 9.7, pK_2^{25} 11.9 (for H_4SiO_4 free acid).** It can be crystallised from mixtures of CCl_4 and petroleum ether or Et_2O, or from acetic anhydride and then dried in a vacuum desiccator over KOH. Ac_2O adheres to the crystals and is removed first by drying at room temperature, then at 100° for several hours. It is soluble in Me_2CO, is very ***hygroscopic*** and effervesces with H_2O. It decomposes at 160-170°. Store at 0° to 6°. [Schenk in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 701 *1963*, *Beilstein* **2** H 171.]

Silver diethyldithiocarbamate *[1470-61-7]* **$C_5H_{10}AgNS_2$, M 256.1, m 172°, 172-175°, 174°, 176-78°, pK_1^{25} 3.36 (for *N,N*-diethyldithio-carbamate).** Purify it by recrystallisation from pyridine or CO_2. Store it in a desiccator in a cool and dark place. [*Beilstein* **4** III 224, **4** IV 391.]

Silver tosylate *[16836-95-6]* **$C_7H_7AgO_3S$, M 279.1.** The anhydrous salt is obtained by recrystallisation from H_2O. Store it in the dark. [Claesson & Wallin *Chem Ber* **12** 1848 *1879*, DOI: 10.1002/cber.187901202170; *Beilstein* **11** H 97, 99.] Used for converting halides to tosylates [Kornblum et al. *J Am Chem Soc* **81** 4113 *1959*, DOI: 10.1021/ja01524a080; Hoffmann *J Chem Soc* 6748 *1965*, DOI: 10.1039/JR9650006748].
***Silver trifluoromethanesulfonate* (Silver triflate)** *[2923-28-6]* **$CAgF_3O_3S$, M 256.9,** has **m 286°, 356°, 356-357°.** Recrystallise it twice from hot CCl_4 [Alo et al. *JCS Perkin Trans 1* 805 *1986*, DOI: 10.1039/P19860000805]. Store it in the dark. It is a useful halogen abstraction agent. [*Beilstein* **3** IV 34.]

Sodium *n*-alkylsulfates. Recrystallise these salts from EtOH/Me_2CO [Hashimoto & Thomas *J Am Chem Soc* **107** 4655 *1985*, DOI: 10.1021/ja00302a010].

Sodium amylpenicillin *[575-47-3]* **$C_{14}H_{21}N_2NaO_4S$, M 350.4, 336.4, m 188°(dec, anhydrous) $[\alpha]_D^{23}$ +319° (c 1, H_2O).** The *monohydrate* crystallises from moist acetone or moist ethyl acetate. Dry it in a vacuum. [Wintersteiner in 'The Chemistry of Penicillin', Clarke, Johnson and Robinson eds, Princeton University Press, p 470 *1949*.]

Sodium 9,10-anthraquinone-1,5-disulfonate (H_2O) *[853-35-0]* **$C_{14}H_8Na_2O_8S_2$, M 412.3, m >300°.** Separate it from insoluble impurities by continuous extraction with water. Recrystallise it twice from hot water and dry it under vacuum. [*Beilstein* **11** II 195, **11** III 634.]

Sodium 9,10-anthraquinone-1-sulfonate (H_2O) (Golden salt) *[107439-61-2, 128-56-3 (Anhydr)]* **$C_{14}H_7NaO_5S$, M 328.3, 310.3 (Anhydr), m >300°, pK_{Est} ~<0 (SO_3H).** Recrystallise it from hot water (4ml/g) after treatment with active charcoal, or from water by addition of EtOH. Dry it under vacuum over $CaCl_2$, or in an oven at 70°. Store it in the dark. [*Beilstein* **11** II 192, **11** III 626, **11** IV 670.]
Sodium 9,10-anthraquinone-2-sulfonate* (H_2O) (9,10-anthraquinone-2-sulfonic acid [Na salt, H_2O])** *[131-08-8, 152377-35-1 (Free acid)]* **$C_{14}H_7NaO_5S$, M 328.3, $C_{14}H_8O_5S$, M 287.3,** has **m >300°, pK_{Est} ~<0 (SO_3H).** It crystallises from H_2O or MeOH (charcoal). It is useful for the determination of DNA as an *in situ* ***fluorescence photochemical probe [Li et al. *Analyt Chim Acta* **340** 291 *1997*, DOI: 10.1016/S0003-2670(96)00446-1], and in ***time-resolved fluorescence*** studies of excited states in porphyrin-quinonesulfonic acid reversed micelles [Costa and Bookfield *JCS Faraday Trans 2,* **82** 991 *1986*, DOI: 10.1039/F29868200991]. [*Beilstein* **11** IV 671.]

Sodium benzenesulfinate (benzenesulfinic acid Na salt) *[873-55-2]* **$C_6H_5NaO_2S$, M 164.2, m >300°, pK^{25} 2.16 (2.74, for $PhSO_2H$).** Dissolve it in the minimum volume of O_2 free H_2O (prepared by bubbling N_2 through for 2 hours) and adding O_2 free EtOH (prepared as for H_2O), set aside at 4° overnight under N_2, filter, wash with EtOH, then Et_2O and dry *in vacuo*. The Na salt is relatively stable to air oxidation, but is best kept under N_2 in the dark. Also recrystallise it from EtOH and dry it at 120° for 4 hours in a vacuum. [Kornblum & Wade *J Org Chem* **52** 5301 *1987*, DOI: 10.1021/jo00233a001; *Beilstein* **11** H 6, **11** IV 3.] Useful for the preparation of vinyl sulfones by reaction with vicinal dibromides [Guan et al. *Synthesis* 1465 2007, DOI: 10.1055/s-2007-966039], and aryl sulfones by Cu(II) acetate-catalysed cross-coupling with boronic acids [Huang & Batey *Tetrahedron* **63** 7667 *2007*, DOI: 10.1016/j.tet.2007.05.029].
Sodium benzenesulfonate *[515-42-4]* **$C_6H_5NaO_3S$, M 180.2,** has **pK_1^{25} 0.70 (2.55) (for $PhSO_3H_2$).** Crystallise it from EtOH or aqueous 70-100% MeOH, and dry it under a vacuum at 80-100°. [Fieser **1** 1044; *Beilstein* **11** H 28, **11** I 10, **11** II 18, **11** III 33, **11** IV 27.]

Sodium bis(trimethylsilyl)amide (hexamethyl disilazane sodium salt) *[1070-89-9]* **$C_6H_{18}NaSi$, M 183.4, m 165-167°(sintering at 140°), 171-175°, b 170°/2mm.** It can be sublimed at 170°/2mm (bath temperature 220-250°) onto a cold finger, and can be recrystallised from $*C_6H_6$ (its solubility is: 10g in 100ml at 60°). It is soluble in THF, $*C_6H_6$ (see above) toluene, slightly soluble in Et_2O and is decomposed by H_2O. [Wannagat & Niederprüm *Chem Ber* **94** 1540 *1961*, DOI: 10.1002/cber.19610940618.] It is available commercially under N_2 in Sure/Seal bottles in tetrahydrofuran (various concentrations) and at ~0.6M in toluene. [Fieser **1** 1046; *Beilstein* **4** IV 4014.] It is a strong ***deprotonating agent***, of esters and ketones to generate enolates and can be titrated in THF solution using ***4-phenylbenzylidenebenzylamine*** as indicator [Watson, B. T & Lebel, H. 'Sodium bis(trimethylsilyl)amide' in *Encyclopedia of Reagents for Organic Synthesis* (Ed: L. Paquette) *2004*, J. Wiley & Sons, NY, DOI: 10.1002/047084289X.rs071m.pub2].

Sodium 4-bromobenzenesulfonate *[5015-75-8, 79326-93-5 (Free acid monohydrate)]* **$C_6H_4BrNaO_3S$, M 258.7, m >300°.** Crystallise it from MeOH, EtOH or distilled water. The ***free acid monohydrate*** has **m 90-93°** (M 255.1). [*Beilstein* **11** H 570, **11** I 14, **11** II 30, **11** III 97.]
***Sodium cacodylate* ($3H_2O$)** *[124-65-2, 6131-99-3]* **$C_2H_{12}AsNaO_5$, M 214.0,** has **m 60°, 77-80°, pK^{25} 6.25.** Recrystallise it from aqueous EtOH. Solubility in H_2O at 20° is 0.5M. [*Beilstein* **4** H 612, **4** I 576, **4** IV 1818, see cacodylic acid above.]
Sodium 4-chlorobenzenesulfonate *[5138-90-9]* **$C_6H_4ClNaO_3S$, M 214.6,** has **pK_{Est} <0 (for SO_3H).** Crystallise it twice from MeOH and dry it under vacuum. [*Beilstein* **11** IV 107.]
Sodium 3-chloro-5-methylbenzenesulfonate *[5138-92-1]* **$C_7H_6ClNaO_3S$, M 228.7,** has **pK_{Est} <0 (for SO_3H).** Crystallise it twice from MeOH and dry it under vacuum. [*Beilstein* **2** I 22.]
Sodium p-cymenesulfonate *[77060-21-0]* **$C_{10}H_{13}NaO_3S$, M 236.3.** Dissolve the salt in water, filter and evaporate to dryness. Recrystallise it twice from absolute EtOH and dry it at 110°.
Sodium 1-decanesulfonate *[13419-61-9]* **$C_{10}H_{21}NaO_3S$, M 244.33,** has **m >300°.** Recrystallise it from absolute EtOH and dry it over silica gel. [*Beilstein* **4** IV 62.]
Sodium n-decylsulfate *[142-87-0]* **$C_{10}H_{21}NaO_4S$, M 260.3.** Rigorously purify it by continuous Et_2O extraction of a 1% aqueous solution for two weeks. [*Beilstein* **1** IV 1818.] It has ***detergent*** activity, and is **toxic** to aquatic organisms.

Sodium dibenzyldithiocarbamate *[55310-46-8]* **$C_{15}H_{14}NNaS_2$, M 295.4 (anhydr),** has **m 230°(dec), 235°(dec), pK^{20} 3.13 (for monobenzyl-dithiocarbamic acid).** The ***free acid***, when recrystallised twice from dry Et_2O, has **m 80-82°**. The ***Na salt*** is reprecipitated from aqueous EtOH or EtOH by addition of Et_2O or Me_2CO [Linder et al. *Anal Chem* **50** 896 *1978*, DOI: 10.1021/ac50029a019]. The ***NH_4 salt*** has **m 130-133°**, the ***Cu salt*** (yellow crystals) has **m 284-286°**, and the ***Ti salt*** has **m 64-70°**. [*Beilstein* **12** IV 2275.]

Sodium 2,5-dichlorobenzenesulfonate *[5138-93-2]* **$C_6H_3Cl_2NaO_3S$, M 249.0,** has **pK_{Est} <0 (for SO_3H).** Crystallise it from MeOH, and dry it under vacuum. [*Beilstein* **11** III 93.]

Sodium diethyldithiocarbamate **($3H_2O$)** *[20624-25-3, 148-18-5]* **$C_5H_{10}NNaS_2$, M 225.3, 171.3 (anhydr),** has **m 94-96°(anhydrous), 95°, 98°, d 1.1 g/cm^3, pK^{20} 3.65 (diethyldithiocarbamic acid).** Recrystallise it from a small volume of H_2O, or dissolve it in the minimum volume of H_2O, add cold Me_2CO, collect it and dry it in air (cf. the dimethyl analogue *[128-04-1]* below). [*Beilstein* **4** III 224, **4** IV 390.] It **complexes** with *softer* metals [Cotton et al. *Advanced Inorganic Chemistry* (6th ed.), *1999*, Wiley-Interscience NY, ISBN 0-471-19957-5], is a **spin trap** used with Fe(II) to detect NO in brain, liver and kidney [Vanin et al. *Methods Enzymology* **359** 27 *2002*, DOI: 10.1016/s0076-6879(02)59169-2] and has **fungicidal** activity.

Sodium di(ethylhexyl)sulfosuccinate **(Aerosol-OT, sodium docusate)** *[577-11-7]* **$C_{20}H_{37}NaO_7S$, M 444.6,** has **m 173-179°(dec).** Dissolve it in MeOH and the inorganic salts which precipitate are filtered off. Water is added and the solution is extracted several times with hexane. The residue is evaporated to one-fifth its original volume, *benzene is added and azeotropic distillation is continued until no water remains. The solvent is evaporated. The white residual solid is crushed and dried *in vacuo* over P_2O_5 for 48 hours [El Seoud & Fendler *JCS Faraday Trans 1* **71** 452 *1975*, DOI: 10.1039/F19757100452]. [*Beilstein* **4** IV 114.] It solubilises major myelin trans membrane proteolipids, and forms reverse micelles in hydrocarbon solvents [Saitoh et al. *J Chromatogr* A **1042** 185 *2004*, DOI:10.1016/j.chroma.2004.04.010]. Used for making microemulsions for the simultaneous determination of natural and synthetic estrogens [Tripodi et al, *Electrophoresis* **27** 4431 *2006*, DOI: 10.1002/elps.200600280]. It has laxative properties.

Sodium 2,2'-dihydroxy-1-naphthaleneazobenzene-5'-sulfonate See **Solochrome Violet R** *[2092-55-9]* below.

Sodium 2,4-dihydroxyphenylazobenzene-4'-sulfonate **(Resorcinol yellow, Tropaeolin O, Acid Orange 6)** *[547-57-9]* **$C_{12}H_9N_2NaO_5S$, M 316.3.** Recrystallise it from absolute EtOH, and it has high solubility in H_2O giving a yellow-red colour. It has λ_{max} at 490nm and CI (colour index) 14270; and is an indicator in the alkaline range imparting a yellow colour at pH ~11 and a brown-orange colour at pH ~12.6. Plasma is stained by it. [*Beilstein* **16** H 275, **16** IV 410.]

Sodium p-(p-dimethylaminobenzeneazo)-benzenesulfonate *[23398-40-5]* **$C_{14}H_{14}N_3NaO_3S$, M 327.3.** Recrystallise it from water and dry it *in vacuo*. [*Beilstein* **16** H 331, **16** I 317, **16** II 169, **16** III 370, **16** IV 510.]

Sodium 2,4-dimethylbenzenesulfonate *[827-21-4]* **$C_8H_9NaO_3S$, M 208.2.** Crystallise it from MeOH and dry it under vacuum. [*Beilstein* **11** III 339.]

Sodium 2,5-dimethylbenzenesulfonate **(sodium *p*-xylenesulfonate)** *[827-19-0]* **$C_8H_9NaO_3S$, M 208.2.** Dissolve it in distilled water, filter it, then evaporate it to dryness. Recrystallise it twice from absolute EtOH or MeOH and dry it at 110° under vacuum. [*Beilstein* **11** III 93, **11** IV 502.]

Sodium dimethyldithiocarbamate hydrate *[128-04-1 (hydrate), 207233-95-2 (anhydrous)]* **$C_3H_6NNaS_2$, M 143.2 (anhydr), m 106-108°, 120-122°, pK^{25} 3.36 (diethyldithiocarbamic acid).** Crystallise it from a small volume of H_2O, or dissolve it in the minimum volume of H_2O and add cold Me_2CO, collect it and dry it in air. The solubility in Me_2CO is ~12.5g/100ml. The ***dihydrate*** loses H_2O on heating at 115° to give the ***hemi-hydrate*** that decomposes on further heating [Kulka *Can J Chem* **34** 1093 *1956*, DOI: 10.1139/v56-142]. [*Beilstein* **4** IV 233.] Fungicide and bactericide.

Sodium N,N-dimethylsulfanilate *[2244-40-8]* **$C_8H_{10}NNaO_3S$, M 223.2,** has **m >300°.** It crystallises from water. [See *Beilstein* **4** IV 270.]

Sodium 1-dodecanesulfonate *[2386-53-0]* **$C_{12}H_{25}NaO_3S$, M 272.4,** has **m >300°.** Recrystallise it twice from EtOH and dry it in an oven at 105° for 2 hours. It picks up moisture to form the 3.5 *hydrate*. Its ***hydrate*** crystallises in several phases. Forms micelles. [Tartar & Wright *J Am Chem Soc* **61** 539 *1939*, DOI: 10.1021/ja01872a001; Wright & Tartar *J Am Chem Soc* **61** 544 *1939*, DOI: 10.1021/ja01872a002; for preparation see Reed & Tartar *J Am Chem Soc* ***57*** 571 *1935,* DOI: 10.1021/ja01306a055; *Beilstein* **4** III 27, **4** IV 64.]

Sodium 4-dodecylbenzenesulfonate *[25155-30-0]* **$C_{18}H_{29}NaO_3S$, M 348.5.** It crystallises from propan-2-ol or H_2O. [Gray et al. *J Org Chem* **20** 511 *1955*, DOI: 10.1021/jo01122a014; *Beilstein* **11** IV 514.] This anionic **detergent** is a **SKIN IRRITANT**.

Sodium dodecylsulfate (SDS, sodium laurylsulfate) *[151-21-3]* **$C_{12}H_{25}NaO_4S$, M 288.4, m 204-207°.** Purify this ***anionic detergent*** by Soxhlet extraction with petroleum ether for 24 hours, followed by dissolution in acetone/MeOH/H_2O 90:5:5(v/v) and recrystallisation [For reversed micelles see Politi et al. *J Phys Chem* **89** 2345 *1985*, DOI: 10.1021/j100257a040]. It has been purified by two recrystallisations from absolute EtOH, aqueous 95% EtOH, MeOH, isopropanol or a 1:1 mixture of EtOH/isopropanol to remove dodecanol, and dried under vacuum. [Ramesh & Labes *J Am Chem Soc* **109** 3228 *1987*, DOI: 10.1021/ja00245a008]. SDS has also been purified by repeatedly foaming whereby a 0.15% aqueous solution is made to foam and the foam is discarded, then the H_2O is removed *in vacuo* and the residue is diluted to the required concentrations [Cockbain & McMullen *Trans Faraday Soc* **47** 322 *1951*, DOI: 10.1039/TF9514700322], or by liquid-liquid extraction [see Harrold *J Colloid Sci* **15** 280 *1960*, DOI: 10.1016/0095-8522(60)90029-5]. Dry it over silica gel. For DNA work it should be dissolved in excess MeOH passed through an activated charcoal column and evaporated until it crystallises out. It has also been purified by dissolving in hot 95% EtOH (14ml/g), filtering and cooling, then drying in a vacuum desiccator. ***Alternatively***, it is crystallised from H_2O, vacuum dried, washed with anhydrous Et_2O and dried invacuum again. These operations are repeated five times [for micellar effects see Maritato et al. *J Phys Chem* **89** 1341 *1985*, DOI: 10.1021/j100254a007; Lennox and McClelland *J Am Chem Soc* **108** 3771 *1986*, DOI: 10.1021/ja00273a035; Dressik et al. *J Am Chem Soc* **108** 7567 *1986*, DOI: 10.1021/ja00284a021]. [*Beilstein* **1** IV 1847.] It is very useful in electrophoresis (PAGE) and chromatography for denaturing proteins for the determination of their **sub-unit** molecular weights [Weber & Osborne *J Biol Chem* **244** 4406 *1969*, http://www.jbc.org/content/244/16/4406; Shapiro et al. *Biochem Biophys Res Commun* **28** 815 *1967*, DOI: 10.1016/0006-291X(67)90391-9].

Sodium ethylmercurithiosalicylate (Thimerosal) *[54-64-8]* **$C_9H_9HgNaO_2S$, M 404.8, m ~230°.** Recrystallise this antibacterial/antifungal salt from EtOH/Et_2O. It is soluble in H_2O (1g/ml) and EtOH (0.13g/ml). **HIGHLY TOXIC.** [Trikojus *Nature* **158** 472 *1946*, DOI: 10.1038/158472a0; *Beilstein* **10** III 213.]
Sodium ethylsulfate *[546-74-7]* **$C_2H_5NaO_4S$, M 148.1.** Recrystallise it three times from MeOH/Et_2O and dry it in a vacuum. It is also available commercially as a solution in MeOH (1.0g/ml). [*Beilstein* **1** H 326, **1** I 164, **1** III 1317, **1** IV 1325.]

Sodium formaldehyde sulfoxylate dihydrate (sodium hydroxymethylsulfinate, Rongalite) *[149-44-0]* **CH_3NaO_3S, M 118.1(anhydr), m 63-64° (dihydrate).** It crystallises from H_2O (solubility is 0.05g/ml at ~20°) as the ***dihydrate*** and decomposes at higher temperatures. Store it in a closed container in a cool place. It is insoluble in EtOH and Et_2O and is a good reducing agent. [For X-ray structure see Truter *J Chem Soc* 3064 *1955,* DOI: 10.1039/JR9550003064.] ***Note*** that this compound {$HOCH_2SO_2Na$} should **not be confused** with formaldehyde sodium bisulfite adduct {$HOCH_2SO_3Na$} from which it is prepared by reduction with Zn. [*Beilstein* **1** IV 3052.]

Sodium hexadecylsulfate (cetyl sodium sulfate) *[1120-01-0]* **$C_{16}H_{33}NaO_4S$, M 344.5, m 187-192°.** Recrystallise it from absolute EtOH or MeOH and dry it in vacuum [Abu-Hamdiyyah & Rahman *J Phys Chem* 91 1530 198, DOI: 10.1021/j100290a0487]. It is a low risk **irritant** of eyes, skin and respiratory tract, but handle with care.

Sodium 2-hydroxy-4-methoxybenzophenone-5-sulfonate *[6628-37-1]* **$C_{14}H_{11}NaO_6S$, M 330.3.** Crystallise it from MeOH and dry it under vacuum.
Sodium p-hydroxyphenylazobenzene-p'-sulfonate *[2623-36-1]* **$C_{12}H_9N_2NaO_4S$, M 299.2.** Recrystallise it from 95% EtOH. ***Sodium metanilate*** *[1126-34-7]* **$C_6H_6NNaO_3S$, M 195.2,** has **m >300°.** It crystallises from hot water. [*Beilstein* **14** H 688.]
Sodium methanethiolate **[sodium methylmercaptide]** *[5188-07-8]* **CH_3NaS, M 70.1,** has **pK^{25} 10.33 (MeS^-).** Dissolve the salt (10g) in EtOH (10ml) and add Et_2O (100ml). Cool and collect the precipitate, wash it with Et_2O and dry it in a vacuum. It is a white powder that is very soluble in EtOH and H_2O. [Chakraborty *e-EROS (Encyclopaedia of Reagents for Organic Synthesis)* October pp 1-5 *2014*, DOI: 10.1002/ 047084289X.rn01716; Billmann & Jensen *Bull Soc Chim Fr* **3** 2318 *1936*, *Beilstein* **1** III 1212.] C-21 thioethers of 16-prednisolone carboxylates were easily prepared from the corresponding mesylate esters by reaction with sodium thiolates (with 1.5 equivs of RSNa/35°/1h) in 60-75% yields [Khan & Lee *Synth Commun* 409 *2007*, DOI: 10.1080/ 00397910601038954].

Sodium 3-methyl-1-butanesulfonate *[5343-41-9]* **$C_5H_{11}NaO_3S$, M 174.2.** It crystallises from 90% MeOH.
Sodium 1-naphthalenesulfonate *[130-14-3]* **$C_{10}H_7NaO_3S$, M 230.2.** Recrystallise it from water or aqueous acetone [Okadata et al. *J Am Chem Soc* **108** 2863 *1986*]. [*Beilstein* **11** IV 521.]
Sodium 2-naphthalenesulfonate *[532-02-5]* **$C_{10}H_7NaO_3S$, M 230.2.** It crystallises from hot 10% aqueous NaOH or water and is dried in a steam oven. [*Beilstein* **11** IV 521.]
Sodium 2-naphthylamine-5,7-disulfonate **(Amido-G-acid)** *[79004-97-0]* **$C_{10}H_7NNa_2O_6S_2$. $6H_2O$, M 455.4.** Crystallise it from water (charcoal, solubility at 20° is 72g/100ml) and dry it in a steam oven. Keep away from light. [*Beilstein* **14** H 784, **14** II 473, **14** IV 2811.]
Sodium 1-octanesulfonate H_2O *[5324-84-5]* **$C_8H_{17}NNaO_3S$, M 216.3.** Recrystallise it from absolute EtOH. [*Beilstein* **4** IV 58.] Used as an **ion-pairing reagent** for HPLC of peptides and proteins.
Sodium phenol-4-sulfonate **($2H_2O$) (4-hydroxybenzenesulfonic acid Na salt)** *[825-90-1, 10580-19-2 H_2O]* **$C_6H_5NaO_4S$, M 232.2,** has **m 300°.** It crystallises from hot water (1g/1ml) by cooling to 0°, or from MeOH, *and is dried in vacuum. [Beilstein **11** II 134.]*
Sodium piperazine-N,N'-bis(2-ethanesulfonate) **H_2O (PIPES-Na salt)** *[76836-02-7]* **$C_8H_{16}N_2Na_2O_6S_2$, M 364.3.** It crystallises from water and EtOH. [*Beilstein* **23/2** V 380.] Useful in buffers.
Sodium isopropyl xanthate **(sodium *O-iso*propyldithiocarbonate)** *[140-93-2]* **$C_4H_7NaOS_2$, M 158.1, pK^{25} 2.16 (for $-S^-$).** It crystallises from ligroin/ethanol.
Sodium sulfanilate **(sodium *p*-aminobenzenesulfonic acid)** *[515-74-2]* **$C_6H_6NNaO_3S$, M 195.2.** It crystallises from water. [*Beilstein* **14** IV 2655.]

Sodium taurocholate [2-(3α,7α,12α-trihydroxy-24-oxo-5-β-cholan-24-ylamino)ethanesulfonic acid sodium salt monohydrate] *[145-42-6; 312693-83-7; 345909-26-4 (x H_2O)]* **$C_{26}H_{44}NNaO_7S$, M 555.7 (monohydrate), m 168°dec (hydrate), $[\alpha]_D^{20}$ +23.9 (c 2.5, H_2O), pK of acid is 1.4.** The non-sulfated bile salt has been synthesised from ***ethyl cholate*** (**m 162-163°**, crystallised from EtOAc/petroleum ether b 30-60° 2:8) *via* the ***hydrazide*** (**m 210°**, sintering at 202°), which was diazotised to the ***azide*** ($NaNO_2$/HCl at 0-2°) and condensed with taurine in aqueous N NaOH at 8-14°/45 minutes. The acidified product was converted to ***Na taurocholate*** which was prepared and purified by precipitation with saturated aqueous NaCl and Et_2O (84% recovery; note that crystallisation does not occur unless enough H_2O is present) [Cortese *J Am Chem Soc* **59** 2532 *1937*, DOI: 10.1021/ja01291a014]. It was also purified by recrystallisation from aqueous EtOH/Et_2O, or by gel chromatography using Sephadex LH-20. It is a useful **anionic detergent** for solubilising proteins and bilirubin [Woslewitz & Schroebler *Experientia* **35** 717 *1979*, PMID: 38133]. It has a CMC of 3-11 mM at 20-25°, with an average micellar weight of 2100. It is hydrolysed by mineral acids to cholic acid and taurine. [Tanaka *Z physiol Chem* **220** 39 *1933*, *Beilstein* **10** III 1655, **10** IV 2078.]

Sodium tetradecylsulfate (sodium meristyl sulfate) *[1191-50-0]* **$C_{14}H_{30}NaO_4S$, M 316.4.** It recrystallises from absolute EtOH [Abu Hamdiyyah & Rahman *J Phys Chem* **91** 1531 *1987*, DOI: 10.1021/j100290a048]. It is ***hygroscopic***. [*Beilstein* **1** H 716, **1** IV 1866.] Used as a cosmetic ingredient.

Sodium tetrakis-(4-fluorophenyl)borate hydrate (Cesibor) *[207683-22-5]* **$C_{24}H_{20}BF_4NaO_2$, M 450.2.** This gravimetric reagent for Cs is purified by passing a solution (10g in 100ml H_2O) through a column of Dowex 50Wx4 (Na form) and eluting with dilute NaCl. Extract the 250-275ml eluate with Et_2O (3 x 50ml), add dry xylene (200ml), evaporate the Et_2O off *in vacuo*, immerse the xylene in a bath at 50° and the salt crystallises out. It is *hygroscopic*. [Moore et al. *Anal Chim Acta* **35** 1 *1966*, DOI: 10.1016/S0003-2670(01)81620-2 ; Tsubouci et al. *Anal Chem* **57** 783 *1985*, DOI: 10.1021/ac00280a051.]

Sodium tetraphenylborate [tetraphenyl boron Na] *[143-66-8]* **$C_{24}H_{20}BNa$, M 342.2.** Dissolve the ***borate salt*** in dry MeOH and add dry Et_2O. Collect the solid and dry it in a vacuum at 80°/2mm for 4 hours. It can also be extracted (Soxhlet) using $CHCl_3$, and it crystallises from $CHCl_3$ as snow-white needles. It is freely soluble in H_2O, Me_2CO but insoluble in petroleum ether and Et_2O. An aqueous solution has pH ~ 5 and can be stored for days at 25° or lower, and for 5 days at 45° without deterioration. Its solubility in polar solvents increases with decrease in temperature [Wittig & Raff *Justus Liebigs Ann Chem* **573** 195 *1951*, DOI: 10.1002/jlac.19515730118]. The ***salt*** can also be recrystallised from acetone/hexane or $CHCl_3$, or from Et_2O/cyclohexane (3:2) by warming the solution to precipitate the compound. Dry it in a vacuum at 80°. It dissolves in Me_2CO at 50-60° to give a clear solution. After standing at this temperature for 10 minutes the mix-

ture is filtered rapidly through a pre-heated Büchner funnel, cooled and the crystals are collected and dried in a vacuum desiccator at room temperature for 3 days [Abraham et al. *JCS Faraday Trans 1* **80** 489 *1984*, DOI: 10.1039/F19848000489]. If the product gives a turbid aqueous solution, the turbidity can be removed by treating with freshly prepared alumina gel and filtering. [*Beilstein* **16** IV 1624.]

Sodium thioglycolate (mercaptoacetic acid Na salt) *[367-51-1]* **$C_2H_3NaO_2S$, M 114.1, m >300°.** It crystallises from 60% EtOH (charcoal). It is ***hygroscopic***. In concentrated aqueous solutions (~70%) it forms 1-2% of ***thioglycolides*** at *ca* percent per month which hydrolyse to the monomer on treatment of acid or alkali. Store at -20°. [*Beilstein* **3** IV 600.]

Sodium 4-toluenesulfinate *[824-79-3, 7257-26-3 hydrate]* **$C_7H_7NaO_2S$, M 178.2, m >290°, pK^{25} 2.80 (1.99)(for $-SO_2^-$).** Recrystallise the salt from water (to constant UV spectrum) and dry it under vacuum, or extract it with hot *benzene, then dissolve it in EtOH/H_2O and heat with decolorising charcoal. The solution is filtered and cooled to give crystals of the ***dihydrate***. Store in a cool dry place. [*Beilstein* **11** I 718, **11** IV 9]
Sodium 4-toluenesulfonate *[657-84-1]* **$C_7H_7NaO_3S$, M 194.2,** has **pK^{25} -1.34 (for $-SO_3^-$).** Dissolve it in distilled water, filter it to remove insoluble impurities and evaporate it to dryness. Then recrystallise it from MeOH or EtOH, and dry it at 110°. Its solubility in EtOH is not high (maximum 2.5%), so that Soxhlet extraction with EtOH may be preferable. ***Sodium p-toluenesulfonate*** has also been crystallised from Et_2O and dried under a vacuum at 50°. [*Beilstein* **11** I 4, **11** II 6, **11** IV 241, cf. Gibson et al. *J Chem Soc* 874 *1923*, DOI: 10.1039/CT9232300874.]

Sodium 2,2',4-trihydroxyazobenzene-5'-sulfonate *[3564-26-9]* **$C_{12}H_9N_2NaO_6S$, M 300.3, pK_1 0.10, pK_2 6.14, pK_3 7.72, pK_4 > 13.** Purify the dye by precipitating the ***free acid*** from aqueous solution using concentrated HCl, then wash it and extract it with EtOH in a Soxhlet extractor. Evaporation of the EtOH leaves the purified ***acid*** which is converted to the sodium salt with an equivalent of NaOH or Na_2CO_3. The characteristic constants (four pKa values) and the UV spectra of the various species have been determined and the dye can be used for the determination of Zr [pK's and UV: Fletcher *Analyt Chem* **32** 1822 *1960*, DOI: 10.1021/ac50153a036; complexing with Zr: Fletcher *Analyt Chem* **32** 1827 *1960*, DOI: 10.1021/ac50153a037].
Sodium 2,4,6-trimethylbenzenesulfonate *[6148-75-0]* **$C_9H_{11}NaO_3S$, M 222.1,** has **m >300°.** Crystallise it twice from MeOH and dry it under vacuum. [*Beilstein* **11** III 345.]
Sodium trimethylsilanolate **(sodium trimethylsilanol)** *[18027-10-6]* **C_3H_9NaSi, M 112.2,** has **m 230°(dec).** It is very soluble in Et_2O and *C_6H_6 but moderately soluble in petroleum ether. It is purified by sublimation at 130-150° in a high vacuum. [Hyde et al. *J Am Chem Soc* **75** 5615 *1953*, DOI: 10.1021/ja01118a042; Tatlock & Rochow *J Org Chem* **17** 1555 *1952*, DOI: 10.1021/jo50012a001; *Beilstein* **4** III 1856.]
Sodium 3,5-xylenesulfonate *[30587-85-0]* **$C_8H_9NaO_3S$, M 208.2.** Dissolve it in distilled water, filter, then evaporate it to dryness and recrystallise it twice from absolute EtOH and then dry it at 110°. [*Beilstein* **11** H 126, **11** I 34.]

Solochrome Violet R [4-hydroxy-3-(2-hydroxynaphthyl-1-ylazo)benzenesulfonic acid sodium salt, Java Chrome Violet B] *[2092-55-9]* **$C_{16}H_{11}N_2NaO_5S$, M 366.3, CI 15670, λ_{max} 501nm, pK_2^{25} 7.22 (OH), pK_3^{25} 13.39 (OH).** Convert the ***acid*** to the ***monosodium*** salt by precipitation with NaOAc/AcOH buffer of pH 4, then purify by precipitating the ***free acid*** from aqueous solution with concentrated HCl, wash and extract it with EtOH in a Soxhlet extractor. The acid precipitates on evaporating the EtOH and is reconverted to the sodium salt as described for *Chlorazole Sky Blue FF*. Dry it at 110°. It is ***hygroscopic***. [Coates & Rigg *Trans Faraday Soc* **57** 1088 *1961*, DOI: 10.1039/TF9615701088; *Beilstein* **16** II 127.] It coordinates with metal ions, e.g. Cu^{2+} and Mg^{2+}.

Strontium thiosalicylate ($5H_2O$) *[15123-90-7]* **$C_7H_5O_2SSr$, M 330.7.** It crystallises from hot water (0.5g/ml) by cooling to 0°. [*Beilstein* **10** IV 272.]

Sulfaguanidine (4-aminobenzenesulfonylguanidine) *[57-67-0]* **$C_7H_{10}N_4O_2S$, M 214.2, m 189-190°, b 488.4°/760mm, pK_1 0.48, pK_2 2.75.** Crystallise the antibacterial from hot water (7ml/g). [*Beilstein* **14** III 1970, **14** IV 2668.]

Sulfanilic acid (4-aminobenzenesulfonic acid) *[121-57-3]* **$C_6H_7NO_3S$, M 173.2, m 288°(dec), pK_1^{25} <1, pK_2^{25} 3.23.** Crystallise the acid (as ***dihydrate***) from boiling water. Dry it at 105° for 2-3 hours, then over 90% H_2SO_4 in a vacuum desiccator. The ***S-benzylisothiuronium salt*** has **m 187°** (from aqueous EtOH). [*Beilstein* **14** IV 2655.]

o-**Sulfobenzoic acid (H_2O)** *[123333-68-6 (H_2O), 632-25-7]* **$C_7H_6O_5S$, M 202.2, m 68-69°, 68-72° (hydrate?), 141°, $pK_{Est(1)}$<1, $pK_{Est(2)}$~3.1 (CO_2H).** Crystallise the acid from water. The ***S-benzylisothiuronium salt*** has **m 205.5-206.5°** (from aqueous EtOH). [*Beilstein* **1** II 215, **1** III 658.] The ***mono-ammonium salt*** *[6939-89-5]* **M 219.5**, crystallises from water.

5-Sulfosalicylic acid *[5965-83-3]* **$C_7H_6O_6S$, M 218.2, m 108-110°, 113°, 120°, pK_1^{25} <0, pK_2^{25} 2.67, pK_3^{25} 11.67.** Crystallise the acid from H_2O. *Alternatively*, it is converted to the ***mono-sodium salt*** which is crystallised from H_2O and washed with a little H_2O, EtOH and then Et_2O. The ***acid*** is recovered by acidifying. The ***S-4-chlorobenzylisothiuronium salt*** has **m 181°** (from dioxane). [*Beilstein* **11** H 411, **11** II 232, **11** III 704.] It precipitates proteins in affected urine; also used for integral colour anodising.

Sulfur trioxide pyridine complex *[26412-87-3]* **$C_5H_5NO_3S$, M 159.2, m 155-165°, ~160°, 175°.** Wash the solid with a little CCl_4, then H_2O to remove traces of pyridine sulfate, and dry it over P_2O_5. [Baumgarten *Chem Ber* **59** 1166 *1926*, DOI: 10.1002/cber.19260590615; *Beilstein* **20/5** V 184]. It is useful for the sulfation of alcohols, sulfonations, deoxygenations and other reductions or oxidations involving DMSO [Olah et al. *Synthesis* 59 *1979*, DOI: 10.1055/s-1979-28557; Olah et al. *Synthesis* 984 *1979*, DOI: 10.1055/s-1979-28902; for conversion of α-amino and peptide aldehydes from respective alcohols without racemisation see Hamada & Shiori *Chem Pharm Bull Jpn* **30** 1921 *1982*, DOI: org/10.1248/cpb.30.1921].

Tetrabutylammonium borohydride *[33725-74-5]* **$C_{16}H_{40}BN$, M 257.3, m 123-128°, 128-129°.** Purify it by recrystallisation from EtOAc followed by careful drying under vacuum at 50-60°. Samples purified in this way showed no signs of loss of ***active*** **H** after storage at room temperature for more than 1 year. Nevertheless samples should be stored at *ca* 6° in tightly stoppered bottles if they are to be kept for long periods (~1 year), with little loss of acrivity. It is soluble in CH_2Cl_2 and $CHCl_3$, moderately soluble in $*C_6H_6$, and poorly soluble in Et_2O and H_2O. [Raber & Guida *J Org Chem* **41** 690 *1976*, DOI: 10.1021/jo00866a022; Brändström et al. *Tetrahedron Lett* **13** 3173 *1972*, DOI: 10.1016/S0040-4039(01)93995-4.]
Tetrabutylammonium tetrafluoroborate *[429-42-5]* **$C_{16}H_{36}BF_4N$, M 329.3,** has **m 161.8°, 161-163°, pK^{25} -4.9 (for HBF_4)**. Recrystallise it from H_2O, aqueous EtOH or from EtOAc by cooling in Dry-ice. Also recrystallise it from ethyl acetate/pentane or dry acetonitrile. Dry it at 80° under vacuum. [Detty & Jones *J Am Chem Soc* **109** 5666 *1987*, DOI: 10.1021/ja00253a017; Hartley & Faulkner *J Am Chem Soc* **107** 3436 *1985*, DOI: 10.1021/ja00298a007.] The ***acetate*** has **m 118±2°** (from BuCl), the ***bromide*** has **m 118°** (from EtOAc) and the ***nitrate*** has **m** 120° (from $*C_6H_6$). [Witschonke & Kraus *J Am Chem Soc* **69** 2472 *1947*, DOI: 10.1021/ja01202a067; Wheeler & Sandstedt *J Am Chem Soc* **77** 2024 *1955*, DOI: 10.1021/ja01612a102; *Beilstein* **4** IV 558.]

Tetraethoxysilane (tetraethyl orthosilicate) *[78-10-4]* **$C_8H_{20}O_4Si$, M 208.3, m -77°, b 165-166°/atm, 169°/760mm, d_4^{20} 0.933, n_D^{25} 1.382.** Fractionate it through an 80cm Podbielniak type column with a heated jacket and partial take-off head. It is soluble in EtOH, and is slowly decomposed by H_2O. *It is **flammable**, and irritates the eyes and mucous membranes.* [Sumrell & Ham *J Am Chem Soc* **78** 5573 *1956*, DOI: 10.1021/ja01602a030; Bradley et al. *J Chem Soc* 5020 *1952*, DOI: 10.1039/JR9520005020; *Beilstein* **1** IV 1360.]

Tetraethylammonium hexafluorophosphate *[429-07-2]* **$C_8H_{20}F_6NP$, M 275.2, m >300°, 331°(dec), pK_1^{25} ~ 0.5, pK_2^{25} 5.12 (for fluorophosphoric acid H_2PO_3F).** Dissolve the salt (0.8g) in hot H_2O (3.3ml) and cool to crystallise. Yield of prisms is 0.5g. Its solubility in H_2O is 8.1g/L at 19° [Lange & Müller *Chem Ber* **63** 1058 *1930*, DOI: 10.1002/cber.19300630510]. [*Beilstein* **4** III 199.] Used in electrolytes for electrochemical synthesis [Ruhlmann & Giraudeau *Chem Commun* 2007 *1996*, DOI: 10.1039/CC9960002007; Webster et al. *J*

Phys Chem **100** 10288 *1996*, DOI: 10.1021/jp9601173].

Tetraethylammonium tetrafluoroborate *[429-06-1]* **$C_8H_{20}BF_4N$, M 217.1, m 235°, 356-367°, 275-277°, 289-291°. pK^{25} -4.9 (for HBF_4).** Dissolve the salt in hot MeOH, filter and add Et_2O. It is soluble in ethylene chloride [Thompson & Kraus *J Am Chem Soc* **69** 1016 *1947*, DOI: 10.1021/ja01197a012; Wheeler & Sandstedt *J Am Chem Soc* **77** 2025 *1955*, DOI: 10.1021/ja01612a103]. It has also been recrystallised three times from a mixture of ethyl acetate/hexane (5:1) or MeOH/petroleum ether, then kept at 95° for 48 hours under vacuum [Hartley & Faulkner *J Am Chem Soc* **107** 3436 *1985*, DOI: 10.1021/ja00298a007; Huang et al. *Anal Chem* **58** 2889 *1986*, DOI: 10.1021/ac00126a070]. It is used as a supporting electrolyte. [*Beilstein* **4** IV 333.]

Tetraethylsilane *[631-36-7]* **$C_8H_{20}Si$, M 144.3, m -82.5°, -82°, b 153.8°/760mm, d_4^{30} 0.77, n_D^{30} 1.427.** Fractionate it through a 3ft vacuum-jacketed column packed with 1/4" stainless steel saddles. The material is finally percolated through a 2ft column packed with alumina and maintained in an inert atmosphere. [Staveley et al. *J Chem Soc* 1992 *1954*, DOI: 10.1039/JR9540001992; Altshuller & Rosenblum *J Am Chem Soc* **77** 272 *1955*, DOI: 10.1021/ja01607a007; *Beilstein* **4** H 625, **4** IV 3895.]

1.1.3.3-Tetraisopropyldisiloxane *[18043-71-5]* **$C_{12}H_{30}OSi_2$, M 246.5, b 129-130°/6mm, d_4^{30} 0.89, n_D^{30} 1.47.** Fractionate it under reduced pressure in a N_2 atmosphere. [Gilman & Clark *J Am Chem Soc* **69** 1499 *1947*, DOI: 10.1021/ja01198a071.]

Tetrakis(hydroxymethyl)phosphonium chloride (THPC) *[124-64-1]* **$C_4H_{12}ClO_4P$, M 190.6, m 151°** (available also as an 80% solution in H_2O, d 1.341g/ml at 25° with n_D^{20} 1.512). THPC is prepared in an efficient fume cupboard by placing a mixture of 40% formaldehyde (90ml) and concentrated aqueous HCl (40ml, sp. gr. 1.2) into a 100ml 3-bulb Ladenburg flask (filling about half of the neck of the flask), the latter is provided with a stopper through which is passed a gas delivery tube that reaches the bottom. The flask is inclined to an almost horizontal position, when PH_3 (from a cylinder) is passed to displace the air, and the solution is heated to ~ 80° [***note*** that at lower temperatures the reaction is slower, and at higher temperatures the vapour pressure of the solution decreases gas absorption]. The bulbs of the flask help to hold back the gas which results in a more complete reaction. The complete reaction may take up to many hours. Some H_2 and PH_3 which escape from the side neck of the flask should be vented through the flue of the fume cupboard. The mixture is then evaporated with stirring on a steam bath or *in vacuo* (~ 50° to 60°) until a white granular solid is obtained (50g, ~ 88%). Its purity is good enough for most purposes. However, it can be purified to analytical purity by recrystallising 1g of THPC from 50ml of AcOH. The low melting flat needles obtained which contain AcOH of crystallisation are converted to the pure substance, **m 151°**, by blowing dry air at 100° over the crystals, or by drying them at 100° *in vacuo* to give a constant weight. It can also be recrystallised from absolute EtOH. [For a Kg scale laboratory preparation see Reeves et al. *J Am Chem Soc* **77** 3923 *1955*, DOI: 10.1021/ja01619a074.] It is very ***deliquescent*** and should be kept in the presence of a desiccant. It is readily soluble in MeOH, slightly soluble in $CHCl_3$, but insoluble in Et_2O. It is quite stable, its aqueous solutions can be boiled without decomposition, and it is unaffected by dilute acids. The ^1H NMR (60MHz, D_2O, DSS) has δ for $4CH_2$ at 4.77 (s, J_{PCH} = 1.7Hz and $J_{^{13}CH}$ = ~153Hz), and the ^{31}P NMR (40MHz, D_2O, external 85% H_3PO_4) has δ at -25.8. With the stoichiometric amount of alkali, the ***free tris(hydroxymethyl)phosphine*** (see *[2767-80-8]* above) is obtained as an oil together with formaldehyde. However with excess of alkali on THPC, H_2 evolution occurs with the liberation of HCHO and formation of ***tris(hydroxymethyl)phosphine oxide*** (see *[1067-12-5]* below) **m 54-55°**. The reaction with alkali becomes more complicated when the mixture is heated, and ***bis(hydroxymethyl)phosphinic acid*** is formed. An 80% w/v aqueous solution of THPC with d_4^{20} 1.33 is available commercially. Also a 70-75% aqueous solution of ***bis[tetrakis(hydroxymethyl)phosphonium] sulfate*** *[55566-30-8]* M 406.3 is commercially available. [Hoffman *J Am Chem Soc* **43** 1684 *1921*, DOI: 10.1021/ja01440a035; Hoffman *J Am Chem Soc* **52** 2995 *1930*, DOI: 10.1021/ja01370a065; *Beilstein* **1** IV 3062.]

Tetramethoxysilane (tetramethyl orthosilicate) *[681-84-5]* **$C_4H_{12}O_4Si$, M 152.2, m 4-5°, b 122°/760mm, d_4^{20} 1.023, n_D^{20} 1.3688.** Purification is as for tetraethoxysilane. It has a vapour pressure of 2.5mm at 0°. [Sakurai in *Encyclopedia of Reagents for Organic Synthesis 2001* John Wiley & Sons, NY, DOI: 10.1002/047084289X.rs012; IR: Sternbach & MacDiarmid *J Am Chem Soc* **81** 5109 *1959*, DOI: 10.1021/ja01528a023; *Beilstein* **1** IV 1266.]

Tetramethylammonium borohydride (TMAB) *[16883-45-7]* **$C_4H_{16}BN$, M 89.0.** Recrystallisation of the borohydride from H_2O three times yields *ca* 94% pure compound. Dry in high vacuum at 100° for 3 hours. The solubility in H_2O is 48% (20°), 61% (40°), in EtOH it is 0.5% (25°), and in MeCN it is 0.4% (25°). It decomposes slowly in a vacuum at 150°, but rapidly at 250°. The rate of hydrolysis of $Me_4N.BH_4$ (5.8M) in H_2O at 40° is constant over a period of 100 hours at 0.04% of original wt/hour. The rate decreases to 0.02%/hour in the presence of Me_4NOH (5% of the wt of $Me_4N.BH_4$). [Banus et al. *J Am Chem Soc* **74** 2346 *1952*, DOI: 10.1021/ja01129a048; *Beilstein* **4** IV 148.]

Tetramethylammonium hexafluorophosphate *[558-32-7]* **$C_4H_{12}F_6NP$, M 219.1,** has **m >300°, d_4^{25} 1.617, pK_1^{25} ~ 0.5, pK_2^{25} 5.12 (for fluorophosphoric acid H_2PO_3F).** The salt (0.63g) is recrystallised from boiling H_2O (76ml), yielding pure (0.45) $Me_4N.PF_6$ after drying at 100°. It is a good supporting electrolyte. [Lange & Müller *Chem Ber* **63** 1058 *1930*, DOI: 10.1002/cber.19300630510; *Beilstein* **4** III 110.]

Tetramethylammonium tetrafluoborate *[661-36-9]* **$C_4H_{12}N^+$ BF_4^-, M 161.0,** has **m 414°, 415°, 418°.** It is prepared by the reaction of tetramethylammonium halide or hydroxide with 40% fluoboric acid (or monohydroxy or methoxy fluoboric acids), in aqueous solution. After concentrating the solutions, adding Et_2O and shaking, the white salts are collected and dried under vacuum. It can be purified by dissolving in the minimum volume of H_2O (or MeOH) shaking with Et_2O, collecting the solid and drying in a vacuum until free of OH bands in the IR spectra. Whichever way it is prepared, the tetrafuoborate (not the trifluohydroxyborate) salt is formed as clearly shown by the absence of OH bands near 3000cm^{-1} in the IR spectra. [Moss & Sharp *J Inorg Nucl Chem* **13** 328 *1960*, DOI: 10.1016/0022-1902(60)80315-6; Wheeler et al. *J Am Chem Soc* **76** 6323 *1954*, DOI: 10.1021/ja01653a024; Wheeler & Nuttle *J Am Chem Soc* **76** 6322 *1954*, DOI: 10.1021/ja01653a023; Wheeler & Sandsted *J Am Chem Soc* **77** 2025 *1955*, DOI: 10.1021/ja01612a103.] [*Beilstein* **4** II 559, **4** IV 148.]

Tetramethylammonium triacetoxyborohydride *[109704-53-2]* **$C_{10}H_{22}BNO_6$, M 263.1,** has **m 93-98°, 96.5-98°.** If impure, wash it with freshly distilled Et_2O and dry it overnight in a vacuum to give a free flowing powder. Check ^{1}H NMR, and if still suspect prepare it freshly from Me_4NBH_4 and AcOH in $*C_6H_6$ and store it away from moisture [Banus et al. *J Am Chem Soc* **74** 2346 *1952*, DOI: 10.1021/ja01129a048; Evans & Chapman *Tetrahedron Lett* **27** 5939 *1986*, DOI: 10.1016/S0040-4039(00)85367-8; Iwamoto et al. *Tetrahedron Lett* **44** 7239 *2003*, DOI: 10.1016/ j.tetlet.2003.08.009; Shangguan et al. *Org Lett* **9** 1093 *2007*, DOI: 10.1021/ol063143k]. It is an **IRRITANT** and **MOISTURE SENSITIVE**.

Tetramethylammonium triphenylborofluoride *[437-11-6]* **$C_4H_{12}N^+$ $C_{18}H_{15}BF_4^-$, M 392.2.** Crystallise it from acetone or acetone/ethanol. [Gordon *Annual Review of Physical Chemistry* 1 59 *1950*, DOI: 10.1146/annurev.pc.01.100150.000423.]

2,4,6,8-Tetramethylcyclotetrasiloxane (TMCTS) *[2370-88-9]* **$C_4H_{16}O_4Si_4$, M 240.4, m -69°, b 134°/750mm, 134.5-134.9°/755mm, d_4^{20} 0.99, n_D^{20} 1.3872.** It is purified by repeated redistillation, and fractions with the required ^{1}H NMR data are collected. [Sokolov *J Gen Chem USSR (Engl Transl)* **29** 262 *1959*, Sauer et al. *J Am Chem Soc* **68** 962 *1946*, DOI: 10.1021/ja01210a014]. [*Beilstein* **4** IV 4099.] A useful component of photochemically formed SiO_x monolayers on oxide (TiO_2) semiconductors [Tada & Tanaka *Thin Solid Films* **281** 404 *1996*, DOI: 10.1016/0040-6090(96)08692-0].

1,1,3,3-Tetramethyldisiloxane *[3277-26-7]* **$C_4H_{14}OSi_2$, M 134.3, m -78°, b 70.5-71°/731mm, 71-72°/atm, d_4^{30} 0.75, n_D^{25} 11.367.** Possible impurity is 1,1,5,5-tetramethyl-3-trimethylsiloxytrisiloxane **b** 154-155°/733mm. Fractionate it, collect fractions boiling below 80° and re-fractionate it. Its purity can be analysed by alkaline hydrolysis and measuring the volume of H_2 liberated followed by gravimetric estimation of silica in the hydrolysate. It is unchanged when stored in glass containers in the absence of moisture for 2-3 weeks. Small amounts of H_2 are liberated on long storage. ***Care*** *should be taken when opening a container due to developed pressure*. [Speier et al. *J Am Chem Soc* **79** 974 *1958*, DOI: 10.1021/ja01561a054; Emeléus & Smythe *J Chem Soc* 609 *1958*, DOI: 10.1039/JR9580000609; IR: Kriegsmann *Z Anorg Chem* **299** 78 *1959*, DOI: 10.1002/zaac.19592990110; *Beilstein* **4** IV 3991.]

***N,N,N'N'*-Tetramethylphosphonic diamide (methylphosphonic bis-dimethylamide)** *[2511-17-3]* **$C_5H_{15}N_2OP$, M 150.2, b 60.5°/0.6mm, 138°/32mm, 230-230°/atm, d_4^{30} 1.0157, n_D^{30} 1.4539.** Dissolve it in heptane or ethylbenzene, shake this with 30% aqueous NaOH, stir for 1 hour, separate the organic layer and fractionate. [Kosolapoff & Payne *J Org Chem* **21** 413 *1956*, DOI: 10.1021/jo01110a009.] Its IR (film) has ν_{max} at 1480, 1460, 1300, 1184, 1065 and 988-970cm^{-1} [Harvey & Mayhood *Can J Chem* **33** 1552 *1955*,

DOI: 10.1139/v55-190].

Tetramethylsilane (TMS) *[75-76-3]* **$C_4H_{12}Si$, M 88.2, m -99°, b 26-28°/atm, 26.3°/760mm, d_4^{20} 0.639, n_D^{20} 1.359.** Distil it from concentrated H_2SO_4 (after shaking with it) or $LiAlH_4$, through a 5ft vacuum-jacketed column packed with glass helices into an ice-cooled condenser, then percolate it through silica gel to remove traces of halide. [For preparation on a 250g scale see Whitmore & Sommer *J Am Chem Soc* **68** 481 *1946*, DOI: 10.1021/ja01207a036; *Beilstein* **4** IV 3875.]

2,4,6,8-Tetramethyl tetravinyl cyclotetrasiloxane *[2554-06-5]* **$C_{12}H_{24}O_4Si_4$, M 344.7, m -44°, -43.5°, b 111-112°/10mm, 145-146°/13mm, 224-224.5°/758mm, d_4^{25} 0.997, n_D^{20} 1.434.** A 7ml sample can be distilled in a small Vigreux column at atmospheric pressure without polymerisation or decomposition. It is soluble in cyclohexane. [Kantor et al. *J Am Chem Soc* **77** 1685 *1955*, DOI: 10.1021/ja01611a090; *Beilstein* **4** IV 4184.]

Tetraphenylarsonium (V) chloride hydrate *[507-28-8]* **$C_{24}H_{20}AsCl$, M 418.8(anhydr), m 258-260°, 261-263°.** A neutralised aqueous solution is evaporated to dryness. The residue is extracted into absolute EtOH, evaporated to a small volume and precipitated by addition of absolute Et_2O. It is again dissolved in a small volume of absolute EtOH or ethyl acetate and re-precipitated with Et_2O. *Alternatively*, it is purified by adding concentrated HCl to precipitate the ***chloride dihydrate***. Redissolve in water, neutralise with Na_2CO_3 and evaporate to dryness. The residue is extracted with $CHCl_3$ and finally crystallised from CH_2Cl_2 or EtOH by adding Et_2O. If the aqueous layer is somewhat turbid treat it with Celite and filter it through filter paper. It can be dehydrated before use in a vacuum. The ***tetrafluoroborate*** salt has **m 293-295°** (needles from MeCN), and the ***picrate*** salt has **m 203-204°** (from EtOH). [Blicke & Monroe *J Am Chem Soc* **57** 720 *1935*, DOI: 10.1021/ja01307a038; Duke & Brown *J Am Chem Soc* **76** 1443 *1954*, DOI: 10.1021/ja01634a091; Popov & Humphrey *J Am Chem Soc* **81** 2043 *1959*, DOI: 10.1021/ja01518a003; Singhal & Raj *Synth Inorg Met-org Chem* **23** 1011 *1993*, DOI: 10.1080/15533179308016878; *Beilstein* **16** III 1006, **16** IV 1170.] It is a useful reagent for Cd, Hg, Zn, as well as ClO_4, and IO_4 among other ions. **POISONOUS.**
Tetraphenylarsonium iodide *[7422-32-4]* **$C_{24}H_{20}I$, M 510.2.** It crystallises from MeOH. [Blicke & Monroe *J Am Chem Soc* **57** 720 *1935*, DOI: 10.1021/ja01307a038; Chatt & Mann *J Chem Soc* 1192 *1940*, DOI: 10.1039/JR9400001192.] [For crystal structure see Dean et al. *Acta Cryst Section C* **59** 484 *2006*, DOI: 10.1107/S0108270103022650]. **POISONOUS.**
Tetraphenylarsonium perchlorate *[3084-10-4]* **$C_{24}H_{20}ClO_4$, M 482.8,** has **pK^{25} -2.4 to -3.1 (for $HClO_4$).** It crystallises from MeOH. [Horner & Haufe *Chem Ber* **101** 2903 *1968*, DOI: 10.1002/cber.19681010841.] **POISONOUS and possibly explosive.**

Tetraphenylbiphosphine (Ph_2P-PPh_2) *[1101-41-3]* **$C_{24}H_{20}P_2$, M 370.4, m 120.5° (evacuated tube), 120-122° (sealed tube), b 258-260°/1mm. pK_{Est} > 0.0.** This useful precursor of diphenylphosphine compounds is made by heating a mixture of diphenylphosphine (6.0g, 32.5mmol, 829-85-6) and chlorodiphenylphosphine (7.1g, 32.5mmol, 1709-66-9) in petroleum ether (100ml, b 90-100°, freshly distilled over Na) under N_2 at reflux for 3.5 hours during which time all the HCl has evolved. The white crystalline biphosphine that separates (~80%) on cooling is collected, washed with ligroin, dried *in vacuo* and recrystallised or distilled at high vacuum, preferably in a N_2 atmosphere. It is soluble In $*C_6H_6$, toluene, CCl_4, and pyridine (yellow solution), and slightly soluble in Et_2O, EtOH and ligroin. The determined molecular weight was 391.6, 374.9 (method of Rast). When it is heated for 3 hours at 250-300° under N_2, phosphorus is liberated. The brown residue is boiled for 1 hour with dilute aqueous NaOH and 3% of H_2O_2, filtered, cooled, the solid that is collected gives ***Ph_3PO*** (m 153° and mixed m with authentic Ph_3PO) after crystallisation from petroleum ether (b 90-100°). ***Diphenylphosphonic acid*** [**m 191-192°** and mixed melting point with authentic $Ph_2P(O)OH$] can be isolated from the mother liquors, making a total yield of products almost quantitative. Reaction of a suspension of the biphosphine (3.3g) in CCl_4 under N_2 with Br (1ml) in CCl_4 is decolourised as it becomes clear. The mixture is then distilled and the oily residue is redistilled to give ***bromodiphenylphosphine*** (**b 146.5-148°/2.5mm**) as a colourless oil in almost quantitative yield. Bubbling dry air through a suspension of the biphosphine (3.3g) in dry toluene (30ml) at ~0° for 3 hours causes the mixture to become yellow in colour, and after dilution with toluene (30ml) and boiling for a short period it becomes clear. On cooling, and recrystallising the solid that separates from fresh toluene provides the white ***dioxide $Ph_2P(O)$-$P(O)Ph_2$*** (**m 167°**, evacuated tube, 1.9g, 53%), with a molecular weight of 418.5, 409.8 (measured by the method of Rast; the required value is 402.4). [Kuchen

& Buchwald *Chem Ber* **91** 2871 *1958*, DOI: 10.1002/cber.19580911246; *Beilstein* **16** H 2871.]
Sodium dipenylphosphine (Ph$_2$PNa) is readily prepared by adding Na to a solution of the diphosphine in dry Et_2O or THF (exothermic!), whereby the colour becomes yellow and the orange Na salt separates. It is sensitive to moisture (giving Ph_2PH) and to CO_2 (giving Ph_2PCOOH); and the necessary precautions have to be taken. It is a useful reagent for preparing a variety of Ph_2P-R derivatives and it is best to prepare it freshly when required. [Kuchen & Buchwald *Chem Ber* **92** 227 *1959*, DOI: 10.1002/cber.19590920126.]

Tetraphenylphosphonium chloride *[2001-45-8]* **$C_{24}H_{20}ClP$, M 374.9, m 273-275°.** Crystallise the chloride from acetone and dry at 70° under vacuum. It can also be recrystallised from a mixture of 1:1 or 1:2 dichloromethane/petroleum ether, the solvents having been dried over anhydrous K_2CO_3. The purified salt is dried at room temperature under a vacuum for 3 days, and at 170° for a further 3 days. It also crystallises from isoPrOH/Et_2O or EtOH/Et_2O. ***Extremely hygroscopic.*** [Wittig & Geissler *Justus Liebigs Ann Chem* **580** 44, 50 *1953*, DOI: 10.1002/jlac.19535800107; Willard et al. *J Am Chem Soc* **70** 737 *1948*, DOI: 10.1021/ja01182a088; *Beilstein* **16** III 851, **16** IV 984.] [For crystal structure of the iodide see Dean et al. *Acta Cryst Section C* **59** m484 *2006*, DOI: 10.1107/S0108270103022650].

Tetraphenylsilane *[1048-08-4]* **$C_{24}H_{20}Si$, M 336.4, m 231-233°, 234-235°, 236.5°, 237°, 236-238°, b 228°/3mm, 479.6°/760mm.** It crystallises from *benzene as clear colourless bladed needles. It decomposes at ~360°/~760mm on attempted distillation. [George et al. *J Am Chem Soc* **77** 6647 *1955*, DOI: 10.1021/ja01629a079; Polis *Chem Ber* **98** 1540 *1885*, DOI: 10.1002/cber.188501801334; Drew & Landquist *J Chem Soc* 1480 *1935*, DOI: 10.1039/JR9350001480; *Beilstein* **16** I 525, **16** II 606, **16** III 1199, **16** IV 1372.]

Tetrasodium pyrene-1,3,6,8-tetrasulfonate *[59572-10-0]* **$C_{16}H_6Na_4O_{12}S_4$, M 610.5.** Recrystallise this salt from aqueous acetone [Okahata et al. *J Am Chem Soc* **108** 2863 *1986*, DOI: 10.1021/ja00271a013].

Thexyl dimethyl silyl chloride (TDSCl, dimethyl-[2,3-dimethyl-2-butyl] chlorosilane) *[67373-56-2]* **$C_8H_{19}ClSi$, M 178.8, b 55-56°/10mm, 158-159°/720mm, d_4^{20} 0.970, n_D^{20} 1.428**. Purify this chlorosilane by fractional distillation, and store it in small aliquots in sealed ampoules. It is very sensitive to moisture and is estimated by dissolving an aliquot in excess of 0.1M NaOH and titrating with 0.1M HCl using methyl red as indicator [Szabó et al. *Helv Chim Acta* **67** 2128 *1984*, DOI: 10.1002/hlca.19840670813].

***N*-(Thexyl dimethylsilyl)dimethylamine (*N*-[2,3-dimethyl-2-butyl]dimethylsilyl dimethyl-amine)** *[81484-86-8]* **$C_{10}H_{25}NSi$, M 187.4, b 156-160°/720mm.** Dissolve the amine in hexane, filter, evaporate and distil. It is a colourless oil which is extremely sensitive to moisture. It is best to store small quatities in sealed ampoules after distillation. For estimation of purity, crush an ampoule in excess 0.1N HCl and titrate the excess acid with 0.1M NaOH using methyl red as indicator. [Szabó et al. *Helv Chim Acta* **67** 2128 *1984* DOI: 10.1002/hlca.19840670813.]

Thioacetanilide *[637-53-6]* **C_8H_9NS, M 151.2, m 75-76°, 76-79°, b 225.1°/atm, d 1.159, pK_{Est} ~13.1.** Crystallise thioacetanilide from H_2O and dry it *in vacuo*. [*Beilstein* **12** I 193, **12** II 142, **12** III 464, **12** IV 378.]

Thiobenzanilide *[636-04-4]* **$C_{13}H_{11}NS$, M 213.2, m 101.5-102°, pK_{Est} ~12.6.** Crystallise thiobenzanilide from MeOH at Dry-ice temperature.

Thio-Michler's Ketone (TMK, [4,4'-bis(dimethylamino)thiobenzophenone] *[1226-46-6]* **$C_{17}H_{20}N_2S$, M 284.4, m 102-106°, λ_{max} 457 nm (ε 2.92 x 10^4 in 30% aqueous *n*-propanol).** Purify the thioketone by recrystallisation from hot EtOH or by trituration with a small volume of $CHCl_3$, followed by filtration and washing with hot EtOH [Tarbell & Wystrach *J Phys Chem* **68** 2110 *1946*, DOI: 10.1021/ja01214a514]. It also recrystallises from $CHCl_3$/ MeOH. [*Beilstein* **14** H 101, **14** I 395, **14** II 60.]

1-Thionaphthol *[529-36-2]* **$C_{10}H_8S$, M 160.2, b 106°/1.5mm, 208.5°/200mm, d_4^{20} 1.161, n_D^{20} 1.6802, pK^{25} 6.34.** It is steam volatile and is purified by distillation in the absence of O_2, as it oxidises to the disulfide. It is soluble in Et_2O and EtOH but very slightly soluble in H_2O and dilute alkalis. The ***S-ethyl derivative***,

[17539-31-0] **M** 188.2, has **b 175-176°/25mm**, and **d° 1.120**. [*Beilstein* **6** III 2943, **6** IV 4241.] It may cause eye, skin, respiratory and digestive tract irritation.
2-Thionaphthol *[91-60-1]* has **m 79-81°, 81.8-82.4°, 82°, b 153.5°/15mm, 286°/760mm, pK^{25} 6.47.** It is steam volatile. It has to be distilled under argon or N_2, as it oxidises to the disulfide, and crystallises from EtOH. It is very soluble in Et_2O and petroleum ether, but slightly soluble in H_2O. The ***S-methyl derivative*** has **m 104-105°** (from *C_6H_6/petroleum ether), and the ***S-ethyl derivative*** *[32551-87-4]* **M** 188.2, has **m 16° and b 175-170.5°/15mm**. The ***S-acetate*** *[831-23-2]* has **m 53.5°** and **b 191°/15mm**, and the ***diethylamine salt*** forms yellow needles **m 107°** from dioxane. [*Beilstein* **6** H 657, **6** I 316, **6** II 610, **6** III 3006, **6** IV 4312.]

Thiophenol (benzenethiol) *[108-98-5]* **C_6H_6S, M 110.2, m -14.9°, -15°, b 46.4°/10mm, 168.0°/760mm, d_4^{20} 1.073, n_D^{20} 1.5897, pK^{25} 6.62.** Dry thiophenol with $CaCl_2$ or $CaSO_4$, and distil it at 10mm pressure or at 100mm (**b 103.5°**) in a stream of nitrogen. The ***2,4-dinitrophenyl thioether*** has **m 121°** (from EtOH), and the ***2,4-dinitrophenyl sulfone*** has **m 161°** (from EtOH). [*Beilstein* **6** IV 1463.]

Thiosalicylic (2-mercaptobenzoic) acid *[147-93-3]* **$C_7H_6O_2S$, M 154.2, m 164-165°, 167°, 165-168°, d 1.49, pK_1^{25} 3.54, pK_2^{25} 8.80.** Crystallise the thio acid from hot EtOH (4ml/g), after adding hot distilled water (8ml/g) and boiling with charcoal. The hot solution is filtered, cooled, the solid is collected and dried *in vacuo* (P_2O_5). Crystallise it from AcOH and sublime *in vacuo*. [*Beilstein* **10** IV 272.]

o-Toluenesulfonamide *[88-19-7]* **$C_7H_9NO_2S$, M 171.2,** has **m 155.5°.** Crystallise the amide from hot H_2O (**m** 153°), then from EtOH or Et_2O/petroleum ether. The ***N-o-toluenesulfonylphthalimide*** has **m 182°** (from EtOH). [Evans & Dehn *J Am Chem Soc* **51** 3651 *1929*, DOI: 10.1021/ja01387a027; *Beilstein* **11** H 86, **11** I 23, **11** II 39, **11** III 167, **11** IV 229.]

p*-Toluenesulfonic acid** *[6192-52-5]* **$C_7H_8O_3S$, M 190.2, m 38° (anhydrous), m 105-107° (monohydrate), pK^{25} 1.55.** Purify the acid by precipitation from a saturated solution at 0° by introducing HCl gas. It can also be crystallised from concentrated HCl, then crystallised from dilute HCl (charcoal) to remove benzenesulfonic acid. It has been crystallised from EtOH/water. Dry it in a vacuum desiccator over solid KOH and $CaCl_2$. *p*-Toluenesulfonic acid can be dehydrated by azeotropic distillation with *benzene or by heating at 100° for 4 hours under water-pump vacuum. The ***anhydrous acid can be crystallised from *benzene, $CHCl_3$, ethyl acetate, anhydrous MeOH, or from acetone by adding a large excess of *benzene. It can also be dried under vacuum at 50°. The ***S-benzylisothiuronium salt*** has **m** 182° (from aqueous EtOH). [*Beilstein* **11** IV 241.]
***p*-Toluenesulfonyl chloride (tosyl chloride)** *[98-59-9]* **$C_7H_7ClO_2S$, M 190.7,** has **m 66-69°, 67.5-68.5°, 69°, b 138-139°/9mm, 146°/15mm, 167°/36mm.** Material that has been standing for a long time contains tosic acid and HCl and has **m** *ca* 65-68°. It is purified by dissolving (10g) in the minimum volume of $CHCl_3$ (*ca* 25ml) filtered, and diluting with five volumes (i.e. 125ml) of petroleum ether (b 30-60°) to precipitate impurities. The solution is filtered, clarified with charcoal and concentrated to 40ml by evaporation. Further evaporation to a very small volume gives 7g of white crystals which are analytically pure, **m** 67.5-68.5°. (The insoluble material is largely tosic acid and has **m** 101-104°.) [Pelletier *Chemistry and Industry* 1034 *1953*.] It also crystallises from toluene/petroleum ether in the cold, from petroleum ether (b 40-60°) or *benzene. Its solution in diethyl ether has been washed with aqueous 10% NaOH until colourless, then dried (Na_2SO_4) and crystallised by cooling in powdered Dry-ice. It has also been purified by dissolving in *benzene, washing with aqueous 5% NaOH, then dried with K_2CO_3 or $MgSO_4$, and distilled under reduced pressure and can be sublimed at high vacuum [Ebel *Chem Ber* **60** 2079 *1927*, DOI: 10.1002/cber.19270600909]. [*Beilstein* **11** IV 375.] It is best prepared by the chlorosulfonation of toluene [Linder & Rodefeld *Ullmann's Encyclopedia of Industrial Chemistry*, Wiley-VCH, DOI: 10.1002/14356007.a03_507; for reactions see Whittaker et al. e-EROS *(Encyclopedia of Reagents for Organic Synthesis)* 15 September *2006*, DOI: 10.1002/047084289X.rt136.pub2].
***p*-Toluenesulfonamide** *[70-55-3]* has **m 137-137.5°, 138°.** Crystallise the amide from hot water, then from EtOH or Et_2O/petroleum ether. [*Beilstein* **11** H 104, **11** IV 376.]
***p*-Toluenesulfonic acid hydrazide (tosylhydrazide)** *[1576-35-8]* **$C_7H_{10}N_2O_2S$, M 186.2, m 108-110°, 109-110°.** Dissolve the hydrazide in hot MeOH (~1g/4ml), filter through Celite and precipitate the material by adding 2-2.5 volumes of distilled H_2O. Dry it in air or in a vacuum. It solubility in H_2O is 5g/L at 15°. [Friedman et al. *Org Synth* Coll Vol **5** 1055 *1973*, DOI: 10.15227/orgsyn.040.0093; *Beilstein* **11** II 66.]

p-**Toluenethiol (*p*-thiocresol)** *[106-45-6]* **C_7H_8S, M 124.2, m 43.5-44°, pK^{25} 6.82.** Crystallise the thiol from petroleum ether (b 40-70°). The ***2,4-dinitrophenyl thioether*** has **m 103°** (from EtOH), and the ***2,4-dinitrophenyl sulfone*** has **m 190°** (from EtOH). [*Beilstein* **6** IV 2153.]

p*-Toluenethiosulfonic acid potassium salt (potassium *p*-toluenethiosulfonate)** *[28519-50-8]* **$C_7H_7KO_2S_2$, M 226.4, m 227-229°.** When a solution of KOH (64,9g, 86.5%, 1.0 mole) in H_2O (28ml) is cooled in an ice bath while it is saturated with H_2S (in an efficient **fume cupboard**) and excess of H_2S is flushed out with N_2 (important to remove excess of H_2S), a fresh solution of **KHS** is obtained. This is diluted with H_2O (117ml) and stirred, under N_2 at 55-60°, while ground *p*-toluenesulfonyl chloride (95.3g, 0.5mole, freed from any acid by dissolving in $*C_6H_6$, washing with 5% aqueous NaOH, drying with Na_2SO_4, evaporating and distilling at 146°/15mm) at such a rate as not to allow the temperature to rise above 60°. The deep yellow colour of the solution disappears after 90g is added and the chloride ceases to dissolve. The mixture is filtered rapidly with suction through a warmed funnel, and the filtrate is set aside at 0-5° for many hours. The solid is filtered off, dissolved in hot 80% EtOH (200ml), filtered to remove traces of S, cooled for many hours at 0-5°, and the white crystals of ***potassium p-toluenethiosulfonate (48-55g, 42-49%) are collected and air dried. [Woodward et al. *Org Synth* Coll Vol **6** 1016 *1988*, DOI: 10.15227/orgsyn.054.0033; *Beilstein* **11** IV 482.]

2-*p*-Toluidinylnaphthalene-6-sulfonic acid (2,6-TNS) *[7724-15-4]* **$C_7H_{15}NO_3S$, M 313.9, decomp on heating, $pK_{Est} \sim 0$.** Crystallise the acid twice from 2% aqueous KOH and dry it under high vacuum for 4 hours at room temperature. It also crystallises from H_2O. It is tested for purity by TLC on silica gel with isopropanol as solvent. The free acid is obtained by acidifying a saturated aqueous solution. The ***sodium salt*** *[53313-85-2]* **$C_7H_{14}NNaO_3S$**, M 335.4, crystallises from H_2O and decomposes on heating. [*Beilstein* **14** H 762.]

p-**Tolyl disulfide** *[103-19-5]* **$C_{14}H_{14}S_2$, M 246.4, m 43-46°, 45°, 45-46°, 47.5°, 168°/45mm.** Purify it by chromatography on alumina using hexane as eluent, then crystallise it from MeOH, and/or distil it in a vacuum. [Kice & Bowers *J Am Chem Soc* **84** 2384 *1962*, DOI: 10.1021/ja00871a022; *Beilstein* **6** H 245, **6** I 212, **6** II 400, **6** III 1432, **6** IV 3206.]

p*-Tolylsulfonylmethyl isocyanide (tosylmethyl isocyanide, TOSMIC)** *[36635-61-7]* **$C_9H_9NO_2S$, M 195.2, m 109-113°, 112-115°, 114-115°(dec), 116-117°(dec).** Use an efficient fume cupboard. Purify TOSMIC by dissolving (50g) in CH_2Cl_2 (150ml) and passing it through a column (40x3cm) containing neutral alumina (100g) in CH_2Cl_2 and eluting with CH_2Cl_2. A nearly colourless solution (700ml) is collected, evaporated *in vacuo* and the residue (42-47g) of ***TOSMIC (**m 113-114° dec**) is recrystallised once from MeOH (**m 116-117°dec**). [Hoogenboom et al. *Org Synth* **57** 102 *1977*, DOI: 10.15227/orgsyn.057.0102; van Leusen et al. *Tetrahedron Lett* **13** 2367 *1972*, DOI: 10.1016/S0040-4039(01)85304-1.] It also crystallises from EtOH (charcoal) [Saito & Itano, *JCS Perkin Trans 1* 1 *1986*, DOI: 10.1039/P19860000001].
If the reagent had deteriorated considerably it can be synthesised in two steps. **Firstly**: ***N-(p-tolylsulfonylmethyl)formamide*** is prepared by adding a mixture of aqueous 34-37% formalin (378g, 350ml, ~4.4moles), H_2O (750ml), excess of formamide (680g, 600ml, 15.5moles) and formic acid (244g, 200ml, 5.3moles) to sodium *p*-toluenesulfinate (267g, 1.5moles), and stirring at 90° to form a clear solution; and then heating at 90-95° is continued for 2 hours (prolonged heating diminishes the yield). The mixture is cooled (ice-salt bath) with continuous stirring, and set aside at -20° overnight after seeding. The white solid is collected, washed by stirring with ice-H_2O (3 x 250ml) and drained well. To remove occluded H_2O, the solid is dissolved in CH_2Cl_2, H_2O is removed (separating funnel), the organic layer is dried ($MgSO_4$), filtered, evaporated, and the residue is dried (over P_2O_5 at 70°) *in vacuo*, to give crude product (134-150g, 42-47%, **m 106-110°**) which is used in the following step. Pure ***N-(p-tolylsulfonylmethyl)formamide***, **m 108-110°,** can be obtained by recrystallisation from $*C_6H_6$ or 95% aqueous EtOH.
In the **second step,** with exclusion of moisture, $POCl_3$ (84g, 50ml, 0.55mole) in 1,2-dimethoxyethane (60ml) is added dropwise to a stirred solution of the crude preceding ***formamide*** (107g, 0.50mole) in 1,2-dimethoxyethane (250ml), anhydrous Et_2O (100ml) and Et_3N (255g, 350ml, 2.52moles) cooled to -5° (ice-salt bath), at such a rate as to keep the temperature between -5° and 0° (requires ~1 hour). During the reaction, the formamide dissolves, white Et_3NH^+ salts separate, and at the end of the reaction the suspension turns brown in

colour. If the mixture is not brownish in colour then more $POCl_3$ needs to be added. Finally the mixture is stirred for 30 minutes at 0° and ice-H_2O (1.5L) is added to give a clear brown solution before a fine brown crystalline solid separates. Stir the mixture for 30 minutes at 0°, collect the solid, wash it with cold H_2O (250ml), dissolve the solid in warm *C_6H_6 (400ml at 40-60°), separate the H_2O, dry the organic layer ($MgSO_4$), filter, add charcoal (2g), heat at 60° for 5 minutes, filter, and add petroleum ether (1L, b 40-60°) with swirling. After 30 minutes, the solid is filtered off, dried *in vacuo* to give ***crude TOSMIC*** (74-82g, 76-84%) **m 111-114°** (dec), which can be used for most purposes. Analytically pure product can be obtained by a *third* purification through neutral Al_2O_3 as stated above. It has IR (Nujol) with ν_{max} at 2150 (N=C), 1320 and 1155 (SO_2) cm^{-1}, and the ^1H NMR ($CDCl_3$) has δ at 7.7 (q, 4H, C_6H_4), 4.6 (s, 2H, CH_2) and 2.5 (s, 3H, CH_3). [Hoogenboom et al. *Org Synth* Coll Vol **6** 987 *1988*, DOI: 10.15227/orgsyn.057.0102.] It is a versatile reagent, provides a formaldehyde anion or dianion equivalent, is used for the synthesis of various keto compounds and under reducing conditions amino and methylamino compounds have been prepared from the same intermediates, and it has been used for the preparation of several classes of heterocyclic compounds [van Leusen *Lect Heterocycl Chem* **5** S111 *1980*, see also a supplementary issue of Vol **17** of *J Heterocycl Chem 1980*]. **TOXIC, handle with care.**

Tribenzyl chlorosilane *[18740-59-5]* **$C_{21}H_{21}ClSi$, M 336.9, m 139-142°, 141-142°, b 300-360°/100mm.** It is recrystallised three times from petroleum ether (in slender colourless needles, **m 141°**). It is sparingly soluble in cold petroleum ether but is soluble in Et_2O. It does not fume in moist air but is decomposed by H_2O to give ***tribenzyl silanol*** **m 106°** (from petroleum ether). [Robinson & Kipping *J Chem Soc* **93** 439 *1908*, DOI: 10.1039/CT9089300439; Jenkins & Post *J Org Chem* **15** 556 *1950*, DOI: 10.1021/jo01149a018; *Beilstein* **16** H 906, **16** IV 1498.]

Tribenzyl phosphine *[7650-89-7]* **$C_{21}H_{21}P$, M 304.4, m 96-101°, b 203-210°/0.5mm, pK_{Est}~8.8.** Dissolve it in Et_2O, dry it over Na_2SO_4, evaporate and distil it in an inert atmosphere. The distillate solidifies on cooling and is sublimed at 140°/0.001mm. This has **m 92-95°**(*evacuated capillary). When air is bubbled through an Et_2O solution, it is oxidised to* ***tribenzyl phosphine oxide****, [4538-55-0],* **M 320.4, m 209-212°** (evacuated capillary) (it crystallises from Me_2CO). [Hinton & Mann *J Chem Soc* 2835 *1959*, DOI: 10.1039/JR9590002835; *Beilstein* **16** H 771, **16** IV 961.]

Tri-*n*-butyl borate *[688-74-4]* **$C_{12}H_{27}BO_3$, M 230.2, m -70°, b 110°/11mm, 136°/30mm, 232.4°, d_4^{20} 0.857, n_D^{20} 1.4092.** The chief impurities are *n*-butyl alcohol and boric acid (from hydrolysis). It must be handled in a dry-box and can readily be purified by fractional distillation, under reduced pressure. [O'Brien *Aust J Chem* **10** 91 *1957*, DOI: 10.1071/CH9570091; Gerrard & Lappert *J Chem Soc* 2545, 2547 *1951*, DOI: 10.1039/JR9510002545; *Beilstein* **1** IV 1544.]

Tri-*n*-butyl chlorosilane *[995-45-9]* **$C_{12}H_{27}ClSi$, M 234.9, b 93-94°/4.5mm, 134-139°/16mm, 250-252°/atm, 142-144°/29mm, d_4^{20} 0.88, n_D^{20} 1.447.** Fractionally distil this silane, and store it in small aliquots in sealed ampoules. [Noller & Post *J Am Chem Soc* **74** 1361 *1952*, DOI: 10.1021/ja01125a600; Gilman et al *J Org Chem* **24** 219 *1959*, DOI: 10.1021/jo01084a018; *Beilstein* **4** IV 4072.]

Tri-*n*-butyl phosphate (butyl phosphate) *[126-73-8]* **$C_{12}H_{27}O_4P$, M 266.3, m -80°, b 47°/0.45mm, 98°/0.1mm, 121-124°/3mm, 136-137°/5.5mm, 166-167°/17mm, 177-178°/27mm, 289°/760mm (some dec), d_4^{20} 0.980, n_D^{20} 1.44249.** The main contaminants in commercial samples are organic pyrophosphates, mono- and di- butyl phosphates and butanol. It is purified by washing successively with 0.2M HNO_3 (three times), 0.2M NaOH (three times) and water (three times), then fractionally distilled under vacuum. [Yoshida *J Inorg Nucl Chem* **24** 1257 *1962*, DOI: 10.1016/0022-1902(62)80202-4.] It has also been purified *via* its ***uranyl nitrate addition compound***, obtained by saturating the crude phosphate with uranyl nitrate. This compound is crystallised three times from *n*-hexane by cooling to -40°, and then decomposed by washing with Na_2CO_3 and water. Hexane is removed by steam distillation; the water is then evaporated under reduced pressure, and the residue is distilled under reduced pressure. [Siddall & Dukes *J Am Chem Soc* **81** 790 *1959*, DOI: 10.1021/ja01513a007.] ***Alternatively***, wash it with water, then with 1% NaOH or 5% Na_2CO_3 for several hours, then finally with water. Dry it under reduced pressure and fractionate it carefully under vacuum. It is a stable colourless oil, sparingly soluble in H_2O (1ml dissolves in 165ml of H_2O), but freely miscible in organic

solvents. [Kuivila & Masterton *J Am Chem Soc* **74** 4953 *1952*, DOI: 10.1021/ja01139a512; Cox & Westheimer *J Am Chem Soc* **80** 5441 *1958*, DOI: 10.1021/ja01553a031; ^{31}P NMR: Van Wazer *J Am Chem Soc* **78** 5715 *1956*, DOI: 10.1021/ja01139a512; Fertig et al. *J Chem Soc* 1488 *1957*, DOI: 10.1039/JR9570001488; *Beilstein* **1** IV 1531.]

Tri-*n*-butyl phosphine (TBP) *[998-40-3]* **$C_{12}H_{27}P$, M 202.3, b 109-110°/10mm, 115-116°/12mm, 149.5°/50mm, 240.4-242.2°/atm, d_4^{20} 0.822, n_D^{20} 1.4463, pK_{Est}~7.6.** Fractionally distil TBP under reduced pressure in an inert atmosphere (N_2) through an 8inch gauze-packed column (**b 110-111°/10mm**), and redistil it in a vacuum, then seal it in thin glass ampoules. It is easily oxidised by air to ***tri-n-butylphosphine oxide***, *[814-29-9]*, **m 64-49°**, **b 150°/1.5mm, 293-296°/745mm**. It has a characteristic odour, it is soluble in EtOH, Et_2O, and $*C_6H_6$, but is insoluble in H_2O; and is less easily oxidised by air than the lower molecular weight phosphines. It forms ***complexes***, e.g. with ***CS_2 (1:1)*** **m 65.5°** (from EtOH). [Davies & Jones *J Chem Soc* 33 *1929*, DOI: 10.1039/JR9290000033; Chernick & Skinner *J Chem Soc* 1401 *1956*, DOI: 10.1039/JR9560001401; *Beilstein* **4** IV 3436.] Unlike with Ph_3P, $(MeO)_3P$, $(Me_2N)_3P$ or Me_3P, when $(n\text{-}Bu)_3P$ is complexed with DEAD, best results are achieved in the **Mitsunobu lactonisation** of the final stage in the synthesis of the strained lactone ***(-)-Echinosporin*** (XK-213) [Smith et al. *J Am Chem Soc* **114** 2567 *1992*, DOI: 10.1021/ja00033a033; Rehnberg & Magnusson *J Org Chem* **55** 5467 *1990*, DOI: 10.1021/jo00307a017].

Tri-tert-butylphosphine *[*13716*-12-6]* **$C_{12}H_{27}P$, M 202.3,** has **m ~30-35°**, **62.3°**, **b 103-103°/13mm, d_4^{20} 0.834, pK^{25} 11.4.** It is prepared from *tert*-butylmagnesium chloride and PCl_3 in Et_2O and finally purified by vacuum fractionation and distillation. [Ger Pat, IG Farbenind DRP 730 638 *1939*, DRP *Org Chem* **3** 1144.] A 1.0M solution in toluene is commercially available (**d^{25} 0.861 g/l**). [*Beilstein* **4** III 1771.]
It is used with $Pd_2(dba)_3$ and Bu_3SnF in the Pd-catalysed regiocontrolled α-arylation of trimethylsilyl enol ethers with aryl halides [Iwama & Rawal *Org Lett* **8** 5725 *2006*, DOI: 10.1021/ol062093g], is a useful ligand for Pd-catalysed **Suzuki-type coupling** of arylboronic acids with phenyliodonium ylides of hydroxyquinones [Kazantzi et al. *Synlett* 2597 *2006*, DOI: 10.1055/s-2006-950447], and is a good ligand for $Ni(acac)_2$ in catalysing the **cross-coupling** of aryl- and heteroaryl- halides with aryl Grignard reagents [Böhm et al. *Angew Chem Int Ed* **39** 1602 *2000*, DOI: 10.1002/(SICI)1521-3773(20000502)39:9<1602].
Tri-tert-butylphosphine oxide *[*6866*-70-2]* **$C_{12}H_{27}PO$, M 218.3,** has **m 64-69°, 70°, 77°.** The oxide has been prepared by treating *t*-Bu_3P (1.7g, 85mmol) in Et_2O (20ml) containing a catalytic amount of KI (0.1g) with 30% of H_2O_2 until the colour of iodine disappears. The mixture is diluted with H_2O, basified with aqueous NaOH, the ethereal layer is evaporated, and the ***phosphine oxide*** (1.5g, 81%, **m 77°**) is obtained by sublimation at 50°/0.1mm. It is a crystalline ***hygroscopic*** solid that is soluble in most organic solvents, and is stable to 250°. Its IR (Nujol) has ν_{max} at 1160 (P=O, s) and 815 (P-C, br s) cm^{-1}; the ^{1}H NMR (C_6D_6, TMS) has δ_H at 0.59 (d, $^3J_{P\text{-}H}$ = 12.1Hz, C-Me_3); the ^{13}C NMR (C_6D_6, TMS) has δ_C at 29.08 (s, CH_3), 38.95 (d, $^1J_{P\text{-}C}$ = 51.27, C), and its ^{31}P NMR (C_6D_6, external H_3PO_4) has δ at 60.86. [Schmidbauer & Blaschke *Z Naturforsch* **33B** 1556 *1978*, Rankin et al. *JCS Dalton Trans* 827 *1985*, DOI: 10.1039/DT9850000827.]

Tri-*n*-butyl phosphite *[102-85-2]* **$C_{12}H_{27}PO_3$, M 250.3, b 114-115°/5mm, 122°/12mm, 130°/17mm, 137°/26mm, d_4^{20} 0.926, n_D^{20} 1.4924.** Fractionate the phosphite through an efficient column. It is stable in air but is slowly hydrolysed by H_2O. [Gerrard *J Chem Soc* 1464 *1940*, DOI: 10.1039/JR9400001464; Fertig et al. *J Chem Soc* 1488 *1957*, DOI: 10.1039/JR9570001488; for complexing with peroxymolybdic acids see Fields *J Am Chem Soc* **80** 2358 *1958*, DOI: 10.1039/JR9570001488; DOI: 10.1021/ja01543a004; for preparations and bond refractions see Gillis et al. *J Am Chem Soc* **80** 2999 *1958*, DOI: 10.1021/ja01545a025; *Beilstein* **1** IV 1527.]

B-Trichloroborazine (B-trichloroborazole) *[933-18-6, 26445-82-9]* **$H_3B_3Cl_3N_3$, M 183.8, m 83.9-84.5°(sealed evacuated cappillary), 87°, b 88-92°/21mm, d_4^{25} 1.58.** Purify the borazine by distillation from mineral oil. It sublimes at 70°/1mm. [Brown & Laubengayer *J Am Chem Soc* **77** 3699 *1955*, DOI: 10.1021/ja01619a007; Emeléus & Videla *J Chem Soc* 1306 *1959*, DOI: 10.1039/JR9590001306.] It is extremely sensitive to moisture and reacts with H_2O exothermically to give boric acid and NH_4Cl. Store it in sealed tubes. It is soluble in $*C_6H_6$, cyclohexane, CS_2, $CHCl_3$, CCl_4, and C_6H_5Cl without decomposition; reacts vigorously MeOH or EtOH liberating HCl, but is insoluble in pyridine and $PhNO_2$. [*Beilstein* **4** III 174, **1** IV 305.]

Trichloromethyl trimethylsilane (trimethylsilyl trichloromethane) *[5936-98-1]* **$C_4H_9Cl_3Si$, M 191.6, m 130-132°, b 146-156°/749mm, 159.1 ±35°/760mm.** This silane distils at atmospheric pressure without decomposition and readily sublimes at 70°/10mm. It has one peak in the ^1H NMR spectrum (CD_2Cl_2) with δ at 0.38. [Speier *J Am Chem Soc* **73** 824 *1951*, DOI: 10.1021/ja01146a099; Hergott & Simchen *Synthesis* 626 *1980*, DOI: 10.1055/s-1980-29144; *Beilstein* **4** IV 3892.]

Trichlorosilane ($SiHCl_3$, silicochloroform) *[10025-78-2]* **HCl_3Si, M 135.4, m -126°, b 31.8°/atm, 32-34°/atm, 36.5°/atm, d_4^{25} 1.342, n_D^{20} 1.4020.** This volatile trichlorosilane can be obtained from silane and HCl in the presence of $AlCl_3$, and is purified by fractional distillation at atmospheric pressure in the strict absence of moisture. However, $SiHCl_3$ is best prepared by placing finely powdered silicon (purified by boiling with HCl and dilute HF) ground with *ca* 10% of $CuCl_2$ in a pyrex glass tube (fitted with an adapter and condenser which should extend into the middle of the distilling flask) and heating (carefully at first) in a furnace while a slow stream of absolutely dry HCl gas (from a gas cylinder, or generated from NaCl and concentrated H_2SO_4) is passed over the mixture with a furnace temperature of 300°. The receiver is cooled by an acetone/Dry-ice mixture, and the crude product is distilled from the receiver. HCl comes off first then $SiHCl_3$ distils over at 36.5° in 50% yield. With careful fractionation, the forerun SiH_2Cl_2, can be recovered. At 300°, $AlCl_3$ disproportionates $SiHCl_3$ to SiH_2Cl_2 and $SiCl_4$. [***Note*** that by using an 4:1 mixture of H_2/HCl the yield of ***SiH_2Cl_2***, *[4109-96-0]* **M 101.0, m -122°, b 8.5°/atm, $d^{-122°}$ 1.22**, can be greatly improved; and ***SiH_3Cl***, which has **m -118°, b -30.5°/atm, $d^{-113°}$ 1.15**. ***$SiHCl_3$*** is a water clear, very volatile liquid which fumes in moist air as it is hydrolysed by H_2O, but is remarkably inert towards metals even the alkali metals such as Na. It is a good **reducing agent**, is soluble in most organic solvents, e.g. *C_6H_6, $CHCl_3$, and CS_2, but not in protic solvents in which it may decompose. It is **TOXIC, should not be inhaled**, and should be handled under an efficient fume hood. [Schenk in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 691-692 *1963*, Fritz *Z Anorg Allg Chem* **280** 134 *1955*, DOI: 10.1002/zaac.19552800111.]

Triethoxysilane *[998-30-1]* **$C_6H_{16}O_3Si$, M 164.3, m -170°, b 131.2-131.8°/atm, 131.5°/760mm, 134-135°/atm, d_4^{20} 0.98753, n_D^{20} 1.4377.** Fractionate it using a column packed with glass helices of *ca* 15 theoretical plates in an inert atmosphere. Store it in aliquots in sealed ampoules because it is sensitive to moisture. [Spauschus et al. *J Am Chem Soc* **72** 1377 *1950*, DOI: 10.1021/ja01159a082; MacKenzie et al. *J Am Chem Soc* **72** 2032 *1950*, DOI: 10.1021/ja01161a042; Havill et al. *J Org Chem* **13** 280 *1948*, DOI: 10.1021/jo01160a017.] A useful reagent for attaching groups onto silica surfaces [Corriu et al. 'Triethoxysilane' in *e-EROS Encyclopedia of Reagents for Organic Synthesis* 2001 John Wiley & Sons, NY, DOI: 10.1002/047084289X.rt215.pub3; *Beilstein* **1** IV 1359.]

Triethylborane *[97-94-9]* **$C_6H_{15}B$, M 98.0, m –92.5°, b 94-97°, 94-95°, n_D^{20} 1.378, d_4^{20} 0.678.** This borane distils at **56-57°/220mm**. It can also be purified *via* its ***ammonia addition complex*** which is distilled in a high vacuum, decomposed with dry HCl, and the Et_3B is distilled out. It is commercially available as a 15% solution in hexane or as 1M solution in hexane. [Brown *J Am Chem Soc* **67** 374 *1945*, DOI: 10.1021/ja01219a007; Bamford et al. *J Chem Soc* 468 *1946*, DOI: 10.1039/JR9460000468; Lin *J Organomet Chem* **317** 277 *1986*, DOI: 10.1016/0022-328X(86)80538-1; *Beilstein* **4** III 1957, **4** IV 4359.]

Triethyl borate (boric acid triethyl ester, boron triethoxide) *[150-46-9]* **$C_6H_{15}BO_3$, M 146.0, m –84.5°, –84.8°, b 44.5°/45mm, 118°/760mm, n_D^{20} 1.378, d_4^{20} 0.864.** Dry the ester over sodium, then distil it. Also fractionate it through a gauze packed column. [Charnley et al. *J Chem Soc* 2288 *1952*, DOI: 10.1039/JR9520002288; for tributyl borate see Johnson & Tompkins *Org Synth* Coll Vol **2** 106 *1943*, DOI: 10.15227/orgsyn.013.0016; *Beilstein* **1** III 1339, **1** IV 1365.]

Triethyl phosphate *[78-40-0]* **$C_6H_{15}O_4P$, M 182.2, m –56.4°, b 40-42°/0.25-0.3mm, 98-98.5°/8-10mm, 90°/10mm, 130°/55mm, 204°/680mm, 215-216°/760mm, d_4^{25} 1.608, n_D^{20} 1.4053.** Dry the phosphate by refluxing it with solid BaO and then fractionally distil it under reduced pressure. It is kept over Na and distilled. Store it in the receiver protected from light and moisture. *Alternatively*, it is dried over Na_2SO_4 and distilled under reduced pressure. The middle fraction is stirred for several weeks over anhydrous Na_2SO_4 and again fractionated under reduced pressure until the specific conductance reaches a constant low value of κ^{25} 1.19 x 10^8, κ^{40} 1.68 x 10^8, and κ^{55} 2.89 x 10^8 ohm^{-1} cm^{-1}. It has also been fractionated carefully under reduced press-

ure through a glass helices-packed column. It is soluble in EtOH, Et_2O and H_2O (dec). [Estok & Wendlandt *J Am Chem Soc* **77** 4767 *1955*, DOI: 10.1021/ja01623a021; Hoffmann et al. *J Am Chem Soc* **78** 6413 *1956*, DOI: 10.1021/ja01605a033; (P NMR) Muller et al. *J Am Chem Soc* **78** 3557 *1956*, DOI: 10.1021/ja01596a002; French et al. *J Chem Soc* 3582 *1959*, DOI: 10.1039/JR9590003582; IR: Bellamy & Beecher *J Chem Soc* 475 *1952*, DOI: 10.1039/JR9520000475; McIvor et al. *Can J Chem* **36** 820 *1958*, DOI: 10.1139/v58-121; Kosolapoff *Organophosphorus Compounds*, Wiley p 258 *1950*, *Beilstein* **1** IV 1339.]

Triethylphosphine *[554-70-1]* **$C_6H_{15}P$, M 118.2, b 100°/7mm, 127-128°/744mm, d_4^{15} 0.812, n_D^{18} 1.457, pK^{25} 8.69 (also available as a 1.0M solution in THF). All operations should be carried out in an efficient fume cupboard because it is flammable, toxic and has a foul odour.** This liquid has the odour of hyacinth flowers. Purify the phosphine by fractional distillation at atmospheric pressure in a stream of dry N_2, as it is oxidised by air to the oxide. In 300% excess of CS_2 it forms ***Et_3PCS_2*** **(m 118-120°** crystallising from MeOH) that decomposes in CCl_4 to give ***Et_3PS*** as a white solid **m 94°** when recrystallised from EtOH. [Screttas & Isbell *J Org Chem* **27** 2573 *1962*, DOI: 10.1021/jo01054a064; Henderson & Streuli *J Am Chem Soc* **82** 5791 *1960*, DOI: 10.1021/ja01507a008; pK: Henderson & Streuli *J Am Chem Soc* **82** 5791 *1960*, DOI: 10.1021/ja01507a008; see also trimethylphosphine.] Store it in sealed vials under N_2.
Alternatively, dissolve it in Et_2O and shake it with a solution of AgI and KI to form the insoluble complex**.** Filter off the complex, dry it over P_2O_5 and the Et_3P is regenerated by heating the silver iodide complex in a tube attached to a vacuum system. It has the odour of hyacinths (see above). [Hewitt & Holliday *J Chem Soc* 530 *1953*, DOI: 10.1039/JR9530000530; Screttas & Isbell *J Org Chem* **27** 2573 *1962*, DOI: 10.1021/jo01054a064; Kosolapoff *Organophosphorus Compounds*, Wiley p 31 *1950*, *Beilstein* **4** IV 3431.] ***Triethylphosphine oxide*** *[597-50-2]* **$C_6H_{15}OP$, M 134.2,** has **m 48-50°, 49°, 48-52°, b 84-85°/3mm,** and is readily obtained by oxidation of triethylphosphine.

Triethyl phosphite *[122-52-1]* **$C_6H_{15}O_3P$, M 166.2, b 48-49°/11mm, b 52°/12mm, 57.5°/19mm, 155°/atm, 157.9°/757mm, d_4^{20} 0.9687, n_D^{20} 1.4135.** Treat the ester with Na (to remove water and any dialkyl phosphonate), then decant and distil it under reduced pressure, with protection against moisture; or distil it in a vacuum through an efficient Vigreux column or a column packed with Penn State 0.16 x 0.16inch protruded nickel packing and a variable volume take-off head. [Ford-Moore & Perry *Org Synth* Coll Vol **4** 955 *1963*, DOI: 10.15227/orgsyn.031.0111; Kosolapoff *Organophosphorus Compounds*, Wiley p 203 *1950*, *Beilstein* **1** IV 1333.]

Triethyl phosphonoacetate (triethyl carboxymethyl phosphonate) *[867-13-0]* **$C_8H_{17}O_5P$, M 224.2, b 83-84°/0.5mm, 103°/1.2mm, 143-144°/11mm, 260-262°/atm, d_4^{20} 1.1215, n_D^{20} 1,4310.** Purify the phosphonoacetate by fractional distillation, preferably *in vacuo*. The ^{31}P NMR has a P resonance at 19.5 relative to orthophosphate. [Kosolapoff *J Am Chem Soc* **68** 1103 *1946*, DOI: 10.1021/ja01210a058; Kosolapoff & Powell *J Am Chem Soc* **72** 4198 *1950*, DOI: 10.1021/ja01165a104; Speziale & Freeman *J Org Chem* **23** 1883 *1958*, DOI: 10.1021/jo01106a015; *Beilstein* **4** IV 3613.] It is deprotonated with MeONa to form a ***phosphonate ylide*** which undergoes a **HWE (Homer-Wadsworth-Emmons) reaction** with a carbonyl groups to generate an *E*-alkene with very high regioselectivity [Wadsworth & Emmons *J Am Chem Soc* **83** 1733 *1961,* DOI: 10.1021/ja01468a042; Wadsworth & Emmons *Org Synth* Coll Vol **5** 547 *1973*; DOI: 10.15227/orgsyn.045.0044].
Triethyl phosphonoformate **(ethyl diethoxyphosphinylformate)** *[1474-78-8]* **$C_7H_{15}O_5P$, M 210.2,** has **b 70-72°/0.1mm, 122.5-123°/8mm, 130-131°/10mm, 138.2°/12.5mm, d_4^{20} 1.22, n_D^{20} 1.423**. Dissolve it in Et_2O, shake this with H_2O (to remove any trace of NaCl impurity), dry (Na_2SO_4), evaporate and distil it using an efficient fractionating column. [Nylén *Chem Ber* **57** 1023 *1924*, DOI: 10.1002/cber.19240570625; Reetz et al. *J Am Chem Soc* **77** 3813 *1955*, DOI: 10.1021/ja01619a040; Monson *Advanced Organic Synthesis* Academic Press p 89 *1972*, *Beilstein* **3** II 103.]
Triethyl 2-phosphonopropionate **[ethyl 2-(diethoxyphosphinyl)propionate]** *[3699-66-9]* **$C_9H_{19}O_5P$, M 238.2,** has **b 76-77°/0.2mm, 143-144°/12torr, 137-138.5°/17mm, d_0^{20} 1.096, n_D^{20} 1.432.** Purify the ester by fractional distillation with high reflux ratio, preferably using a spinning band column. [Kosolapoff & Powell *J Am Chem Soc* **72** 4198 *1950*, DOI: 10.1021/ja01165a104; Kresze et al. *Justus Liebigs Ann Chem* **756** 112 *1972*, DOI: 10.1002/jlac.19727560111; *Beilstein* **4** IV 3617.] See HWE reaction above.

Triethylsilane *[617-86-7]* **$C_6H_{15}SiH$, M 116.3, b 105-107°/atm, 107-108°/atm, d_0^{20} 0.734. n_D^{20} 1.414.** Reflux triethylsilane over molecular sieves, then distil it**.** It is passed through neutral alumina before use [Randolph & Wrighton *J Am Chem Soc* **108** 3366 *1986*, DOI: 10.1021/ja00272a035]. Useful reducing agent in stereochemically controlled reduction of 2-chromanols [Li et al. *Org Lett* **8** 4711 *2006*, DOI: 10.1021/ja00272a035]. [Fieser & Fieser's *Reagents for Org Synth* **1** 1218 *1967*, *Beilstein* **4** IV 3895.]

Triethylsilyloxy-1,4-pentadiene (1,4-pentadien-3-yloxy-trimethylsilane) *[62418-65-9]* **$C_{11}H_{22}OSi$, M 198.4, b 72-74°/12mm, 140°/atm, d_4^{20} 0.842, n_D^{20} 1.439**. Dissolve the diene in pentane, wash this with H_2O, dry (Na_2SO_4), evaporate, and distil it under vacuum. R_F values on Kieselgel 60 are 0.15 (pentane) and 0.60 (*C_6H_6). [IR, NMR, MS: Oppolzer et al. *Helv Chim Acta* **64** 2002 *1981*, DOI: 10.1002/hlca.19810640705.]

Tri-*n*-hexylborane *[1188-92-7]* **$C_{18}H_{39}B$, M 266.3, b 127°/1.5mm, b 185-188°/30mm.** Treat the borane with hex-1-ene and 10% anhydrous Et_2O for 6 hours at gentle reflux under N_2, then distil it in a vacuum through an 18inch glass helices-packed column under N_2 taking the fraction **b 130°/2.1mm** to **137°/1.5mm**. The distillate may still contain some ***di-n-hexylborane*** [Brown & Subba Rao *J Am Chem Soc* **81** 6423 *1959*, DOI: 10.1021/ja01533a023; Mirviss *J Am Chem Soc* **83** 3051 *1961*, DOI: 10.1021/ja01475a020]. [*Beilstein* **4** IV 4362.]

Triisoamyl phosphate (TAP) *[919-62-0]* **$C_{15}H_{33}O_4P$, M 308.4, b 143°/3mm.** Purify the ester by repeated crystallisation of its addition compound with ***uranyl nitrate*** from hexane. Decompose the complex, and distil the ester at high vacuum. [Siddall *J Am Chem Soc* **81** 4176 *1959*, DOI: 10.1021/ja01525a015.] [see *tributyl phosphate* and Cherbuliez in *Organo Phosphorus Compounds* (Kosolapoff & Maier eds) Wiley Vol **6** pp 211-577 *1973*.] It is a useful liquid extractant for reactor fuel reprocessing [Syed Hadi & Shulka *J Radioanal Nucl Chem* **258** 563 *2003*, DOI: 10.1023/B:JRNC.0000011753.65662.64].
Triisobutyl phosphate *[126-71-6]* **$C_{12}H_{27}O_4P$, M 266.3,** has **b 119-129°/8-12mm, 192°/760mm, d_4^{20} 0.962, n_D^{20} 1.421.** Purify the phosphate by repeated crystallisation of its addition compound with ***uranyl nitrate*** from hexane. (see *tributyl phosphate*.) [Siddall *J Am Chem Soc* **81** 4176 *1959*, DOI: 10.1021/ja01525a015; see Cherbuliez in *Organo Phosphorus Compounds* (Kosolapoff & Maier eds) Wiley Vol **6** pp 211-577 *1973*.] This phosphate is a strong solvent for liquefying concrete, for textile auxiliaries and paper coating compounds. See preceding liquid extractant.

Triisooctyl thiophosphate *[30108-39-5]* **$C_{24}H_{51}O_3PS$, M 450.7.** Purify the ester by passing its solution in CCl_4 through a column of activated alumina. [See Ailman & Magean in *Organo Phosphorus Compound* (Kosolapoff & Maier eds) Wiley Vol **7** pp 487-465 *1973*, and tri-p-tolyl phosphate below.] Used to extract Ag.

Tri-isopropyl borate [(iso-PrO)$_3$B, boric acid tri-isopropyl ester, Boron iso-propoxide] *[5419-55-6]* **$C_9H_{21}BO_3$, M 188.1, m -59°, b 75°/76mm, 90°/120mm, 139-141°/760mm, d_4^{25} 0.815, n_D^{20} 1.376.** The borate ester is prepared in 85% yield from *iso*-propanol (250ml) and $NaBH_4$ (6.84g) followed by dropwise addition of AcOH (0.18g) over a period of 11 minutes, and then refluxing for 4 hours (fume cupboard and a 'Dry-Ice' condenser as 16.15L of H_2 are released, CARE due to its flammability). Then fractionate the ester through a Widmer column. [Brown et al. *J Am Chem Soc* **78** 3613 *1956*, DOI: 10.1021/ja01596a015.] The ester is a good **reagent for borylation**, e.g. *ortho*-borylating 1-substituted naphthalenes, by reacting with 1-halo- or cyano-naphthalenes (after treatment with LiTMP) to form 2-boryl esters which are later used in Pd-catalysed cross-coupling reactions [Lysén et al. *Synthesis* 3478 *2006*, DOI: 10.1055/s-2006-950239]. [*Beilstein* **1** H 363, **1** II 382, **1** III 1468, **1** IV 1488.]

Triisopropyl phosphite *[116-17-6]* **$C_9H_{21}O_3P$, M 208.2, b 58-59°/7mm, 63-64°/11mm, 197-199°/760mm, d_4^{25} 0.844, n_D^{25} 1.4082.** Distil the phosphite from sodium, under vacuum, through a column packed with glass helices. (This removes any dialkyl phosphonate.) [Ford-Moore & Williams *J Chem Soc* 1465 *1947*, DOI: 10.1039/JR9470001465; Arbuzoff *Chem Ber* **38** 1171 *1905*, DOI: 10.1002/cber.190503801212; see Verkade & Coskren in *Organo Phosphorus Compound* (Kosolapoff & Maier eds) Wiley Vol **2** pp 1-187 *1972*, *Beilstein* **1** IV 1476.]

Trimesitylphosphine *[23897-15-6]* **$C_{27}H_{33}P$, M 388.5, m 185-188°, 205-206°, pK_{Est}~8.0.** It recrystallises from EtOH [Boere et al. *J Am Chem Soc* **109** 7781 *1987*, DOI: 10.1021/ja00259a029]. The ***P-methyl iodide*** has **m 269°** (yellow powder from EtOH or H_2O). [*Beilstein* **16** H 774.]

Trimethallyl phosphate *[14019-81-9]* **$C_{12}H_{21}O_4P$, M 260.3, b 134.5-140°/5mm, n^{25} 1.4454.** Purify it as for triisoamyl phosphate. [Cherbuliez in *Organo Phosphorus Compounds* (Kosolapoff & Maier eds) Wiley Vol **6** pp 211-577 *1973*.]

Trimethoxysilane *[2487-90-3]* **$C_3H_{10}O_3Si$, M 122.2, m -114.8°, 81.1°/760mm, 84°/atm, d_4^{20} 0.957, n_D^{20} 1.359**. Likely impurities are $Si(OMe)_4$ and $H_2Si(OMe)_2$. Efficient fractionation is essential for removing these impurities [IR: Sternbach & MacDiarmid *J Am Chem Soc* **81** 5109 *1959*, DOI: 10.1021/ja01528a023; Helferich & Hausen *Chem Ber* **57** 795 *1924*, DOI: 10.1002/cber.19240570516; *Beilstein* **1** IV 1266.]

Trimethyl borate (methylborate, trimethoxyboron) *[121-43-7]* **$C_3H_9BO_3$, M 103.9, m -34°, b 67-68°/742mm, 68-69°/atm, d_4^{20} 0.928, n_D^{20} 1.3610**. Carefully fractionate the borate through a gauze-packed column. Re-distil and collect it in weighed glass vials and seal them. Keep it away from moisture. It undergoes alkyl exchange with alcohols and forms azeotropes, e.g. with MeOH: the azeotrope consists of 70% $(MeO)_3B$ and 30% MeOH with **b 52-54°/760mm**, d 0.87. [Charnley et al. *J Chem Soc* 2288 *1952*, DOI: 10.1039/JR9520002288; Gerrard & Lappert *Chemistry and Industry* 53 *1952*, Schlesinger et al. *J Am Chem Soc* **75** 213 *1953*, DOI: 10.1021/ja01097a056.] It was also dried with Na and then distilled. [*Beilstein* **1** IV 1269.]

Trimethyl boroxine ($Me_3B_3O_3$) *[823-96-1]* **$C_3H_9B_3O_3$, M 125.5, m -38°, b 80°/742mm, 79.3°/755mm, d_4^{20} 0.902, n_D^{20} 1.362.** Possible impurity is methylboronic acid. If present, then add a few drops of concentrated H_2SO_4 and distil it immediately, then fractionate it through an efficient column. [McCusker et al. *J Am Chem Soc* **79** 5179 *1957*, DOI: 10.1021/ja01576a026; IR: Goubeau & Keller *Z Anorg Allgem Chem* **272** 303 *1953*, DOI: 10.1002/zaac.19532720510; *Beilstein* **4** IV 4378.] Useful in the preparation of CBS (Corey-Bakshi-Shibata) catalysts for asymmetric reductions [Gilmore & Jones *Tetrahedron Asym* **14** 2115 *2003*, DOI: 10.1016/S0957-4166(03)00401-4].

1,3-S,S'-Trimethylene di(*p*-toluenethiosulfonate) [1,3-di(*p*-tosylthio)propane, 1,3-trimethylene di(thiotosylate)] *[3866-79-3]* **$C_{17}H_{20}O_4S_4$, M 416.6, m 64-67°.** This reagent is prepared from potassium thiosulfonate (40g, 0.18 mole, see above [28519-50-8]) and 1,3-dibromopropane (20g, 0.1 mole) which are added to a solution of 95% EtOH (150ml) containing KI (10-20mg, to activate the dibromide), and the stirred mixture is boiled under reflux in the dark under N_2 for 8 hours. After cooling to ~25°, the mixture is diluted with an equal volume of cold H_2O and shaken. After the mixture settles, the supernatant is removed by decantation, the pale yellow residual oil is washed with cold H_2O (3 x 200ml), once with cold 95% EtOH (100ml) and once with cold absolute EtOH (100ml) also by decantation. The oil is then dissolved in Me_2CO (10ml), diluted with hot absolute EtOH (80ml), and stirred under N_2 at 0°. If some oil separates, it should be re-dissolved by adding enough Me_2CO (say ~5ml). The solution is seeded with crystals (a small portion of the oil stored at -30° for a few days crystallises and issued a seed*), stirred under N_2 at 0° for 1 hour then for several hours at -30°. The microcrystals are collected (20.2g) and have **m 63.5-65.0°**. This can be used for reactions; but if purer material is required then it should be recrystallised three times from EtOH (180ml, 9 parts) to provide white needles (17.2g, 41%) with **m 66-67°**. The ***thioester*** always separates as an oil when solutions are cooled to room temperature.
*If difficulties are experienced to crystallise the ester then seed crystals could be obtained by chromatography through a column of Woelm neutral alumina (Activity Grade I) and eluting with *C_6H_6. The centre fractions giving solid with m 67° are combined and recrystallised from EtOH (9parts) to give the pure ***trimethylene dithiotosylate*** with **m 67.5°**. On a Durapak-Carbowax 400/Poracil C column (Waters Associates, 3ft x 0.125in) with $CHCl_3$ as eluent it exhibits a single peak. It has IR ($CHCl_3$) with ν_{max} at 810 (m), 1015 (w), 1075 (s), 1140 (s), 1180 (w), 1300 (m), 1325 (s), 1410 (w), 1440 (w), 1490 (w), 1590 (w), 2930 (w), and 3030 (w) cm^{-1}; and the ^1H NMR ($CDCl_3$, TMS) has δ at 1.98 (quintet, *J* = 7Hz, 2H, $CH_2C\boldsymbol{H}_2CH_2$), 2.43 (s, 6H, $2C\boldsymbol{H}_3$), 2.97 (t, *J* = 7Hz, 4H, $C\boldsymbol{H}_2CH_2C\boldsymbol{H}_2$), 7.30 (d, *J* = 9Hz, 4H, Arom) and 7.75 (d, *J* = 9Hz, 4H, Arom). [Woodward et al. *Org Synth* Coll Vol **6** 1016 *1988*, DOI: 10.15227/orgsyn.054.0033.]
This reagent is useful for the synthesis of 1,3-dithianes from carbonyl compounds and activated methylene

groups. Thus a ketone (0.163mmol), reagent (0.218mmol) and dry NaOH (0.907mmol) in EtOH (6ml) are refluxed for 6 hours, dilute with CH_2Cl_2, wash with aqueous $NaHCO_3$, evaporate the extract and purify the residue through a silica gel column by eluting with 1:2 EtOAc/hexane containing 2% of *N*-methylpyrrolidine to give the desired ***1,3-dithiane*** [McMurry et al. *J Org Chem* **49** 3803 *1984*, DOI: 10.1021/jo00194a026; see also Saksena & Ganguly *Tetrahedron Lett* **22** 5227 *1981*, DOI: 10.1016/S0040-4039(01)92466-9]. It also forms 1.3-dithianes, e.g. ***2,2-(trimethylenedithio)cyclohexanone***, from the respective enamine, i.e. 1-pyrrolidinecyclohex-1-ene [Woodward et al. *Org Synth* **54** 39 *1974*, DOI: 10.15227/orgsyn.054.0039].

Trimethylphenylsilane (phenyltrimethylsilane) *[768-32-1]* **$C_9H_{14}Si$, M 150.3, b 67.3°/20mm, 98-99°/80mm, 170.6°/738mm, d_4^{25} 0.8646, n_D^{20} 1.491.** Fractionally distil the silane at atmospheric or reduced pressure (Podbielniak column and estimate it by GC with a column packed with Silicone Fluid No 710 on Chromosorb P support. [Gilman et al. *J Org Chem* **18** 1743 *1953*, DOI: 10.1021/jo50018a019; Maienthal et al. *J Am Chem Soc* **76** 6392 *1954*, DOI: 10.1021/ja01653a043; House & Respess *J Organomet Chem* **4** 95 *1965*, DOI: 10.1016/S0022-328X(00)82372-4; Roberts et al. *J Am Chem Soc* **71** 2923 *1949*, DOI: 10.1021/ja01176a10; Freiser et al. *J Am Chem Soc* **75** 2821 *1953*, DOI: 10.1021/ja01108a009; *Beilstein* **16** I 525, **16** II 605, **16** III 1198, **16** IV 1361.]

Trimethyl phosphate *[512-56-1]* **$C_3H_9O_4P$, M 140.1, m -46°, b 77°/12mm, 94°/22mm, 110°/60mm, 197.2°/atm, 196-197°/760mm, d_4^{20} 1.0213, n_D^{20} 1.3961**. Purify the phosphate by fractionation through an efficient column at high reflux ratio. It is quite soluble in H_2O; the solubility is 1:1 at 25°. [Becher *J Am Chem Soc* **74** 2923 *1952*, DOI: 10.1021/ja01131a502; IR: Bergmann et al. *J Chem Soc* 847 *1952*, DOI: 10.1039/JR9520000847; McIvor et al. *Can J Chem* **36** 820 *1958*, DOI: 10.1139/v58-121; Kosolapoff *Organophosphorus Compounds*, Wiley p 258 *1950*, and Cherbuliez in *Organo Phosphorus Compounds* (Kosolapoff & Maier eds) Wiley Vol **6** pp 211-577 *1973*, *Beilstein* **1** IV 1259.]

Trimethylphosphine *[594-09-2]* **C_3H_9P, M 76.1, m -86°, b 38-39°/atm, 38-40°/760mm, pK^{25} 8.65, (also available as a 1.0M solution in THF or toluene). All operations should be carried out in an efficient fume cupboard because it is flammable, toxic and has a foul odor.** Distil trimethylphosphine at atmospheric pressure in a stream of dry N_2 (apparatus should be held together with springs to avoid loss of gas from increased pressure in the system) and the distillate run into a solution of AgI in aqueous KI whereby the ***silvercomplex [$Me_3PAgI]_4$*** separates steadily. Filter off the complex, wash it with saturated aqueous KI solution, then H_2O and dry it in a vacuum desiccator over P_2O_5. The dry complex is heated in a flask (in a stream of dry N_2) in an oil bath at 140°, when pure Me_3P distils off (bath temperature can be raised up to 260°). The vapour pressure of ***Me_3P*** at 20° is 466mm and the **b** is **37.8°** [Thomas et al. *Inorg Synth* **9** 59 *1967*, DOI: 10.1002/9780470132401.ch18]. *Alternatively*, freshly distilled Me_3P (6g) is shaken with a solution of AgI (13.2g, 1.1mol) in saturated aqueous KI solution (50ml) for 2 hours. A white solid, not wetted with H_2O, separates rapidly. It is collected, washed with the KI solution, H_2O, and dried [Mann et al. *J Chem Soc* 1828 *1937*, DOI: 10.1039/JR9370001828]. The ***silver complex*** is stable if kept dry in the dark, in which state it can be kept indefinitely. Me_3P can be generated from the complex when required. Store it under N_2 in a sealed container. It has been distilled in a vacuum line at -78° *in vacuo* and condensed at -96° [IR and NMR: Crosbie & Sheldrick *J Inorg Nucl Chem* **31** 3684 *1969*, DOI: 10.1016/0022-1902(69)80363-5]. The pK^{22} by NMR was 8.80 [Silver & Lutz *J Am Chem Soc* **83** 786 *1961*, DOI: 10.1021/ja01465a008; pK^{25} 8.65: Henderson & Streuli *J Am Chem Soc* **82** 5791 *1960*, DOI: 10.1021/ja01507a008]. This **electron-rich phosphine ligand** when complexed with various metals makes efficient catalysts for numerous cross-coupling and other reactions. The **$[Me_2PAgI]_4$** *complex [12389-34-3]* is a flammable solid which has **m 140-142°**. It is decomposed by heating gently in one arm of an inverted U tube. The other arm is kept in a freezing mixture. The complex dissociates, and pure Me_3P collects in the cold arm and is used at once. It should not be allowed to come in contact with air [for $AsMe_3$ see Mann & Wells *J Chem Soc* 702 *1938*, DOI: 10.1039/JR9380000702]. The ***CS_2 complex*** has **m 119°** (crystallising from 95% EtOH) and decomposes in CCl_4 to give Me_3PS **m** 154° (from EtOH) [Sorettas & Isbell *J Org Chem* **27** 2573 *1962*, DOI: 10.1021/jo01054a064].

Trimethylphosphine HCl is unstable and volatilises at 75°/0.4mm (120°/14mm). [Brown *J Am Chem Soc* **67** 503 *1945*, DOI: 10.1021/ja01219a514; IR: Wagstaffe & Thompson *Trans Faraday Soc* **40** 41 *1944*, DOI: 10.1039/TF9444000041; Kosolapoff *Organo-phosphorus Compounds,* Wiley p 31 *1950*, *Beilstein* **4** IV 3429.]

Trimethyl phosphite *[121-45-9]* **$C_3H_9O_3P$, M 124.1, m -78°, b 22°/23mm, 86-86.5°/351mm, 111-112°/760mm, 111°/atm, d_4^{20} 1.0495, n_D^{20} 1.408**. Treat the phosphite with Na (to remove water and any dialkyl phosphonate), then decant and distil it with protection against moisture. It has also been treated with sodium wire for 24 hours, then distilled in an inert atmosphere onto activated molecular sieves [Connor et al. *JCS Dalton Trans* 511 *1986*, DOI: 10.1039/DT9860000511]. It can be fractionally distilled using a spinning band column at high reflux ratio. It is a colourless liquid which is slowly hydrolysed by H_2O. [Gillis et al. *J Am Chem Soc* **80** 2999 *1958*, DOI: 10.1021/ja01545a025; ^{31}P NMR: Callis et al. *J Am Chem Soc* **79** 2719 *1957*, DOI: 10.1021/ja01568a015; Kosolapoff *Organophosphorus Compounds*, Wiley p 203 *1950*, Fieser **1** 1233; *Beilstein* **1** IV 1256.]

Trimethylsilyl acetamide *[13435-12-6]* **$C_5H_{13}NOSi$, M 131.3, m 38-43°, 46-49°, 52-54°, b 84°/18mm, 185-186°/atm.** Distil the amide repeatedly in an inert atmosphere with all operations to be performed in an anhydrous atmosphere. In the presence of moisture, ***trimethylsilanol*** (**b 31-34°/26mm**) is formed and is a likely impurity (check by NMR). [Birkofer et al. *Chem Ber* **96** 1473 *1963*, DOI: 10.1002/cber.1963096054; for reactions of the dianion see Kuzma et al. *J Org Chem* **49** 2015 *1984*, DOI: 10.1021/jo00185a038; Fieser **1** 1235; *Beilstein* **4** IV 4011.]

Trimethylsilyl acetonitrile **(TMSAN)** *[18293-53-3]* **$C_5H_{11}NSi$, M 113.2,** has **b 49-51°/10mm, 65-70°/20mm, d_4^{20} 0.8729, n_D^{20} 1.4420.** Check if NMR and IR spectra show impurities; if present dissolve it in $*C_6H_6$ (10 volumes), wash it with buffer (AcOH/AcONa pH *ca* 7) several times, dry ($CaCl_2$) it, filter, evaporate and distil it. Its IR (CCl_4) has ν_{max} at 2215 (CN) cm^{-1}, and ^1H NMR (CCl_4) with δ at 0.23 (s, 9H, $SiMe_3$), and 1.53 (s, 2H, CH_2CN). [Matsuda et al. *JCS Perkin Trans 1* 26 *1979*, DOI: 10.1039/P19790000026; *Beilstein* **4** IV 3974.] This nitrile cyanomethylates various carbonyl compounds under Lewis base-catalysis [Kawano et al. *Chem Lett* **34** 1508 *2005*, DOI: org/10.1246/cl.2005.1508].

Trimethylsilyl azide *[4648-54-8]* **$C_3H_9N_3Si$, M 115.2,** has **b 52-53°/175mm, 92-95°/atm, 95-99°/atm, d_4^{20} 0.878, n_D^{20} 1.441.** Distil the azide through a Vigreux column in a N_2 atmosphere maintaining the oil bath temperature thermostat at 135-140°**.** Check the purity by ^1H NMR [$CHCl_3$, δ: single peak at 13cps from Me_4Si]. Likely impurities are siloxane hydrolysis products. The azide is thermally stable even at 200° when it decomposes slowly without explosive violence. All the same, it is advisable to carry out the distillation behind a thick safety screen in a fumehood because unforseen **EXPLOSIVE** azides may be formed on long standing. [Birkofer & Wegner *Org Synth* Coll Vol **6** 1030 *1988*, DOI: 10.15227/orgsyn.050.0107.]

Trimethylsilyl chloride **(TMCS trimethyl chlorosilane, chlorotrimethylsilane)** *[75-77-4]* **C_3H_9ClSi, M 108.6,** has **m -40°, b 56-57°/atm, 58°/760mm, d_4^{20} 0.86, n_D^{20} 1.388.** Likely impurities are other chlorinated methylsilanes and tetrachlorosilane (**b** 57.6°), some of which can form azeotropes. To avoid the latter, very efficient fractional distillation is required. It has been fractionated through a 12 plate glass helices-packed column with only the heart-cut material being used. It has also been fractionated through a 90cm with 19mm diameter Stedman column. Purify it by redistilling from CaH_2 before use. [Sauer et al. *J Am Chem Soc* **70**, 4254 *1948*, DOI: 10.1021/ja01192a511; Langer et al. *J Org Chem* **23** 50 *1958*, DOI: 10.1021/jo01095a017; Fieser **1** 1232; *Beilstein* **4** IV 4007.] **FLAMMABLE and CORROSIVE.**

Trimethylsilyl chloroacetate *[18293-71-5]* **$C_5H_{11}ClO_2Si$, M 166.7,** has **m -20°, b 57-58°/14mm, 70-71°/30mm, 159°/760mm, d_4^{20} 1.057, n_D^{20} 1.4231.** Purify the chloroacetate by repeated fractionation, and taking the fractions with clean NMR spectra. [Anderson *J Am Chem Soc* **74** 2371 *1952*, DOI: 10.1021/ja01129a502; *Beilstein* **4** IV 4004.] It has been used for the synthesis of substituted acetic acids [Akita et al. *J Organomet Chem* **348** 91 *1988*, DOI: 10.1016/0022-328X(88)80342-5].

Trimethylsilyl cyanide *[7677-24-9]* **C_4H_9NSi, M 99.2,** has **m 8-11°, 10.5-11.5°, 11-12°, 12-12.5°, b 54-55°/87mm, 67-71°/168mm, 114-117°/760mm, 118-119°/760mm, d_4^{20} 0.79 n_D^{20} 1.43916.** The material should have only one sharp signal in the ^1H NMR (in CCl_4 with $CHCl_3$ as internal standard) with δ at 0.4, and the IR with ν_{max} at 2210cm^{-1} (C=) [McBride & Beachall *J Am Chem Soc* **74** 5247 *1952*, DOI: 10.1021/ja01141a003; Prober *J Am Chem Soc* **77** 3224 *1955*, DOI: 10.1021/ja01617a023]; otherwise purify it by fractionating through an 18 x 1/4inch column. [Evers et al. *J Am Chem Soc* **81** 4493 *1959*, DOI: 10.1021/ja01526a013.] It has also been carefully distilled using a 60cm vacuum jacketed column. If the volume of sample is small, the cyanide can be chased (in the distillation) with xylene that had been previously distilled over P_2O_5. It is **HIGHLY TOXIC** and **FLAMMABLE**. [Evans et al. *J Org Chem* **39** 914 *1974*, DOI: 10.1021/jo00921a012; *Beilstein* **4** IV 3893.]

Trimethylsilyldiazomethane (diazomethyl)trimethylsilane) *[18107-18-1]* **$C_4H_{10}N_2Si$, M 114.2, distils**

between 0°/100mm and 40°/15mm. This diazo-silane is non-explosive, and non-mutagenic, and the careful precautions used in preparing diazomethane are not strictly necessary here. It is a good safe and **stable substitute for diazomethane** and excess of reagent can be evaporated off. It is available commercially as 2.0M solutions in Et_2O or hexane. Solutions in hexane can be stored for periods of more than 6 months at 0° in the absence of light without noticeable decomposition. Care should be taken, however, when opening a container, as it may become pressurised by N_2 which may be released, and should be done at ~0°. Several methods were used for preparing this diazo-silane and some start from trimethylsilylmethylmagnesium chloride, e.g. by reaction with diazomethane (7-74%, Lappert et al. *J Chem Soc (A)* 2954 1970, DOI: 10.1039/J19700002954; Martin *Synth Commun* **13** 809 1983, DOI: 10.1080/00397918308063714), or with TsN_3 (~17%, Barton & Hoekman *React Inorg. Met-Org Chem* **9** 297 *1979*, DOI: 10.1080/00945717908069745], but the transfer of the azo group is most practical, high yielding and used on a large scale when diphenyl phosphorazidate is used, and is described here.

Trimethylsilylmethylmagnesium chloride *[13170-43-9]* is prepared in an inert atmosphere (e.g. argon) under strictly anhydrous conditions from Mg turning (10.7g, 0.44g-atom), anhydrous Et_2O (40ml) and 1,2-dibromoethane (0.1ml to initiate reaction) which are stirred at ~25° for 15 minutes, then 10ml of a mixture of trimethylsilylmethyl chloride (45.4g, 370mmol, freshly distilled at 97°/atm, see *[2344-80-1]*) in anhydrous Et_2O (100ml) is added with stirring all at once to start the reaction followed by the rest in a dropwise manner at such a rate as to maintain gently reflux during the addition (~2 hours). After the exothermic reaction subsides, reflux and stirring are continued for 1 hour then the mixture is cooled to ~25°, and this Grignard reagent is used in the next step. Under strictly anhydrous conditions and in a maintained argon atmosphere, a solution of diphenyl phosphorazidate (91.2g, 330mmol, freshly distilled at 134-136°/0.2mm see *[26386-88-9]*) in anhydrous Et_2O (350ml) is cooled and stirred in an ice-NaCl bath until the temperature is -10°, and the preceding Grignard reagent is added dropwise (*via* a funnel or a cannula) at such a rate as to maintain the inner temperature of the solution below 0° (addition requires ~ 1.5 hours, forming a large amount of white precipitate when two-thirds of the reagent is added). After addition is complete, the ice-salt bath is replaced by an ice bath while stirring for 2 hours, then stirring is continued for 14-16 hours. The mixture is again cooled in an ice-salt bath until the inner temperature drops to -15°, and cold H_2O (35ml) is added dropwise while keeping the inner temperature below 0° (requiring ~ 1 hour), and the resulting yellow silyldiazomethane mixture is stirred for a further 0.5 hours. The mixture is filtered, the white solid is washed with Et_2O (3 x 100ml), the combined filtrate and washings are washed with cold H_2O (2 x 100ml), dried (Na_2SO_4), and the filtrate is placed in a 1L flask equipped with a Teflon-coated magnetic stirrer bar and a 30cm Vigreux column (1.5cm diameter). The mixture is slowly concentrated to *ca* 200ml by distillation at ~760mm with a bath temperature below 45° during ~6 hours (the colour of the distilled Et_2O is yellow due to some co-distillation of the diazo-silane. This rate of distillation is important as a faster rate results in decreased yields of the diazo-silane. The concentration time can be reduced to ~ 4 hours if a 30cm Widmer column is used. The remaining deep-yellow solution is then distilled, in the same equipment, by reducing the pressure to 100mm at 0° (bath temperature) and then at 15mm and 40° (bath temperature) while the distillate is collected in a receiver in a Dry-ice/Me_2CO bath until distillation is complete. The distillate is dried ($MgSO_4$), filtered and diluted with redistilled hexane (100ml). This solution is then concentrated again by distillation through the 30cm Vigreux column until the temperature of the vapour reaches 68° (with final oil bath temperature at 87°) which requires ~3 hours. About 80-110ml of the residual yellow hexane solution contains 220-230mmol of ***trimethylsilyldiazomethane*** (67-70% based on the phosphorazidate). Its IR (hexane) has ν_{max} at 2075, 1260 and 885 cm^{-1}, the ^1H NMR (100MHz, hexane, $CHCl_3$ as internal standard) has δ at 0.16 (s, 9H, -Si(C**H**$_3$)$_3$) and 2.58 (s, 1H, -C**H**N_2), and the ^1H NMR (100MHz, *C_6H_6) has δ at -0.03 (s, 9H, -Si(C**H**$_3$)$_3$) and 2.23 (s, 1H, -C**H**N_2).

The concentration of ***trimethylsilyldiazo-methane*** in hexane can be determined by adding 91mg (0.5mmol) of dibenzyl (see *[103-29-7]*) in 1ml of the hexane solution containing it, and measuring the ^1H NMR. The concentration of the azo-silane (*x* mmol/ml) is calculated from the formula: $x = 2a/b$, where *a* is the integral value (mm) of the methine proton (δ: 2.58) of *trimethylsilyldiazomethane*, and *b* is the integral value (mm) of the methylene protons (δ: 2.99) of dibenzyl. [Shioiri et al. *Org Synth* Coll Vol **8** 612 *1993*, DOI: 10.15227/orgsyn.068.0001].

It has been used for stereo and/or regio selective dipolar cycloadditions, e.g. with chiral acrylamides it produces $^2\Delta$-pyrazoline carboxylic acids (azaprolines) after protio-desilylation [Mish et al. *J Am Chem Soc* **119** 8379 *1997*, DOI: 10.1021/ja971708p], or with diethyl *trans*-glutaconate where the pyrazoline ester is oxidised to the respective pyrazole [Di & Rein *Tetrahedron Lett* **45** 4703 *2004*, DOI: 10.1016/j.tetlet.2004.04.097]. It also acts

as a carbene source in stereoselective [1 + 4] annulation reactions with silylvinylketenes to form a variety of cyclopent-2-enones in good to excellent yields [Moser et al. *J Org Chem* **71** 6542 *2006*, DOI: 10.1021/jo060994x]. It is commercially available in Et_2O (2.0M, d 0.733g/ml at 25°) and in hexanes (2.0M, d 0.733g/ml at 25°)

2-Trimethylsilyl-1,3-dithiane *[13411-42-2]* **$C_7H_{16}S_2Si$, M 192.2, b 54.5°/0.17mm, 100°/8mm, d_4^{20} 1.04, n_D^{20} 1.533.** Fractionally distil the dithiane through an efficient column and collect the fractions that have the correct NMR and IR spectra. Its ^1H NMR (CCl_4) has τ at 6.36 ($SiMe_3$), 9.87 (SCHS) and dithiane H at 7 and 8 (ratio 1:9:4:2) from Me_4Si; the UV has λ_{max} at 244nm (ε 711), sh 227nm (ε 800). [Corey et al. *J Am Chem Soc* **89** 434 *1967*, DOI: 10.1021/ja00978a048; for use as an acyl anion equivalent see Smith & Baldi *J Amer Chem Soc* **119** 6925 1997, DOI: 10.1021/ja00978a048; Smith et al. *J Am Chem Soc* **125** 14435 *2003*, DOI: 10.1021/ja0376238].

2-(Trimethylsilyl)ethanesulfonyl chloride (SES-Cl) *[106018-85-3]* **$C_5H_{13}ClO_2SSi$, M 200.8, b 60°/0.1mm, 146.8°/760mm, d_4^{25} 1.059, n_D^{25} 1.4444.** Check IR; if the bands at ~3200 (OH) cm^{-1} are strong, then much of the SES-Cl had hydrolysed, and it should be treated with $POCl_3$ (with cooling) and stirred at ~25° for about 1 hour, poured into ice cold H_2O, extracted with CH_2Cl_2, washed with $NaHCO_3$, dried (Na_2SO_4), evaporated, and it distils as a yellow oil in a vacuum. This procedure is used for converting the Na salt *[18143-30-1]* to SES-Cl. It reacts with amines to form amides, e.g. SES-NRR', which on heating with CsF (i.e. F^- ions) in DMF at 95° provide the amine (NHRR'), SO_2 and $CH_2{=}CH_2$ [Weinreb et al. *Tetrahedron Lett* **27** 2099 *1986*, DOI: 10.1016/S0040-4039(00)84458-5]. [Ribière et al. *Chem Rev* **106** 2249 *2006*, DOI: 10.1021/cr0300587]

Trimethylsilyl ethanol *[2916-68-9]* **$C_5H_{14}OSi$, M 118.3, b 53-55°/11mm, 71-72°/10mm, 75°/41mm, 95°/100mm, 211-213°/760mm, d_4^{25} 0.8254, n_D^{25} 1.4220.** If the NMR spectrum is not clean, then dissolve the alcohol in Et_2O, wash it with aqueous NH_4Cl solution, dry (Na_2SO_4), evaporate and distil it. The ***3,4-dinitrobenzoyl derivative*** has **m 66°** (from EtOH). [NMR: Speier et al. *J Am Chem Soc* **79** 974 *1957*, DOI: 10.1021/ja01561a054; *Z Naturforsch* **14b** 137 *1959*, *Beilstein* **4** IV 3951.] Protecting reagent for phosphate [Wada & Sekine *Tetrahedron Lett* **35** 757 *1994*, DOI: 10.1021/ol061461d; Sawabe et al. *Tetrahedron Lett* **33** 7685 *1992*, DOI: 10.1016/0040-4039(93)88016-C; Chao et al. *J Org Chem* **59** 6687 *1994*, DOI: 10.1021/jo00101a029] and carbonyl groups [Kita et el. *JCS Perkin Trans I* 2639 *1993*, DOI: 10.1039/P19930002639]; also used to prepare *N*-protected amines *via* alcoholysis of the respective isocyanates [Kobayashi & Motoyama *Synlett* 2670 *2006*, DOI: 10.1055/s-2006-950435; Crawley & Funk *Org Lett* **8** 3995 *2006*, DOI: 10.1021/ol061461d].

2-(Trimethylsilyl)ethoxymethyl chloride (SEMCl) *[76513-69-4]* **$C_6H_{15}ClOSi$, M 166.7, b 57-59°/8mm, 170-172°/atm, d_4^{20} 0.942, n_D^{20} 1.4350.** Dissolve SEMCl in pentane, dry it ($MgSO_4$), evaporate and distil the residual oil in a vacuum. Stabilise it with 10 ppm of diisopropylamine. Store it under N_2 in a sealed container in a refrigerator. [Lipshutz & Pegram *Tetrahedron Lett* **21** 3343 *1980*, DOI: 10.1016/S0040-4039(00)78684-9.] SEM is a good protecting group for acohols forming SEM-ethers which are stable over a wide pH range but can be selectively cleaved with fluoride ions under mild aprotic conditions [Wada et al. *Tetrahedron Lett* **36** 1683 *1995*, DOI: 10.1016/0040-4039(95)00130-5].

2-(Trimethylsilyl)ethoxymethyltriphenylphosphonium chloride (SEM-triphenylphosphonium chloride) *[82495-75-8]* **$C_{24}H_{30}ClOPSi$, M 429.0, m 140-142°, 145-149°.** Wash the solid with AcOH and recrystallise it from CH_2Cl_2/EtOAc. Dry it in a vacuum desiccator. ***Hygroscopic***. The ^1H NMR ($CDCl_3$) has δ at -0.2 (s, Me_3Si), 0.8 (t, 8Hz, CH_2Si), 3.83 (t, 8Hz, OCH_2), 5.77 (d, J_{PH} = 4Hz, P^+-CH_2O) and 7.70 (m, aromatic H). [Schönauer & Zbiral *Justus Liebigs Ann Chem* 1031 *1983*, DOI: 10.1002/jlac.198319830615.]

Trimethylsilylethyl phenylsulfone (phenyl-2-trimethylsilylethylsulfone) *[73476-18-3]* **$C_{11}H_{18}O_2SSi$, M 242.4, m 50-53°, 52°.** Dissolve the sulfone in Et_2O, wash it with saturated HCO_3^- followed by saturated NaCl, H_2O and dried ($MgSO_4$). Filtration followed by evaporation leaves residual crystals with **m 52°**. [Hsiao & Shechter *Tetrahedron Lett* **23** 1963 *1982*, DOI: 10.1016/S0040-4039(00)87234-2; Hsiao & Shechter *J Org Chem* **53** 2688 *1985*, DOI: 10.1021/jo00247a006.]

Trimethylsilyl isocyanate *[1118-02-1]* **C_4H_9NOSi, M 115.2, b 90-92°/atm, b 91.3-91.6°/atm, d_4^{20} 0.850 n_D^{20} 1.43943.** Purify it by repeated fractionation as for the isothiocyanate below. [Eaborn *J Chem Soc* 3077 *1950*, DOI: 10.1039/JR9500003077; *Beilstein* **4** III 1861, **4** IV 4011.]

Trimethylsilyl isothiocyanate *[2290-65-5]* **C_4H_9NSSi, M 131.3, m -49°, -33°, b 142.6-143.1°/759mm, 143.8°/760mm, n_D^{20} 1.4809.** The ^{1}H NMR spectrum should have only one peak; if not, purify it by repeated fractionation in an all-glass system using a 50cm (4mm internal diameter) column without packing. [Anderson *J Am Chem Soc* **69** 3049 *1947*, DOI: 10.1021/ja01204a036; Fehér & Blümcke *Chem Ber* **90** 1934 *1957*, DOI: 10.1002/cber.19570900933; Neidlein & Hege *Synthesis* 50 *1975*, DOI: 10.1055/s-1975-23663; *Beilstein* **4** III 1861, **4** IV 4011.] It reacts with aziridines and cyclohexene oxide, without a catalyst, to provide *N*-substituted *trans*-2-amino-1-isothiocyanates or *trans*-2-hydroxy-1-isothiocyanates [Prusinowska & Gawronski *Synth Commun* **39** 2795 *2009*, DOI: 10.1080/00397910802691890].

(Trimethylsilyl)methanol *[3219-63-4]* **$C_4H_{12}OSi$, M 104.2, b 120-122°/754mm, 122-123°/768mm, d_4^{20} 0.83 n_D^{20} 1.4176.** If the NMR indicates impurities (should have only two signals), then dissolve it in Et_2O, shake this with aqueous 5N NaOH, M H_2SO_4, saturated aqueous NaCl, dry ($MgSO_4$) and distil it using an efficient column at atmospheric pressure. The ***3,5-dinitrobenzoate*** has **m 70-70.5°** (from 95% EtOH). [Huang & Wang *Acta Chem Sin* **23** 291 *1957*, http://sioc-journal.cn/Jwk_hxxb/EN/; cf. *Chem Abstr* **52** 19911 *1958*, Seyferth *J Am Chem Soc* **81** 1844 *1959*, DOI: 10.1021/ja01517a018; and Speier et al. *J Am Chem Soc* **70** 1117 *1948*, DOI: 10.1021/ja01183a074; *Beilstein* **4** III 1844, **4** IV 2876.]

(Trimethylsilyl)methylamine (aminomethyl trimethylsilane) *[18166-02-4]* **$C_4H_{13}NSi$, M 103.2, b 101.6°/735mm, d_4^{20} 0.77, n_D^{20} 1.416.** A possible contaminant is hexamethyldisiloxane. It should have two ^{1}H NMR signals in $CDCl_3$; if not, dissolve it in $*C_6H_6$, shake it with 15% aqueous KOH, separate, dry (Na_2SO_4), filter, evaporate and distil it using a still of *ca* 10 theoretical plates. The water azeotrope has **b 83°/735mm**; hence it is important to dry the extract well. The ***hydrochloride*** has **m 198-199°** (from MeOH or Me_2CO). [Noll et al. *J Am Chem Soc* **73** 3867 *1951*, DOI: 10.1021/ja01152a092; *Beilstein* **4** IV 3878.]

(Trimethylsilyl)methyl chloride (chloromethyltrimethylsilane, silico-neopentyl chloride) *[2344-80-1]* **$C_4H_{11}ClSi$, M 122.7, b 97.1°/734mm, 98.2-98.7°/747mm d_4^{25} 0.979, n_D^{20} 1.4180.** This chloride is prepared by stirring a mixture of TMS (174g, 2 moles, Me_4Si see *[75-76-3]*) in dry CCl_4 (150ml) and PCl_5 (3g) [use suitably placed traps of Dry-ice/Me_2CO to prevent loss of TMS] under a reflux condenser and irradiated with a 450 watt GE sunlight lamp while dry chlorine is bubbled through for 4 hours at a rate of 0.5 mole per hour (check weight of flask occasionally). The mixture is then fractionated using a 15-plate glass helix packed column to give the ***trimethylsilylmethyl chloride*** (53g, 0.44 mole), **b 97.1°/734mm**, ***polychlorinated tetramethylsilane*** (93g) and recovered TMS (62g, 0.7 mole). The ***chloride*** can be analysed by placing ~0.2g in a gelatin capsule in a Parr bomb and fused with Na_2O_2 (15g) and sucrose (1g). The melt is treated with H_2O, acidified with HNO_3 and the chloride ion is determined by titration using the Volhard method. [Whitmore & Sommer *J Am Chem Soc* **68** 481 *1946*, DOI: 10.1021/ja01207a036; *Beilstein* **4** IV 3877.] It has also been prepared by reaction of chloro-dimethyl-chloromethyl-silane and MeMgBr in Et_2O [Whitmore et al. *J Am Chem Soc* **69** 1976 *1947*, DOI: 10.1021/ja01200a043; Roedel *J Am Chem Soc* **71** 269 *1949*, DOI: 10.1021/ja01169a068]. [*Beilstein* **4** IV 3877.] It is readily converted to ***trimethylsilylmethylmagnesium chloride*** (see *[13170-43-9]* above) in ~90% yield. It reacts with *n*-BuLi in pentane to give ***trimethylsilylmethylLi*** [Sommer et al. *J Am Chem Soc* **71** 2746 *1949*, DOI: 10.1021/ja01176a043], which reacts with anhydrous cerium (III) chloride to form ***trimethylsilylmethyl cerium dichloride***. The latter reacts with acyl halides to provide bis-β-silylethyl tertiary alcohols that efficiently undergo a trimethylchlorosilane-promoted **Peterson reaction** to generate allylsilanes in high overall yields [Anderson & Fuchs *Synth Commun* **17** 621 *1987*, DOI: 10.1080/00397918708075736]. It is useful also for Peterson olefination and homologation of aldehydes and ketones *via* 1,2-epoxysilanes [Lee et al. *Tetrahedron* **45** 5877 *1989*, DOI: 10.1016/S0040-4020(01)89114-6]. ***Trimethylsilylmethyl bromide*** *[18243-41-9]* has **M 167.1, b 115.5° /atm, d_4^{25} 1.17, n_D^{20} 1.444** [*Beilstein* **4** IV 3878], and ***trimethylsilylmethyl iodide*** *[4206-67-1]* has **M 214.1, b 139-141°/atm, d_4^{25} 1.433, n_D^{20} 1.491 [***Beilstein* **4** IV 3878], and both should be stored in the dark.

Trimethylsilylmethyl phenylsulfone (phenyltrimethylsilylmethylsulfone) *[17872-92-3]* **$C_{10}H_{16}O_2SSi$, M 228.4, m 28-32°, b 121°/0.01mm, 160°/6mm, n_D^{20} 1.5250.** Fractionate the sulfone at high vacuum and recrystal-

lise it from pentane at -80°. If too impure (cf. IR), dissolve it in CH_2Cl_2 (*ca* 800ml for 100g), wash this with 2M aqueous NaOH (2 x 200ml), brine, dry, evaporate and distil it. [Craig et al. *JCS Perkin Trans 1* 1949 *1985*, DOI: 10.1039/P19850001949; IR and NMR: Cooper *J Am Chem Soc* **76** 3713 *1954*, DOI: 10.1021/ja01643a035.]

1-Trimethylsilyloxy-1,3-butadiene *[6651-43-0]* **$C_7H_{14}OSi$, M 142.3, b 131°/760mm (mixture of isomers), 49.5°/25mm (*E*-isomer), d_4^{20} 0.8237, n_D^{20} 1.447.** Purify the butadiene by fractional distillation, and collect the fractions with the required ^1H NMR. Store it under N_2 — it is a flammable and moisture-sensitive liquid. [Caseau et al. *Bull Soc Chim Fr* 16658 *1972*, Belge Patent 670,769, *Chem Abstr* **65** 5487d *1966*.] Used in the stepwise Diels-Alder reaction with 4,6-dinitrobenzofuroxan [Linder et al. *Org Lett* **1** 6 *2012*, PMID: 22126093].

1-(Trimethylsilyloxy)cyclopentene *[19980-43-9]* **$C_8H_{16}OSi$, M 156.3, b 45°/11mm, 75-80°/20-21mm, d_4^{20} 0.878, n_D^{20} 1.441.** If too impure as seen by the NMR spectrum, then dissolve it in 10 volumes of pentane, shake with cold $NaHCO_3$ (3 x 500ml), then 1.5M HCl (200ml) and aqueous $NaHCO_3$ (200ml) again, dry (Na_2SO_4), filter, evaporate and distil it through a short Vigreux column. Its ^1H NMR ($CDCl_3$) has δ at 0.21 (s, 9H), 1.55 (m, 2H), 1.69 (m, 2H), 2.05 (br d, 4H) and 4.88 (br s, 1H). GLC in a 6ft x 1/8inch with 3% SP2100 on 100-120 mesh Supelcoport column should give one peak. Store dry. [For the ***cyclohexene*** analogue *[6651-36-1]* **$C_9H_{18}OSi$,** M 170.3, **b 64-65°/15mm, 165°/atm**, see Varghese et al. *Org Synth* Coll Vol **8** 460 *1993*, DOI: 10.15227/orgsyn.067.0141.]

2-(Trimethylsilyloxy)furan *[61550-02-5]* **$C_7H_{12}O_2Si$, M 156.3, b 34-35°/9-10mm, 42-50°/17mm, 40-42°/25mm, d_4^{20} 0.950, n_D^{20} 1.436.** Fractionally distil the furan using a short path column. Its ^1H NMR in CCl_4 has δ at 4.90 (dd, *J* = 1.3Hz, 3H), 6.00 (t, *J* = 3Hz, 4H) and 6.60 (m, 5H). [Yoshii et al. *Heterocycles* **4** 1663 *1976*, DOI: 10.3987/R-1976-10-1663.]

4-Trimethylsilyloxy-3-penten-2-one (*cis*) (acetylacetone enol trimethylsilyl ether) *[13257-81-3]* **$C_8H_{16}O_2Si$, M 172.3, b 66-68°/4mm, 61-63°/5mm, 205.1°/760mm, d_4^{20} 0.917, n_D^{20} 1.452.** Fractionally distil the enone, and store it in glass ampoules which are sealed under N_2. It hydrolyses readily in contact with moisture giving, as likely impurities, hexamethyldisiloxane and 2,4-pentanedione. It is a silylating agent. [West *J Am Chem Soc* **80** 3246 *1958*, DOI: 10.1021/ja01546a018; *Beilstein* **4** IV 4003.]

1-(Trimethylsilyl)-2-phenylacetylene (1-phenyl-2-trimethylsilylacetylene) *[78905-09-6, 2170-06-1]* **$C_{11}H_{14}Si$, M 174.3, b 45-46°/0.1mm, 67°/5mm, 87.5°/9mm, d_4^{20} 0.8961 n_D^{20} 1.5284.** Dissolve the acetylene in Et_2O, wash with H_2O, dry and fractionate it through a Todd column. [Benkeser & Hickner *J Am Chem Soc* **80** 5298 *1958*, DOI: 10.1021/ja01552a072.]

3-(Trimethylsilyl)-1-propyne (trimethyl[propargyl]silane) *[13361-64-3]* **$C_8H_{12}Si$, M 112.3, b 99-100°/760mm, d_4^{20} 0.7581, n_D^{20} 1.4091.** Fractionally distil the propyne, and add 2,6-di-*tert*-butyl-*p*-cresol (~0.5%) to stabilise it. [For polymerisation see Matsuda et al. *J Am Chem Soc* **105** 7473 *1983*, DOI: 10.1021/ja00363a061; use for the three-carbon elongation of aldehydes see Maeta & Suzuki *Tetrahedron Lett* **33** 5969 *1992*, DOI: 10.1016/S0040-4039(00)61102-4; Petrov et al. *Doklady Acad Nauk USSR* **93** 293 *1953*, cf. *Chem Abstr* **48** 13616 *1954*, *Beilstein* **4** IV 3938.]

2-Trimethylsilylpyridine *[13737-04-7]* **$C_6H_{13}NSi$, M151.3, b 47-49°/5mm, 69°/14.5mm, 74°/21mm, d_4^{25} 0.9113, n_D^{20} 1.489.** Purify it by distillation in a vacuum, but if it is discoloured then dissolve it in Et_2O or $^*C_6H_6$, wash it with H_2O, dry over Na_2SO_4, filter, evaporate and distil the residue. It is more readily hydrolysed than the 3- or 4-trimethylsilyl isomers and the relative rates of hydrolysis in H_2O:MeOH:EtOH are 740:120:1; pyridine and trimethylsilanol or the alkoxytrimethylsilane being liberated. Acids inhibit the reaction but bases have little effect. [Anderson et al. *J Chem Soc* B 450 *1968*, DOI: 10.1039/J29680000450; synthesis from 2-chloropyridine and Mg/Me_3SiCl/HMPT then H_2O/$NaHCO_3$ in 62% yield: Effenberger & Häbich *Justus Liebigs Ann Chem* **1979** 842 *1979*, DOI: 10.1002/jlac.197919790613; Itami *Tetrahedron* **57** 5045 *2001*, DOI: 10.1016/S0040-4020(01)00348-9.]

3-Trimethylsilylpyridine *[13779-37-2]* **$C_6H_{13}NSi$, M151.3, b 94°/30mm, d_4^{25} 0.9113, n_D^{20} 1.4913.** Purify it as for the 2-isomer above except that less care needs be taken as it hydrolyses relatively (extremely) slowly. [Anderson et al. *J Chem Soc* B 450 *1968*, DOI: 10.1039/J29680000450.]
4-Trimethylsilylpyridine *[18301-46-7]* has**, b 107°/48mm, d_4^{25} 0.9113, n_D^{20} 1.4868.** Purify it as for the 2-isomer above except that less care needs be taken as it hydrolyses relatively (extremely) slowly. [Anderson et al. *J Chem Soc* B 450 *1968*, DOI: 10.1039/J29680000450.]

1-Trimethylsilyl-1,2,4-triazole *[18293-54-4]* **$C_5H_{11}N_3Si$, M 141.3, b 74°/12mm, 85.6°/760mm, d_4^{20} 0.99, n_D^{20} 1.4604.** Fractionally distil it at atmospheric pressure in an inert atmosphere because it is moisture sensitive. [Birkofer et al. *Chem Ber* **93** 2804 *1960*, DOI: 10.1002/cber.19600931207.]

Trimethylsilyl trifluoromethane ($TMSCF_3$, trifluoromethyl trimethylsilane, Ruppert's reagent) *[81290-20-2]* **$C_4H_9F_3Si$, M 142.2, b 54-55°/atm, 55-55.5°/atm, d_4^{20} 0.962, n_D^{20} 1.332.** Purify the silane by distilling it from trap to trap in a vacuum of 20mm using a bath at 45° and Dry-ice/Me_2CO bath for the trap. The liquid in the trap is then washed with ice cold H_2O (3x), the top layer is collected, dried (Na_2SO_4), and the liquid is decanted and fractionated through a helices-packed column at atmospheric pressure. ^1H, ^{13}C, ^{19}F, and ^{29}Si NMR can be used for assessing the purity of fractions. [Ruppert et al. *Tetrahedron Lett* **25** 2195 *1984*, DOI: 10.1016/S0040-4039(01)80208-2; Krishnamurti et al. *J Org Chem* **56** 984 *1991*, DOI: 10.1021/jo00003a017; *Beilstein* **4** IV 3892.] **$TMSCF_3$** adds the trifluoromethyl nucleophile to aldehydes and ketones [Parkash et al. *J Org Chem* **71** 6806 *2006*, DOI: 10.1021/jo060835d].

2,8,9-Trimethyl-2,5,8,9-tetraaza-1-phosphabicyclo[3.3.3]undecane (Verkade Superbase, 2,8,9-trimethyl-*pro*-azaphosphatrane) *[120666-13-9]* **$C_9H_{21}N_4P$, M 216.3, m 110-115°, pKa 26.8 (DMSO).** The free superbase can be prepared in three ways. When tris(dimethylamino)phosphine (8.8g, 54mmol, toxic see *[1608-26-0]*) and tris[2-(methylamino)-ethyl]amine (10.0g, 53mmol), see *[65604-89-9]*) are dissolved in dry xylene and refluxed for 21 days, then the solvent is removed *in vacuo*, a residual thick oil is obtained. On heating this oil at 105°/0.05mm the ***pro-azaphosphatrane*** (53g, 24.5mmol, 46%) sublimes out as a colourless waxy solid.
In a second preparation the ***trimethyl-pro-azaphosphatrane hydrochloride*** (0.87g, 3.4mmol, see *[138800-17-6]* below) dissolved in MeCN (10ml) is added dropwise to a suspension of freshly sublimed *tert*-BuOK (0.41g, 3.7mmol) in MeCN (20ml), stirred for 30 minutes, the solvent is removed *in vacuo*, the residue is extracted with hexane (2 x 30ml), evaporated, and the residue is sublimed at 60°/0.01mm to give the pure ***superbase*** (80%) as a white solid. [Schmidt et al. *Z Anorg Allg Chem* **578** 75 *1989*, DOI: 10.1002/zaac.19895780109.]
In a third preparation the ***trimethyl-azaphosphatrane hydrochloride*** is heated slowly with a large excess of anhydrous NaOH under vacuum. No reaction occurs below 200°, but above this temperature sudden sublimation of the free superbase occurs. Extraction of the sublimate, and/or the reaction mixture, with $*C_6H_6$ followed by evaporation of the solvent provided pure ***free base*** (53% yield). Sometimes charring occurs during this reaction resulting in lower yields. [Lensink et al. *J Am Chem Soc* **111** 3478 *1959*, DOI: 10.1021/ja00191a081.]
The ***free base*** is an unusually strong Lewis base. It deprotonates phenol (pKa 10), protonated **'Proton Sponge'** [1,8-(bismethylamino)naphthalene HI (pKa 12.3, Alder et al. *JCS Chem Commun* 723 *1968*, DOI: 10.1039/C19680000723,), diethyl malonate (pKa 13, Pearson & Dillon *J Am Chem Soc* **75** 2439 *1953*, DOI: 10.1021/ja01106a048), H_2O (measured pKa at 25° 13.9965, pKa at 20° 14.1669, Harned & Robinson *Trans Farad Soc* **36** 973 *1940*, DOI: 10.1039/TF9403600973; or pKa 15.74 ? Reeve et al. *Can J Chem* **57** 2747 *1979*, DOI: 10.1139/v79-444), but does not react with *tert*-BuOH (pKa 16.5, Reeve et al. *Can J Chem* **57** 2747 *1979*, DOI: 10.1139/v79-444),], to give the protonated base as the only product. In the presence of 1 equivalent of H_2O an equilibrium mixture of **free base to cation** of *ca* 4:1 is obtained (from NMR studies) [Lensink et al. *J Am Chem Soc* **111** 3478 *1989*, DOI: 10.1021/ja00191a081]. The ***un-methylated analogous free base*** is not very stable although it ***hydrochloride*** is quite stable and it is a *stronger base* than the 2,8,9-trimethyl- or the respective 2,8,9-tribenzyl- derivative. The upper limit of the pKa of the trimethyl compound in DMSO is ~26.8 (by ^{13}P NMR) [Laramay & Verkade *J Am Chem Soc* **112** 9421 *1990*, DOI: 10.1021/ja00181a070]. The ***free base*** has IR (Nujol) with ν_{max} at 1332 s, 1303 m, 1244 s, 1226 s, 1197 m, 1145 s, 1128 s, 1053 s, 1004 s, 960 w, 887 m, 850 s, 767 w, 650 s and 634 s cm^{-1}; the ^1H NMR (300MHz, CD_3CN, TMS) has δ at 2.60 (d, 9H, $^3J_{PH}$ = 11.0 Hz, CH_3) and 2.76 (br s, 12H, CH_2); the ^{13}C NMR (75MHz, C_6D_6, TMS) has δ at 37.2 ($^2J_{PC}$ = 41.0 Hz, CH_3), 49.4 (d, $^2J_{PC}$ = 6.7 Hz, $N_{eq}\mathbf{C}H_2$) and 51.3 (s, $N_{ax}\mathbf{C}H_2$); the ^{31}P NMR (122MHz, C_6D_6, 85% H_3PO_4) has δ at 120.8; and the HRMS has *m/z* 216.15088 (calc for M is 216.15039). [Schmidt et al. *Z Anorg Allg Chem* **578**

75 *1989*, DOI: 10.1002/zaac.19895780109; Lensink et al. *J Am Chem Soc* **111** 3478 *1989*, DOI: 10.1021/ja00191a081; Laramay & Verkade *J Am Chem Soc* **112** 9421 *1990*, DOI: 10.1021/ja00181a070; Laramay & Verkade *Z Anorg Allg Chem* **605** 163 *1991*, DOI: 10.1002/zaac.19916050120; Schmidt et al. *Inorg Chem* **29** 2214 *1990*, DOI: 10.1021/ic00337a008]. In addition to being easily protonated (see following entry), the free base has been readily converted to P-substituted adducts (***five-coordinated phosphatranes***), where the P-H is replaced by P-X, where -X is -O (by using Me_3SiO_2), -S (by using S_8), -Se (by using Se), -N_3P (by using PhN_3), -NPh (by using PhN_3 and heating), -CS_2 (by using CS_2) and -$PtCl_2$ [by using $(Et_2S)_2$-$PtCl_2$] in 60 to >80% yields [Schmidt et al. *Z Anorg Allg Chem* **578** 75 *1989*, DOI: 10.1002/zaac.19895780109]. ***Note*** that the difference between the ***pro-phosphatranes*** and the ***phosphatranes*** is that the latter possess an apical N→P bond as evidenced by the shorter bond distance in X-Ray diffraction analyses and the large decrease in the δ ^{31}P chemical shifts in the NMR spectra.

2,8,9-Trimethyl-2,5,8,9-tetraaza-1-phosphabicyclo[3.3.3]undecane hydrochloride (Verkade Superbase HCl, 2,8,9-trimethylazaphosphatrane HCl) *[138800-17-6]* **$C_9H_{21}N_4P$.HCl, M 252.7, m 132-136°.** Like the preceding free base it is prepared in different ways — two are described here. A solution of PCl_3 (1.22g, 8.85mmol) in CH_2Cl_2 (5.0ml) is added to a solution of P(NMe) (2.89g, 17.7mmol, toxic see *[1608-26-0]*) in CH_2Cl_2 (5.0ml), then cooled to 5°, and TREN (3.88g, 26.5mmol, see *[4097-89-6]*) in CH_2Cl_2 (25ml) is added during ~15 minutes. The precipitate formed is filtered off, washed with CH_2Cl_2 (25ml) and dried to give the pure ***hydrochloride*** (5.58g, ~100%). Crystals for X-Ray diffraction can be grown from concentrated MeOH solutions. The ***2,8,9-tribenzyl hydrochloride*** can be similarly prepared in 89% yield by using tris-(*N-benzylaminoethyl*)amine in place of TREN. [Laramay & Verkade *Z Anorg Allg Chem* **605** 163 *1991*, DOI:10.1002/zaac.19916050120].
In the **second preparation** tris[2-(methylamino)-ethyl]amine (1.67g, 11.4mmol), see *[65604-89-9]*) in CH_2Cl_2 (20ml) is added with stirring to a mixture of $ClP(NMe_2)_2$ (1.76g, 11.4mmol, TOXIC) and Et_3N (1.5g, 15mmol) in CH_2Cl_2 (30ml) during 5 minutes, then the mixture is stirred at ~25° for 1 hour, the volatiles are evaporated off *in vacuo* to give the ***hydrochloride*** quantitatively. It can be recrystallised from hexane/$CHCl_3$ (82% yield) in colourless crystals. When the hydrochloride salt is treated with $AgBF_4$ in CH_2Cl_2 the ***HBF_4 salt*** is obtained quantitatively. The salts are very difficult to deprotonate (see preceding entry). The X-ray crystal structure shows a short intra-annular bond between the apical N atom and the P atom with a robust P—H bond, the positive charge being on the apical N atom. [Laramay & Verkade *J Am Chem Soc* 112 9421 *1990*, DOI: 10.1021/ja00181a070; Lensink et al. *J Am Chem Soc* 111 3478 *1989*, DOI: 10.1021/ja00191a081.] It has ^{1}H NMR (300MHz, $CDCl_3$, TMS) with δ at 2.61 (d, 9H, $^3J_{PH}$ = 17.4 Hz, CH_3) and 3.03 (dt, 6H, $N_{ax}CH_2$, $^3J_{PH}$ = 11.0 Hz, $^3J_{HH}$ = 6.2 Hz), 3.58 (dt, 6H, $N_{eq}CH_2$, $^3J_{PH}$ = 4.7 Hz, $^3J_{HH}$ = 6.2 Hz), 5.20 (d, 1H, $^1J_{PH}$ = 6.2 Hz); the ^{13}C NMR (75MHz, $CDCl_3$) has δ at 34.4 (d, $^2J_{PC}$ = 17.1 Hz, *C*H_3), 41.3 (d, $^2J_{PC}$ = 6.1 Hz, N_{ax}*C*H_2) and 47.3 (d, $^2J_{PC}$ = 7.3 Hz, N_{eq}*C*H_2); the ^{31}P NMR (122MHz, $CDCl_3$, 85% H_3PO_4) has δ at -10.6 [Lensink et al. *J Am Chem Soc* 111 3478 *1989* DOI: 10.1021/ja00191a081].

Trimethyl vinyl silane *[754-05-2]* **$C_5H_{12}Si$, M 100.2, b 54.4°/744mm, 55.5°/767mm, d_4^{25} 0.6865, n_D^{25} 1.3880.** If the ^{1}H NMR spectrum shows impurities, then dissolve it in Et_2O, wash it with aqueous NH_4Cl solution, dry over $CaCl_2$, filter, evaporate and distil it at atmospheric pressure in an inert atmosphere. It is used as a co-polymer and may polymerise in the presence of free radicals. It is soluble in CH_2Cl_2. [Nagel & Post *J Org Chem* **17** 1379 *1952*, DOI: 10.1021/jo50010a016; *Beilstein* **4** IV 3922.] A useful reagent for preparing trimethylsilylethylsulfoxides, which in the presence of fluoride ions (e.g with TBAF), provide a convenient source of sulfenate anions ($R'SO^-$) that react with RX to form the corresponding sulfoxides (R'SOR) [Foucoin et al. *Synthesis* 1315 *2007*, DOI: 10.1055/s-2007-966017], and in the efficient O-silylation of a variety of alcohols using Rh(I)/HCl catalyst at room temperature [Park & Jun *Org Lett* **9** 4073 *2007*, DOI: 10.1021/ol701909e]

2,4,6-Trinitrobenzenesulfonic acid hydrate (TNBS, picrylsulfonic acid) *[2508-19-2]* **$C_6H_3N_3O_9$, M 293.2, m 180°, λ_{max} 240nm (ε 650 $M^{-1}cm^{-1}$), d^{25} 0.955g/ml. pK_{Est}~ <0.** It is also available as 0.1M and 5%w/v solutions in H_2O. Recrystallise TNBS from 1M HCl, or a mixture of EtOH (50ml), H_2O (30ml) and concentrated HCl (70ml) for 65g of acid, and dry it at 100°. It is a strong oxidising acid, keep away from reducing agents otherwise it can detonate. The ***diethanolamine salt*** had **m 182-183°** [Golumbic *J Org Chem* **11** 518 *1946*, DOI: 10.1021/jo50010a016]. [*Beilstein* **11** III 161.]

Tri(4-nitrophenyl)phosphate *[3871-20-3]* **$C_{18}H_{12}N_3O_{10}P$, M 461.3, m 155-156°, 156°, 156-158°, 157-159°.** This phosphate has been recrystallised from AcOH, dioxane, AcOEt and Me_2CO and dried it in a vacuum over P_2O_5. [Ketelaar & Gersmann *J Am Chem Soc* **72** 5777 *1950*, DOI: 10.1021/ja01168a532; Moffatt & Khorana *J Am Chem Soc* **79** 3741 *1957*, DOI: 10.1021/ja01571a035.]

Tri(*n*-octyl)phosphine (TOP) *[4731-53-7]* **$C_{24}H_{51}P$, M 370.6, m 30°, 48°, b 175°/0.3mm, 194-195°/1mm, 240°/10mm, 291°/50mm, 284-291°/50mm, 442°/760mm, 445°/760mm, 493°/760mm, d^{25} 0.831g/ml, n_D^{25} 1.666, pK_{Est} ~8.2.** Among various syntheses, it is also prepared by reaction of di-*n*-octylmagnesium and PCl_3, and purified by fractional distillation at as high a vacuum as possible. It reacts with with PCl_3 (275°/1hr) to form *n*-octylphosphorous dichloride, a useful synthetic intermediate. **TOP** has basic properties [cf. pKa of *n*-Bu_3P = 8.33, see Henderson & Streuli *J Am Chem Soc* **82** 5791 *1960*, DOI: 10.1021/ja01507a008; cf. compare NH_3, PH_3 with AsH_3: Davies & Addis *J Chem Soc* 1622 *1937*, DOI: 10.1039/JR9370001622]. [For synthesis from $TOPCl_2$ see Horner et al. *Chem Ber* **92** 2088 *1959*, DOI: 10.1002/cber.19590920920; for synthesis from 1-octene and PH_3 see Rauhut et al. *J Org Chem* 26 5138 *1961*, DOI: 10.1021/jo01070a087; Pass et al. *Monatsh Chem* **90** 792 *1959*, DOI: 10.1007/BF00905667; *Beilstein* **4** IV 3438].
It is a useful solvent in extraction (mineral acids) processes, in formulation of flame retardants, in formulating fumigants and used to coat nanomaterials for manufacturing semiconductors. Tri-*n*-octylphosphine (TOP) alone has been used both as solvent and stabiliser, and is required in a simple method which is suitable for the large-scale preparation of high-quality CdS nanorods [for *Trioctylphosphine as Both Solvent and Stabiliser to Synthesise CdS Nanorods* see Chen et al. *Nanoscale Res Lett* **4**(10) 1159 *2009*, DOI: 10.1007/s11671-009-9375-x, PMCID: PMC2893852]. **IRRITATES** skin, eyes lungs and may cause burns — work in an efficient fume cupboard and use protective clothing.

Tri(*n*-octyl)phosphine oxide (TOPO) *[78-50-2]* **$C_{24}H_{51}OP$, M 386.7, m 50-52°, 52-54°, 59.5-60°, b 201-202°/2mm, 411.2°/760mm, pK_a 8.80 in $MeNO_2$.** Mason, McCarty and Peppard [*J Inorg Nuclear Chem* **24** 967 *1962*, DOI: 10.1016/0022-1902(62)80214-0] purified the oxide by stirring a 0.1M solution in *benzene with an equal volume of 6M HCl at 40° in a sealed flask for 48 hours, then washed the *benzene solution successively with water (twice), 5% aqueous Na_2CO_3 (three times) and water (six times). The *benzene and water were then evaporated under reduced pressure at room temperature. Zingaro and White [*J Inorg Nucl Chem* **12** 315 *1960*, DOI: 10.1016/0022-1902(60)80378-8] treated a petroleum ether solution of the oxide with aqueous $KMnO_4$ (to oxidise any phosphinous acids to phosphinic acids), then with sodium oxalate, H_2SO_4 and HCl (to remove any manganese compounds). The petroleum ether solution was slurried with activated alumina (to remove phosphinic acids), filtered, evaporated and the residue was recrystallised from petroleum ether or cyclohexane at -20°. It can also be recrystallised from EtOH. [Prepared in >95% yield by oxidation of TOP with SO_3 in CH_2Cl_2: Olah et al. *J Org Chem* **48** 1670 *1983*, DOI: 10.1021/jo00158a034; *Beilstein* **4** IV 3466.] *Alternatively*, crystallisation can be performed by dissolving TOPO (400g) in dry MeCN (3L) by heating and stirring, filtering, and the colourless clear filtrate is cooled to ~20° overnight, the colourless plates are collected by filtration and dried *in vacuo* for 24 hours (yield 90-95%). $\{^1H\}^{31}P$ NMR (162MHz, toluene-d_6) has δ at 40.1. [Owen et al. *J Am Chem Soc* **130** 12279 *2008*, DOI: 10.1021/ja804414f]. Its applicatons include extraction of carboxylic acids, metals and hydrogen bonding organic compounds [review: Watson & Rickelton *Solvent Extr Ion Exch* **10** 879 *1992*, DOI: 10.1080/07366299208918141]. For preparing CdSe, CdS and CdTe nanomaterials see Chapter 7.

Tri(*neo*-pentyl) phosphate *[14540-59-1]* **$C_{15}H_{33}O_4P$, M 308.4.** Crystallise it from hexane. [See Cherbuliez in *Organo Phosphorus Compounds* (Kosolapoff & Maier eds) Wiley Vol **6** pp 211-577 *1973*.]

Triphenylarsine *[603-32-7]* **$C_{18}H_{15}As$, M 306.2, m 58-61°, 61°, 60-62°, b 360°/atm, 373°/760mm.** Recrystallise Ph_3As from EtOH or aqueous EtOH [Dahlinger et al. *JCS Dalton Trans* 2145 *1986*, DOI: 10.1039/DT9860002145; Boere et al. *J Am Chem Soc* **109** 7781 *1987*, DOI: 10.1021/ja00259a029]. [Shriner & Wolf *Org Synth* Coll Vol **4** 910 *1963*, DOI: 10.15227/orgsyn.030.0095; *Beilstein* **16** H 829, **16** I 431, **16** II 407, **16** III 921, **16** IV 1139.] Useful compound in metal coordination chemistry. **HIGHLY TOXIC.**
Triphenylarsine oxide *[1153-05-5]* **$C_{18}H_{15}AsO$, M 322.2,** has **m 191-193°**, **194-196°** (*anhydrous*)**, b 468°/atm, d 1.45 g/cm^3, pK^{25} 0.99** (from H_o scale in H_2SO_4)**, 2.10** (in H_2O). The anhydrous oxide crystallises from *C_6H_6, whereas the ***monohydrate*** separates from EtOH with **m 118°** (**m 114-117°** was also reported). [*Beilstein* **16** H 846, **16** I 433, **16** II 433, **16** III 1022, **16** IV 1176.] **HIGHLY TOXIC.**

Triphenyl borane (borane triphenyl, triphenyl boron) *[960-71-4]* **$C_{18}H_{15}B$, M 242.1, m 134-140°, 137°, 139-141°, 142-142.5°, 145°, 147.5-148°, 151°, b 203°/15mm.** Recrystallise the borane three times from Et_2O or *C_6H_6 under N_2 and dry it at 130°. It can be distilled in a high vacuum at 300-350° and has been distilled (**b 195-215°/~15mm**) in vacuum using a bath temperature of 240-330°. N_2 is introduced into the apparatus before dismantling. It forms complexes with amines. [Nielsen et al. *Chemistry and Industry* 1069 *1957*, Wittig et al. *Justus Liebigs Ann Chem* **563** 110 *1949*, DOI: 10.1002/jlac.19495630113; Bent & Dorfman *J Am Chem Soc* **57** 1259 *1935*, DOI: 10.1021/ja01310a025; *Beilstein* **16** IV 1623.]

Triphenyl phosphate *[115-86-6]* **$C_{18}H_{15}O_4P$, M 326.3, m 49.5-50°, b 245°/11mm, 370°/atm, d_4^{25} 1.2055 g/cm^3.** Crystallise the phosphate from EtOH or petroleum ether (b 60-80°)/EtOH. [Cox & Westheimer *J Am Chem Soc* **80** 5441 *1958*, DOI: 10.1021/ja01553a031; Krishnakumar & Sharma *Synthesis* 558 *1983*, DOI: 10.1055/s-1983-30424; Cherbuliez in *Organo Phosphorus Compounds* (Kosolapoff & Maier eds) Wiley Vol **6** pp 211-577 *1973*, *Beilstein* **6** III 658, **6** IV 720.] It has been used as an effective ligand with phase transfer catalysts [Nakoji et al. *J Org Chem* **67** 7418 *2002*, DOI: 10.1021/jo0260645]. Also useful as a plastisier and a fire retardant.

Triphenylphosphine *[603-35-0]* **$C_{18}H_{15}P$, M 262.3, m 77-78°, 79°, 79-81°, 80.5°, 80-81°, b >360°(377°, in inert gas), d_4^{25} 1.194, d_4^{80} 1.075 (liq), pK^{25} 2.73.** The phosphine crystallises from hexane, MeOH, diethyl ether, CH_2Cl_2/hexane or 95% EtOH. Dry it at 65°/<1mm over $CaSO_4$ or P_2O_5. Chromatograph it through alumina using (4:1) *benzene/$CHCl_3$ as eluent. [Blau & Espenson et al. *J Am Chem Soc* **108** 1962 *1986*, DOI: 10.1021/ja00268a039; Buchanan et al. *J Am Chem Soc* **108** 1537 *1986*, DOI: 10.1021/ja00267a025; Randolph & Wrighton *J Am Chem Soc* **108** 3366 *1986*, DOI: 10.1021/ja00272a035; Asali et al. *J Am Chem Soc* **109** 5386 *1987*, DOI: 10.1021/ja00252a014.] It has also been crystallised twice from petroleum ether and 5 times from Et_2O/EtOH to give crystals with **m 80.5°**. *Alternatively*, dissolve it in concentrated HCl, and upon dilution with H_2O it separates because it is weakly basic, it is then crystallised from EtOH/Et_2O. It recrystallises unchanged from AcOH. [Forward et al. *J Chem Soc* Suppl. p121 *1949*, Muller et al. *J Am Chem Soc* **78** 3557 *1956*, DOI: 10.1021/ja01596a002.] ***3Ph$_3$P.4HCl*** crystallises out when HCl gas is bubbled through an Et_2O solution, it has **m 70-73°**, but recrystallises very slowly and is deliquescent. ***Ph$_3$P.HBr*** *[6399-81-1]* has **m 196°** (**dec**). The ***hydriodide***, made by adding Ph_3P to hydriodic acid, is not hygroscopic and decomposes at **~100°**. The ***chlorate* (1:1) *salt*** has **m 165-167°**, but decomposes slowly at **100°**. All salts hydrolyse in H_2O to give Ph_3P [IR, UV: Sheldon & Tyree *J Am Chem Soc* **80** 2117 *1958,* DOI: 10.1021/ja01542a024; pK: Henderson & Streuli *J Am Chem Soc* **82** 5791 *1960*, DOI: 10.1021/ja01507a008; Kosolapoff, *Organophosphorus Compounds*, Wiley *1950*]. [*Beilstein* **16** IV 951.] § It is also available commercially on a support of polystyrene cross-linked with 2% divinylbenzene as the free base *[39319-11-4]*, loading of ~3.2 nmol/g, 100-200 mesh], and as the ***hydrobromide*** [loading 2.5-3.0 mmol Br, 200-400 mesh].

Triphenylphosphine dibromide *[1034-39-5]* **$C_{18}H_{15}Br_2P$, M 422.1,** has **m 235°, 245-255°(dec).** The dibromide recrystallises from MeCN/Et_2O. Although it has been recrystallised from EtOH, this is not recommended as it converts alcohols to alkyl bromides since it has brominating power. It deteriorates on keeping, and it is best to prepare it afresh. [Anderson & Freenor *J Am Chem Soc* **86** 5037 *1964*, DOI: 10.1021/ja01076a084; Horner et al. *Justus Liebigs Ann Chem* **626** 26 *1959*, DOI: 10.1002/jlac.19596260104; Fieser **1** 1247; *Beilstein* **16** III 864.] The ***diiodide*** *[6396-07-2]* $C_{18}H_{15}I_2P$, M 516.1, has **m** 210-220°. [*Beilstein* **16** IV 1013.]

Triphenylphosphine oxide *[791-28-6]* **$C_{18}H_{15}OP$, M 278.3,** has **m 152.0°, 156-157°, pK_{Est} ~ -2.10 (aqueous H_2SO_4), pK^{25} 2.9 (in $MeNO_2$).** It crystallises from absolute EtOH and is dried *in vacuo*. The ***gold chloride complex*** has **m 177.5-178.5°**. [Addison & Sheldon *J Chem Soc* 2705 *1956*, DOI: 10.1039/JR9560002705; Cox & Westheimer *J Am Chem Soc* **80** 5441 *1958*, DOI: 10.1021/ja01553a031; *Beilstein* **16** III 864, **16** 1011.]

Triphenyl phosphite *[101-02-0]* **$C_{18}H_{15}O_3P$, M 310.3, m 16-20°, 21-23°, b 181-189°/1mm, 183-184°/1mm, d_4^{20} 1.183.** Its ethereal solution is washed succesively with aqueous 5% NaOH, distilled water and saturated aqueous NaCl, then dried with Na_2SO_4 and distilled under vacuum after evaporating the diethyl ether. [Walsh *J Am Chem Soc* **81** 3023 *1959*, DOI: 10.1021/ja01521a028; Verkade & Coskren in *Organo Phosphorus Compounds* (Kosolapoff & Maier eds) Wiley Vol 6 pp 211-577 *1973*, Fieser **1** 1249; *Beilstein* **6** IV 695.] It has been used as an effective ligand with phase transfer catalysts [Nakoji et al. *J Org Chem* **67** 7418 *2002*, DOI: 10.1021/jo0260645].

Triphenylphosphorylidene acetaldehyde (formylmethylenetriphenylphosphorane) *[2136-75-6]* **$C_{20}H_{17}OP$, M 304.3, m 185-187°, 186-187°(dec).** Recrystallise it from Me_2CO, or dissolve it in $*C_6H_6$, wash with N NaOH, dry ($MgSO_4$), evaporate, and crystallise the residue from Me_2CO. It can be prepared from its precursor, ***formylmethyltriphenylphosphonium chloride*** (which crystallises from $CHCl_3$/EtOAc), by treatment with Et_3N and extraction with $*C_6H_6$. [Tripett & Walker *J Chem Soc* 1266 *1961*, DOI: 10.1039/JR9610001266] A useful Wittig reagent for the two-carbon homologation of aldehydes and ketones to form α,β-unsaturated carbonyl compounds [Wang & Pagenkopf *Org lett* **9** 3703 *2007*, DOI: 10.1021/ol701797e; Nagamitsu et al. *J Org Chem* **72** 2744 *2007*, DOI: 10.1021/jo062089i].

Triphenylphosphorylidene acetonitrile **(cyanomethylenetriphenylphosphorane)** *[16640-68-9]* **$C_{20}H_{16}NP$, M 301.3,** has **m 189-195°, 195-196°.** The phosphorane is prepared from (cyanomethyl)triphenylphosphonium chloride (**m 278-279°**, ν_{max} at 2090 cm^{-1} for –CN, from $ClCH_2CN$ and Ph_3P in MeCN) by treatment with dilute NaOH in H_2O, followed by isolation and recrystallisation from EtOAc. It has ν_{max} at 2174 cm^{-1} for –C=C–CN. Like the preceding phosphorane it is a useful Wittig reagent for the two-carbon homologation of aldehydes and some ketones to form α,β-unsaturated nitriles [Trippett & Walker *J Chem Soc* 3874 *1959*, DOI: 10.1039/JR9590003874; cf. Ohno et al. *J Org Chem* **72** 4378 *2007*, DOI: 10.1021/jo0700528].

(Triphenylphosphoranylidene)ketene [Bestmann ylide (triphenylphosphoranylidene)ethenone, ketenylidene(triphenyl)phosphorane) *[15596-07-3]* **$C_{20}H_{15}OP$, M 302.3, m 167-173°, 173°.** This versatile reagent is prepared in a dry inert atmosphere (N_2 or argon) by first mixing $NaNH_2$ (19.5g, 0.5mole) in toluene (1.3L, dried by passage through alumina) and bis(trimethylsilyl)amine (81g, 105ml, 0.5mol, toxic and corrosive), and heated (70-80° bath temperature) under a reflux condenser until a clear and colourless solution of sodium hexamethyldisilazanide (see hexamethyl disilazane sodium salt *[1070-89-9]*) is obtained, and evolution of NH_3 ceased (2-4 hours). ***Note*** that repeated purging with argon or N_2 reduces the reaction time. The condenser is removed and under argon or N_2, (methoxycarbonylmethylene)triphenylphosphorane (167g, 0.5mol, *[2605-67-6]*) is added in large portions, and the mixture is again heated (70-80° bath temperature) with stirring for 24-30 hours until the colour of the solution assumes a bright yellow hue [and the IR band of a film of aliquots between KBr plates, with ν_{max} at 1616 cm^{-1} of the starting ylide has disappeared, and is replaced by a strong band of the product with ν_{max} at 2090 cm^{-1} of constant intensity, indicating completion of reaction]. While still hot, and under argon or N_2, the mixture is filtered rapidly [through a 20/40 standard taper vacuum filtration adapter and a 350ml fritted funnel of coarse porosity open to the atmosphere through a 2 cm thick layer of basic Al_2O_3 (III) and a 1cm Celite pad on top, and occasional scraping the top of the pad] into a 2L 24/40 single necked flask. The filtration requires 30-60 minutes and the funnel temperature should be kept between 30-50° to avoid crystallisation. The filtrate is flushed with inert gas and evaporated (rotavap) to dryness. The residue is recrystallised from hot dry toluene (1g/5ml) followed by cooling at -20° overnight. While the mixture is cold, the solids are filtered off, washed with cold toluene (3 x 100ml at 0°). The combined filtrates are evaporated in the same way at low temperature as before to give a second crop. The combined crops are dried to constant weight at high vacuum (0.01mm) to give pure ***triphenylphosphoranylidene)ketene*** (106.8-114.9g, 74-76% and ~99.97% pure by ^1H NMR) as a pale yellow, flaky powder with **m 173°**. It is remarkably stable, it can be stored at ~25° under argon or N_2 for months and can be handled at ~25° without obvious deterioration. It has IR (KBr) with ν_{max} at 2090 (s), 1625 (m), 1436 (m) and 1110 (m) cm^{-1}; the ^1H NMR (400MHz, $CDCl_3$) has δ at 7.44-7.54 (m, 6H), 7.55-7.63 (m, 3H) and 7.64-7.77 (m, 6H); the ^{13}C NMR (100MHz, $CDCl_3$) has δ at -10.5 (d, $^3J_{P\text{-}C}$ = 185.4 Hz, Cα), 128.8 (d, $^3J_{P\text{-}C}$ = 12.9 Hz, C-*ortho*), 129.6 (d, $^1J_{P\text{-}C}$ = 98.5 Hz, C-*ipso*), 132.2 (s, C-*para*), 132.3 (s, C-*meta*) and 145.6 (d, $^2J_{P\text{-}C}$ = 63.0 Hz, Cβ); and the ^{31}P NMR (162MHz, $CDCl_3$) has δ at 6.0. Possible detectable impurities are starting ester ylide and toluene detected by ^1H NMR spectroscopy which have singlets at δ 3.60 and 2.36 respectively. It is a nucleophilic-only C_2-building block that reacts with a range of electrophiles in a variety of ways. It also undergoes cycloaddition reactions at the polar P-Cα bond as well as at the Cα=Cβ double bond, and multi-component and domino reactions [Schobert *Org Synth* **82** 140 *2005*, DOI: 10.15227/orgsyn.082.0140.]

Triphenyl silane *[789-25-3]* **$C_{18}H_{16}Si$, M 260.4, m 43-45°, 45°, b 148-151°/1mm, 152°/2mm.** Purify it by recrystallisation from MeOH. [Gilman & Zuech *J Am Chem Soc* **81** 5925 *1959*, DOI: 10.1021/ja01531a021; Westermark *Acta Chem Scand* **9** 947 *1955*, DOI: 10.3891/acta.chem.scand.09-0947; IR: Kaplan *J Am Chem Soc* **76** 5880 *1954*, DOI: 10.1021/ja01651a105; *Beilstein* **16** II 605, **16** III 1199, **16** IV 1369.]

Triphenylsilanol (hydroxytriphenylsilane) *[791-31-1]* **$C_{28}H_{16}OSi$, M 276.4, m 150-153°, 151-153°, 154-155°, 156°, b 389°/760mm.** It is purified by dissolving in petroleum ether, passing through an Al_2O_3 column, eluting thoroughly with CCl_4 to remove impurities and then eluting the silanol with MeOH. Evaporation gives crystals with **m 153-155°**. It can be recrystallised from petroleum ether, CCl_4 or from *benzene or Et_2O/petroleum ether (1:1). It has also been recrystallised by partial freezing from the melt to constant melting point. [George & Gilman *J Am Chem Soc* **81** 3288 *1959*, DOI: 10.1021/ja01522a034; IR: Tatlock & Rochow *J Org Chem* **17** 1555 *1952*, DOI: 10.1021/jo50012a001 and Richards & Thompson *J Chem Soc* 124 *1949*, DOI: 10.1039/JR9490000124; *Beilstein* **16** IV 1480.]

Triphenyl vinyl silane *[18666-68-7]* **$C_{18}H_{15}Si$, M 286.5, m 58-59°, 57-59.5°, 67-68°, 69°, 68-71°, b 190-210°/3mm.** The vinyl-silane has been recrystallised from EtOH, 95% EtOH, EtOH/*C_6H_6, petroleum ether (b 30-60°) and Et_2O, and has been distilled under reduced pressure. [Cason & Brooks *J Am Chem Soc* **74** 4582 *1952*, DOI: 10.1021/ja01138a039; Nagel & Post *J Org Chem* **17** 1379 *1952*, DOI: 10.1021/jo50010a016; *Beilstein* **16** IV 1371.]

Tri(*n*-propyl) borate *[688-71-1]* **$C_9H_{21}BO_3$, M 188.1, b 64°/9mm, 175-177°/atm, d $_4^{20}$ 0.857, n $_D^{20}$ 1.395.** Dry the ester over sodium and then distil it, preferably in a vacuum. (cf. tributyl borate.) [Charnley et al. *J Chem Soc* 2288 *1952*, DOI: 10.1039/JR9520002288; *Beilstein* **1** IV 1436.]

Tri(iso-propyl) borate* [(*iso*-PrO)$_3$B, boric acid tri-*iso*-propyl ester, Boron *iso*-propoxide]** *[5419-55-6]* **$C_9H_{21}BO_3$, M 188.1,** has **m -59°, b 75°/76mm, 90°/120mm, 139-141°/760mm, d $_4^{25}$ 0.815, n $_D^{20}$ 1.376.** The borate ester is prepared in 85% yield from *iso*-propanol (250ml) and $NaBH_4$ (6.84g) followed by dropwise addition of AcOH (0.18g) over a period of 11 minutes, and then refluxing for 4 hours (fume cupboard and a 'Dry-ice' condenser as 16.15L of H_2 are released, CARE due to its flammability). Then fractionate the ***ester through a Widmer column. [Brown et al. *J Am Chem Soc* **78** 3613 *1956*, DOI: 10.1021/ja01596a015.] It is moisture sensitive. The ester is a good reagent for borylation, e.g. *ortho*-borylating 1-substituted naphthalenes, by reacting with 1-halo- or cyano- naphthalenes (after treatment with LiTMP) to form 2-boryl esters which are later used in Pd-catalysed cross-coupling reactions [Lysén et al. *Synthesis* 3478 *2006*, DOI: 10.1055/s-2006-950239]. [*Beilstein* **1** H 363, **1** II 382, **1** III 1468, **1** IV 1488.]

Tri(quinol-8-yl) phosphate *[52429-99-9]* **$C_{27}H_{18}N_3O_4P$, M 479.4, m 193-197°, 202-203°, 638°/760mm.** Purify the phosphate by recrystallisation from dimethylformamide. The purity is checked by paper chromatography, R_F 0.90 [*i*-PrOH/saturated $(NH_4)_2SO_4/H_2O$, 2:79:19 as eluent], its IR (KBr) has ν_{max} at 1620, 1570 (C=C, C=N) and 1253 (P=O) cm¹. [Takaku et al. *Bull Chem Soc Jpn* **47** 779 *1974*, DOI: 10.1246/bcsj.47.779.]

Tri-*o*-tolylphosphine *[6163-58-2, 1038-95-5]* **$C_{21}H_{21}P$, M 304.4, m 123-125°, 125-126°, 127-129°, 129-130°, pK_{Est} ~1.0.** Like PPh_3, it crystallises from hexane, MeOH, diethyl ether, CH_2Cl_2/hexane or 95% EtOH. Dry it at 65°/<1mm over $CaSO_4$ or P_2O_5. Purify further by chromatography through alumina using (4:1) *benzene/$CHCl_3$ as eluent. Of the phosphine ligands studied, P(*o*-Tol)$_3$ (6 mol%) was the best in the $Ru_3(CO)_{12}$ (2 mol%) catalysed *N*-alkylation of primary amines and secondary alcohols (e.g. hexylamine with 1-phenylethanol to give *N*-octyl 1-phenethylamine) in high yields at 90-110° [Tillack et al *Tetrahedron Lett* **47** 8881 *2006*, DOI: 10.1016/j.tetlet.2006.10.042]. The Heck reaction between aryl halides and *n*-butyl acrylates to provide substituted styrenes in ~80 to >90% yields at ~120° is catalysed by $Pd(OAc)_2$ (2 mol%) and P(*o*-Tol)$_3$ (8 mol%) without extensive P-C bond cleavage [Herrmann et al. *J Mol Catal A: Chem* **103** 133 *1995*, DOI: 10.1016/1381-1169(95)00140-9]. [*Beilstein* **16** III 835.]

Tris(2-biphenylyl) phosphate *[132-28-5]* **$C_{36}H_{27}O_4P$, M 554.6, m 115.5-117.5°.** Crystallise it from MeOH containing a little acetone. (cf. triphenyl phosphate.)

Tris(2,4-di-tert-butylphenyl)phosphite *[31570-04-4]* **$C_{42}H_{63}O_3P$, M 646.9,** has **m 181-184°, 187°.** If the ester is suspect, e.g. partly hydrolysed, dissolve it in Et_2O, wash the solution successively with aqueous 5% NaOH, H_2O and saturated aqueous NaCl, then shake with charcoal, filter, dry with Na_2SO_4, filter again, evaporate and add petroleum ether when the volume has decreased considerably to crystallise the ester. [Verkade & Coskren in *Organophosphorus Compounds* (Kosolapoff & Maier eds) Wiley Vol 6 pp 211-577 *1973*.] It is used as a processing stabiliser for polymers.

Tris(1,2-dioxyphenyl)cyclotriphosphazene {trispiro[1,3,5,2,4,6-triazatriphosphorine]-2,2':-2,4":2,6"'-tris (1,3,2)benzodioxaphosphole} *[311-03-5]* **$C_{18}H_{12}O_6N_3P_3$, M 459.0, m 244-245°, 245°, 245-246°.** Recrystallise this phosphazine from *C_6H_6 or chlorobenzene, then triple sublime it (175°/0.1mm, 200°/0.1mm, 230°/0.05mm). Its UV has λ_{max} nm (log ε) at 276 (3.72), 271 (3.79) 266sh (3.68) and 209 (4.38) in MeCN. Its IR has ν_{max} at 1270 (O-Ph), 1220 (P=N), 835 (P-O-Ph) and 745 (Ph) cm^{-1}. [Alcock *J Am Chem Soc* **86** 2591 *1964*, DOI: 10.1021/ja01067a015; for cyclophosphazene clathrates see Alcock et al. *J Am Chem Soc* **98** 5120 *1976*, DOI: 10.1021/ja00433a012; for mobility in a solid benzene-cyclophospazene inclusion compound see Meirovitch et al. *J Phys Chem* **88** *1522 1984*, DOI: 10.1021/j150652a016.]

Tris(2-ethylhexyl) phosphate (TEHP, tri-isooctylphosphate, 'trioctyl' phosphate. *[78-42-2, 25103-23-5]* **$C_{24}H_{51}O_4P$, M 434.6, m -75°, -74°, b 186°/1mm, 215°/4mm, 219°/5mm, 450°/760mm, d^{25} 0.92042, n_D^{20} 1.44464.** TEHP, in an equal volume of diethyl ether, is shaken with aqueous 5% HCl, and the organic phase is filtered to remove traces of pyridine (used as a solvent during manufacture) as its hydrochloride. This layer is shaken with aqueous Na_2CO_3, then water, and the ether is distilled off at room temperature. The ester is then filtered, dried for 12 hours at 100°/15mm, and again filtered, then shaken intermittently for 2 days with activated alumina (100g/L). It is decanted through a fine sintered-glass disc (with exclusion of moisture), and distilled under vacuum. [French & Muggleton *J Chem Soc* 5064 *1957*, DOI: 10.1039/JR9570005064.] *Benzene can be used as a solvent (to give 0.4M solution) instead of ether. Its IR has ν_{max} at 1702, 1701, 481 and 478cm^{-1} [Bellamy & Becker *J Chem Soc* 475 *1952*, DOI: 10.1039/JR9520000475]. The ***uranyl nitrate*** salt is purified by crystallisation from hexane [Siddall & Dukes *J Am Chem Soc* **81** 790 *1959*, DOI: 10.1021/ja01513a007; Siddall *J Am Chem Soc* **81** 4176 *1959*, DOI: 10.1021/ja01525a015]. [*Beilstein* **1** IV 1786.]

Tris(hydroxymethyl)phosphine (phosphinidynetrimethanol) *[2767-80-8]* **$C_3H_9O_3P$, M 124.1, m 48-56°, 55°, b 111-113°/2.5mm, 311.7°/760mm. n_D^{20} 1.5497, pK 5.5 (half neutralisation point, glass electrode).** It is obtained in two ways by neutralising precisely with THPC {***tetrakis(hydroxylmethyl)phosphonium chloride***, *[124-64-1]*}. In the *first* method, NaOH (1.6g, 40mmol) in H_2O (25ml) is added rapidly to THPC (7.6g, 40mmol, see above *[124-64-1]*) in H_2O (50ml) under N_2 at room temperature in a closed system connected to a glass buret. No evolution of gas should be observed on stirring for 20 hours indicating that the stoichiometric amount of alkali has been added. Any liberation of gas (H_2) would indicate that excess of alkali had been added which would liberate H_2 with the formation of the corresponding phosphine oxide (see next entry, and Hoffman *J Am Chem Soc* **52** 2995 *1930*, DOI: 10.1021/ja01370a065). The solvent is then removed *in vacuo* at 50-60°, EtOH (under N_2) is added, the solid NaCl is filtered off, and the EtOH is removed *in vacuo* (45°) to give the ***free base*** (4.8g, 97%) as a clear viscous liquid which can be distilled at high vacuum in an atmosphere of N_2 (N_2 bleed). An IR (film) should indicate the absence of P=O and the presence of primary OH and P-CH_2 bands [Grayson *J Am Chem Soc* **85** 79 *1963*, DOI: 10.1021/ja00884a016].
In the *second* method, under N_2 flushing and stirring, a solution of THPC (25g, 131mmol) in distilled H_2O (100ml), into which is immersed a glass pH electrode, is treated with ~ 150ml (0.21 equivalents) of 20-50 mesh Dowex-1 x 8 resin (in the OH^- form) during 45 minutes until the pH was ~8.3-8.5. The resin is filtered off, washed with H_2O, the combined aqueous solutions are evaporated (rotavap) at 65-70°, then under high vacuum for 30 minutes, then further at -30° to give the ***free base*** as a viscous liquid which formed a waxy solid. Its IR (film between NaCl plates) should have no bands at ν_{max} 1052 (of THPC), or 1043 or 1135 (for P=O), but intense broad absorption at 1010 cm^{-1}. The ^1H NMR (60MHz, D_2O, internal TMS, or DSS at 0) has δ for CH_2 at 4.15 (J_{PCH} = 5.5Hz, $J_{^{13}CH}$ = ~ 148Hz); and the ^{31}P NMR (40MHz, D_2O, external 85% H_3PO_4) has δ at -25.8. [Ellzey et al. *J Org Chem* **37** 3453 *1972*, DOI: 10.1021/jo00795a015.] With *n*-butyl iodide it formed ***n-butyl phosphonium iodide*** which gave, on treatment with sodium tetraphenylboron, the ***n-butyl tris(hydroxymethyl)phosphonium tetraphenylboron complex***, **m 145-146°(dec)** after drying and recrystallising from Me_2CO/*C_6H_6; and the ***methiodide*** gave with Ph_4BNa, the ***methyl tris(hydroxymethyl)phosphonium tetraphenylboron complex***, **m 170-171°(dec)** after drying and recrystallising from Me_2CO/*C_6H_6 [Grayson *J Am Chem Soc* **85** 79 *1963*, DOI: 10.1021/ja00884a016.]
Tris(hydroxymethyl)phosphine oxide *[1067-12-5]* **$C_3H_9O_4P$, M 137.1,** has **m 50-52°, 54-55° (69° and 70° have also been reported).** The oxide is prepared by slowly adding about 130% excess (over an equimolar amount) of 20-50 mesh Dowex-1 x 8 resin (in the OH^- form) to an aqueous solution of tris(hydroxymethyl)phosphine (25.0g, see preceding entry) which led to vigorous evolution of H_2. After standing overnight the resin is filtered off, and the filtrate is evaporated (rotavap, vacuum) to give the ***oxide***

(16.1g, 88%) which is recrystallised from absolute EtOH to yield hygroscopic crystals (11.9g). Store in a dry atmosphere. The IR has strong bands at ν_{max} 1043 and 1134 cm^{-1}; the ^1H NMR (60MHz, D_2O, internal TMS, or DSS at 0) has δ for CH_2 at 4.20 (J_{PCH} = 3.1Hz, $J_{^{13}CH}$ = ~ 146Hz); and the ^{31}P NMR (40MHz, D_2O, external 85% H_3PO_4) has δ at -48.7. [Ellzey et al. *J Org Chem* **37** 3453 *1972*, DOI: 10.1021/jo00795a015; Anteunis et al. *Bull Soc Chim Belg* **74** 622 *1965*, DOI: 10.1002/bscb.19650741114.] The ***tribenzoate***, prepared by boiling THPC with excess of aqueous NaOH solution until no further evolution of H_2 occurred followed by treatment with a slight excess of PhCOCl, gave fine needles **m 111°** upon recrystallisation from MeOH [Hoffman *J Am Chem Soc* **43** 1684 *1921*, DOI: 10.1021/ja01440a035].

Trisodium 8-hydroxy-1,3,6-pyrenetrisulfonate (Pyranine Solvent Green 7) *[6358-69-6]* **$C_{16}H_7Na_3O_{10}S_3$, M 523.4, m >300(dec), CI 59040, λ_{max} 403nm.** Purify the salt by chromatography through an alumina column, and elute with *n*-propanol/water (3:1, v/v). Recrystallise it from aqueous acetone (5:95, v/v) using decolorising charcoal. [*Beilstein* **1** III 565.] **IRRITANT.**

Trisodium 1,3,6-naphthalenetrisulfonate *[5182-30-9]* **$C_{10}H_5Na_3O_9S_3$, M 434.3.** The ***free acid*** is obtained by passing the salt through an ion-exchange column and converting it to the lanthanum salt by treatment with La_2O_3. This salt is crystallised twice from hot water. [The much lower solubility of $La_2(SO_4)_3$ and its retrograde temperature dependence allows a good separation from sulfate impurity]. The lanthanum salt is then passed through an appropriate ion-exchange column to obtain the free acid, the sodium or potassium salt. (The sodium salt is ***hygroscopic***.) [Atkinson et al. *J Am Chem Soc* **83** 1570 *1961*, DOI: 10.1021/ja01468a008.] It can also be recrystallised from aqueous acetone [Okahata et al. *J Am Chem Soc* **108** 2863 *1986*, DOI: 10.1021/ja00271a013].

Tris(2,2,2-trifluoroethyl) phosphite *[370-69-4]* **$C_6H_6F_9O_3P$, M 328.1, b 130-131°/743mm, 128.8±40°/760mm, d_4^{20} 1.487, n_D^{20} 1.324**. Fractionate the phosphite through a 10inch Helipak column [Krogh et al. *J Org Chem* **19** 1124 *1954*, DOI: 10.1021/jo01372a018]. [*Beilstein* **1** IV 1371.]

Tris(trimethylsilyl)silane (TTMSS) *[1873-77-4]* **$C_3H_{10}Si_4$, M 248.7, b 73°/5mm, 82-84°/12mm, d_4^{20} 0.808, n_D^{20} 1.4900.** Purify it by fractional distillation and taking the middle cut. Store it under N_2 or argon as it is **PYROPHORIC** and is an **IRRITANT**. [Chatgilialoglu et al. *J Org Chem* **53** 3641 *1988*, DOI: 10.1021/jo00250a051; Chatgilialoglu *Acc Chem Res* **25** 188 *1992*, DOI: 10.1021/ar00016a003; NMR: Gilman et al. *J Organomet Chem* **4** 163 *1965*, DOI: 10.1016/S0022-328X(00)84384-3; Dickhaut & Giese *Org Synth* 141 *2003*, DOI: 10.1002/0471264180.os070.19] It is a radical-based reducing agent as in the dehydrohalogenation reactions of halides to the respective hydrocarbons [Balestri et al. *J Org Chem* **56** *678 1991,* DOI: 10.1002/0471264180.os070.19; for a review see Boxer et al. *Aldrichimica Acta* **42** 3 *2009*].

Tri(*p*-tolyl) phosphate *[78-32-0, 20756-92-7, 1330-78-5 (isomeric tritolyl phosphate mixture)]* **$C_{21}H_{21}O_4P$, M 368.4, m 77°, 74-78°, b 232-234°/atm, d^{25} 1.16484, n_D^{20} 1.56703.** Dry the ester with $CaCl_2$, percolate it through a column of alumina, then distil it under a vacuum. *Alternatively*, pass it through a packed column of alumina at 150°, with a counter-current stream of nitrogen, under reduced pressure, to remove residual traces of volatile impurities. It also crystallises from petroleum ether (b 60-80°). [Cherbuliez in *Organic Phosphorus Compounds* (Kosolapoff & Maier eds) Wiley-Interscience Vol **6** pp 454-457 *1973*.]

Tropaeolin 00 {4-[(4-anilinophenyl)azo]benzenesulfonic acid Na salt} *[554-73-4]* **$C_{18}H_{14}N_3NaO_3S$, M 375.4, $pK_{Est(1)}$~ 2.3, $pK_{Est(2)}$~ 5.8, $pK_{Est(3)}$~ 10.3.** Recrystallise it twice from water [Kolthoff & Gus *J Am Chem Soc* **60** 2516 *1938*, DOI: 10.1021/ja01277a068]. It is an indicator which is red at pH 1.4 and orange-yellow at pH 3.2. [*Beilstein* **16** II 171.]

Vinyl chlorosilane *[75-94-5]* **$C_2H_3Cl_3Si_4$, M 161.5, m -95°, b 17.7°/46.3mm, 82.9°/599.4mm, 92°/742mm, 91-91.5°/atm, d_4^{20} 0.1.2717, n_D^{20} 1.435.** Fractionally distil the chlorosilane at atmospheric pressure. It is water sensitive and is stored in the dark and it is likely to polymerise. [Müller & Schnurrbusch *Chem Ber* **91** 1805 *1958*, DOI: 10.1002/cber.19580910903; Munkelt & Müller *Chem Be r* **92** 1012 *1959*, DOI: 10.1002/cber.19590920503; Polarography: Abrahamson & Reynolds *Anal Chem* **24** 1827 *1952*,

DOI: 10.1021/ac60071a033; *Beilstein* **4** IV 4258.]

3-Vinylphenylboronic acid ([3-ethenylphenyl]-dihydroxyborane) *[15016-43-0]* **$C_8H_9BO_2$, M148.0, m 141-147°, 145-160°, $pK_{Est(1)}$ ~8.8.** This binder for paper or glass crystallises in white plates from H_2O (**m 144-145°**), and its IR has ν_{max} at 919 and 995 ($CH_2CH=CH_2$), 1350 (B-O) and 3220 (OH) cm^{-1}. The ***dibromo derivative*** crystallises in white needles from H_2O with **m 196-197.5°**. [Dale & Rush *J Org Chem* **27** 2598 *1962*, DOI: 10.1021/jo01054a071; *Beilstein* **16** III 1279, **16** IV 1677.]

Vinylphosphonic acid *[1746-03-8]* **$C_2H_5O_3P$, M 108.0, m 41-45°, d^{25} 1.389, pK_1^{20} 3.48, pK_2^{20} 8.54 (50% EtOH).** This fireproofing agent, and ingredient for making polymers, is obtained as a syrup on hydrolysing vinylphosphonyl dichloride with cold H_2O and solidifies on prolonged drying over P_2O_5/KOH. When distilled at 235-240°/0.0006mm, it gives the ***anhydride*** (d_4^{20} 1.304, n_D^{20} 1.5874) [Kabachnik & Medvedi *Izvest Akad Nauk SSSR, Ser Khim* 868 *1953*, *Chem Abstr* **54** 10834 *1960*]. It is best kept as the ***sodium salt*** (**m 350°**) which precipitates when a solution of EtOH containing NaOEt (from 2g of Na) is added to vinylphosphonic acid (3.2g), and is recrystallised from EtOH (5.1g, quantitative). The ***p-anisidinium salt*** forms mauve prisms **m 250°** (from EtOH/Et_2O). The ***dimethyl ester***, *[4645-32-3]* **M** 136.1, **d_4^{20}** 1.1405, **n_D^{20}** 1.4330, has **b 72.5°/10mm** and **197-202°/760mm**. [Kabachnik et al. *J Gen Chem USSR* (Engl Trans) **33** 375 *1963*, Svara et al. *Ullmann's Encyclopedia of Industrial Chemistry*, *2008 on line*, Wiley-VCH, DOI: 10.1002/14356007.a19_545.pub2; *Beilstein* **4** IV 3560.]

Xylenol Orange **{3*H*-2,1-benzoxathiol-3-ylidene-bis-[(6-hydroxy-5-methyl-*m*-phenylene)-methyl-nitrilo]-tetraacetic acid, S,S-dioxide}** *[1611-35-4]* **$C_{31}H_{32}N_2O_{13}S$, M 672.6, m 210°(dec), ε_{578} 6.09 x 10^4 (pH 14), ε_{435} 2.62 x 10^4 (pH 3.1), pK_1 -1.74, pK_2 -1.09 (aqueous H_2SO_4-HNO_3), pK_3 2.58, pK_4 3.23, pK_5 6.46, pK_6 10.46, pK_7 12.28.** It is generally contaminated with starting material (cresol red) and semi-xylenol orange. Purify it by ion-exchange chromatography using DEAE-cellulose, eluting with 0.1M NaCl solution, which will give the sodium salt *[3618-43-7]*, Cresol Red, semi-xylenol orange and iminodiacetic acid bands elute first. This method will give the ***sodium salt*** *[3618-43-7]* **$C_{31}H_{28}N_2Na_4O_{13}S$, m 195°(dec)**, of the dye. To obtain the ***free acid***, dissolve the salt in H_2O and acidify it with AcOH. Filter it off, wash it with H_2O and dry it first in air and then in a vacuum desiccator over P_2O_5 in the dark [Sato et al. *Anal Chim Acta* **94** 217 *1977*, DOI:10.1016/S0003-2670(01)83654-0]. Useful indicator for metal ion titrations, also as a metallochromic ligand employed in chelation ion chromatography of trace metal ions [Paull & Haddad *Trends Analyt Chem* **18** 107 *1999*, DOI:10.1016/S0165-9936(98)00104-6; Gay et al. *Analyt Biochem* **273** 142 *1999*, DOI: 10.1006/abio.1999.4207]. [*Beilstein* **19** II 111, **19** III/IV 1135, **19/3** V 461.]

Zinc diethyldithiocarbamate *[14324-55-1]* **$C_{10}H_{20}N_2S_4Zn$, M 361.9, m 172-183°, 178-181°, d 1.462, pK^{25} 3.04 (for $Et_2NCS_2^-$).** Crystallise this herbicide several times from hot toluene or from hot $CHCl_3$ by addition of EtOH. It also crystallises from xylene, **m 180°**. [*Beilstein* **4** II 613.] **TOXIC.**

Zinc dimethyldithiocarbamate **(Ziram)** *[137-30-4]* **$C_6H_{12}N_2S_4Zn$, M 305.8,** has **m 151-152°, 248-250°, pK^{25} 3.36 (for $Me_2NCS_2^-$ in H_2O), pK^{20} 1.23 (octanol/H_2O).** Crystallise this herbicide several times from hot toluene or from hot $CHCl_3$ by addition of EtOH. It has low solubility (65mg/L) in H_2O at 25°. [*Beilstein* **4** III 149, **4** IV 234.]

Zinc ethylenebis(dithiocarbamate) **(Zineb)** *[142-14-3 monomer, 9006-42-2 polymer, 12122-67-7]* **$C_4H_8N_2S_4Zn$, M 275.7.** Crystallise this herbicide several times from hot toluene or from hot $CHCl_3$ by addition of EtOH. It is a skin irritant. [*Beilstein* **4** III 149, **4** IV 234.]

Zinc phenol-o-sulfonate **($8H_2O$) (Phenozin)** *[1300-55-6, 127-82-2]* **$C_{12}H_{10}O_8S_2Zn$, M 411.7.** Phenozin crystallises from warm water by cooling to 0°. It effloresces in dry air, and loses all its H_2O at 120°. Its solubility in H_2O is 63% at 20° and 250% at boiling point, and in EtOH it is 55% at 50°. [*Beilstein* **11** IV 574.]

Zinc trifluoromethanesulfonate (zinc triflate) *[54010-75-2]* **$(CF_3SO_3)_2$ Zn, M 363.5, m >300°.** This zinc salt should be dried at 125° for 2 hours at 3mm before use. It is soluble in CH_2Cl_2 but insoluble in petroleum ether. It is a good catalyst for the preparation of dithioketals [Corey & Shimoji *Tetrahedron Lett* **24** 169 *1983*, DOI: 10.1016/S0040-4039(00)81357-X], and is a Lewis acid catalyst in silylations [Jiang & Zhu (2005). *Tetrahedron Letters* **46** 517 *2005*, DOI: 10.1016/j.tetlet.2004.10.175]. [*Beilstein* **16** H 392.]

CHAPTER 4

PURIFICATION OF INORGANIC AND METAL-ORGANIC CHEMICALS

INTRODUCTION

The most common method of purification of inorganic species is by recrystallisation, usually from water. However, especially with salts of weak acids or of cations other than the alkaline and alkaline earth metals, care must be taken to minimise hydrolysis. This can be achieved, for example, by recrystallising acetates in the presence of dilute acetic acid. Nevertheless, there are many inorganic chemicals that are too insoluble or are hydrolysed by water so that no general purification method can be given. It is convenient that many inorganic substances have large temperature-solubility coefficients for their solubility in water, i.e. large amounts dissolve in boiling water and on cooling to <25° large amounts of crystals separate. In cases where the temperature-solubility coefficients are small, crystallisation can be achieved by slow partial solvent evaporation.
Organo-metallic compounds, on the other hand, behave very much like organic compounds, e.g. they can be redistilled and may be soluble in organic solvents. A note of **caution** should be made about handling organo-metallic compounds, e.g. arsines, because of their **potential toxicities**, particularly when they are volatile. Generally the suppliers of such compounds provide details about their safe manipulation. These should be read carefully and adhered to closely. If in any doubt, always assume that the materials are lethal and treat them with utmost care. The same **safety precautions** about the handling of substances as stated in Chapter 3 should be followed here (see Chapter 1).

For information on **ionization (pK)** see Chapter 1, and Chapter 3. In order to avoid repetition, the literature (or predicted) pK values of anionic and/or cationic species are usually reported at least once, and in several cases are entered for the free acid or free base; e.g. Na_2SO_4 will have a pK value for Na^+ at the entry for NaOH and the pK values for SO_4^{2-} at the entries for H_2SO_4. When the pK values of the organic counter-ions are not given in this chapter, as in case of sodium benzoate, the reader is referred to the value(s) in Chapter 3, 'Aromatic Compounds', e.g. of benzoic acid.

Abbreviations of titles of periodicals are defined as in the Chemical Abstracts Service Source Index (CASSI). References to Fieser & Fieser's *Reagents for Organic Synthesis* will be shortened to Fieser throughout, e.g. Fieser **2** 254, **11** 88, etc. All temperatures are in degrees Centigrade unless otherwise stated. Other abbreviations are self evident.

Benzene, which has been used as a solvent successfully and extensively in the past for reactions and purification by chromatography and crystallisation, is now considered a **very dangerous substance**, so it has to be used with extreme care. It is important that an alternative solvent to benzene (e.g. toluene, toluene/petroleum ether, or a petroleum ether to name a few) should be used first. However, if benzene has to be used, then all operations have to be performed in well-ventilated fumehoods and precautions taken to avoid inhalation and contact with skin and eyes. Whenever benzene is mentioned in the text, an asterisk e.g. *C_6H_6 or *benzene, is inserted to remind the user that special precaution should be adopted.

Organic dyes which are *not* complexed or are salts of metals are included in 'Miscellaneous As, B, P……' in Chapter 3 (use the CAS Registry Numbers to find them). Commercially available polymer-supported reagents are indicated with **§** under the appropriate reagent.

This chapter is subdivided into two sections: the **Purification of Inorganic Compounds** and the **Purification of Metal-Organic Compounds** which includes ammonium and metal salts of organic acids.

Purification of Laboratory Chemicals.

INORGANIC COMPOUNDS

Alumina (aluminium oxide) (neutral) *[1344-28-1]* **Al_2O_3, M 102.0 (anhydrous).** Stir the oxide with hot 2M HNO_3, either on a steam bath for 12 hours (changing the acid every hour) or three times for 30 minutes, then wash it with hot distilled water until the washings have pH 4, and follow by three washings with hot MeOH. The product is dried at 270° [Angyal & Young *J Am Chem Soc* **81** 5251 *1959*, DOI: 10.1021/ja01528a055]. For the preparation of alumina for chromatography see Chapter 1. [For α, β and γ Al_2O_3 see Becher in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 822-823 *1963* and Wagner in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **II** p 1662 *1965*, for chromatography see Fieser **1** 19 and in later volumes.] Also commercially available in various physical forms and dryness.

Aluminium ammonium sulfate dodecahydrate *[7784-26-1]* **$AlNH_4(SO_4)_2.12H_2O$, M 453.3, m 93°, m 95°, pK_1^{25} 4.89, pK_2^{25} 5.43, pK_3^{25} 5.86 (Al^{3+} aquo), pK_4^{25} 11.22 [aluminate $Al(OH)_4^-$].** Crystallise it from hot H_2O and cool in ice. When the melt is heated, it loses NH_3 and H_2SO_4, and gives pure alumina at red heat. Solubility (%) in H_2O is 3.9% (0°), 15.0 (20°) and 135 (100°). Crystals for X-ray studies were easily grown in aqueous solution and were ground into spheres about 0.15mm in diameter [crystal structure: Larson & Cromer *Acta Cryst* **22** 793 *1967*, DOI: 10.1107/S0365110X67001586].

Aluminium bromide *[7727-15-3]* **$AlBr_3$, M 266.7, m 97°, b 114°/10mm, d_4^{18} 3.205.** Reflux it and then distil it from pure aluminium chips in a stream of nitrogen into a flask containing more of the chips. It is then redistilled under vacuum into ampoules [Tipper & Walker *J Chem Soc* 1352 *1959*, DOI: 10.1039/JR9590001352]. Anhydrous conditions are essential, and the white to very light brown solid distillate can be broken into lumps in a dry-box (under nitrogen). It fumes in moist air. [Becher in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 812-813 *1963*, Fieser **1** 22 and in 7 later volumes.]

Aluminium caesium sulfate dodecahydrate *[7784-17-0 ($12H_2O$), 14284-36-7]* **$AlCs(SO_4)_2.12H_2O$, M 352.1 (anhydr), 568.2, m 110°(dec).** Recrystallise it from hot water (3ml/g).

Aluminium chloride (anhydrous) *[7446-70-0]* **$AlCl_3$, M 133.3, m 192.6°, d_4^{17} 2.465.** Sublime it several times in an all-glass system under nitrogen at 30-50mm pressure. It has also been sublimed in a stream of dry HCl and has been subjected to a preliminary sublimation through a section of granular aluminium metal [for manipulative details see Jensen *J Am Chem Soc* **79** 1226 *1957*, DOI: 10.1021/ja01562a051]. It fumes in moist air. Used in Friedel-Crafts reactions. It is also commercially available as a 0.1M solution in nitrobenzene [7446-70-0], in functionalised silica gel (70-120mesh, with a 1.5mmol/g loading) for use as a Lewis acid and Friedel-Crafts reactions, and as $AlCl_3$.THF complex [192656-42-1] as a 0.5M solution in THF

Aluminium fluoride (anhydrous) *[7784-18-1 (anhydr), 32287-65-3 (H_2O), 15098-87-0 ($3H_2O$)]* **AlF_3, M 84.0 (anhydr), m 1292°(subliming), d^{25} 3.1g/cm^3(anhydr).** The technical material may contain up to 15% alumina, and minor impurities such as aluminium sulfate, cryolite, silica and iron oxide. Reagent grade AlF_3 (hydrated) contains only traces of impurities, but its water content is variable (and may be up to 40%). It can be dried by calcining at 600-800° in a stream of dry air (some hydrolysis occurs), followed by vacuum distillation at low pressure in a graphite system, heated to approximately 925° (condenser at 900°) [Henry & Dreisbach *J Am Chem Soc* **81** 5274 *1959*, DOI: 10.1021/ja01529a003]. Its solubility in H_2O is 0.5%. [Kwasnik in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 225-226 *1963*, Aigueperse et al. 'Fluorine Compounds, Inorganic' in *Ullmann's Encyclopedia of Industrial Chemistry* Wiley-VCH, Weinheim, *2005*, DOI: 10.1002/ 14356007.a11_307]

Aluminium nitrate nonahydrate *[7784-27-2 ($9H_2O$); 13473-90-0 (anhydr)]* **$Al(NO_3)_3.9H_2O$, M 375.1, m 72.8°, 73°, 73.5°, b 135°/atm, d^{25} 1.72g/cm^3.** Crystallise the nitrate from dilute HNO_3, and dry it by passing dry nitrogen through the crystals for several hours at 40°. After 2 recrystallisations of ACS grade, it had S, Na and Fe at 2.2, 0.01 and 0.02 ppm, respectively.

Aluminium potassium sulfate dodecahydrate (alum) *[7784-24-9]* **$AlK(SO_4)_2.12H_2O$, M 474.4, m 92°, d^{25} 1.757g/cm^3.** Crystallise it from weak aqueous H_2SO_4 (*ca* 0.5ml/g). Its solubility (%) in H_2O is 5.7 (0°), 12.0

(20°) and 136.9 (100°). Crystals for X-ray studies were easily grown in H_2O solution and were ground into spheres about 0.15mm in diameter [crystal structure: Larson & Cromer *Acta Cryst* **22** 793 *1967*, DOI: 10.1107/S0365110X67001586].

Aluminium rubidium sulfate dodecahydrate *[7784-29-4, 1350-57-9 (anhydr)]* **$AlRb(SO_4)_2$. $12H_2O$, M 520.8, 304.6 (anhydr), m 99-109°, 100°(dec), d 1.90g/cm^3.** Crystallise the double salt from aqueous H_2SO_4 (*ca* 2.5ml/g). Crystals for X-ray studies were easily grown in aqueous solution and were ground into spheres about 0.15mm in diameter. It is insoluble in EtOH. [Prepn: *Gmelin's, Aluminium* (8th edn) **35B** p 525-527 *1934*; crystal structure: Larson & Cromer *Acta Cryst* **22** 793 *1967*, DOI: 10.1107/S0365110X67001586.]

Aluminium sulfate (anhydrous) *[10043-01-3]* **M 342.2(anhydr), m 765°(dec), d ^{25} 2.71g/cm^3, $Al_2(SO_4)_3$ 14-18 H_2O** *[17927-65-0]*, **d ^{25} 1.69g/cm^3, $Al_2(SO_4)_3$ 18 H_2O** *[7784-31-8]*. It crystallises from hot dilute H_2SO_4 (1 ml/g) on cooling in ice. When a solution of alumina (Al_2O_3) in concentrated H_2SO_4 is slowly cooled, $Al_2(SO_4)_3$ 17 or $18H_2O$ deposits as a crystalline mass. $Al_2(SO_4)_3$ $17H_2O$ is the stable form in equilibrium with its saturated aqueous solution at 25° [Smith *J Am Chem Soc* **64** 41 *1942*, DOI: 10.1021/ja01253a012]. This is purified by dissolving it in a small volume of H_2O and adding EtOH until the sulfate readily crystallises from the oily supersaturated solution. It forms $Al_2(SO_4)_3$ $16H_2O$ between 0-112°. On gradual heating, the hydrate melts, giving the anhydrous salt at *ca* 250°. Several hydrates up to $27H_2O$ have been described. Further heating to red heat (~ 600-800°) causes decomposition to Al_2O_3 + SO_3 + SO_2 and O_2 [Cobb *J Soc Chem Ind* **29** 250 *1910*]. The ACS reagent is $Al_2(SO_4)_3$ $18H_2O$ (98+%).

Ammonia (gas) *[7664-41-7]* **NH_3, M 17.0, pK^{25} 9.25.** Major contaminants are water, oil and non-condensable gases. Most of these impurities are removed by passing the ammonia through a trap at -22° and condensing it at -176° under vacuum. Water is removed by distilling the ammonia into a tube containing a small lump of sodium. Also dry it by passage through porous BaO, or over alumina followed by glass wool impregnated with sodium (prepared by soaking the glass wool in a solution of sodium in liquid ammonia and evaporating off the ammonia). It can be rendered oxygen-free by passage through a solution of potassium in liquid ammonia. [Schenk in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 460-463 *1963*.] **AMMONIA (gas, liquid or aqueous solution) is very irritating and should not be inhaled in any quantity as it can lead to olfactory paralysis (temporary or permanent).**

Ammonia (liquid) *[7664-41-7]* **NH_3, M 17.0, m -77.8°, b -33.35°, n $^{20}_{D}$ 1.325, d $^{20}_{4}$ 0.597, d^{-79} 0.817g/ml.** Dry the liquid, and store it, with sodium in a steel cylinder, then distil and condense it by means of liquid air, the non-condensable gases being pumped off. In order to obtain liquid NH_3 from a cylinder, turn the cylinder upside-down (i.e. with the valve at the bottom, use a metal stand to secure it in this position; a special stand can be constructed for it) and lead a plastic tube from the tap to a measuring cylinder placed in an efficient fume cupboard which is kept running. Turn the tap on and allow the ammonia to be released. At first, gas and liquid will splatter out (make sure that the plastic tube is secure), but soon the liquid will drip into the measuring cylinder. The high latent heat of evaporation will cool the ammonia so that the liquid will remain cool and not boil vigorously. If the ammonia is required dry, the necessary precautions should be taken, i.e. the gas is allowed to flow through tubes packed with coarse CaO pellets. **AMMONIA (gas, liquid or aqueous solution) is very irritating and should not be inhaled in any quantity as it can lead to olfactory paralysis (temporary or permanent).**

Ammonia (aqueous) *[7664-41-7]* **NH_3. xH_2O, M 17.0 + H_2O, d $^{20}_{4}$ 0.90 (saturated, 27% w/v, 14.3 N), pK^{25} 9.25 (pK$_b$ at 25° = 4.75, i.e. pK$_a$ = 14.00-4.75 = 9.25, or K_b = 1.81 x 10^{-5}).** Obtained metal-free by saturating distilled water, in a cooling bath, with ammonia (from a cylinder) gas. *Alternatively*, isothermal distillation can be used by placing a dish of concentrated aqueous ammonia and a dish of pure water in an empty desiccator and leaving to equilibrate for several days. **AMMONIA (gas, liquid or aqueous solution) is very irritating and should not be inhaled in any quantity as it can lead to olfactory paralysis (temporary or permanent).**

Ammonium bisulfate (ammonium hydrogen sulfate) *[7803-63-6]* **(NH_4) HSO_4, M 115.1, m 121-145°, ~147°, d $^{20}_{4}$ 1.79, pK^{25} 1.96 (HSO_4^-).** It crystallises from water at room temperature (1ml/g) on adding EtOH

and cooling. $(NH_4)HSO_4$ is formed as deliquescent rhombic crystals on cooling a solution of $(NH_4)_2SO_4$ in hot concentrated H_2SO_4 but EtOH decomposes it to $(NH_4)_3H(SO_4)_2$. *Alternatively*, if the salt is slightly acidic, it is extracted (Soxhlet) with dry Et_2O (no reaction) until the runnings are neutral. This is found to be the most efficient way of purifying $(NH_4)HSO_4$, **m 145°**, free from traces of H_2O and H_2SO_4. It is ***extremely*** hygroscopic and should be stored in glass bottles in desiccators. When $(NH_4)HSO_4$ is shaken with 5 to 7 times its weight of EtOH (dried over lime or CaC_2 and distilled with **b 77.1-77.2°/726mm**) for 18 hours, filtered quickly then extracted with Et_2O (Soxhlet) until the washings are neutral (litmus), a salt with the formula $(NH_4)_3H(SO_4)_2$ is produced. This salt is not deliquescent and decomposes before melting. [Dunnicliff *J Chem Soc* **123** 476 *1923*, DOI: 10.1039/CT9232300476; *Gmelin's, Ammonia* [8th Ed.] **23** 405-406 *1936*.]. When powdered $(NH_4)_2SO_4$ is heated in a Pt dish below 100°, it loses NH_3, and at 300° it is completely converted to fused $(NH_4)HSO_4$, **m 140°**, but >300° it decomposes to SO_2 and N_2 [Smith *J Soc Chem Ind* **14** 629 *1895*, **15** 3 *1896*]. [Dunnicliff *J Chem Soc* **123** 731 *1923*, DOI: 10.1039/CT9232300731.] Used in hair waving and as a source of weak acid.

Ammonium bromide *[12124-97-9]* **NH_3 HBr, M 98.0, m 450°(sublimes), d $_4^{20}$ 2.43.** It crystallises from 95% EtOH and is slightly hygroscopic.

Ammonium chloride *[12125-02-9]* **NH_3 HCl, M 53.5, m 338°(sublime point, without melting), d $_4^{20}$ 1.53.** Crystallise it several times from conductivity water (1.5ml/g) between 90° and 0°. It sublimes. The salt is fully ionised in aqueous solution, i.e. $K \approx \infty$. A 1M aqueous solution of NH_4Cl has a pH of ~4.7, i.e. is acidic. After one crystallisation, ACS grade has: metal(ppm) As (1.2), K (1), Sb (7.2), V (10.2). [Becher in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 812 *1963*.]

Ammonium chromate *[7788-98-9]* **$(NH_4)_2CrO_4$, M 152.1, m 185°(dec), d $_4^{20}$ 1.81, pK $_1^{25}$ 0.74, pK $_2^{25}$ 6.49 (for H_2CrO_4).** Crystallise it from weak aqueous ammonia (*ca* 2.5ml/g) by cooling from room temperature. It loses NH_3 on heating to form ammonium dichromate (below). [Prepn: *Gmelin's, Chromium* (8th edn) **52B** p 707-712 *1962*.] Used as a reagent in analytical chemistry, in textile and wool dyeing, and in sensitising photographic gelatin. **POISONOUS.**

Ammonium dichromate *[7789-09-5]* **$(NH_4)_2Cr_2O_7$, M 252.1, m 170°(dec), d $_4^{20}$ 1.26.** It crystallises from weak aqueous HCl (*ca* 1ml/g). It decomposes rapidly on heating. (Possible **carcinogen, irritates skin** possibly forming ***chrome sores***, and is **POISONOUS**)

Ammonium dihydrogen arsenate *[13462-93-6]* **$(NH_4)H_2AsO_4$, M 159.0, Sp gr 2.311g/ml, n 1.577, m 300°(dec).** Crystallise it from water (1ml/g). **POISONOUS**.

Ammonium dihydrogen orthophosphate *[7722-76-1]* **$(NH_4)H_2PO_4$, M 115.0, m 190°(dec), d $_4^{20}$ 1.80.** Crystallise it from water (0.7ml/g) between 100° and 0°. It is slightly soluble in EtOH and insoluble in Me_2CO. With $NaHCO_3$ (a baking powder), it is used in fermentation and culture media. It is a fire retardant for paper and related fibrous materials.

Ammonium ferric sulfate dodecahydrate *[7783-83-7 ($12H_2O$), 10138-04-2 (anhydrous)]* **$(NH_4)Fe(SO_4)_2$. $12H_2O$, M 482.2, m ~37° , 39-41°, d $_4^{20}$ 1.71.** Crystallise it from aqueous ethanol. Its solubility is 1M in dilute HCl, and 1.24g/100ml in H_2O.

Ammonium ferrous sulfate hexahydrate [Mohr's salt] *[7783-85-9 ($6H_2O$), 10045-89-3 (anhydrous)]* **$(NH_4)_2Fe(SO_4)_2$. $6H_2O$, M 392.1, 284.05(anhydr), m 100°(dec), d $_4^{20}$ 1.86.** A solution in warm water (0.67g/ml) is cooled rapidly to 0°, and the resulting light bluish-green monoclinic crystals are filtered at the pump, washed with cold distilled water and pressed between sheets of filter paper to dry it. The solubility at 25° is 0.36g/ml. It separates as an almost white powder when a saturated aqueous solution is diluted with EtOH.

Ammonium hexachloroiridate (IV) *[16940-92-4]* **$(NH_4)_2IrCl_6$, M 441.0, d ^{25} 2.86g/ml.** It is precipitated several times from aqueous solution by saturation with ammonium chloride. This removes any palladium and rhodium. It is then washed with ice-cold water and dried over conc H_2SO_4 in a vacuum desiccator. If osmium

or ruthenium is present, it can be removed as the tetroxide by heating with conc HNO_3, followed by concentrated $HClO_4$, until most of the acid has been driven off. (This treatment is repeated.) The near-dry residue is dissolved in a small amount of water and added to excess $NaHCO_3$ solution and bromine water. On boiling, iridic (but not platinic) hydroxide is precipitated. It is dissolved in HCl and precipitated several times, then dissolved in HBr and treated with HNO_3 and HCl to convert the bromides to chlorides. Saturation with ammonium chloride and cooling precipitates ammonium hexachloroiridate which is filtered off and purified as above [Woo & Yost *J Am Chem Soc* **53** 884 *1931*, DOI: 10.1021/ja01354a008]. This commercially important iridium compound is the most common complex of Ir(IV) [Renner et al. 'Platinum group metals and compounds' in *Ullmann's Encyclopedia of Industrial Chemistry*, Wiley *2002*, DOI: 10.1002/14356007.a21_075].

Ammonium hexacyanoferrate II hydrate *[14481-29-9]* **$(NH_4)_4[Fe(CN)_6]$. xH_2O, M 284.1, m dec on heating.** The pale yellow ***trihydrate*** powder can be washed with 10% aqueous NH_3, filtered, then washed several times with EtOH and Et_2O, and dried at room temperature. It decomposes in a vacuum above 100° and should be stored away from light and under N_2. In light and air it decomposes by losing NH_3. [Lux in *Handbook of Preparative Inorganic Chem (Ed. Brauer)* Academic Press Vol **II** p 1509 *1965*; *Gmelin's, Iron* (8^{th} edn) **59B** p 1024 *1932*.] Used as a spot test reagent for Ca [Feigl, Tüpfelanalyse, Anorganischer Teil Akadem Verlager, Frankfurt/Main, p228 *1960*].

Ammonium hexafluorophosphate *[16941-11-0]* **NH_4PF_6, M 163.0, d_4^{18} 2.181, pK_1^{25} ~0.5, pK_2^{25} 5.12 (for fluorophosphoric acid H_2PO_3F).** It crystallises from H_2O in square plates and decomposes on heating before melting. Its solublility in H_2O at 20° is 74.8% w/v, and it is very soluble in Me_2CO, MeOH, EtOH and MeOAc, but is decomposed by boiling mineral acids. It does **not** etch glass. [Lange & Müller *Chem Ber* **63** 1058 *1930*, DOI: 10.1002/cber.19300630510; Woyski et al. *Inorg Synth* **3** 111 *1951*, DOI: 10.1002/9780470132340.ch29; Kwasnik in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 195 *1963*.]

Ammonium hexafluorosilicate *[16919-19-0]* **$(NH_4)_2SiF_6$, M 178.1, d^{25} 2.01g/ml, pK_2 1.92 (for H_2SiF_6).** Crystallise the salt from water (2ml/g). After 3 recrystallisations, the Technical grade salt has Li, Na, K and Fe at 0.3, 0.2, 0.1 and 1.0 ppm respectively. Used as a flux in soldering and for etching glass. [*Gmelin's, Ammonium* (8^{th} edn) **23** p414-415 *1936*.]

Ammonium hypophosphite (ammonium phosphinate)*[7803-65-8]* **NH_4. H_2PO_2, M 83.0, m 155-160°.** Crystallise it from hot EtOH. Its solubility in H_2O at ~25° is 1g/ml, and it liberates PH_3 (**TOXIC**) at ~240°.

Ammonium iodate *[13446-09-8]* **NH_4IO_3, M 192.9, m 150°(dec), d^{25} 3.309g/ml, pK^{25} 0.79 (IO^{3-}).** Ammonium iodate crystallises from water (8ml/g) on cooling from 100° to 0°.

Ammonium iodide *[12027-06-4]* **NH_4I, M 144.9, sublimes with dec at ~405°, d_4^{20} 2.51.** The iodide crystallises from EtOH on addition of ethyl iodide, and is very ***hygroscopic***. Store it in a tightly stoppered bottle, in the dark. Its solubility is 0.4g/ml in MeOH, 0.27g/ml in EtOH, 0.67g/ml in glycerol, and 1.67g/ml in H_2O at 25°, and 2.0g/ml in H_2O at ~100°. [Schmeisser in *Handbook of Preparative Inorganic Chem (Ed. Brauer)* Academic Press Vol **I** p 289-290 *1963*.]

Ammonium magnesium chloride hexahydrate *[60314-43-4 ($12H_2O$), 12125-06-3 (anhydrous)]* **NH_4Cl $MgCl_2$, M 256.8, 148.7(anhydr).** It crystallises from water (6ml/g) by partial evaporation in a desiccator over KOH (deliquescent).

Ammonium magnesium sulfate hexahydrate *[20861-69-2]* **NH_4MgSO_4. $6H_2O$, M 246.4, 138.4(anhydr).** It crystallises from water (1ml/g) between 100° and 0°.

Ammonium manganous sulfate hexahydrate (diammonium manganese II sulfate hexahydrate) *[7785-19-5, 13566-22-8]* **$NH_4SO_4.NH_4MnSO_4$. $6H_2O$, M 391.3, 138.4(anhydr).** It crystallises from water (2ml/g) by partial evaporation in a desiccator.

Ammonium molybdate *[13106-76-8]* **$(NH_4)_2MoO_4$, M 196.0, pK_1^{25} 0.9 (proton addition), pK_2^{25} 3.57, pK**

$^{25}_{3}$ 4.08 (for H_2MoO_4). Crystallise the salt from water (2.5ml/g) by partial evaporation in a desiccator. When a solution of MoO_3 in excess of hot concentrated NH_3 is cooled, ***normal*** ammonium molybdate $(NH_4)_2MoO_4$ crystallises out. However, when this solution is made to evaporated which allows the pH to drop to 6, the ***common*** hydrated ammonium ***paramolybdate*** $(NH_4)_6Mo_7O_{24}$ $4H_2O$ {or $3[(NH_4)_2O].\ 7MoO_3.\ 4H_2O$, *[12054-85-2]* M 1235.9} crystallises out. This was an **old formula** which was confirmed by Sturdivant. [Sturdivant *J Am Chem Soc* **59** 630 *1937*, DOI: 10.1021/ja01283a010; Grüttner & Jauder in *Handbook of Preparative Inorganic Chem (Ed. Brauer)* Academic Press Vol **II** p 1711 *1965*.]

Ammonium nickel (II) sulfate hexahydrate *[7785-20-8 ($6H_2O$), 15699-18-0 (anhydrous)]* **$(NH_4)_2Ni(SO_4)_2.6H_2O$, M 395.0, m 58-89°, d $^{20}_{4}$ 1.923.** Crystallise this salt from water (3ml/g) on cooling from 90° to 0°.

Ammonium nitrate *[6484-52-2]* **NH_4NO_3, M 80.0, m 165°(moist salt), 169°, 169.6°, b 210°/atm(dec explosively), d $^{20}_{4}$ 1.725.** It is crystallised twice from distilled water (1ml/g) by adding EtOH, or from warm water (0.5ml/g) by cooling in an ice-salt bath. Its solubility in H_2O is 1.18g/ml (0°), 1.5g/ml (20°), 2.3g/ml (40°), 4.1g/ml (60°), 5.76g/ml (80°) and 10.2g/ml (100°). Dry it in air, then under vacuum. After 3 recrystallisations of ACS grade, it contained Li and B at 0.03 and 0.74 ppm, respectively. It is ***deliquescent***. [Early & Lowry *J Chem Soc* **115** 1387 *1919*, DOI: 10.1039/CT9191501387; **121** 963 *1922*, DOI: 10.1039/CT9222100963; Hendricks et al. *J Am Chem Soc* **54** 2766 *1932*, DOI: 10.1021/ja01346a020.] It is a high nitrogen fertiliser in agriculture, a useful explosive in mining and ammunition and should be **handled with care**.

Ammonium perchlorate *[7790-98-9]* **$NH_4\ ClO_4$, M 117.5, d $^{20}_{4}$ 1.95, pK^{25} -2.4 to -3.1 (for $HClO_4$).** It is recrystallised twice from distilled water (2.5ml/g) between 80° and 0°, and dried in a vacuum desiccator over P_2O_5. Drying at 110° might lead to slow decomposition to the chloride. Useful in pyrotechnic materials and rocket propellants. [Jacobs & Whitehead *Chem Rev* **69** 551-50 *1969*, DOI: 10.1021/cr60260a005; *Gmelin's, Ammonium* (8th edn) **23** p 196-200 *1936*.] **POTENTIALLY EXPLOSIVE**.

Ammonium persulfate (APS, ammonium peroxydisulfate) *[7727-54-0]* **$(NH_4)_2\ S_2O_8$, M 228.2, m dec when heated wet liberating oxygen, d $^{20}_{4}$ 1.98.** Recrystallise it at room temperature from EtOH/water. It is freely soluble in H_2O: 0.5 (0.11)g/ml at 20°, and 2g/ml at 100°, also soluble in MeOH, but less so in EtOH and Me_2CO, and insoluble in most other organic solvents. Stable when pure and dry, but decomposes when moist evolving O_2 and O_3, and gradually loses NH_3 on exposure to air. It is a bleacher and a free radical initiator being used for polymerising acrylamide gels. [Feher in *Handbook of Preparative Inorganic Chem (Ed. Brauer)* Academic Press Vol **I** p 190 *1963*, Fieser **1** 952, **2** 348, **3** 238, **5** 5, **5** 15, **6**, 20, **12** 33.]

Ammonium reineckate (Reineckate salt) *[13573-16-5]* **$NH_4[Cr(NH_3)_2(SCN)_4]$, M 336.4 (anhydrous), m 268-272°(dec), 270-273°(dec), d 1.49g/cm^3.** Crystallise this dark red solid from water, between 30° and 0°, while working under artificial light. Solutions of reineckate salt (aqueous or alcoholic) decompose slowly at room temperature in the dark (~2 weeks) and more rapidly at higher temperatures or in diffuse sunlight. The solutions are blue in colour and liberate HCN **(POISONOUS)**. Store it dry in the dark under a vacuum. [Dakin *Org Synth* Coll Vol **2** 555 *1943*, DOI: 10.15227/orgsyn.015.0074.] Used to precipitate primary, secondary amines and some amino acids, e.g. crystalline products with proline and hydroxyproline, and gives a red colour or precipitate with Hg^{2+} compounds.

Ammonium selenate *[7783-21-3]* **$(NH_4)_2\ SeO_4$, M 179.0, d $^{20}_{4}$ 2.19, m dec on heating.** Crystallise the selenate from water at room temperature by adding EtOH and cooling. Its solubility in H_2O is 117% at 7° and 197% at 100°. [King *J Phys Chem* **41** 797 *1937*, DOI: 10.1021/j150384a003.] Used for mothproofing.

Ammonium sulfamate *[7773-06-0]* **$NH_4\ NH_2SO_3$, M 114.1, m 132-135°, dec at 160°.** Crystallise it from water at room temperature (1ml/g) by adding EtOH and cooling. [Sisler et al. *Inorg Synth* **2** 179 *1946*, DOI: 10.1002/9780470132333.ch53.]

Ammonium sulfate *[7783-20-2]* **$(NH_4)_2\ SO_4$, M 132.1, m 230°(dec), 280°(dec), d $^{20}_{4}$ 1.77.** Crystallise it twice from hot water containing 0.2% EDTA to remove metal ions, then finally from distilled water. Dry it in a

desiccator for 2 weeks over $Mg(ClO_4)_2$. After 3 recrystallisations, ACS grade had Ti, K, Fe, Na at 11, 4.4, 4.4, 3.2 ppm respectively. Extensively used in H_2O or aqueous buffer at various concentrations to fractionate, precipitate and/or crystallise proteins, purification of antibodies and crystallography of nucleic acids and proteins.

Ammonium tetrafluoroborate *[13826-83-0]* **NH_4BF_4, M 104.8, m 220°(sublimes), d ^{25} 1.871 g/cm^3, pK^{25} 2.77 (for HBF_4).** Crystallise it from conductivity water (1m/g) between 100° and 0°.

Ammonium thiocyanate (ammonium rhodanide) *[1762-95-4]* **NH_4SCN, M 76.1, m 138°(dec), 149°(dec), pK^{25} -1.85 (for HSCN), 149.** Crystallise it three times from dilute $HClO_4$ to give material optically transparent at wavelengths longer than 270nm. It has also been crystallised from absolute MeOH or from acetonitrile, and is soluble in H_2O (1.28g/1ml at 0°), EtOH, Me_2CO and liquid NH_3. It is a useful source of the SCN anion. Used for preparing herbicides, transparent artificial resins, matches, rustproofing materials, textile dyeing and printing, stabilising agents in photography, separation of Hf and Zr, titrimetric analysis, and detection of Cu, Ag, Zn, Pb and Hg which form precipitates that can be extracted into organic solvents. [A.F.Wells *Structural Inorganic Chemistry* 5th edn, OUP Oxford UK *1984*, ISBN 9780198553700.]

Ammonium tungstate (VI) *[11120-25-5, 89127-99-1]* **$H_{40}N_{10}O_{41}W_{12}$ = $(NH_4)_{10}W_{12}O_{41}$, M 3042.6, [$(NH_4)_2WO_4$, M 283.9], pK $^{25}_1$ 2.20, pK $^{25}_2$ 3.70 (for tungstic acid, H_2WO_4).** It crystallises as the ***pentahydrate*** from warm water on adding EtOH and cooling. It decomposes at 600° to give ***tungsten(VI) oxide*** (WO_3) which yields elemental ***tungsten*** on heating in an atmosphere of H_2. The metal is used in the manufacture of tungsten alloys. The tungstate anion can be complex, forming a white tungsten-oxygen cage, e.g. ***ammonium paratungstate*** which has the $[H_2W_{12}O_{42}]^{10-}$ anion. [Greenwood & Earnshaw, *Chemistry of the Elements*, 2nd ed. B-H, Oxford, pp 1012–1014 *1997*, ISBN 0080379419.]

Ammonium (meta) vanadate *[7803-55-6]* **NH_4VO_3, M 117.0, d $^{20}_{10}$ 2.326.** Wash the salt with H_2O until free from Cl^- ions and dry it in air. It is soluble in H_2O (5.18g/100ml at 15°, 10.4g/100ml at 32°) but is more soluble in dilute NH_3. It crystallises from conductivity water (20ml/g). When heated at relatively low temperature, it loses H_2O and NH_3 to give vanadium oxide (V_2O_5), and at 210° it forms lower oxides. [Baker et al. *Inorg Synth* **3** 117 *1950*, DOI: 10.1002/9780470132340.ch30.] Its solubility in H_2O is 0.52% (15°), 1% (32°) and 1.6% (50°). After washing the technical grade salt with H_2O, it had Na, Mn and U at 0.06, 0.2 and 0.1 ppm, respectively. [Brauer in *Handbook of Preparative Inorganic Chem (Ed. Brauer)* Academic Press Vol **II** p 1272-1273 *1965*.]

Antimony (V) pentafluoride *[7783-70-2]* **SbF_5, M 216.7, m 7.0°, 8.3°, b 141°, 150°, 148-150°, d $^{20}_4$ 2.99, pK^{25} 2.55 [for $HSb(OH)_6 = Sb(OH)_6^- + H^+$].** Purify it by vacuum distillation, preferably in a quartz apparatus, and store it in quartz or aluminum bottles. It is a ***hygroscopic*** viscous liquid which reacts ***violently*** with H_2O and is hydrolysed by alkalies. *It is* **POISONOUS** *and attacks the skin.* [Woolf & Greenwood *J Chem Soc* 2200 *1950*, DOI: 10.1039/JR9500002200; Kwasnik in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 200 *1963*.]

Antimony trichloride *[10025-91-9]* **$SbCl_3$, M 228.1, m 73°, 73.4°, b 220.3°/760mm, 283°/atm, pK $^{25}_1$ 1.4, pK $^{25}_2$ 11.0 (11.8), pK $^{25}_3$ 12.95 (for Sb^{3+} aquo).** Dry the trichloride over P_2O_5 or by mixing it with toluene or xylene and distilling (water is carried off with the organic solvent), then distil it twice under dry nitrogen at 50mm, and sublime it twice in a vacuum into ampoules and seal. It can be crystallised from CS_2 and is ***deliquescent***. It fumes in moist air and is decomposed by H_2O with precipitation of the basic chloride, but forms a clear solution in dilute HCl. It is soluble in AcOH (4.4g/g at 25°), Me_2CO (5.4g/g at 18°), PhCOCl (1.7g/g at 25°), 36.7%w/w HCl (7.9g/g at 20°), *p*-cymene (1.5g/g at 30°). It is a useful reagent in the **Carr-Price test** for detecting vitamin A and related carotenoids producing a blue complex which can be evaluated colorimetrically. [Patnaik *Handbook of Inorganic Chemicals*. McGraw-Hill, *2002*, ISBN 0-07-049439-8.]

Antimony trifluoride *[7783-56-4]* **SbF_3, M 178.8, m 235°(dec), 292°, b 376°/atm, d $^{20}_4$ 4.379.** It crystallises from MeOH to remove oxide and oxyfluoride, then it is sublimed under vacuum in an aluminium cup on to a water-cooled copper condenser. Its solubility is 443g/100g in H_2O at 20° and 562g/100g in H_2O at 30° with

partial hydrolysis. Store it in a glass or steel vessel. [Woolf *J Chem Soc* 273 279 *1955*, DOI: 10.1039/JR9550000273; Kwasnik in *Handbook of Preparative Inorganic Chem (Ed. Brauer)* Academic Press Vol **I** p 199 *1963*].

Antimony triiodide *[7790-44-5]* **SbI_3, M 502.5, m 167°, 168°, 170°, b 401°/atm, 420°/atm.** It sublimes under vacuum as a ruby-red solid with an orange vapour. It hydrolyses to the yellow oxyiodide (SbOI) with H_2O. It is insoluble in CCl_4 but is soluble in aqueous KI, HCl, EtOH, Me_2CO, and CS_2. [Bailar et al. *Inorg Synth* **I** 104 *1939*, DOI: 10.1002/9780470132326.ch36; Schenk in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 614 *1963*.]

Antimony trioxide *[1309-64-4]* **Sb_2O_3, M 291.5, m 656°, b 870°/10mm, 1424°/atm, 1550°/atm.** Dissolve the trioxide in the minimum volume of dilute HCl, filter, and add six volumes of water to precipitate the basic antimonous chloride (free from Fe and Sb_2O_5). The precipitate is redissolved in dilute HCl, and added slowly, with stirring, to a boiling solution (containing a slight excess) of Na_2CO_3. The oxide is filtered off, washed with hot water, then boiled and filtered. The process is repeated until the filtrate gives no test for chloride ions. The product is dried in a vacuum desiccator [Schuhmann *J Am Chem Soc* **46** 52 *1924*, DOI: 10.1021/ja01666a008]. After one crystallisation (precipitation?), the oxide from a Chinese source had: metal (ppm) Al (8), Ag (0.2), As (56), Cr (6), Ge (0.4), Mn (0.2), Na (16), Ni (2.2) Pb (2.4), Sn (0.4) and V (32). It sublimes in a vacuum at 400°, being yellow on heating and pale buff in colour on cooling. Used in pigments, enamels, glass, flame-proofing canvas and as a mordant. [Schenk in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 615-616 *1963*.]

Aqua regia. This is prepared by adding slowly concentrated HNO_3 (1 volume) to concentrated hydrochloric acid (3 volumes) in a glass container. This mixture is used to dissolve metals, including noble metals and alloys, as well as minerals and refractory substances. It is done by suspending the material and boiling (**EFFICIENT FUME CUPBOARD — EYE PROTECTION**] to dryness and repeating the process until the residue dissolves in H_2O. If the aqua regia is to be stored for long periods it is advisable to dilute it with one volume of H_2O which will prevent it from releasing chlorine and other chloro and nitrous compounds which are objectionable and toxic. Store it cool in a fume cupboard. However, it is good laboratory practice to prepare it freshly and dispose of it down the fume cupboard sink with copious amounts of water.

Argon *[7440-37-1]* **Ar, M 39.9481 (atomic weight standard), m -189.34°, b -185.848°, d 1.784g/L (at STP, 0°/101.325 kPa), 1.3954g/L (liquid at b.p.)** Argon is rendered oxygen-free by passage over reduced copper at 450°, or by bubbling through alkaline pyrogallol and H_2SO_4, then dried with $CaSO_4$, $Mg(ClO_4)_2$, or Linde 5A molecular sieves. Other purification steps include passage through ***Ascarite*** (**CARE: asbestos** impregnated with sodium hydroxide), through finely divided uranium at about 800° and through a -78° cold trap.
Alternatively, the gas is passed over CuO pellets at 300° to remove hydrogen and hydrocarbons, over Ca chips at 600° to remove oxygen and, finally, over titanium chips at 700° to remove nitrogen. It has also been purified by freeze-pump-thaw cycles and by passage over sputtered sodium [Arnold & Smith *JCS Faraday Trans 2* **77** 861 *1981*, DOI: 10.1039/F29817700861]. Argon is inert and ***non-toxic*** and is 2.5 times more soluble in H_2O than N_2. It comprises 0.934% by volume and 1.288% by mass of the Earth's crust. Being 38% denser than air, it is considered a **dangerous asphixiant** in confined spaces. This inert gas is a useful shield in metal arc welding, a gas in fluorescent tubes and light bulbs and a communly used carrier gas in GLC. [Haynes ed. *CRC Handbook of Chemistry and Physics* (92nd ed.) Boca Raton, FL, CRC Press p. 4.121 *2011*, ISBN 1439855110; Hwang et al. 'Noble Gases' in Kirk Othmer's *Encyclopedia of Chemical Technology*, Wiley, pp 343–383 *2005*, DOI: 10.1002/ 0471238961.0701190508230114.a01.]

Arsenic acid (arsenic pentoxide hydrate, arsenic V oxide hydrate, orthoarsenic acid) *[12044-50-7]* **As_2O_5 xH_2O, M 229.8 + xH_2O, d ^{25} 4.32g/ml, pK_1^{25} 2.26, pK_2^{25} 6.76, pK_3^{25} 11.29 (H_3AsO_4).** The acid crystallises from concentrated solutions of boiling concentrated HNO_3 as rhombic crystals. Dry it in a vacuum to give the ***hemihydrate*** (hygroscopic). Heating above 300° yields As_2O_5. [Simon & Thaler *Z Anorg Allgem Chem* **246** 19 *1941*, DOI: 10.1002/zaac.19412460104; Schenk in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 601 *1963*.] **POISONOUS.**

Arsenic tribromide *[7784-33-0]* **$AsBr_3$, M 314.6, m 31.1°, b 89°/11mm, 221°/760mm, d $_4^{20}$ 3.67.** Distil it under vacuum. It hydrolyses in H_2O (fumes in moist air), but less readily than $AsCl_3$. It has a characteristically ***high refractive index*** (~2.3) as well as a ***very high diamagnetic susceptibility***. **POISONOUS.** [Schenk in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 597 *1963*.]

Arsenic trichloride (butter of arsenic) *[7784-34-1]* **$AsCl_3$, M 181.3, m -16°, b 25°/11mm, 130.0°/atm, d $_4^{20}$ 2.2, n $_D^{20}$ 1.006**. Reflux the trichloride with arsenic for 4 hours, then fractionally distil it. The middle fraction is stored with sodium wire for two days, then again distilled [Lewis & Sowerby *J Chem Soc* 336 *1957*, DOI: 10.1039/JR9570000336]. It fumes in moist air forming the solid hydroxy-chloride [$AsCl(OH)_2$] and is readily hydrolysed by H_2O to form arsenious acid. Useful in the ceramic industry. **POISONOUS.** [Schenk in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 596 *1963*.]

Arsenic triiodide *[7784-45-4]* **AsI_3, M 455.6, m 146°, b 400°/atm, d $_4^{25}$ 4.688.** It crystallises from acetone and sublimes below 100°. It is very slowly hydrolysed by H_2O (much more slowly than the chloride), e.g. 0.083g dissolves in H_2O (1ml) to give a yellow solution from which it can be recovered unchanged within 5hrs, by extraction into $*C_6H_6$, toluene or xylene. However, in time the aqueous acidic solution will form HI and As_2O_3. **POISONOUS.** [Bailar et al. *Inorg Synth* **1** 103 *1939*, DOI: 10.1002/9780470132326.ch36; Schenk in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 597-598 *1963*.]

Arsenic III oxide (arsenic trioxide, arsenous oxide) *[1327-53-3]* **As_2O_3, M 197.8, three forms: m ~200°(amorphous glass), m 275°(sealed tube, octahedral, common form, sublimes > 125° without fusion but melts under pressure), and m ~312°, b 465°/atm, pK $_1^{20}$ 9.27, pK $_2^{20}$ 13.54, pK $_3^{20}$ 13.99 (for H_3AsO_3).** It crystallises in an ***octahedral form*** (common form) from H_2O or from dilute HCl (1:2), and is then washed, dried and sublimed (193°/760mm). Analytical reagent grade material is suitable for use as an analytical standard after it has been dried at 105° for 1-2 hours or has been left in a desiccator for several hours over concentrated H_2SO_4. *Alternatively*, As_2O_3 (15g) is dissolved by heating in a mixture of H_2O (60ml) and HCl (90g, s.g. 1.1), and crystallisation occurs on cooling, accompanied by brilliant flashes of light.
The ***amorphous*** form is a colourless transparent glass (**m 200°**) which is obtained when the vapour is slowly condensed below the vaporisation temperature, and should be kept in a sealed tube because it changes to the ***octahedral*** form (**m 275°**) in the presence of moisture. [Rushton & Daniels *J Am Chem Soc* **48** 384 *1926*, DOI: 10.1021/ja01413a011.]
A third ***monoclinic*** form, is obtained by heating the oxide in a sealed tube at 400° (the vitreous, amorphous form remains at the bottom of the tube) with the ***monoclinic*** form subliming onto the intermediate part of the tube at 200° (**m 312°**), and the ***octahedral*** form deposits at the top of the tube. The transition temperature between the last two forms is ~250°. **POISONOUS (particularly the vapour, handle in a ventilated fume cupboard).** [Schenk in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 600 *1963*; Grund et al. 'Arsenic and Arsenic Compounds' *Ullmann's Encyclopedia of Industrial Chemistry*, Weinheim: Wiley-VCH, *2005*, DOI: 10.1002/14356007.a03_113.pub2.]

Barium (metal) *[7440-39-3]* **Ba M 137.3, m 725°, 727°, b 1640°(1537°)/760mm, d $_4^{20}$ 3.56(3.76).** Barium is cleaned by washing with diethyl ether to remove adhering paraffin, then filed in an argon-filled glove box, washed first with ethanol containing 2% concentrated HCl, then with dry ethanol. It is dried in a vacuum and stored under argon [Addison et al. *J Chem Soc* 3868 *1962*, DOI: 10.1039/JR9620003868]. It has also been purified by double distillation under 10mm of argon pressure. Useful as a catalyst for making graphitic nanofilaments [Liang et al. *Nanotech in Catalysis* **2** 543 *2004*].

Barium bromide dihydrate *[7791-28-8 ($2H_2O$), 10553-31-8 (anhydrous)]* **$BaBr_2$. $2H_2O$, M 333.2, m at 75° loses first H_2O and at 120° it loses the second H_2O and melts at 847°, 857°, b 1835°/atm, d 4.78g/cm^3.** It crystallises from H_2O (0.92g/ml at 0°) by partial evaporation in a desiccator. The ***anhydrous salt*** is readily prepared by drying the dihydrate at 200°. Drying at temperatures of 120° gives a product which is either a lower hydrate or a different crystalline modification of the anhydrous material. The ***anhydrous salt*** is ***deliquescent*** and should be handled in a drybox. [Brackett et al. *J Phys Chem* **67** 2132 *963,* DOI: 10.1021/j100804a038.] [Ehrlich in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 930 *1963*.]

Barium chlorate monohydrate *[10294-38-9 (hydrate), 13477-00-4 (anhydrous)]* **$Ba(ClO_3)_2.H_2O$, M 322.3, m 414°, d ^{25} 3.18g/cm^3.** It crystallises from H_2O (1ml/g) between 100° and 0°, and loses $1H_2O$ at 120°. [Schmeisser in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 314 *1963*.]

Barium chloride dihydrate *[10326-27-9]* **$BaCl_2.2H_2O$, M 244.3, m ~120°(dec, hydrate); M 208.2, 963° (anhydrous), d ^{25} 3.856g/cm^3.** It is crystallised twice from water (2ml/g) and dried in an oven to constant weight. The solubilities of the ***hydrate*** (% of anhydrous wt) in H_2O are 31.6 at 0°, 35.7 at 20° and 58.7 at 100°. Drying the dihydrate at 200° gives a mixture of ***monoclinic*** and ***orthorhombic*** forms. Conversion of the ***monoclinic*** form to the more stable ***orthorhombic*** modification is very slow (> 1 week). Attempted preparation of a pure sample of the ***orthorhombic*** form from the dihydrate by heating under vacuum at 60° overnight provided a ***cubic*** form which is stable at 925-960°. The ***cubic*** form does not revert appreciably to the ***orthorhombic*** form at room temperature, but at 200° the conversion is complete in 2 days. Thus the three forms can be obtained for X-ray diffraction. The ***anhydrous*** salts are ***deliquescent*** and should be handled in a drybox. [Brackett et al. *J Phys Chem* **67** 2132 *963,* DOI: 10.1021/j100804a038.]

Barium dithionate dihydrate *[13845-17-5]* **$Ba(S_2O_6).2H_2O$, M 333.5, m >150° loses SO_2, d ^{25} 4.54g/cm^3, pK^{25} 0.49 (for $H_2S_2O_6$, theory pK_1 -3.4, pK_2 -0.2).** Purify by successive crystallisations from water at room temperature by evaporation. Its solubility in H_2O is 7.9% (0°), 15.7% (20°) and 19.9% (30°). [Pfanstiel etal. **2** 167 *1946*, DOI: 10.1002/9780470132333.ch50; Fehér in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 397 *1963*; crystal structure: Rausell-Colom & Garcia-Blanco *Acta Cryst* **21** 672 *1966*, DOI: 10.1107/ S0365110X66003682.]

Barium ferrocyanide hexahydrate *[13821-06-2]* **$Ba_2[Fe(CN)_6]$, M 594.8, m 80°(dec), pK_3^{25} 2.57, pK_4^{25} 4.35 (for ferrocyanide).** Prepare the complex salt by boiling Prussian Blue with the equivalent of $Ba(OH)_2$ solution, or $FeSO_4$ and $Ba(CN)_2$, and it crystallises in yellow *monoclinic* crystals from hot water (100ml/g). The hydrate loses most of its H_2O on heating at 40° becoming colourless, and decomposes at 80° evolving HCN. [Grat-Cabanac *Bull Soc Chim Fr* 1743 *1956*.]

Barium fluoride *[7787-32-8]* **BaF_2, M 175.3, m 1353°, 1368°, b 2260°, d_4^{20} 4.83.** Wash it well with distilled H_2O and dry it in a vacuum. Its solubility in H_2O is 1.6g (10°), 1.6g (20°) and 1.62g (30°) per L, and is soluble in mineral acids and aqueous NH_4Cl. It may be stored in glass bottles. [Kwasnik in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 234 *1963*.]

Barium hydroxide octahydrate *[12230-71-6]* **$Ba(OH)_2.8H_2O$, M 315.5, m 78°, pK_1^{25} 13.13, pK_2^{25} 13.36.** It crystallises from water (1ml/g) and readily absorbs CO_2 from air. It effloresces to the ***monohydrate*** *[22326-55-2] M 189.4*. It dehydrates to $Ba(OH)_2$ *[17194-00-2] M171.3,* in dry air at 100°. An aqueous solution (***baryta water***) absorbs CO_2 to form a white precipitate of $BaCO_3$. This base catalyses the β-elimination of phosphoserine residues; and a 0.3N solution of $Ba(OH)_2$ *[17194-002]* M 171.3, has been used for precipitating proteins in turbid fluids like whole blood in assays based on Somogyi-Nelson's method. [Hatanaka & Kobara *Agricultural and Biological Chemistry* **44** 2943 *1980*, DOI: 10.1080/00021369.1980.10864408.]

Barium hypophosphite monohydrate *[14871-79-5]* **$Ba(H_2PO_2)_2.H_2O$, M 285.4.** Prepared by heating white phosphorus with $Ba(OH)_2$ and purified by precipitating it from aqueous solution (3ml/g) on adding EtOH. Its solubility in H_2O is 28.6% at 17° and 33.3% at 100°. [Klement in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 557 *1963*.]

Barium iodate monohydrate *[7787-34-0]* **$Ba(IO_3)_2.H_2O$, M 487.1 (anhydr), m 130°(loses H_2O), 476°(dec).** The iodate is purified by recrystallisation from a large volume of hot water. Its solubility in H_2O is 1g/3.35L at 25° and 1g/0.625L at the boiling point. [Lambert et al. *Inorg Synth* **7** 13 *1963*, DOI: 10.1002/ 9780470132388.ch4.]

Barium iodide dihydrate *[7787-33-9 ($2H_2O$), 13718-50-8 (anhydrous)]* **$BaI_2.2H_2O$, M 427.2, m 740°(dec).** The ***dihydrate*** salt crystallises from water (0.5ml/g) by partial evaporation in a desiccator. The ***anhydrous*** salt is

best obtained by heating the dihydrate to 400° in vacuum with no evidence of more than one modification (compare with $BaCl_2$). The monohydrate can apparently be obtained by heating the dihydrate at 500° in the presence of HI, or under vacuum at 150-200°. The ***anhydrous*** salt is ***deliquescent*** and should be handled in a drybox. [Brackett et al. *J Phys Chem* **67** 2132 *963,* DOI: 10.1021/j100804a038.] **POISONOUS.**

Barium manganate (VI) *[7787-35-1]* **$BaMnO_4$, M 256.3, d $_4^{20}$ 3.77.** Wash the salt (blue-green crystals) with cold conductivity H_2O by decantation until the supernatant gives a faint test for Ba^{2+}. Remove excess H_2O in a vacuum (IMPORTANT), then heat at 100° and the last traces of H_2O are removed in a vacuum desiccator over P_2O_5. Store it over KOH. It disproportionates in hot H_2O or dilute acid into $Ba(MnO_2)_2$ and MnO_2 (see below). It is a mild oxidant, and is used in some wall paints. [Schlesinger & Siems *J Am Chem Soc* **46** 1965 *1924*, DOI: 10.1021/ja01674a001; Nyholm et al. *Inorg Synth* **11** 56 *1968*, DOI: 10.1002/9780470132425.ch11.]

Barium nitrate *[10022-31-8]* **$Ba(NO_3)_2$, M 261.4, m 593°(dec).** Crystallise it twice from water (4ml/g) and dry it overnight at 110°. It decomposes at higher temperatures to give mostly the oxide and the peroxide with only a little of the nitrite. **POISONOUS.** [Ehrlich in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 941 *1963*.] The salt is used for making BaO, produces a green light in flares and pyrotechnics, and in fluorescent tubes.

Barium nitrite monohydrate *[7787-38-4]* **$Ba(NO_2)_2.H_2O$, M 247.4, m 217°(anhydr)**. Barium nitrite monohydrate crystallises in yellow-white hexagonal crystals from water (1ml/g) on cooling in an ice-salt bath, and is insoluble in EtOH. Although stable in air it melts at ~184° with partial hydrolysis and concentrated aqueous solutions undergo hydrolysis at 100°. It may be dehydrated *in vacuo* over P_2O_5, and the ***anhydrous*** salt has d° 3.52g/ml at 0° and melts at **217°** then decomposes at **~325°**. **POISONOUS.**

Barium oxide (calcined baryta) *[1304-28-5]* **BaO, M153.3, m 1923°, b ~2000°/atm, d ^{25} 5.72g/cm^3.** Best to prepare it by heating pure $BaCO_3$ with C, or other pure barium salts, e.g. $Ba(NO_3)_2$. It is a white powder which is used to absorb H_2O and CO_2 from gases (e.g. air, O_2, N_2). It does not become sticky with moisture, but dissolves in H_2O ***exothermically*** to form $Ba(OH)_2$ (***baryta water***, alkaline) which is used to absorb CO_2. Solubility in H_2O is 0.035g/1ml (20°) and 0.91g/1ml (100°). It is soluble in EtOH but insoluble in Me_2CO and liquid NH_3, and the porous grade is used for drying solvents that are not affected by alkali. IRRITATES skin, eyes, should not be inhaled and is harmful to aquatic and other organisms. [Ehrlich in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 933 *1963*.]

Barium perchlorate *[13465-95-7]* **$Ba(ClO_4)_2$, M 336.2(anhydr), m 505°, d ^{25} 3.2g/cm^3. pK^{25} -2.4 to -3.1 (for $HClO_4$).** Recrystallise the perchlorate twice from water (solubility is 66.5g/100ml at 25°). The hydrate has [15318-52-2, xH_2O]. [Schmeisser in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 320 *1963*.]

Barium permanganate *[7787-36-2]* **$Ba(MnO_4)_2$, or $BaMn_2O_8$, M 375.2, m 200°(dec), d ^{25} 3.77g/cm^3.** Obtained by disproportionation of $BaMnO_4$ in dilute H_2SO_4, the $BaSO_4$ and MnO_2 are filtered off and the filtrate is evaporated to give dark violet to brown rhombic crystals. The reaction is very slow because the solubility of the manganate is low. Dry in a vacuum. It is poorly soluble in cold H_2O (but 62.5g/100ml at 30°), and decomposes in EtOH. [Lux in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 1462 *1963*.] The salt is a mild versatile oxidising agent used under aprotic and non-aqueous solutions [Firouzabadi et al. *Tetrahedron* **46** 6869 *1990*, DOI: 10.1016/S0040-4020(01)87874-1].

Barium sulfate *[7722-43-7]* **$BaSO_4$, M 233.4, m 1345°, >1580°, d ^{25} 4.50g/cm^3.** Wash the sulfate five times by decantation with hot distilled water, dialyse it against distilled water for one week, then freeze-dry and dry in an oven at 105° to constant weight (~12 hours). It is ***practically insoluble*** in H_2O (solubility is 0.0024g/L at 25°), an analytical product of ***sulfate determination***, but is soluble in concentrated H_2SO_4. Used as a catalyst support, in making various kinds of paper whiter, in white pigments, and because of its high density it is useful as a radiocontrast agent for X-ray imaging.

Barium tetrathionate *[82203-66-5]* **BaS_4O_6, M 361.6, m 100-110°**(forming $BaSO_4$, SO_2 and S)**.** Purify the

tetrathionate by dissolving it in a small volume of water and precipitating it with EtOH below 5°. After drying, the salt is stored in the dark at 0°. Aqueous solutions are stable, but alcoholic solutions in the presence of acid decompose it to give barium thiosulfate. [see Frehér in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 399-401 *1963* for potassium tetrathionate $K_2S_4O_4$.]

Barium thiocyanate dihydrate *[2092-17-3]* **$Ba(SCN)_2.2H_2O$, M 253.5(anhydr), pK^{25} -1.85 (for HSCN).** It is crystallised from water (2.5ml/g) by partial evaporation in a desiccator. It is ***deliquescent***. [Herstein et al. *Inorg Synth* **3** 24 *1950*, DOI: 10.1002/9780470132340.ch5.]

Barium thiosulfate *[35112-53-9]* **BaS_2O_3, M 249.5, m 220°(dec), pK_1^{25} 0.6, pK_2^{25} 1.74 (for $H_2S_2O_3$).** It is very slightly soluble in water and is washed repeatedly with chilled water and dried in air at 40°. Analytical standard in iodometry.

Beryllium carbonate *[744998-97-8, 13106-47-3]* **$BeCO_3$, M 69.0, m 54°, b 100°/atm (dec).** The commercial carbonate contains more than 1% of impurities. It is best purified by converting it to the basic acetate (see [1332-52-1]) which should be sublimed, converted into the nitrate with HNO_3 see below *[13587-99-4]*) and evaporated in a Pt dish until free from excess acid. The residual nitrate salt is dissolved in a small volume of H_2O and enough ammonium carbonate solution is added to redissolve the beryllium carbonate that precipitates and gives a clear solution. This is then evaporated in a Pt dish until course $BeCO_3$ separates. It is washed thoroughly with pure H_2O, then distilled EtOH and dried *in vacuo*. It has low solubility in H_2O (0.36g/100ml at 25°). $Be(OH)_2$, BeO and Be salts are generally insoluble in NH_3 but dissolve in **aqueous** $(NH_4)_2CO_3$ solution to form the carbonate. [Ehrlich in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 893 *1963*.] Beryllium compounds are potentially **carcinogenic**.

Beryllium chloride *[7787-47-5]* **$BeCl_2$, M 79.9, m 399°, 405°, b 488°/atm, d^{25} 1.89.** The anhydrous chloride is obtained by heating Be powder or chips (or BeO + C) with Cl_2 gas in a furnace at 300-350° for *ca* 40 hours when anhydrous $BeCl_2$ sublimes out as a white to faintly yellow crystalline mass or orthorhombic crystals. It is purified further by sublimation at ~300° *in vacuo*. It is very hygroscopic and reacts exothermically with H_2O which becomes acidic. The solid should be stored in a tightly stoppered vessel and handled in a dry atmosphere much like anhydrous $AlCl_3$ and has similar catalytic properties to it. It is insoluble in $*C_6H_6$ and toluene but is soluble EtOH, Et_2O, pyridine and CS_2 with which it probably ***complexes***. The conductivity of fused $BeCl_2$ is ~0.001 of that of fused NaCl implying that 1 molecule in 1000 is ionised. [Tannenbaum et al. *Inorg Synth* **5** 22 *1957*, DOI: 10.1002/9780470132364.ch7; Ehrlich in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 889 *1963*.] Beryllium compounds are potentially **carcinogenic**.

Beryllium hydroxide *[13327-32-7]* **$Be(OH)_2$, M 43.0, d^{25} 1.89g/cm^3.** The hydroxide exists in two forms, a metastable **α-form** and a stable **β-form**. The former is obtained in amorphous form by precipitating a Be salt with NH_3 in the absence of CO_2 and allowing it to age by prolonged heating (~ 24 hours) with NH_4OH solution. ***β-Be(OH)₂*** is made by boiling a saturated solution of the amorphous α-form in 10N aqueous NaOH until a permanent turbidity is attained. On slow cooling fine crystals (regular double pyramids) of the β-form separate, and are purified by washing with warm H_2O until the washings are no longer alkaline, then drying at 80°. The mother liquours can be reused in the above process. It is very slightly soluble in H_2O and dilute NaOH, but both forms are amphoteric and are soluble in hot concentrated aqueous NaOH solutions and in acids. It dehydrates on strong heating to BeO. Several sodium beryllates are known. [Ehrlich in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 894, 895 *1963*.] Beryllium compounds are potentially **carcinogenic**.

Beryllium nitrate *[13587-99-4*; *7787-55-5 ($3H_2O$)]* **$Be(NO_3)_2$, M 133.0, m ~60° (for $3H_2O$), b 142°/atm (dec), d^{25} 1.56g/cm^3.** The nitrate does not crystallise easily and is ***very deliquescent***. It can be prepared from the metal by digesting it with conc HCl until most of it has dissolved, filter any insoluble material through a 0.45 micron acetate filter. Then at low boil, add concentrated HNO_3 with low heat to reduce to a slurry. Repeat with careful addition of HNO_3 as many times as necessary (3-6 additions) until the slurry tests negative for chloride ions with 0.1N aqueous $AgNO_3$. Then isolate the nitrate as described below [J. Papa personal communication. *2011*, see end of Chapter 1]. *Alternatively* it is obtained by heating recrystallised, then sublimed, basic beryllium

acetate {$Be_4O(OAc)_6$, see [1332-52-1]}, with pure concentrated HNO_3 in a degassed pyrex container until the volatiles are removed. Heat well below 1100°, so as not to decompose it to give pure BeO. It picks up moisture to give the white to pale yellow ***trihydrate***. Store it in a well stoppered bottle in a cool place. [Ehrlich in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 893 *1963*.] Berylluim compounds are potentially **carcinogenic**.

Beryllium oxide (beryllia) *[1304-56-9]* **BeO, M 25.0, m 2507°, 2530°, b 4120°/atm, d^{25} 3.01.** It is prepared by calcining the nitrate at 1100° {see $Be(NO_3)_2$ above *[13587-99-4]*}, and this oxide always contains ~0.35ml of gas (N_2, O_2) per gram of oxide. *Alternatively*, freshly prepared beryllium carbonate is calcined in a Pt boat placed in an electric furnace at 900°. BeO is amphoteric, dissolving slowly in acids and in alkalis but if heated strongly it becomes refractory and difficult to dissolve except in hydrofluoric acid. It is *almost insoluble* in H_2O (0.002g/ml at 25°). Like ceramics it is a good electrical insulator, but it is a good conductor of heat like some metals. [Ehrlich in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 893 *1963*.] Beryllium compounds are potentially **carcinogenic**.

Beryllium potassium fluoride *[7787-50-0]* **BeK_2F_4, M 163.4 m ~350°.** It crystallises from hot water (25ml/g). Beryllium compounds are potentially **carcinogenic**.

Beryllium sulfate tetrahydrate *[7787-56-6]* **$BeSO_4$. $4H_2O$, M 177.1, m ~100°(dec), d^{25} 1.713, pK_1^{25} 3.2, pK_2^{25} ~6.5 (Be^{2+}).** It crystallises from a concentrated solution of weak aqueous H_2SO_4 (with partial evaporation), and is dried in air. It is quite soluble in H_2O. The ***tetrahydrate*** loses H_2O at ~100° to give the ***dihydrate***. [cf. *Gmelin's Beryllium* (8th edn) **26** 169 1930.] Beryllium compounds are potentially **carcinogenic**.

Bismuth *[7440-69-9]* **Bi, M 209.0, m 271-273°, 271.44°, 271.04 ±0.06°, b 1450°/atm, 1560°/atm, d^{25} 9.8g/cm^3.** Melt it in an atmosphere of dry helium, then filter it through dry Pyrex wool to remove any bismuth oxide present [Mayer et al. *J Phys Chem* **64** 238 *1960*, DOI: 10.1021/j100831a013].
Precipitated bismuth prepared by reduction of $BiCl_2$ in HCl with hypophosphorous acid, filtering it off, washing with H_2O and drying *in vacuo*, is a very fine dull grey powder with particles size <0.015mm (<15microns) which is easily dispersed in H_2O. Bi dissolves in dilute mineral acids to give the respective salts ***without*** liberation of H_2, whereas the red-hot metal reacts with H_2O to form Bi_2O_3 and hydrogen. A poor conductor of electricity, its resistance increases in a magnetic field, and it forms alloys with other metals, e.g. with Fe.

Bismuth trichloride *[7787-60-2]* **$BiCl_3$, M 315.3, m 230-232°, 233.6°, b 447°/atm, pK^{25} 1.58 *for* hydrolysis ($Bi_3^+ = BiOH_2^+ + H^+$).** Sublime the trichloride under high vacuum (or ~450°/atm), or dry it under a current of HCl gas, followed by fractional distillation, once under HCl and once under argon. [Mayer et al. *J Phys Chem* **64** 238 *1960*, DOI: 10.1021/j100831a013; Schenk in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 621 ($BiCl_3$), 622 (BiOCl) *1963*.] It is ***deliquescent***, and hydrolyses in H_2O or aqueous EtOH to give **BiOCl** *[7787-59-9] M 260.4, d 7.72,* which melts at low red heat. It dissolves in EtOH, Me_2CO, EtOAc, HCl and HNO_3. $BiCl_3$ is a source of bismuth salts and catalysts for organic reactions.

Boric acid (orthoboric acid, boracic acid) *[10043-35-3]* **H_3BO_3, M 61.8, m 160°(dec), 171°, pK^{25} 9.23.** Crystallise the acid three times from H_2O (3ml/g) between 100° and 0°, after filtering through sintered glass. Dry it to constant weight over metaboric acid in a desiccator. It is steam volatile. After two recrystallisations of ACS grade, it had Ag at 0.2 ppm. Its solubility (%) in H_2O is 2.66 at 0°, 4.0 at 12° and 24 at 80°. At 100° it loses H_2O to form ***metaboric acid*** (HBO_2). When it is heated to redness or slowly to 200°, or over P_2O_5 *in vacuo*, it dehydrates to ***boric anhydride*** (B_2O_3) [1303-82-6] to give a white hard glass or crystals with **m ~294°**. The glass softens on heating and liquefies at red heat. It is an astringent, a fungicide and an antibacterial. [McCulloch *J Am Chem Soc* **59** 2650 *1937*, DOI: 10.1021/ja01291a050; Kelley *J Am Chem Soc* **63** 1137 *1941*, DOI: 10.1021/ja01849a072; Briscoe et al. *J Chem Soc* 70 *1926*, DOI: 10.1039/JR9262900070; Conti *J Soc Chem Ind* **44** 343T *1925*.]

Boron trichloride (trichloroborane) *[10294-34-5]* **BCl_3, M 117.2, m -107°, b 0°/476mm, 12.5°/atm, d^0 1.3728, d_4^{12} 1.35, (also available as a 1.0M solution in toluene, *p*-xylene, CH_2Cl_2, heptane or hexanes).** Purify it (from chlorine) by passage through two mercury-filled bubblers, then fractionally distil it under a slight

vacuum. In a more extensive purification the nitrobenzene addition compound is formed by passage of the gas over nitrobenzene in a vacuum system at 10°. Volatile impurities are removed from the crystalline yellow solid formed by pumping at -20°, and the BCl_3 is recovered by warming the addition compound at 50°. Passage through a trap at -78° removes entrained nitrobenzene, the BCl_3 finally condensing in a trap at -112° [Brown & Holmes *J Am Chem Soc* **78** 2173 *1956*, DOI: 10.1021/ja01591a042]. *Alternatively*, purify it by condensing it into a trap cooled in acetone/Dry-ice, where it is pumped for 15 minutes to remove volatile impurities. It is then warmed, recondensed and again pumped. [Gamble et al. *Inorg Synth* **3** 27 *1950*, DOI: 10.1002/9780470132340.ch6.]
It fumes in moist air. **TOXIC, do not breath in the vapours.** It forms addition compounds with Et_2O; and with dimethyl sulfide it forms ***$Me_2S.BCl_3$*** *[5523-19-3]* **M 179.3,** which has **m 88-90°**, and is a convenient solid form of it (also commercially available as a 1.0M soluions in CH_2Cl_2, heptane, hexanes, toluene and *p*-xylene) — **beware** of the foul odour of Me_2S; work in an efficient fume cupboard and absorb the sulfide vapours by flushing them with a stream of N_2 into lead acetate solution which will precipitate insoluble black PbS. [Gamble et al. *Inorg Synth* **3** 27 *1950*, DOI: 10.1002/9780470132340.ch6; Gerrard & Leppert *Chem Rev* **58** 1081 *1958*, DOI: 10.1021/cr50024a003.] Boronated aluminas (highly acidic) prepared from BCl_3 effect region- and diastereoselectivity in Diels-Alder reactions [McGinnis et al. *J Org Chem* **61** 3496 *1996*, DOI: 10.1021/jo951077m]. High-temperature synthesis of two layered graphite-like materials with p-type semiconductor properties was achieved by the interaction of MeCN with BCl_3, and acrylonitrile with BCl_3, in a H_2 and N_2 atmosphere in a quartz tube at 1000° [Kawaguchi *Chem Mater* **8** 1197 *1996*, DOI: 10.1021/cm950471y]

Boron trifluoride *[7637-07-2]* **BF_3, M 67.8, b -101°/760mm.** The usual impurities-bromine, BF_5, HF and non-volatile fluorides are readily separated by distillation. Brown and Johannesen [*J Am Chem Soc* **72** 2934 *1950*, DOI: 10.1021/ja01163a035] passed BF_3 into benzonitrile at 0° until the latter was saturated. Evacuation to 10^{-5}mm then removed all traces of SiF_4 and other gaseous impurities. [A small amount of the BF_3-benzonitrile addition compound sublimes and is collected in a U-tube cooled to -80°]. The pressure is raised to 20mm by admitting dry air, and the flask containing the BF_3 addition compound is warmed with hot water. The BF_3 that evolves is passed through a -80° trap (to condense any benzonitrile) into a tube cooled in liquid air. The addition compound with anisole can also be used. BF_3 can be dried by passing it through H_2SO_4 saturated with boric oxide. It fumes in moist air. [It is commercially available as a 1.3M solution in MeOH or PrOH.] [Booth et al. *Inorg Synth* **I** 21 *1939*, DOI: 10.1002/9780470132326.ch8; Kwasnik in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** pp 219-222 *1963*.] The following are ***BF_3 complexes*** that are among the commercially available sources of the reagent: **BF_3. $2H_2O$** *[13319-75-0]* M 103.8, d ^{25} 1.636g/ml; **BF_3. 2AcOH** *[373-61-5]* M 187.9, d ^{25} 1.353g/ml; **BF_3. MeCN** *[420-16-6]* M 108.9, d ^{20} 0.87-0.88g/ml; **BF_3. Me_3COMe** *[123334-27-0]* M 155.9, d ^{25} 1.381g/ml; **BF_3. $(n\text{-}Bu)_2O$** *[593-04-4]* M 198.0, d ^{25} 0.99g/ml; **BF_3. Et_2O** *[109-63-7]* M 141.9, d ^{25} 1.15g/ml, m -58°, b 126-129°/atm; **BF_3. Et_2NH** *[75-23-0]* M 112.9, m 85-89°; **BF_3. MeOH** *[373-57-9]* M 99.9, d ^{25} 1.203g/ml, b 59°/4mm; **BF_3. Me_2O** *[353-42-4]* M 113.9, d ^{25} 1.239g/ml, m -15°, b 126-127°/atm; **BF_3. Me_2S** *[353-43-5]* M 129.9, d ^{25} 1.235g/ml; **BF_3. H_3PO_4** *[13669-76-6]* M 165.8, d ^{25} 1.84g/ml, b 147°/atm; **BF_3. n-PrOH** *[762-48-1]* M 127.9, d ^{25} 1.379g/ml; **BF_3. THF** *[462-34-0]* M 139.9, d ^{25} 1.268g/ml, m -123°, b 180°/atm. **TOXIC.**

Bromine *[7726-95-6]* **Br_2, M 159.8, m –7.2°, b 58.8°/atm, 59°/atm, d_4^{20} 3.102, n_D^{20} 1.661.** Reflux the brown liquid with solid KBr and distil; dry the distillate by shaking it with an equal volume of conc H_2SO_4, then redistil it. The H_2SO_4 treatment can be replaced by direct distillation from BaO or P_2O_5. A more extensive purification [Hildenbrand et al. *J Am Chem Soc* **80** 4129 *1958*, DOI: 10.1021/ja01549a004] is to reflux about 1L of bromine for 1 hour with a mixture of 16g of CrO_3 in 200ml of conc H_2SO_4 (to remove organic material). The bromine is distilled into a clean, dry, glass-stoppered bottle, and chlorine is removed by dissolving *ca* 25g of freshly fused CsBr in 500ml of the bromine and standing overnight. To remove HBr and water, the bromine is then distilled back and forth through a train containing alternate tubes of MgO and P_2O_5. [Schmeisser in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 275 *1963*.] Also available commercially are ***bromine solution*** *[7726-95-6]* 1.0M in ***trimethyl phosphate***, **volumetric standard** bromine 0.0950-0.1050 N in H_2O, and ***bromine on polymer support*** on Amberlite IRA-900 Br_3^- form (loading: 1.2-1.8.mmol/g active bromine (Br_3^-) [Cacchi et al. *Synthesis* 64 *1979*, DOI: 10.1055/s-1979-28560; Bongini et al. *Synthesis* 143 *1980*, DOI: 10.1055/s-1980-28952; Smith et al. *JCS Perkin Trans 1* 1877 *1992*, DOI: 10.1039/P19920001877].

HIGHLY TOXIC.

Bromine pentafluoride *[7789-30-2]* **BrF_5, M 174.9, m –60.5°, b 41.3°, 40.25°, d^{25} 2.466.** Purify it *via* its KF complex, as described for chlorine trifluoride. [Kwasnik in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** pp 158-159 *1963*.] While working on a metal vacuum line excess fluorine is removed by passage through a trap at -134°, the reactor is heated to 60° at the end to drive off any product adsorbed on the solids. BrF_5 is then transferred to a metal storage cylinder. It is a ***powerful oxidant***, reacts violently with H_2O to give $HBrO_3$ and HF, and is an extremely effective ***fluorinating agent***. Its IR has ν_{max} at 587, 644 and 683 cm^{-1} [Hyde & Boudakian *Inorg Chem* **7** 2648 *1968*, DOI: 10.1021/ic50070a039; for IR and Raman see Begun et al. *J Chem Phys* **42** 2236 *1965*, DOI: 10.1063/1.1696273.] **HIGHLY TOXIC.**

Cadmium *[7440-43-9]* **Cd, M 112.4, m 320.9°, 321.1°, b 765°/atm, 767°/atm, d_4^{20} 8.642.** Any oxide contaminant is removed by filtering the molten metal, under vacuum, through quartz wool. Its solubility in Hg is 5.2% (18°), and it is soluble in mineral acids. [Wagenknecht & Juza in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **11** p 1092 *1965*.] All Cadmium compounds are considered **carcinogenic** or potentially **carcinogenic**.

Cadmium bromide *[7789-42-6 (anhydrous), 13464-92-1 ($4H_2O$)]* **$CdBr_2$. $4H_2O$, M 344.3, m 566°, b 863°, 963°, d_4^{20} 5.192.** Crystallise it from water (0.57g/ml at 10°, 1.26g/ml at 100°) between and 0°, and dry it at 110°. It forms the ***monohydrate*** below 36° and the ***tetrahydrate*** above 36°. It is ***hygroscopic***. [Wagenknecht & Juza in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **II** p 1096 *1965*.] **Carcinogenic**.

Cadmium chloride *[10108-64-2, 7790-78-5 ($2.5H_2O$), 654054-66-7 (xH_2O)]* **$CdCl_2$, M 183.3(anhydr), m 568°, b 960°/atm, d_4^{20} 4.06**. Crystallise it from water (1ml/g) by addition of EtOH and cooling. [Pray et al. *Inorg Synth* **5** 153 *1957*, DOI: 10.1002/9780470132364.ch43; Wagenknecht & Juza in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **II** p 1093 *1965*.] **Carcinogenic.**

Cadmium fluoride *[7790-79-6]* **CdF_2, M 150.4, m >1000°, 1049°, b 1748°/atm, d_4^{20} 6.35.** Crystallise it by dissolving it in hot water (25ml/g at 25°) at 60°, filtering, then cooling. It is soluble in mineral acids and HF but insoluble in EtOH and liquid NH_3. [Kwasnik in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 243 *1963*.] **Carcinogenic.**

Cadmium iodide *[7790-80-9]* **CdI_2, M 366.2, m 388°, b 787°/atm, d_4^{20} 5.66.** Crystallise it from ethanol (2ml/g) by partial evaporation, or from H_2O [solubility is 78.7g/100ml (0°), 84.7g/100ml (20°), 125.0g/100ml (100°)]. The salt is also soluble in Et_2O, Me_2CO and in NH_3, and turns yellow on exposure to light. It is used in the production of phosphors, in lithography, in photography, in electroplating, in analytical chemistry and as a nematocide. [Wagenknecht & Juza in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **II** p 1096 *1965*.] **Carcinogenic.**

Cadmium nitrate tetrahydrate *[10022-68-1, 10325-94-7 (anhydrous)]* **$Cd(NO_3)_2$, $4H_2O$, M 308.5, m 59.5° (hydrate), b 132°/760mm, d^{25} 3.6g/cm^3(anhydrous), d^{25} 2.45g/cm^3($4H_2O$).** Crystallise the nitrate from water [solubility is 1.1g/ml (0°), 1.3g/ml (18°), 1.4g/ml (30°), 3.2g/ml (60°)] by cooling in an ice-salt bath. The salt is also soluble in Et_2O, EtOAc, Me_2CO, ROH, dilute acids and in NH_3. Used as a flash in photography and emulsions; and for colouring glass and porcelain. [*Gmelin's Cadmium (8th edn)* **33** pp 76-78 *1925*, Suppl p 446 *1959*.] **Carcinogenic.**

Cadmium potassium iodide *[13601-63-3]* **$KCdI_3$, M 532.2.** Crystallise it from ethanol by partial evaporation. **Carcinogenic.**

Cadmium selenide *[1306-24-7]* **CdSe, M 191.4, m 1268°, d^{25} 5.816g/cm^3, n_D^{25} 2.5.** It is prepared by heating Cd in a stream of H_2Se (foul odour, work in a well ventilated fume cupboard), then subliming it under H_2 at dull red heat. *Alternatively*, CdSe is precipitated from an aqueous $CdSO_4$ solution and H_2Se (or a soluble metal

selenide) as for CdS below, and is almost insoluble in water (hence wash well with H_2O). It is a white to brown salt which turns red on exposure to sunlight. It exists in three forms: an unstable ***sphalerite cubic form***, which is converted into the ***wurzite form*** (hexagonal) with a transition starting at 300° and completing at 700°; and a ***rock-salt cubic*** form only seen at high pressures. [Wagenknecht & Juza in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **II** p 1099 *1965*.] Bulk crystalline CdSe is prepared by the High-Pressure Vertical Bridgman *(HPVB)* method using high pressures (10-100atm) of inert gas [in for *Device for crystal growth by vertical direct crystallization of melt* see Kulakov & Fadeev Pat. USSR N 774286] or high-pressure vertical zone melting (*HPVB)* of crystalline selenide [for *HPVB and HPVZM shaped growth of CdZnTe, CdSe and ZnSe crystals* see Kolesnikov et al. *Proc SPIE* **4787** 93-104 *2002*]. For CdSe nanoparticle and quantum dots see Chapter 7. It is used in phosphors, semiconductors, photoelectric cells etc.

Cadmium sulfide *[1306-23-6]* **CdS, M 144.5, m 1750°, d ^{25} 4.826g/cm^3, n $^{25}_{D}$ 2.529.** CdS is prepared by precipitation from an aqueous 0.1M solution of $CdSO_4$, $Cd(NO_3)_2$, $CdCl_2$, $CdBr_2$ or CdI_2 at 30° or 100° by adding S^- ions in the form of H_2S or a sulfide salt, e.g. Na_2S. The colour of the precipitate varies from yellow to orange to red depending on the original salt used and on whether the original solution is neutral or acidic, e.g. by addition of a few drop of the respective concentrated acid, e.g. H_2SO_4, HNO_3, HCl, HBr or HI respectively. At the lower or higher temperature the cubic or the hexagonal form separate. This is a test for Cd in qualitative analysis. The salt is collected, washed well with H_2O until no salts filter through, then washed with EtOH, Et_2O and is dried in air at room temperature or preferably in a vacuum. Commercial salts should be washed free from other salts as stated and dried. The differences in colour are due to particle size. When used as a pigment (**Cadmium Yellow, CI pigment yellow 37,** cf. Ryan et al. US Pat 07/104,716 to Raychem Corp 2 Oct *1987*) the dried salt is ground and calcined for an hour or so, but note that the temperature must be kept below 980°, as it sublimes above it. Its solubility in H_2O is 0.13w/w% at 25°, and it liberates H_2S in strong acid. **Carcinogenic.**
It is a useful pigment for paints, plastics, is piezoelectric, used in solar cells when combined with other metals (e.g. Cu_2S), and for the preparation of nanomaterials see entry in Chapter 7.
[Milligan *J Phys Chem* **38** 797 *1934*, DOI: 10.1021/j150357a009; Wagenknecht & Juza in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **II** pp 1098-1099 *1965*.] **TOXIC.**

Cadmium sulfate *[7790-84-3 (for $3CdSO_4$ $8H_2O$), 15244-35-6] (2.67 H_2O), 10124-36-4 (anhydrous)]* **$CdSO_4$, M 208.4 (anhydrous), 769.5 (hydrate), m 40° ($8H_2O$), 105° (H_2O), 1000° (anhydr), d^{25} 4.69g/cm^3(anhydr), d^{25} 3.79g/cm^3(H_2O), 3.08g/cm^3($8H_2O$), n $^{25}_{D}$ 1.565.** The sulfate crystallises from distilled water as a ***hydrate*** by partial evaporation in a desiccator. It gives the ***monohydrate*** on heating at 80°. Its solubility in H_2O is 0.75g/ml (0°), 0.76g/ml (25°), and 0.54g/ml (99°) for the ***anhydrous salt***; 0.77g/ml (25°) for the ***monohydrate salt***, and the ***octahydrate salt*** is freely soluble.] It is insoluble in EtOH, Me_2CO or EtOAc. It forms a white precipitate of $Cd(OH)_2$ with aqueous NH_3 which dissolves in excess of NH_3 to form soluble **$[Cd(NH_3)_4]SO_4$**. [*Gmelin's Cadmium (8th edn)* **33** p 121 *1925*, Suppl pp 609-610 *1959*.] **Carcinogenic.**

Cadmium telluride *[1306-25-8]* **CdTe, M 240.0, m 1041°, b 1130°/atm, d ^{25} 6.20g/cm^3, n $^{25}_{D}$ 2.67.** It is prepared by heating stoichiometric amounts of Te and Se (both purified by sublimation *in vacuo*) in a crucible at 500° under a pressure of 40atm of N_2. On completion of the reaction, the temperature is raised above the melting point (1050°) and then decreased slowly as well as the N_2 pressure when an ingot of polycrystalline CdTe is obtained. This is purified by recrystallising from the melt under 1atm pressure of Cd. Zone melting under such conditions gives spectroscopically purer brown-black crystals [For *Preparation and Electrical Properties of CdTe Single Crystals* see Kröger & Nobel *J Electronic & Control* **1** 190 *1955*, DOI: 10.1080/00207215508961407; for prep and phys props of H_2Te see Dennis & Anderson *J Am Chem Soc* **36** 882 *1914*, DOI: 10.1021/ja02182a012] CdTe is insoluble in H_2O, but decomposes slowly on prolonged exposure to moist air. Thin CdTe films, prepared from pure Cd and Te in an evacuated Vycor tube, can be deposited by condensation across the shot gaps between Aquadag electrode in Dewar tubes. [Kretschmar & Schilberg *J Appl Phys* **28** 865 *1957*, DOI: 10.1063/1.1722876.] Used in photoconductors and solar cells, and for the preparation of nanomaterials see entry in Chapter 7. **Carcinogenic.**

Calcium *[7440-70-2]* **$CdSO_4$, M 40.1, m 842°, 845°, b 1484°/atm, d ^{25} 1.55g/cm^3, d ^{845} 1.378g/cm^3(liquid).** Clean the silver white soft metal by washing it with ether to remove adhering paraffin, file the surface in an argon-filled glove box, and wash it with ethanol containing 2% of conc HCl. Then wash it with dry ethanol, dry

it in a vacuum and store it under pure argon [Addison et al. *J Chem Soc* 3868 *1962*, DOI: 10.1039/JR9620003868]. Ca sublimes below 800° at high vacuum, oxidises slowly in moist air and reacts with cold H_2O slowly.

Calcium bromide monohydrate *[62648-72-0, 71626-99-8 (xH_2O), 7789-41-5 (anhydrous)]* **$CaBr_2$. H_2O, M 217.9, d $^{20}_{4}$ 3.35.** Crystallise the bromide from EtOH or Me_2CO. It loses H_2O on heating, is anhydrous at 750°, then it loses Br_2 at higher temperatures. It is ***deliquescent***. [Ehrlich in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 930 *1963*.]

Calcium carbonate (limestone, chalk) *[471-34-1]* **$CaCO_3$, M 100.1, m 1339° (calcite), 825° (aragonite), n $^{25}_{D}$ 1.59, d ^{25} 2.711g/cm^3(calcite), d ^{25} 2.83g/cm^3 (aragonite), pK^{25} 9.0.** Pure $CaCO_3$ is produced from pure quarried ***marble*** (as for food or pharmaceuticals). It is *quite insoluble* in H_2O (0.013g/ cm^3 at 25°, pK_{SP} 3.3x10^{-9}) and is best prepared from pure CaO, adding distilled H_2O [to give $Ca(OH)_2$] and bubbling CO_2 through the solution, collecting the white precipitate, washing thoroughly with H_2O until the filtrate is no longer alkaline and dried *in vacuo* to give ***precipitated calcium carbonate*** **(PCC)** [Ropp in *Encyclopedia of the alkaline earth compounds* Elsevier pp 359–370. ISBN 9780444595508]. The carbonate exists in equilibrium with CaO and CO_2 and is best calcined above ~898° at atmospheric pressure (101kPa or 760mm) when CO_2 is ***outgassed*** and pure CaO (quickline) is formed. It effervesces with dilute mineral acids to give CO_2. [Fieser **1** 103, **2** 57, **4** 67, **5** 89; Rohleder & Kroker *Calcium Carbonate: From the Cretaceous Period Into the 21st Century* Springer Science & Business Media. *2001*, ISBN 3-7643-6425-4.]

Calcium chloride (anhydrous) *[10043-52-4]* **$CaCl_2$, M 111.0, m 772°, b >1600°, d$^{15}_{4}$ 2.15.** It is available as fused granules or cubic crystals. It is very ***hygroscopic***, very soluble in H_2O (exothermic), and EtOH. Store it in a tightly closed container. Used for drying many organic solvents (except MeOH and EtOH) and extracts e.g. ethereal, chloroform extracts. Also for removing EtOH (added to inhibit formation of phosgene) from $CHCl_3$. Useful desiccant. [Ehrlich in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 931 *1963*.] For drying agent properties see Chapter 1.

Calcium chloride dehydrate *[10035-04-8]* **$CaCl_2$. $2H_2O$, M 147.0, m 175°(dehydrates), 772°(dec).** Crystallise it from ethanol. It is ***hygroscopic***. It loses H_2O at 200° so it can be dried at high temperatures to dehydrate it. The ***hexahydrate*** *[7774-34-7]* has **m 30°** and **d** 1.67. [Fieser **1** 104, **4** 368.]

Calcium dithionite (calcium hydrosulfite) *[13812-88-9, 15512-36-4]* **CaS_2O_4, M 168.2, m dec on heating, d ^{25} 2.83g/cm^3** Crystallise it from water, or water followed by acetone and dry it in air at room temperature. Reducing agent which may **ignite** in contact with moist air. If spilled into excess H_2O (at least 5 fold) half the theoretical yield of SO_2 gas will evolve in ~7minutes. Reaction with oxidising agents could be violent. [*Development of the Table of Initial Isolation and Protective Distances for the 2008 Emergency Response Guidebook*, ANL/DIS-09-2, D.F. Brown et al. Argonne National Laboratory, Argonne, Illinois, June *2009*.]

Calcium hexacyanoferrate (II) undecahydrate (yellow prussiate of lime) *[13821-08-4]* **$Ca_2[Fe(CN)_6]$. $11H_2O$, M 490.1, 292.1(anhydr)** Recrystallise it three times from conductivity H_2O and dry it in air to constant weight over the partially dehydrated salt. [James *Trans Faraday Soc* **45** 855 *1949*, DOI: 10.1039/TF9494500855.] *Alternatively*, the Ca salt can be purified by precipitation with absolute EtOH in the cold (to avoid oxidation) from an air-free saturated aqueous solution. The pure lemon yellow crystals are centrifuged, dried in a vacuum desiccator first over dry charcoal for 24 hours, then over partly dehydrated salt and stored in a dark glass stoppered bottle. No deterioration occurrs after 18 months. No trace of Na, K or NH_4 ions can be detected in the salt from the residue after decomposition of the salt with conc H_2SO_4. Analyses indicate 11mols of H_2O per mol of salt. The solubility in H_2O is 36.45g (24.9°) and 64.7g (44.7°) per 100g of solution. [Farrow *J Chem Soc* 49 *1926*, DOI: 10.1039/JR9262900049.]

Calcium hydroxide *[1305-62-0]* **$Ca(OH)_2$, M 74.1, m loses H_2O on heating, d ^{25} 2.24g/cm^3, pK^{25} 12.7 (for Ca^{2+}).** Heat analytical grade calcium carbonate at 1000° during 1 hour. Allow the resulting oxide to cool and add slowly to water. Heat the suspension to boiling, cool and filter through a sintered glass funnel of medium

porosity (to remove soluble alkaline impurities). Dry the solid at 110° and crush it to a uniformly fine powder. Store it in a tightly stoppered bottle as it absorbs CO_2 from air to form $CaCO_3$. [Ehrlich in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 934 *1963*.]

Calcium iodate *[7789-80-2 (anhydrous), 10031-33-1 ($6H_2O$)]* **$Ca(IO_3)_2$, M 389.9, m >540°, d ^{25} 4.520g/cm^3, pK^{25} 0.79 (for HIO_3).** Crystallise it from water (100ml/g at 100° and 100ml/0.1g at 0°) [Bahl & Singh *J Indian Chem Soc* **17** 397 *1940*]. Used as iodine supplement, in lotions and ointments as antiseptic and deodorant.

Calcium iodide x-hydrate *[71626-98-7 (xH_2O), 10102-68-8 (anhydrous)]* **CaI_2, M 293.9 (anhydr), m 740°, 779°, b 1100°/atm, d ^{25} 3.956g/cm^3.** Dissolve the salt in acetone, which is then diluted and evaporated. This drying process is repeated twice, then the CaI_2 is recrystallised from acetone/diethyl ether and stored over P_2O_5. It is very *hygroscopic* when anhydrous and is light sensitive [Cremlyn et al. *J Chem Soc* 520 528 *1958*, DOI: 10.1039/JR9580000520]. The yellow ***hexahydrate*** has **m 42°**. It is soluble in H_2O, MeOH, EtOH and Me_2CO but insoluble in Et_2O.

Calcium nitrate tetrahydrate *[13477-34-4 ($4H_2O$), 35054-52-5 (xH_2O), 10124-37-5]* **$Ca(NO_3)_2$, M 236.1($4H_2O$), 164.1(anhydr), m 42.7°, 45°(hydrate, dec), 561°(anhydrous), d ^{25} 2.504g/cm^3(anhydr), d ^{25} 1.896g/cm^3($4H_2O$), pK^{25} 6.0.** Crystallise the nitrate four times from water [solubility: 1.9g/ml (0°), 1.3g/ml (20°), 3.6g/ml (100°) for $4H_2O$; 1.2g/ml (20°), 2.7g/ml (40°) for anhydrous salt] by cooling in a $CaCl_2$-ice freezing mixture. The ***tetrahydrate*** is dried over concentrated H_2SO_4 and stored over P_2O_5, to give the ***anhydrous salt***. It is ***deliquescent***. Its solubility in EtOH is 0.5g/ml (20°) and 0.6g/ml (40°); and 1.3g/ml (10°), 1.4g/ml (40°) and 1.4g/ml (60°) in MeOH; and 0.013g/ml (20°) in Me_2CO. It is soluble in NH_3 but almost insoluble in HNO_3. After 3 recrystallisations of ACS grade salt, it had Co, Fe, Mg, Sr and Zn at 0.2, 1. 0, 0.02, 10 and 0.02 ppm resp. [Bassett & Taylor *J Chem Soc* **105** 1926 *1914*, DOI: 10.1039/CT9140501926.]

Calcium nitrite dihydrate *[13780-06-8 (30% w/w aqueous solution)]* **$Ca(NO_2)_2$. $2H_2O$, M 168.1($2H_2O$), 132.1(anhydr), m 390° (dec on heating), d $^{20}_{D}$ 2.22, n $^{20}_{D}$ 1.3946.** Crystallise it from hot water (1.4ml/g) by adding ethanol and cooling to give the *hydrate*. It is *deliquescent*. [Ray & Ogg *J Am Chem Soc* **79** 265 *1957*, DOI: 10.1021/ja01559a003.] It has many applications, e.g. rust inhibitor of steel, antifreeze, large scale hydraulic, heavy oil detergent.

Calcium permanganate tetrahydrate *[10118-76-0 (anhydrous)]* **$Ca(MnO_4)_2$. $4H_2O$, M 350.0 (for $4H_2O$), 277.9(anhydr), m 140°(dec), d ^{25} 2.49g/cm^3.** Crystallise the purple solid from water [3.3g/ml (14°), 3.4g/ml (25°)] by partial evaporation in a desiccator. It is ***deliquescent***. It is soluble in NH_4OH and decomposes in EtOH. ***Note*** that it loses oxygen more readily than the potassium salt. It is an oxidising agent.

Calcium sulfate dihydrate *[10101-41-4]* **$CaSO_4$. $2H_2O$, M 172.2, m 150°(dec), d $^{20}_{4}$ 2.32, pK^{25} 7.3, K_{sp} 3.14 x 10^{-5} mol^2.L^{-2}.** It loses only part of its H_2O at 100-150° (see below). It is soluble in H_2O and very slowly soluble in glycerol. It is insoluble in most organic solvents.

Calcium sulfate hemihydrate *[10034-76-1]* **$CaSO_4$. $0.5H_2O$, M 145.2.** Its solubility in H_2O is 0.2parts/100 at 18.75°. It dehydrates completely >650°. Dry it below 300° to give a solid with estimated pore size *ca* 38% of volume. ***Anhydrous*** $CaSO_4$ (**Drierite**) *[7778-18-9]* M 136.1, d ^{25} 2.96g/cm^3, m 1460°, pK^{25} 10.4, K_{sp} 4.93 x 10^{-5} mol^2.L^{-2}, has a high affinity for H_2O and will absorb 6.6% of its weight of H_2O to form the ***hemihydrate*** (**gypsum**). It sets to a hard mass with H_2O; hence it should be kept in a tightly sealed container. The solubility of gypsum in H_2O is unusual: 0.176% at 0°, 0.209% at 30°, 0.210% at 40°, 0.204% at 50° and 0.200% at 60°. [Hulett *J Am Chem Soc* **27** 49 *1905*, DOI: 10.1021/ja01979a008; James & Partington *J Chem Soc* **107** 1019 *1915*, DOI: 10.1039/CT9150701019; Namba *J Soc Chem Ind* **40** 2797 *1920*, D.R. Linde (ed.) *CRC Handbook of Chemistry and Physics* 83rd Edition, CRC Press, *2002*]

Calcium thiosulfate (hypo, hydrosulfite) *[10124-41-1]* **CaS_2O_3, M 152.2, m 43-49°, pK$^{25}_1$ 0.6, pK$^{25}_2$ 1.74 (for $H_2S_2O_3$).** Recrystallise the thiosulfate from water below 60° in a N_2 atmosphere, followed by drying with EtOH and Et_2O. Store it in a refrigerator. The ***hexahydrate*** can decompose spontaneously at 43-49°. Store it in a cool closed container. A ~6% aqueous solution is a useful sulfur fertiliser. [Pethybridge & Taba *JCS Faraday*

Trans 1 **78** 1331 *1982*, DOI: 10.1039/F19827801331.]

Carbon dioxide *[124-38-9]* **CO_2, M 44.0, m -56.6°, sublimes at -78.5°, triple point 5.1atm at -0°, d 1562kg/m^3 (solid at -78.5°), d 770kg/m^3 (liquid at 56atm and 20°), d 1.977kg/m^3 (gas at 1atm and -56.6°; 1.67 times that of air), pK_1^{25} 6.35, pK_2^{25} 10.33 (for carbonic acid: H_2CO_3).** Pass the gas over CuO wire at 800° to oxidise CO and other reducing impurities (such as H_2), then over copper dispersed on Kieselguhr at 180° to remove O_2. Drying it at -78° removes the water vapour. Final purification is by vacuum distillation at liquid nitrogen temperature to remove non-condensable gases [Anderson et al. *J Chem Soc* 3498 *1962*, DOI: 10.1039/JR9620003498]. Sulfur dioxide contaminant can be removed at 450° using silver wool combined with a plug of platinised quartz wool. Halogens are removed by using Mg, Zn or Cu, heated to 450°. [Glemsner in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 647 *1963*, Fieser **3** 40, and in 5 later volumes.] At temperature and pressures above the critical point (31.1° at 7.38MPa), CO_2 is a ***supercritical fluid*** in which chemical reactions can be performed. Solid CO_2 is commercially available as ***Dry-Ice***, and in organic solvents is used in cooling baths (see Table 8, Materials for Cooling Baths in Chapter 1).

Carbon disulfide *[75-15-0]* **CS_2, M 76.1, m -112 to -111°, -110.8°, b 46.3°, d_4^{20} 1.264, n_D^{20} 1.627.** Shake it for 3 hours with three portions of $KMnO_4$ solution (5g/L), twice for 6 hours with mercury (to remove sulfide impurities) until no further darkening of the interface occurs, and finally with a solution of $HgSO_4$ (2.5g/L) or cold, saturated $HgCl_2$. Dry it with $CaCl_2$, $MgSO_4$, or CaH_2 (with further drying by refluxing over P_2O_5), followed by fractional distillation in diffuse light. **Alkali metals cannot be used as drying agents**. It has also been purified by standing with bromine (0.5ml/L) for 3-4 hours, shaking rapidly with KOH solution, then copper turnings (to remove unreacted bromine), and drying with $CaCl_2$. CS_2 is highly **TOXIC** has a **foul odour** and is highly **FLAMMABLE**. *Work in a good fumehood*.
Small quantities of CS_2 have been purified (including removal of hydrocarbons) by mechanical agitation of a 45-50g sample with a solution of 130g of sodium sulfide in 150ml of H_2O for 24 hours at 35-40°. The aqueous sodium thiocarbonate solution is separated from unreacted CS_2, then precipitated with 140g of copper sulfate in 350g of water, with cooling. After filtering off the ***copper thiocarbonate***, it is decomposed by passing steam into it. The distillate is separated from H_2O and distilled from P_2O_5. [Ruff & Golla *Z Anorg Chem* **138** 17 *1924*, DOI: 10.1002/zaac.19241380103; Fieser **1** 114, **5** 94, **6** 95; *Beilstein* **3** IV 395.] Available commercially in various grades of purity including *Spectroscopic grades*.

Carbon monoxide *[630-08-0]* **CO, M 28.0, m -205°, -200°, b -191.5°/atm, d^{25} 1.282g/cm^3, d 789kg/m^3(liquid), d 1250kg/m^3(at 0°/1atm), d 1145kg/m^3(at 25°/1atm), n_D^{25} 1.0003364.** Iron carbonyl is a likely impurity in CO stored under pressure in steel tanks. It can be decomposed by passing the gas through a hot porcelain tube at 350-400°. Passage through alkaline pyrogallol solution removes oxygen (and CO_2). Removal of CO_2 and water are effected by passage through soda-lime followed by $Mg(ClO_4)_2$ or P_2O_5 and collected over Hg. Carbon monoxide can be condensed and distilled at -195°. It is sparingly soluble in H_2O (27.6g/L at 25°), but is readily absorbed by a solution of CuCl in HCl to give the white crystalline ***adduct $CuCl.CO.2H_2O$***. It burns in air with a bright blue flame but a mixture of 2 volumes of CO and 1volume of O_2 explode when kindled, although in a small jar the combustion is not violent. **HIGHLY POISONOUS gas** as it reacts with haemoglobin to form ***bright red carboxyhaemoglobin*** which is stable and not readily decomposed by oxygen. The **TOXIC LEVEL** of CO is 50ppm (~55mg/m^3). **The ANTIDOTE should be at hand and always available in laboratories using CO; and staff should be trained to administer it.** [Gilliland et al. *Inorg Synth* **2** 81 *1946*, DOI: 10.1002/9780470132333.ch22; Glemser in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 645-646 *1963*.]

Carbonyl bromide (bromophosgene) *[593-95-3]* **$COBr_2$, M 187.8, b 64.5°/760mm(dec), d 2.52g/cm^3(15°).** Purify it by distillation from Hg and from powdered Sb to remove free bromine, then distil it in a slight vacuum to remove volatile SO_2 (the major impurity) [Carpenter et al. *JCS Faraday Trans 2* 384 *1977*, DOI: 10.1039/F29777300384]. **TOXIC.**

Carbonyl sulfide *[463-58-1]* **COS, M 60.1, m -138°, b -47.5°/atm -50.2°/atm, d^{25} 2.51g/L.** Purify the ***sulfide-like smelling*** gas by scrubbing it through three consecutive fritted washing flasks containing conc NaOH at 0° (to remove HCN), and then through concntrated H_2SO_4 (to remove CS_2) followed by a mixture of NaN_3

and NaOH solution; or passed through traps containing saturated aqueous lead acetate, then through a column of anhydrous $CaSO_4$. Then it is freeze-pumped repeatedly and distilled through a trap packed with glass wool and cooled to -130° (using an *n*-pentane slurry). It liquefies at 0°/12.5mm. Use stainless steel containers. The gas is stored over conc H_2SO_4, because in the presence of moisture and bases it decomposes to CO and H_2S. [Glemser in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 654 *1963*.] **TOXIC**

Ceric (IV) ammonium nitrate *[16774-21-3]* **$Ce(NH_4)_2(NO_3)_6$, M 548.2, pK_1^{25} -1.15, pK_2^{25} -0.72, pK_3^{25} 1.68, pK_4^{25} 2.29 (for aquo Ce^{4+}).** Ceric ammonium nitrate (125g) is warmed with 100ml of dilute HNO_3 (1:3 v/v) and 40g of NH_4NO_3 until it dissolves, and filtered through a sintered-glass funnel. The orange-red solid which separates on cooling in ice is filtered off on a sintered funnel (at the pump) and air is sucked through the solid for 1-2 hours to remove most of the nitric acid. Finally, the solid is dried at 80-85°. A primary standard in ***iodometry*** [Smith & Fly *Anal Chem* **21** 1233 *1949*, DOI: 10.1021/ac60034a027; Smith *Talanta* **10** 709 *1963*, DOI: 10.1021/ac60034a027]. This nitrate is also commercially available as a silica gel supported oxidising agent [Hwu et al. *J Org Chem* **65** 5077 *2000*, DOI: 10.1021/jo000024o].

Cerium(III) sulfate [cerous sulfate,] *[13454-94-9 anhydrous*; *10450-59-6 8H_2O*; *13550-47-5 12 H_2O]* **$Ce_2(SO_4)_3$, M 568.4 (anhydr), m 920°(dec), d_4^{25} 2.89, pK^{25} 9.29 (for hydrolysis of Ce^{3+}).** To prepare cerous sulfate, cerium oxide [CeO_2, 0.3g) or chloride is dissolved in hot 6N H_2SO_4 (20ml), filtered through a sintered glass funnel and allowed to crystallise over concentrated H_2SO_4 in a vacuum dessicator. The crystals are filtered off, washed twice with H_2O (10ml) and once with EtOH (10ml), and dried in air for 4 hours to provide the ***pentahydrate***. *Alternatively*, a neutral or slightly acidic (with H_2SO_4) aqueous solution of the sulfate is treated with ¾ of its volume of EtOH. The salt is thus obtained rapidly and quantitatively without the evaporation stage. The ***anhydrous*** sulfate is formed by heating any sulfate hydrate salt at 400-500°, but is ***hygroscopic***. The hydrate loses most of its H_2O at *ca* 250°, and above 650° it loses SO_3 also to give the basic salt. [Wendlandt *J Inorg Nucl Chem* **7** 51 *1958*, DOI: 10.1016/0022-1902(58)80026-3; Wetzel in *Handbook of Preparative Inorganic Chem (Ed. Brauer)* Academic Press Vol **11** p 1156 *1965*.] When a fairly concentrated solution of the anhydrous salt in ice H_2O, is allowed to evaporate at 40-50°, the ***octahydrate salt*** separates as colourless rhombic pyramids [Koppel *Z Anorg Chem* **41** 377 *1904*, DOI: 10.1002/zaac.19040410123]. The ***dodecahydrate*** is obtained in fine needles when a clear fairly concentrated solution of cerous sulfate is allowed to evaporate over concentrated H_2SO_4 in a desiccator in a refrigerator [Koppel *Z Anorg Chem* **41** 377 *1904*, DOI: 10.1002/zaac.19040410123]. [Vanino *Handbuch der Präparativen Chemie* Vol **I**, 3rd Edn, pp 754-755, Stuttgart *1925*.]

Cerium(IV) sulfate [ceric sulfate,] *[13590-82-4 anhydrous]* **$Ce(SO_4)_2$, M 332.2, d_4^{25} 3.01, pK_1^{25} -1.15, pK_2^{25} -0.72, pK_3^{25} 1.68, pK_4^{25} 2.29 (for hydrolysis of Ce^{4+}).** Ceric sulfate is prepared by heating pure ceric oxide (CeO_2) with an excess of concentrated H_2SO_4 for an hour, cooling, adding glacial acetic acid, stirring, allowing to settle and decanting off. The process is repeated several times and the yellow orthorhombic crystals of the sulfate are filtered off (sintered glass), washed with glacial acetic acid and dried in a vacuum desiccator over NaOH/KOH and/or soda lime. [Vanino *Handbuch der Präparativen Chemie* Vol **I**, 3rd Edn, pp 754-755, Stuttgart *1925*, Meyer & Aufrecht *Chem Ber* **37** 140 *1904*, DOI: 10.1002/cber.19040370124.] It is a strong ***oxidising agent*** (oxidation potential of a 1 to 8N H_2SO_4 solution at 25° is 1.42 ±0.1 volts), and like ceric ammonium sulfate is used in volumetric analysis. Solutions in dilute H_2SO_4 are standardised by titration with pure arsenious oxide, iron or ferrous ammonium sulfate. Although it is its own end-point indicator (Ce^{4+} ions are yellow and C^{3+} ions are colourless), the end point is not as sharp as that of permanganate, and it is best to use 0.005M*N*-phenylanthranilic acid as indicator (colour change from yellow-green to purple at end point) [J. Mendham, R.C. Denney, J.D. Barnes and M.J.K. Thomas, *Vogel's Quantitative Chemical Analysis*, 6th Edn, Prentice Hall, Harlow, *2000*, ISBN 0582226287].

Ceric sulfate tetrahydrate is obtained thus: pure ceric ammonium nitrate *[16774-21-3]* in a small volume of H_2O is treated with ammonia, $Ce(OH)_4$ separates, is collected and is dissolved in concentrated H_2SO_4. This solution is evaporated to dryness and the residue is crystallised from H_2O (perhaps a small amount of H_2SO_4 should be added to avoid hydrolysis). A small volume of H_2O should be used as boiling with a large volume of H_2O leads to separation of the basic salt. The yellow-orange powder or orthorhombic crystals lose H_2O to give the anhydrous salt at 180-200°, but decomposes >350° to give the basic salt $CeOSO_4$. [Vanino *Handbuch der Präparativen Chemie* Vol **I**, 3rd Edn, pp 755-756, Stuttgart *1925*, Muthmann & Stützel *Chem Ber* **33** 1763 *1900*,

DOI: 10.1002/cber.19000330255.]

Cesium bromide *[7787-69-1]* **CsBr, M 212.8, m 636°, b *ca* 1300°/atm, d $_4^{20}$ 4.44.** It is very soluble in H_2O, soluble in EtOH but insoluble in Me_2CO. Dissolve it in the minimum volume of H_2O, filter and precipitate it by adding Me_2CO. Filter off the solid and dry it at 100°. Also recrystallise it from water [1.06g/ml (15°), 1.24g/ml (25°)] by partial evaporation in a desiccator. Used as a beam splitter in spectrometers.

Cesium carbonate *[534-17-8]* **Cs_2CO_3, M 325.8, m 610°(dec), 792°(at red heat).** Crystallise it from ethanol (10ml/g) by partial evaporation. [Dönges in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 988 *1963*.] It promotes efficient *O*-alkylation of alcohols to produce alkyl carbonates, and is used for the aerobic oxidation of arylalkanes to aryl ketones [Park et al. *Synthesis* 3617 *2006*, DOI: 10.1055/s-2006-950189].

Cesium chloride *[7647-17-8]* **CsCl, M 168.4, m 645°, b 1303°atm, d $_4^{20}$ 3.99.** It is soluble in H_2O but can be purified by crystallisation from H_2O [solublity in g percent: 162.3(0.7°), 182.2(16.2°) and 290(at bp 119.4°)] and dried in high a vacuum. It is soluble in EtOH and is ***deliquescent***; keep it in a tightly closed container. [Dönges in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** pp 951-955 *1963*.] For further purification of CsCl, a concentrated aqueous solution of the practically pure reagent is treated with an equivalent weight of I_2 and Cl_2 is bubbled into the solution until preciptation of ***$CsCl_2I$*** is complete. Recrystallisation yields a salt that is free from other alkali metals. It is then decomposed to pure CsCl on heating. [Harned & Schupp *J Am Chem Soc* **52** 3886 *1930*, DOI: 10.1021/ja01373a019.] It can also be recrystallised from acetone/water, or from water (0.5ml/g) by cooling in a $CaCl_2$/ice bath. Dry it at 78° under vacuum. It is a very useful salt for making solutions for the separation of RNA and DNA by density gradient centrifugation [Maniatis et al. *Molecular Cloning: A Laboratory Manual* Cold Spring Harbor Laboratory Press (Cold Spring Harbor) *1989*, ISBN 0-87969-309-6].

Cesium chromate *[56320-90-2]* **Cs_2CrO_4, M 381.8, d ^{25} 4.237g/cm^3, pK_1^{25} 0.74, pK_2^{25} 6.49 (for H_2CrO_4).** Crystallise the yellow chromate from water (0.71g/ml at 13°) by partial evaporation in a desiccator. [Boer et al. *Z Anorg Allgem Chem* **191** 113 *1930*, DOI: 10.1002/zaac.19301910114; Hein & Herzog in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **11** p 1389 *1963*.]

Cesium fluoride *[13400-13-0]* **CsF, M 151.9, m 682°, 703°, b 1251°/atm, d ^{25} 4.115g/cm^3, n $_D^{25}$ 1.477.** Crystallise it from aqueous solution by adding ethanol. The solubility in H_2O is 3.67g/ml at 18°. CsF chains with one or two atom thickness can be grown inside carbon nanotubes [Senga & Suenaga *Nature Commun* **6** 7943 *2015*, DOI: 10.1038/ncomms8943]. The strong Si—F bond makes CsF (soluble in dioxane, THF and DMF) a useful reagent for de-silylation reactions [see Smith et al. *Org Synth* Coll Vol **10** 107 *2002*, DOI: 10.15227/orysyn.078.0082]. CsF is a base in ***Suzuki cross-coupling*** of *ortho*-substituted biaryls [Li et al. *J Orgmet Chem* **691** 5688 *2006*, DOI: 10.1016/ j.jorganchem.2006.09.023], and is employed as a reagent for nucleophilic fluorination of primary halides and sulfonates in protic media, e.g. *tert*-butyl and *tert*-pentyl alcohols [Kim et al. *J Am Chem Soc* **128** 16394 *2006*, DOI: 10.1021/ja0646895].

Cesium iodide *[7789-17-5]* **CI, M 259.8, m 621°, b~1280°/atm, d $_4^{20}$ 4.51, n $_D^{25}$ 1.739.** Crystallise from warm water (1ml/g) by cooling to -5°. Like CsF, it has been grown in carbon nanotubes [Senga et al. *Nature Materials* **13** 1050 *2014*, DOI: 10.1038/nmat4069], and used in phosphor screens for imaging, scintillators, calorimeters and various particle detectors [Kalivas et al. *Appl Phys A* **78** 915 *2004*, DOI: 10.1007/s00339-003-2089-5].

Cesium nitrate *[7789-18-6]* **$CsNO_3$, M 194.9, m 414°(dec), d $_4^{20}$ 3.65.** It crystallises from water [solubility: 0.2g/ml (~10°), 2.0g/ml (100°)] between 100° and 0°. After 1 crystallisation of 99.9% grade salt, it had K, Na and Se at 0.8, 0.4 and 0.2 ppm respectively. [Watt et al. *Inorg Synth* **4** 5 *1953*, DOI: 10.1002/ 9780470132357.ch2.]

Cesium perchlorate *[13454-84-7]* **$CsClO_4$, M 232.4, m 250°(dec), d ^{25} 3.327g/cm^3, n $_D^{25}$ 1.4887, pK^{25} -2.4 to -3.1 (for $HClO_4$).** Crystallise it from water (4ml/g) between 100° and 0°. It decomposes above 250° to CsCl. Strong oxidant.

Cesium sulfate *[10294-54-9]* **Cs_2SO_4, M 361.9, m 1005°, 1010°, d_4^{20} 4.243.** Crystallise it from water (0.5ml/g) by adding ethanol and cooling. It is very soluble in H_2O (1.7g/ml at 0°), but insoluble in most organic solvents. Used to prepare dense aqueous solutions for ***density gradient*** centrifugation of DNA. [Gmelin's, Cesium (8th edn) **25** pp 218-225 *1938*.]

Chlorine *[7782-50-5]* **Cl_2, M 70.9, m -101.5°, b -34.0°/atm, d_4^{20} 2.898.** Pass the gas in succession through aqueous $KMnO_4$, dilute H_2SO_4, conc H_2SO_4, and a drying tower containing $Mg(ClO_4)_2$. Or bubble it through water, dry it over P_2O_5 and distil it from bulb to bulb in a vacuum line. One volume of water dissolves 4.6 volumes of Cl_2 at 0°, 2.15 volumes at 20°, 1.22 volumes at 50° and 0.39 volumes at 90°. [Schmeisser in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 272 *1963*.] **HIGHLY TOXIC.**

Chlorine trifluoride *[7790-91-2]* **ClF_3, M 92.5, m -76.34°, b 12.1°/atm, 11.75°/atm, d^{25} 4mg/cm^3.** Impurities include chloryl fluoride, chlorine dioxide and hydrogen fluoride. Passed it first through two U-tubes containing NaF to remove HF, then through a series of traps in which the liquid is fractionally distilled. It can be purified *via* the KF complex; $KClF_4$, formed by adding excess ClF_3 to solid KF in a stainless steel cylinder in a dry-box and shaking overnight. After pumping out the volatile materials, pure ClF_3 is obtained by heating the bomb to 100-150° and condensing the evolved gas in a -196° trap [Schack et al. *Chem Ind (London)* 545 *1967*]. It attacks glass very vigorously, and reacts with H_2O violently to form HF, HCl and O_2. **HIGHLY TOXIC.**

Chlorosulfonic acid (chlorosulfuric acid) *[7790-94-5]* **$ClSO_3H$, M 116.5, m -80°, b 151-152°/750mm, d_4^{20} 1.753, n_D^{20} 1.4929, pK^{25} -5.9 (aqueous H_2SO_4).** Distil the acid at atmospheric pressure in an all-glass apparatus, taking the fraction boiling at 156-158°. It reacts **EXPLOSIVELY** with water, **wear gloves and face protection.** [Cremlyn *Chlorosulfonic acid: A Versatile Reagent*, Royal Society of Chemistry UK, *2002*, p 308, ISBN 0854044981, Fieser **1** 140, **2** 70, **6** 121, Fehér in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 385 *1963*].

Chromium ammonium sulfate dodecahydrate *[34275-72-4 (hydrate), 10022-47-6 ($12H_2O$), 13548-43-1 (anhydrous)]* **$NH_4Cr(SO_4)_2$. $12H_2O$, M 478.4, m 94° loses $9H_2O$ then dehydrates at 300°, d_4^{20} 1.72.** Crystallise the blue-violet double salt from a saturated aqueous solution at 55° by cooling slowly with rapid mechanical stirring. The resulting fine crystals are filtered on a Büchner funnel, partly dried on a porous plate, then equilibrated for several months in a vacuum desiccator over crude chromium ammonium sulfate (partially dehydrated by heating at 100° for several hours before use) [Johnston et al. *J Am Chem Soc* **75** 3922 *1953*, DOI: 10.1021/ja01112a013].

Chromium (II) chloride (anhydrous) *[10049-05-5]* **$CrCl_2$, M 122.9, m 824°, d_4^{14} 2.75**. It is obtained from the ***dihydrate*** by heating *in vacuo* at 180°. It is a very ***hygroscopic*** white powder which dissolves in H_2O to give a sky blue solution. It is stable in dry air but oxidises rapidly in moist air and should be stored in air tight containers. It sublimes at 800° in a current of HCl gas and should be cooled in the presence of HCl gas. *Alternatively*, it can be washed with air-free Et_2O and dried at 110-120°. [Burg et al. *Inorg Synth* **3** 150 *1950*, DOI: 10.1002/9780470132340.ch40; Balthis et al. (4 H_2O) *Inorg Synth* **1** 125 *1939*, DOI: 10.1002/9780470132326.ch46; Fieser **1** 149, **2** 76, **3** 60, **4** 144, **7** 73, **9** 511, **11** 132, **12** 136, **13** 84, **14** 94, **15** 95, **16** 93, **17** 84; Hein & Herzog in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **II** pp 1336-1338 *1965*.] $CrCl_3$ is useful for the preparation of a very active ***precatalyst*** for ethylene polymerisation [Small et al. *Macromolecules* **37** 4375 *2004*, DOI: 10.1021/ma035554b], promotes the condensation of aldehydes with trisubstituted chloroalkenes [Falck et al. *Tetrahedron Lett* **45** 3039 *2004*, DOI: 10.1016/j.tetlet.2004.02.101], converts terminal olefins into *trans*-iodocyclopropanes in excellent yields when used with CHI_3 and tetra-alkyl ethylenediamine [Takai et al *J Organomet Chem* **692** 520 *2007*, DOI: 10.1016/j.jorganchem.2006.06.047], and for the preparation of bis(indenyl)chromium dimer and related compounds [Heinemann et al. *Organometallics* **15** 5462 *1996*, DOI: 10.1021/om960899m].

Chromium (III) chloride (anhydrous) *[10025-73-7, 10060-12-5 ($6H_2O$)]* **$CrCl_3$, M 158.4(anhydrous), m 1152°, b 1300°/atm dissociates, d^{25} 2.87g/cm^3(25°, anhydrous), d^{25} 1,760g/cm^3(hexahydrate), pK_1^{25} 3.95,**

pK_2^{25} 5.55, pK_3^{25} 10.5 (for Cr^{3+}). The chloride is purple when anhydrous and dark green when hexahydrated. Sublime the chloride in a stream of dry HCl. *Alternatively*, the impure chromic chloride (100g) is added to 1L of 10% aqueous $K_2Cr_2O_7$ and several millilitres of concentrated HCl, and the mixture is brought to a gentle boil with constant stirring for 10 minutes. (This removed a reducing impurity.) The solid is separated and washed by boiling with successive 1L lots of distilled water until the wash water no longer gives a test for chloride ion, then dry it at 110°. The ***anhydrous*** chloride is only slightly soluble in H_2O, dissolving slowly but more rapidly if a wetting agent is added. The ***hexahydrate*** has a solubility of 585g/L at ~25°, and X-ray analysis showed that it was *trans*-**dichlorotetraaquochromium (III) chloride dihydrate *'Bjerrum-green'*** [Dance & Freeman *Inorg Chem* **4** 1555 *1965*, DOI: 10.1021/ic50033a006]. [For preparation see Heisig et al. *Inorg Synth* **2** 193 *1946*, DOI: 10.1002/9780470132333.ch59; and Pray *Inorg Synth* **5** 153 *1953*, DOI: 10.1002/9780470132364.ch43]. [Poulsen & Garner *J Am Chem Soc* **81** 2615 *1959*, DOI: 10.1021/ja01520a005; Hein & Herzog in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **II** p 1338 *1965*]. It has uses as a mordant, in tanning, as a waterproofing agent and corrosion inhibitor, as well as an olefin polymerising catalyst.

Chromium (III) nitrate nonahydrate *[7789-02-8]* **$Cr(NO_3)_3$, M 400.2, m ~60° (dec >100°).** The pure deep purple nonahydrate salt is best prepared freshly from pure recrystallised (3 times) chromium (VI) trioxide and pure nitric acid. A solution is prepared by dissolving 1g of CrO_3 in 3ml of H_2O and 2ml of pure HNO_3, and carefully, with stirring (behind a screen) pure MeOH (0.5-1.0ml) is added dropwise carefully (shield) with cooling to avoid a violent reaction. A bluish colour develops as Cr(VI) is reduced to Cr(III). When this solution is diluted to 130,000ppm of the salt, analysis detected by ICP/MS gave the following trace elements (ppm in brackets): Sr (33), Na (3.5), Mo, Ni, Cu, Si and Mg (0.13 each), Se, Zn, Al (0.026 each), Ti (1.5), Fe (4.9), Co (0.07), Sn (0.065), Ba (0.013 and W (0.078). Evaporation of the methanolic solution in high vacuum over $CaCl_2$ eventually yields pure deep violet rhombic crystals of chromium (III) nitrate ***nonahydrate***. An aqueous solution of this salt becomes green on heating but reverts to the violet colour on cooling.
The pale green (blue-violet) ***anhydrous*** **chromium (III) nitrate**, *[13548-38-4]* **M** 238.0, **m dec >60°**, is best obtained pure by mixing a solution of chromium hexacarbonyl in CCl_4 with excess of N_2O_5 in CCl_4 under N_2 for 12 hours, whereby evolution of gasses occurs. Filter off the salt and wash it with CCl_4 in a closed system under N_2, and dry it *in vacuo*. It is very soluble in H_2O, EtOAc and Me_2SO but insoluble in $*C_6H_6$, CCl_4 and $CHCl_3$. The ***deliquescent*** powder reacts vigorously with Et_2O. [Addison & Chapman *J Chem Soc* 508 539 *1964*, DOI: 10.1039/JR9640000508.] **Cr(VI)** ions are **CARCINOGENIC** as they cause DNA breaks, and Cr(III) ions affect DNA synthesis.

Chromium (III) potassium sulfate dodecahydrate (chrome alum) *[7788-99-0, 10141-00-6]* **$CrK(SO_4)_2.12H_2O$, M 499.4, m 89°, b 400°/atm, d^{25} 1.38g/cm^3, pK_1^{25} 0.74, pK_2^{25} 6.49 (for H_2CrO_4, chromic acid).** Crystallise it from hot water (solubility: 0.24g/ml at 25°) by cooling (dark purple needles). Aqueous solutions are dark violet but turn green if heated above 50°. It is used in tanning leather and to harden photographic gel emulsions.

Chromium (III) oxide (chromium sesquioxide, Pigment Green 17, Chromia) *[1333-82-0]* **Cr_2O_3, M 152.0, m 2435°, b 3000-4000°/atm, d^{25} 5.22g/cm^3, n_D^{25} 2.551, CI 77288.** This Cr(III) oxide is insoluble in H_2O, organic solvents, but is ***amphoteric***, dissolving in acids to give the hydrated chromium cation $[Cr(H_2O)_6]^{3+}$, and reacts in bases to give $[Cr(OH)_6]^{3-}$ salts. In concentrated alkali it provides chromite ions. It is best prepared by decomposition of chromium salts, e.g. $Cr(NO_3)_3$ or ammonium dichromate $[(NH_4)_2Cr_2O_7]$ (***exothermic***, a reaction with a low ignition temperature <200°, frequently used in ***'volcano' demonstrations***). The oxide is a hard solid and useful as an abrasive in sharpening (stropping) the edges of knives. On heating it turns brown in colour but reverts to green on cooling. It is used as a pigment (Viridian or Chrome Green) in paints, for colouring glass, printing banknotes, and dyeing fabrics. [Gerd Anger et al. 'Chromium Compounds' in *Ullmann's Encyclopedia of Industrial Chemistry* Wiley-VCH, Weinheim, *2005*, DOI: 10.1002/14356007.a07_067].

Chromium (IV) trioxide (chromic anhydride) *[1333-82-0]* **CrO_3, M 100.0, m 197°, dec at 250° to Cr_2O_3, d^{20} 2.70 (pK_1^{25} 0.74, pK_2^{25} 6.49, for H_2CrO_4, chromic acid).** It forms red crystals from water between 100° and -5°, [solubility: 1.65g/ml (0°), 1.69g/ml (25°), 1.72g/ml (40°) and 1.98g/ml (100°)], or from water/concentrated HNO_3 (1:5). It separates when potassium or sodium dichromate are dissolved in concentrated H_2SO_4. Filter it

off using a sintered glass funnel. Dry it in a vacuum desiccator over NaOH pellets. It is dark purple under anhydrous conditions. It is a ***hygroscopic***, powerful oxidant and can ***ignite*** with organic compounds. [Fieser **1** 44, **1** 144, **2** 72, **3** 54, **4** 96, **5** 140, **7** 70, **9** 115, **10** 99, **12** 131, **15** 92, **17** 86; Keyes et al. *Industrial Chemicals* (Lowenheim & Moran eds.) 4th edn J. Wiley pp 270-274 *1975*.] CrO_3-NH_4Cl oxidises hydrobenzoins to the respective benzils in $CHCl_3$ in high yields at ~25° under ultrasound irradiation [Li & Sun *Lett Org Chem* **3(11)** 842 *2006*, DOI: 10.2174/157017806779116987]. It is a skin and pulmonary **IRRITANT**, and a **CANCER SUSPECT.**

Chromyl chloride *[14977-61-8]* **CrO_2Cl_2, M 154.9, m -96.5°, b 115.7°/atm, 117°/atm, d ^{25} 1.911.** Purify it by distillation under reduced pressure. It hydrolyses violently with H_2O and is a powerful ***oxidant*** which explodes with P, and ***ignites*** in contact with S, NH_3, EtOH and many organic compounds. [Freeman et al. 'Aldehydes by Oxidation of Terminal Olefins with Chromyl Chloride: 2,4,4-Trimethylpentanal' *Org Synth* Coll. Vol **6**, 1028 *1988*, DOI: 10.15227/orgsyn.051.0004.] Its formation is used as a specific test for chloride: if the sample containing chloride is mixed with $K_2Cr_2O_7$ and concentrated H_2SO_4, the solution forms red CrO_2Cl_2 and red fumes are liberated — This does not happen when chloride is absent or in the presence of fluorides, bromides, iodides and cyanide. [Freeman 'Chromyl Chloride' in *Encyclopedia of Reagents for Organic Synthesis* J. Wiley & Sons, NY, L. Paquette ed. 2004, DOI: 10.1002/047084289.] **TOXIC.**

Claisen alkali (alkali Claisen). Prepare this from KOH (35g) in H_2O (25ml) and dilute it to 100ml with MeOH. **STRONGLY CAUSTIC.**

Cobaltous ammonium sulfate hexahydrate *[13596-46-8, 13586-38-4]* **$(NH_4)_2Co(SO_4)_2.6H_2O$, M 395.5, m 120°(dec), d ^{25} 5.22g/cm^3.** Crystallise it from boiling water (2ml/g) by cooling. Wash it with ethanol and dry it in a vacuum.

Cobaltous bromide hexahydrate *[85017-77-2 (xH_2O), 7789-43-7 (anhydrous)]* **$CoBr_2.6H_2O$, M 326.9 ($6H_2O$), M 218.7(anhydr), m 47°(dec, $6H_2O$), 678°(anhydr), d $^{20}_{4}$ 4.9.** Crystallise it from water (1ml/g) by partial evaporation in a desiccator (red-purple, hydrate). The ***anhydrous*** salt (bright green) is soluble in EtOH, Me_2CO, MeOAc to form blue-coloured solutions. [Glemser in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **II** p 1517 *1965*.]

Cobaltous chloride hexahydrate *[7791-13-1 ($6H_2O$), 69098-14-2 (xH_2O), 7646-79-9 (anhydrous)]* **$CoCl_2.6H_2O$, M 237.9, m 87°(dec), d $^{20}_{4}$ 1.92.** A saturated aqueous solution at room temperature is fractionally crystallised by standing overnight. The first half of the material that crystallises in this way is used in the next crystallisation. The process is repeated several times, water being removed in a dry-box using air filtered through glass wool and dried over $CaCl_2$ [Hutchinson *J Am Chem Soc* **76** 1022 *1954*, DOI: 10.1021/ja01633a025]. It has also been crystallised from dilute aqueous HCl. The ***hexahydrate*** **m 86°** forms pink to red ***deliquescent*** crystals. It loses $4H_2O$ on heating at 52-56° and forms the violet ***dihydrate*** which loses a further H_2O at 100° to form the violet ***monohydrate*** which loses the last H_2O molecule at 120-140° to give the pale blue ***anhydrous deliquescent*** salt **m 735°** (**724°**) and **b 1049°.** A pink solution of $CoCl_2$ in H_2O becomes blue on heating to 50° or adding conc HCl which may precipitate the ***mono*** or ***dihydrate***. The solid ***dihydrate*** gives a blue-purple solution with EtOH. **Note**: $CoCl_2$ in H_2O is a '***sympathetic ink***', i.e. writing with an aqueous solution is almost invisible on paper, but becomes blue on warming the paper. On cooling or standing, the writing becomes invisible again. The ***anhydrous*** salt is soluble in H_2O, EtOH, Et_2O, Me_2CO and pyridine. [Glemser in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **II** p 1515 *1965*.]

Cobaltous nitrate hexahydrate *[10026-22-9]* **$Co(NO_3)_2.6H_2O$, M 291.0, m ~55°($6H_2O$), 100-105°(dec), d $^{20}_{4}$ 1.88.** Crystallise the red nitrate from water (1ml/g), or ethanol (1ml/g), by partial evaporation. After 3 crystallisations from H_2O it contains: metal (ppm) As (8), Fe (1.2), K (1), Mg (4), Mn (4), Mo (4), Na (0.6), Ni (18), Zn (1.6). The ***hexahydrate*** gives the pink ***anhydrous*** salt by the action of HNO_3 and N_2O_5. The ***hexahydrate*** melts at **~55°** to give a red liquid which decomposes on further heating at 100-105° to form Co_3O_4.

Cobaltous perchlorate hexahydrate *[13478-33-6]* **$Co(ClO_4)_2.6H_2O$, M 365.9, m 1534°, pK^{25} -2.4 to -3.1 (for $HClO_4$).** Crystallise the red solid from warm water (0.7ml/g) by cooling. Used in battery manufacture.

Cobaltous potassium sulfate *[13596-22-0]* **$CoK_2(SO_4)_2$, M 329.3, d $_4^{20}$ 2.22(anhydr).** Crystallise it from water (1ml/g) between 50° and 0°, and dry it in a vacuum desiccator over conc H_2SO_4. Red, monoclinic prismatic, crystals (***hexahydrate***) are obtained that lose H_2O on heating above 75° to form the reddish-brown ***dihydrate*** that is stable between 120-150°. It becomes ***anhydrous*** (violet solid) above 220°. [*Gmelin's, Cobalt* (8th ed.) **58** (part A) p 414 *1932*, and supplement pp 782-786 *1961*.]

Cobaltous sulfate heptahydrate *[10026-24-1 ($7H_2O$), 60459-08-7 (xH_2O), 10124-43-3 (anhydrous)]* **$CoSO_4.7H_2O$, M 281.1, m (see text), d $_4^{20}$ 2.03.** Crystallise it three times from conductivity water (1.3ml/g) between 100° and 0° depending on which hydrate is required. The ***heptahydrate*** crystallises below 44° and is ***efflorescent*** with **m 97°**. Between 44° and 70° the monoclinic ***hexahydrate*** $CoSO_4.6H_2O$ **m 41.5°** is formed, and above 70° the ***monohydrate*** $CoSO_4.H_2O$ **m 71°** is obtained. The pale reddish or lavender-coloured ***anhydrous*** salt is obtained by heating the hydrate above 250°, boiling with conc H_2SO_4 or by heating with $(NH_4)_2SO_4$).

Cupric ammonium chloride dihydrate *[10534-87-9 (hydrate), 15610-76-1 (anhydrous)]* **$(NH_4)_2CuCl_4.2H_2O$, M 277.5, m 110-120°(anhydrous) then dec at higher temperature, d $_4^{20}$ 1.993.** Crystallise it from weak aqueous HCl (1ml/g). It crystallises out of a hot solution of $CuCl_2$ saturated with NH_3 gas.

Cupric (II) bromide *[7789-45-9]* **$CuBr_2$, M 223.4, m 498°, b 900°/atm, d $_4^{20}$ 4.77.** Crystallise it twice by dissolving it in water (140ml/g), filtering to remove any Cu_2Br_2, and concentrating under vacuum at 30° until crystals appear. The cupric bromide is then allowed to crystallise by leaving the solution in a vacuum desiccator containing P_2O_5. [Hope et al. *J Chem Soc* 5226 *1960*, DOI: 10.1039/JR9600005226; Glemser & Sauer in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **II** p 1009 *1965*, Fieser **1** 161, **2** 84, **5** 158, **6** 138, **14** 100, **15** 100.]

Cupric (II) chloride *[7447-39-4]* **$CuCl_2$, M 134.4, m 498°, 620°, 630°(dec).** Crystallise the chloride from hot dilute aqueous HCl (0.6ml/g) by cooling in a $CaCl_2$-ice bath. It is dehydrated by heating on a steam bath under vacuum. It is ***deliquescent*** in moist air but ***efflorescent*** in dry air. The ***dihydrate*** is emerald green but blue when free from solvent. Concentrated solutions are yellow-green in colour but are blue when free from solvent. Concentrated solutions are yellow-green and become yellow on adding conc HCl. A very dilute solution is pure **blue** due to **$Cu(H_2O)_4^{2+}$** [Donnan & Bassett *J Chem Soc* **81** 939 *1902*, DOI: 10.1039/CT9028100939.]. $CuCl_2$ is very ***deliquescent*** and is soluble in MeOH or EtOH to give **green** crystals of **$Cu(ROH)_2Cl_2$**. [Glemser & Sauer in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **II** p 1008 *1965*, Fieser **1** 163, **2** 84, **3** 66, **4** 105, **5** 158, **6** 139, **7** 79, **8** 119, **9** 123, **10** 106, **13** 85, **14** 100.] Used with Pd in the catalytic synthesis of 3-haloindoles *via* annulation [Tang et al. *Synthesis* 1841 *2007*, DOI: 10.1055/s-2007-983717.]

Cupric (II) nitrate trihydrate *[10031-43-3 ($3H_2O$), 13478-38-1 ($6H_2O$), 19004-19-6 ($2.5H_2O$), 3251-23-8 (anhydrous)]* **$Cu(NO_3)_2.3H_2O$, M 241.6($3H_2O$), m 26.4°($6H_2O$, dec), 114.5°($3H_2O$, dec), 256°(anhydr, dec), b 170°/atm($3H_2O$, dec), d $_4^{20}$ 2.0.** Crystallise it from weak aqueous HNO_3 (0.5ml/g) by cooling from room temperature. The ***anhydrous*** salt can be prepared by dissolving copper metal in a 1:1 mixture of liquid NO_2 and ethyl acetate and purified by sublimation [Evans et al. *JCS Faraday Trans 1* **75** 1023 *1979*, DOI: 10.1039/F19797501023]. The ***hexahydrate*** dehydrates to the ***trihydrate*** at 26°, and the ***anhydrous salt*** sublimes between 150 and 225°/high vacuum, but melts at **255-256°** and is ***deliquescent***.

Cupric (II) perchlorate hexahydrate *[10294-46-9 (hydrate), 13770-18-8]* **$Cu(ClO_4)_2.6H_2O$, M 370.5, m 230-240°, d ^{25} 2.225g/cm^3, pK^{25} -2.4 to -3.1 (for $HClO_4$).** Crystallise it from distilled water. The ***anhydrous salt*** is hygroscopic.

Cupric (II) sulfate (blue vitriol, blue stone) *[7758-98-7 (anhydrous), 7758-99-8 ($5H_2O$), 16448-28-5 ($3H_2O$), 23254-43-5 ($4\text{-}6H_2O$), 19086-18-1 ($7H_2O$)]* **$Cu(SO_4)_2.5H_2O$, M 159.6, m 110°(hydrate), >560°(anhydr).** After adding 0.02g of KOH to a litre of nearly saturated aqueous solution of the sulfate, it is left for two weeks, then the precipitate is filtered on to a fibreglass filter with pore diameter of 5-15 microns. The filtrate is heated to 90° and allowed to evaporate until some $CuSO_4.5H_2O$ crystallises out. The solution is then filtered hot and cooled rapidly to give crystals which are freed from mother liquor by filtering under suction [Geballe & Giauque

J Am Chem Soc **74** 3513 *1952*, DOI: 10.1021/ja01134a017]. *Alternatively*, crystallise the sulfate from water (0.6ml/g) between 100° and 0°. The ***pentahydrate*** is slowly ***efflorescent***, losing $2H_2O$ at 30°, two more H_2O are lost at 110° and a ***white*** anhydrous powder (desiccant) is obtained on heating above 250°. [Hoffman *Copper(II) Sulfate, in Encyclopedia of Reagents for Organic Synthesis*, John Wiley & Sons. *2001*, DOI: 10.1002/047084289X.rc247].

Cuprous (I) bromide *[7787-70-4]* **CuBr, M 143.4, m 497°, 504°, b 1345°, d $_4^{20}$ 4.72.** Purify it as for cuprous iodide but using aqueous NaBr. [Keller et al. *Inorg Synth* **2** 1 *1946*, DOI: 10.1002/9780470132333.ch1; Glemser & Sauer in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **II** p 1006 *1965*, Fieser **1** 165, **2** 9, **2** 90, **3** 7, **4** 108, **5** 163, **6** 143, **7** 79, **8** 116, **11** 140, **14** 99, **16** 96.]

Cuprous (I) bromide dimethylsulfide complex *[54678-23-8]* **CuBr.CH_3SCH_3, M 205.6, m 132°(dec).** If it needs to be prepared afresh then wash CuBr (25g) with MeOH (4 x 50ml) to remove coloured impurities, and dry for 1 hour *in vacuo*, then dissolve the green-tinted white powder in Me_2S (60ml) **[foul odour**, use an efficient fume cupboard] and filter to remove insoluble impurities. Dilute the filtrate with hexane (200ml) and collect the colourless crystals by filtration under suction. Wash the light sensitive crystals five times with hexane and dry them under a stream of dry N_2 for 3 hours. Do **not** dry under vacuum, as loss of Me_2S would occur with deleterious effect on its reactions. If the sample is reasonably good then dissolve it in MeOH and crystallise it by diluting the solution with an equal volume of hexane, collect the crystals, wash with hexane and dry as stated previously. [Wuts *Synth Commun* **11** 139 *1981*, DOI: 10.1080/00397918108064294; Fieser **6** 225, **8** 117, **10** 104, **15** 100, **16** 96.] Catalyst used for the addition of alkyl, alkenyl and aryl Grignard reagents to Fullerenes in which 5 organic groups add to [60]fullerene, and 3 groups to [70]fullerene [Matsuo et al. *Org Synth* **83** 80 *2006*, DOI: 10.15227/orgsyn.083.0080].

Cuprous (I) chloride *[7758-89-6]* **CuCl, M 99.0, m 430°, b~1400°.** Dissolve it in strong HCl, precipitate it by diluting with water and filter it off. Wash the solid with ethanol and diethyl ether, then dry it and store it in a vacuum desiccator [Österlöf *Acta Chem Scand* **4** 374 *1950*, DOI: 10.3891/acta.chem.scand.04-0374]. *Alternatively*, to an aqueous solution of $CuCl_2.2H_2O$ is added, with stirring, an aqueous solution of anhydrous sodium sulfite. The colourless product is dried at 80° for 30 minutes and stored under N_2. Cu_2Cl_2 can be purified by zone-refining [Hall et al. *JCS Faraday Trans 1* **79** 343 *1983*, DOI: 10.1039/F19837900343]. [Glemser & Sauer in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **II** p 1005 *1965*, Fieser **1** 166, **2** 91, **3** 67, **4** 109, **5** 164, **6** 145, **7** 80, **8** 118, **11** 140, **12** 141, **13** 85, **15** 101.]

Cuprous (I) cyanide *[544-92-3]* **CuCN, M 89.6, m 474°, d ^{25} 2.92g/cm^3.** Wash the cyanide thoroughly with boiling H_2O, then with EtOH. Dry it at 100° to a fine soft powder. It dissolves in excess alkali cyanide solutions to form the very soluble ***complex ion $Cu(CN)_4^{3-}$.*** [Bassett & Corbett *J Chem Soc* **125** 1660 *1924*, DOI: 10.1039/CT9242501660; Barber et al. *J Chem Soc* 79 *1943*, DOI: 10.1039/JR9430000079.] Applied in a widely useful ***thiosulfate-assisted*** preparation of new diamine-CuCN complexes [Stocker et al. *Inorg Chem* **38** 984 *1999*, DOI: 10.1021/ic970226b].

Cuprous (I) iodide *[7681-65-4]* **CuI, M 190.5, m 605°, b 1336°/atm, d $_4^{25}$ 5.63.** It can be freshly prepared by dissolving an appropriate quantity of CuI in boiling saturated aqueous NaI over 30 minutes. Pure CuI is obtained by cooling and diluting the solution with water, followed by filtering and washing sequentially with H_2O, EtOH, EtOAc, Et_2O and pentane, then drying *in vacuo* for 24 hours [Dieter et al. *J Am Chem Soc* **107** 4679 *1985*, DOI: 10.1021/ja00302a014]. *Alternatively*, wash it with H_2O, then EtOH and finally with Et_2O containing a little iodine. Traces of H_2O are best removed first by heating at 110° and then at 400°. Exess of I_2 is removed completely at 400°. It dissolves in Et_2O if an amine is present to form the ***amine complex***. On heating it becomes red, then black, but changes to white on cooling. It is sparingly soluble in H_2O or alkali iodide solutions but readily soluble in NH_3 (which absorbs CO), and in cyanide or thiosulfate solutions. [Glemser & Sauer in *Handbook of Preparative Inorganic Chemistry (Ed Brauer)* Academic Press Vol **II** p 1007 *1965*, Bawn & Ledwith *Chem Ind (London)* 1180 *1957*, Fieser **1** 169, **2** 92, **3** 69, **5** 167, **6** 147, **7** 81, **8** 121, **10** 107, **11** 141, **12** 141, **16** 98, **17** 87.] Useful catalyst for the Ullmann type *N*-arylation of amines and amino acids [see Jiang et al. *Synlett* 1837 *2007*, DOI: 10.1055/s-2007-982564], and the preparation of sulfenamides [see Taniguchi *Synlett* 1917 *2007*, DOI: 10.1055/s-2007-984539], and some catalysed reactions by CuI have

been reviewed by Coeffard [see *Synlett* **15** 2456 *2007*, DOI: 10.1055/s-2007-986636].

Cuprous (I) thiocyanate *[18223-42-2, 1111-67-7]* **CuSCN, M 121.6, m 1084°, d ^{25} 2.84g/cm^3. pK^{25} -1.85 (for HSCN).** Purify the grey-greenish yellow solid as for cuprous iodide but using aqueous NaSCN. [Demmerle et al. *Ind Eng Chem* **42** 2 *1950*, DOI: 10.1021/ie50481a002; Newman *Analyst* **88** 500 *1963*, DOI: 10.1039/AN9638800500.]

Cyanamide (carbidiimide) *[420-04-2]* **$NCNH_2$, M 42.0, m 43°, 45°, 46°, b 83°/0.5mm, 85-87°/0.5mm, pK$_1^{20}$ -0.36 (1.1 at 29°), pK$_2^{20}$ 10.27.** Purify it by placing *ca* 15g in a Soxhlet thimble and extracting exhaustively (2-3 hours) with two successive portions of Et_2O (400ml, saturated with H_2O by shaking before use) containing two drops of 1N acetic acid. Two successive portions of Et_2O are used so that the NH_2CN is not heated for too long. Each extract is dried over Na_2SO_4 (30g), then combined and evaporated under reduced pressure. The NH_2CN may be stored unchanged at 0° in Et_2O solution in the presence of a trace of AcOH. Extracts from several runs may be combined and evaporated together. The residue from evaporation of an Et_2O solution is a colourless viscous oil which sets to a solid and can be recrystallised from a mixture of 2 parts of $*C_6H_6$ and 1 part of Et_2O. Concentrating an aqueous solution of NH_2CN at high temperatures causes **EXPLOSIVE** polymerisation. [Kurzer & Lawson *Org Synth* Coll Vol **4** 645 *1963*, DOI: 10.15227/orgsyn.034.0067; Pinck et al. *Inorg Synth* **3** 39 *1950*, DOI: 10.1002/9780470132340.ch9; Soloway & Lipschitz *J Org Chem* **23** 613 *1958*, DOI: 10.1021/jo01098a603.] *Hygroscopic*. [*Beilstein* **3** IV 145.]

Cyanogen bromide *[506-68-3]* **BrCN, M 105.9, m 49-51°, 50-53°, b 60-62°/atm, d ^{25} 2.02g/cm^3.** *All operations with this substance should be performed in a very efficient fume cupboard—it is very* **POISONOUS** *and should be handled in small amounts. Fresh commercial material is satisfactory for nearly all purposes and does not need to be purified. It is a white crystalline solid with a strong cyanide odour. If it is reddish in colour and partly liquid or paste-like, then it is too 'far gone' to be purified, and fresh material should be sought.* It can be purified by distillation using small amounts at a time, and using a short wide-bore condenser because it readily solidifies to a crystalline white solid which may clog the condenser. *An appropriate gas mask should be used when transferring the molten solid from one container to another, and the operation should be done in an efficient fume cupboard.* The melting point (**m 49-51°**) should be measured in a sealed tube. [Hartman & Dreger *Org Synth* Coll Vol **2** 150 *1948*, DOI: 10.15227/orgsyn.011.0030.] Also commercially available are a 5.0M solution in MeCN (d ^{25} 1.903g/cm^3), and a 3.0M solution in CH_2Cl_2 (d ^{25} 1.443g/cm^3). BrCN is a useful reagent for peptide cleavage [Orlando et al. *Org Mass Spectrom* **28** 1395 *1993*, DOI: 10.1002/ oms.1210281207], and for cleaving peptides bound to a support for sequencing by mass spectrometry [Anspach et al. *Appl Biochem Biotechnol* **44** 135 *1944*, DOI: 10.1007/ BF02921651]. **POISONOUS.**

Cyanogen iodide *[506-78-5]* **ICN, M 152.9, m 146.7°, 146-147°, m 146.7°, d ^{25} 1.84g/cm^3.** *This compound is* **POISONOUS**, *and the precautions for cyanogen bromide (above) apply here.* The reagent (*ca* 5.9g) is dissolved in boiling $CHCl_3$ (15ml), filtered through a plug of glass wool into a 25ml Erlenmeyer flask. Cool to room temperature for 15 minutes, then place it in an ice-salt bath and cool to -10°. This cooling causes a small aqueous layer to separate as ice. The ice is filtered with the CNI, but melts on the filter and is also removed with the $CHCl_3$ used as washing liquid. The CNI which is collected on a sintered glass funnel is washed 3x with $CHCl_3$ (1.5ml at 0°) and freed from last traces of solvent by placing it on a watch glass and exposing it to the atmosphere in a good fume cupboard at room temperature for 1 hour to give colourless needles (*ca* 4.5g), **m** 146-147° (sealed capillary totally immersed in the oil bath). The yield depends slightly on the rapidity of the operation; in this way loss by sublimation can be minimised. If desired, it can be sublimed under reduced pressure at temperatures at which CNI is only slowly decomposed into I_2 and $(CN)_2$. The vacuum will need to be renewed constantly due to the volatility of CNI. [Bak & Hillebert *Org Synth* Coll Vol **4** 207 *1963*, DOI: 10.15227/orgsyn.032.0029.]

Decaborane *[17702-41-9]* **$B_{10}H_{14}$, M 122.2, m 99.7-100°, b 100°/19mm, 213°/atm, d ^{25} 0.94g/cm^3.** Purify decaborane by vacuum sublimation at 80°/0.1mm, followed by crystallisation from methylcyclohexane, CH_2Cl_2, or dry olefin-free-*n*-pentane, the solvent being subsequently removed by storing the crystals in a vacuum

desiccator containing $CaCl_2$. It is soluble in H_2O but is slowly decomposed to give H_2. It is soluble in alkali, and on acidification it liberates H_2. **TOXIC.** [Greenwood in *Comprehensive Chemistry (Ed Bailar et al.)* Pergamon Press Vol **1** pp 818-837 *1973*.]

Deuterium (heavy hydrogen) *[7782-39-0]* **D_2, M 4.028, m -254.43°/atm, b -249.49°/atm, d ^{25} 0.169g/cm^3, d 0.189Kg/m^3 (at STP i.e. 0°/101.325kPa), d 162.4kg/m^3 (liquid), critical temp -234.75°, critical pressure 128.5mm (triple point).** Pass the gas over activated charcoal at -195° [MacIver & Tobin *J Phys Chem* **64** 451 *1960*, DOI: 10.1021/j100833a018]. Purify it also by diffusion through nickel [Pratt & Rogers, *JCS Faraday Trans I* **92** 1589 *1976*, DOI: 10.1039/F19767201589]. It is as flammable as H_2. Always check deuterium for radioactivity to determine the amount of tritium in it (see D_2O below). [A Hydrogen Isotope of Mass 2, Urey et al. *Phys Rev* **39** 164 *1932*, DOI: 10.1103/PhysRev.39.164; D_2 Isotope effect: Wiberg *Chem Rev* **55** 713 *1955*, DOI: 10.1021/cr50004a004.]

Deuterium oxide *[7789-20-0]* **D_2O, M 20, f 3.8°/760mm, b 101.4°/760mm, d $^{20}_4$ 1.105, pK^{20} 14.955.** Distil 'heavy water' from alkaline $KMnO_4$ [de Giovanni & Zamenhof *Biochem J* **87** 79 *1963*, DOI: 10.1042/bj0870079]. **NOTE that D_2O invariably contains tritiated water and will therefore be RADIOACTIVE; always check the radioactivity level of D_2O in a scintillation counter before using.** [For pKa of D_2O see Covington et al. *J Phys Chem* **70** 3820 *1966*, DOI: 10.1021/j100884a011.]

***cis*-Diamminedichloroplatinum(II) (Cisplatin)** *[15663-27-1]* **$Pt(NH_4)_2Cl_2$, M 300.1, m 270°(dec).** Recrystallise it from dimethylformamide and check the purity by IR and UV-VIS spectroscopy. [Raudaschl et al. *Inorg Chim Acta* **78** L43 *1983*, DOI: 10.1016/S0020-1693(00)86472-5.] **HIGHLY TOXIC, SUSPECTED CARCINOGEN.**

Diammonium hydrogen orthophosphate *[7783-28-0]* **$(NH_4)_2HPO_4$, M 132.1, m 155°(dec).** Crystallise it from water (1ml/g) between 70° and 0°. Its solubility in H_2O is 59% at room temperature and 200% at the boiling point. It slowly evolves NH_3 and should be stored in a well-stoppered container. After one crystallisation, ACS grade salt had Fe, Mo, Na, Se and Ti at 1, 0.2, 1.4, 0.2 and 0.8ppm, respectively. [Gmelin's, Ammonium (8th edn) **23** pp422-426 *1936*.]

Dinitrogen tetroxide (nitrogen dioxide) *[10544-72-6]* **N_2O_4, M 92.0 m -11.2°, b 21.69°/atm, d ^{21} 1.44246, n $^{21}_D$ 1.00112(liquid).** Purify it by oxidation at 0° in a stream of oxygen until the blue colour changes to red-brown. *Alternatively*, distil it from P_2O_5, then solidify it by cooling in a deep-freeze (at –78°, giving nearly colourless crystals). Oxygen can be removed by alternate freezing and melting cycles. **TOXIC VAPOUR.** [Schenk in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** pp 488-489 *1963*.]

Disodium hydrogen orthophosphate (anhydrous) *[7558-79-4]* **Na_2HPO_4, M 142.0, m 250°, d ^{25} 1.7g/cm^3, (see pK of H_3PO_4).** Crystallise the salt twice from warm water, by cooling. Dry in air, then in an oven overnight at 130°. It should be dried before use as it is slightly ***hygroscopic***. It forms di-, hepta- and deca-hydrates.

Ferric Bromide *[10031-26-2]* **$FeBr_3$, M 395.6, m >130°(dec), >200°(dec), d ^{25} 4.50g/cm^3.** Sublime it in a sealed tube with Br_2 at 120°-200°. Decomposition to $FeBr_2$ and Br_2 occurs above 200°, or by boiling in H_2O. It is soluble in AcOH, EtOH, Et_2O and H_2O. Store it in a tightly stoppered bottle away from light. [Lux in *Handbook of Preparative Inorganic Chemistry (Ed.Brauer)* Academic Press Vol **II** p 1494 *1965*, Gregory & Thackrey *J Am Chem Soc* **72** 3176 *1950*, DOI: 10.1021/ja01163a102.]

Ferric chloride (anhydrous) *[7705-08-0]* **$FeCl_3$, M 162.2, m >300°(dec), 304°, 306°, d ^{25} 2.898g/cm^3.** Sublime it at 200° in an atmosphere of chlorine. It is an 'iron-black' coloured powder with green irridescence. It is soluble in $*C_6H_6$, EtOH, Et_2O, Me_2CO and pyridine in which the ***monomeric species*** '$FeCl_3$' exist whereas in the vapour state it exists in the ***dimeric*** 'Fe_2Cl_6' form. Decomposes to $FeCl_2$ and Cl_2 above 315°. It is soluble in H_2O (0.7g/ml at 0°), in Me_2CO (0.63/ml at 18°) in MeOH (very soluble), EtOH (0.83g/ml) and Et_2O (very

soluble). Store it in a weighing bottle inside a desiccator as it absorbs moisture from air to form the yellow ***hexahydrate*** (see next entry). [Tarr et al. *Inorg Synth* **3** 191 *1950*, DOI: 10.1002/9780470132340.ch51; Pray et al. *Inorg Synth* **5** 153 *1957*, DOI: 10.1002/9780470132364.ch43; Epperson et al. *Inorg Synth* **7** 163 *1963*, DOI: 10.1002/9780470132388.ch45; Fieser **1** 390, **2** 199, **3** 145, **4** 236, **5** 307, **7** 153, **8** 228, **10** 185.]

Ferric chloride hexahydrate *[10025-77-1]* **$FeCl_3$. $6H_2O$, M 270.3, m 37°(dec), b 280-285°/atm(partial decomposition), d ^{25} 1.83g/cm^3, pK $_1^{25}$ 2.83, pK $_2^{25}$ 4.59 (for hydrolysis of Fe^{3+}).** An aqueous solution, saturated with the salt at room temperature, is cooled to -20° for several hours. Separation of the crystals is slow, even with scratching and seeding, and it is generally necessary to stir this overnight. The presence of free HCl retards crystallisation. [Linke *J Phys Chem* **60** 91 *1956*, DOI: 10.1021/j150535a022; Fieser **1** 390, **2** 199, **3** 145, **4** 236, **5** 307, **6** 259, **7** 153, **8** 228, **9** 222, **10** 185, **12** 230, **14** 164, **15** 158, **16** 190.]

Ferric nitrate nonahydrate *[7782-61-8 ($9H_2O$), 13476-08-9 (H_2O), 10421-48-4 (anhydrous)]* **$Fe(NO_3)_3$. $9H_2O$, M 404.0, m 47°(dec), b 125°/atm, d ^{25} 1.6429g/cm^3($9H_2O$), d ^{25} 1.68g/cm^3($6H_2O$).** It crystallises from aqueous solutions of moderately strong HNO_3 as the pale violet ***nonahydrate*** **m 40°** and is soluble in EtOH and Me_2CO. With more concentrated aqueous solutions (containing some HNO_3), the ***hexahydrate*** crystallises out **m 60.5°**. The ***anhydrous*** salt is ***slightly deliquescent*** and decomposes at 47°. [Lambert & Thomson *J Chem Soc* **97** 2426 *1910*, DOI: 10.1039/CT9109702426; *Gmelin's, Iron* (8th edn) **59** Part B pp 161-172 *1932*.] Solutions of this nitrate are used by metalsmiths and jewellers for etching Ag and Ag alloys. $Fe(NO_3)_3$ on Silica Gel (15-20wt% salt) is a useful ***oxidising reagent***.

Ferric perchlorate nonahydrate *[13537-24-1 ($9H_2O$), 15201-61-3 (xH_2O)]* **$Fe(ClO_4)_3$. $9H_2O$, M 516.3, pK^{25} -2.4 to -3.1 (for $HClO_4$).** Crystallise it twice from concentrated $HClO_4$, the first time in the presence of a small amount of H_2O_2 to ensure that the iron is fully oxidised [Sullivan *J Am Chem Soc* **84** 4256 *1962*, DOI: 10.1021/ja00881a012]. Extreme care should be taken with this preparation because it is potentially **EXPLOSIVE**.

Ferric sulfate x-hydrate *[10028-22-5 (anhydrous), 15244-10-7 (H_2O)]* **$Fe_2(SO_4)_3$. xH_2O, M 399.9 + xH_2O, m 480°(anhydr), 175°(H_2O), d ^{25} 3.097g/cm^3(anhydr), d ^{25} 1.898g/cm^3($5H_2O$).** Dissolve the sulfate in the minimum volume of dilute aqueous H_2SO_4 and allow it to evaporate at room temperature until yellowish-white crystals start to form. Do not concentrate by boiling off the H_2O as basic salts will be formed. Various ***hydrates*** are formed; the common ones are the ***nona*** and ***dodeca hydrates*** which are violet in colour. The ***anhydrous*** salt is colourless and is quite ***hygroscopic***, but it dissolves in H_2O slowly unless ferrous sulfate is added. [*Gmelin's, Iron* (8th edn) pp 439-462 *1932*.]

Ferrous bromide *[20049-65-4, 7789-46-0]* **$FeBr_3$, M 215.7 + xH_2O, m 684°, b 927°/atm, 934°/atm, d^{25} 4.63.** It crystallises from air-free H_2O to provide the ***hexahydrate*** as pale green to bluish-green rhombic prisms. On heating at 49° H_2O is lost and the ***tetrahydrate*** is formed. On further heating at 83° more H_2O is lost and the ***dihydrate*** is formed as a light yellow to dark brown ***hygroscopic*** powder. The ferrous iron in aqueous solutions of these salts readily oxidises to ferric iron. The salts should be stored over H_2SO_4 under N_2 in tightly closed containers. They have some solubility in MeOH, EtOH and THF. [Baxter *Z Anorg Chem* **38** 232 *1904*, DOI: 10.1002/zaac.19040380119; Kühln & Ernst *Z Anorg Allgem Chem* **317** 84 *1962*, DOI: 10.1002/zaac.19623170112; Lux in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **II** p 1493 *1965*, Winter *Inorg Synth* **14** 99 *1973*, DOI: 10.1002/9780470132456.ch20.]

Ferrous chloride tetrahydrate *[13478-10-9 ($4H_2O$), 16399-77-2 ($2H_2O$)]* **$FeCl_2$. $9H_2O$, M 198.8, m 105°($4H_2O$, dec), 120°($2H_2O$, dec), d ^{25} 3.16g/cm^3(anhydr), d ^{25} 2.39g/cm^3($2H_2O$), d ^{25} 1.93g/cm^3($4H_2O$), pK $_1^{25}$ 6.7, pK $_2^{25}$ 9.3 (for aquo Fe^{2+}).** A 550ml round-bottomed Pyrex flask is connected, *via* a glass tube fitted with a medium porosity sintered-glass disc, to a similar flask. To 240g of $FeCl_2.4H_2O$ in the first flask is added conductivity water (200ml), 38% HCl (10ml), and pure electrolytic iron (8-10g). A stream of purified N_2 gas is passed through the assembly, escaping through a mercury trap. The salt is dissolved by heating which is continued until complete reduction has occurred. By inverting the apparatus and filtering (under N_2 pressure) through the sintered glass disc, unreacted iron is removed. After cooling and crystallisation, the unit is again inverted, and the crystals of ferrous chloride are filtered free from mother liquor by applied N_2 pressure. Partial

drying by overnight evacuation at room temperature gives a mixed hydrate which, on further evacuation on a water bath at 80°, loses water of hydration and absorbed HCl (with vigorous effervescence) to give a white powder of $FeCl_2.2H_2O$ (see below). [Gayer & Wootner *J Am Chem Soc* **78** 3944 *1956*, DOI: 10.1021/ja01597a021; ($2H_2O$) Gayer et al. *Inorg Synth* **5** 179 *1957*, DOI: 10.1002/9780470132364.ch48; Kovacic & Brace 'Iron(II) Chloride' *Inorg. Synth.* **6** 172 *1960*, DOI: 10.1002/9780470132371.ch54]

Ferrous chloride *[7758-94-3]* **$FeCl_2$, M 126.8, m 674°, b 1023°, d^{25} 3.16.** It sublimes in a stream of HCl at *ca* 700°, or in H_2 below 300°. Its vapour pressure at 700° is 12mm. It forms white ***hygroscopic*** rhombohedral crystals with a green tint which oxidise in air to $FeCl_3$ and Fe_2O_3. It is soluble in H_2O, EtOH Me_2CO but insoluble in Et_2O. The ***tetrahydrate*** is pale green to pale blue in colour and loses $2H_2O$ at 105-115°. The ***dihydrate*** loses H_2O at 120°. [***Anhydrous*** $FeBr_2$ can be obtained by carefully dehydrating the ***tetrahydrate*** in a stream of HBr and N_2, and it can be sublimed under N_2.] The ferrous iron in aqueous solutions of these salts readily oxidises to ferric iron. (See above.) [Kovacuumic & Brace *Inorg Synth* **6** 172 *1960*, DOI: 10.1002/9780470132371.ch54; Lux in *Handbook of Preparative Inorganic Chemistry (Ed Brauer)* Academic Press Vol **II** p 1491 *1965*.]

Ferrous perchlorate hexahydrate *[13933-23-8, 1350-69-9, 335159-18-7]* **$Fe(ClO_4)_2.6H_2O$, M 362.8, pK^{25} -2.4 to -3.1 (for $HClO_4$).** Crystallise it from $HClO_4$. [**CARE, see ferric perchlorate above.**]

Ferrous sulfate heptahydrate (green vitriol) *[7782-63-0 ($7H_2O$), 13463-43-9 (xH_2O), 17375-41-6 (H_2O), 7720-78-7 (anhydrous)]* **$FeSO_4.7H_2O$, M 278.0($4H_2O$), 151.9(anhydr), m ~60-64°($7H_2O$, dec), 300°(H_2O, dec), 680°(anhydr, dec), d^{25} 1.895g/cm^3($7H_2O$), d^{25} 1.934g/cm^3($6H_2O$), d^{25} 2.15g/cm^3($5H_2O$), d^{25} 3.0g/cm^3(H_2O), d^{25} 3.65g/cm^3(anhydrous).** Crystallise the sulfate from 0.4M H_2SO_4, or precipitate it from an aqueous solution with EtOH. It is ***efflorescent*** in dry air, and is converted to the ***tetrahydrate*** at 57°, then to the ***monohydrate*** (white-yellow) at 65° [or by heating the ***heptahydrate*** (blue-green crystals) in a vacuum at 140°; the ***anhydrous*** salt forms white crystals]. At 650° it decomposes to Fe_2O_3, SO_2 and SO_3. The solubility in H_2O is 0.45g/ml(77°) and 0.36g/ml(90°) for the ***monohydrate***, 0.66g/ml(0°), 0.21g/ml(10°), 0.29g/ml(25°), 0.40g/ml(40°) and 0.51g/ml(54°) for the ***heptahydrate***; in ethylene glycol it is 0.06g/ml(20°); but it is insoluble in EtOH. It forms a brown-black complex, $FeSO_4.NO$, with nitric oxide and is used in a qualitative test for nitrates ('**brown ring' test**). Used medically as an iron supplement. [Wildermuth et al. 'Iron Compounds' in *Ullmann's Encyclopedia of Industrial Chemistry* Wiley-VCH, Wienheim, *2005*.]

Fluorine *[7782-41-4]* **F_2, M 38.0, m -219.7°, b -188.1°/atm, d 1.696g/L(STP: 0°/101.325kPa).** Pass the gas through a bed of NaF at 100° to remove HF and SiF_4. [For description of stills used in fractional distillation, see Greenberg et al. *J Phys Chem* **65** 1168 *1961*, DOI: 10.1021/j100825a017; Stein et al. *Purification of Fluorine by Distillation, Argonne National Laboratory,* ANL-6364 1961 (from Office of Technical Services, US Dept of Commerce, Washington 25); Aigueperse, et al., Ullmann (ed.) 'Fluorine Compounds, Inorganic' *Ullmann's Encyclopedia of Industrial Chemistry* Wiley-VCH Weinheim **15** 397–441 *2000*, DOI: 10.1002/14356007, ISBN 3527306730.] **HIGHLY TOXIC use strictest precautions — do not inhale.**

Fluoroboric acid (tetrafluoroboric acid, fluoboric acid) *[16872-11-0]* **HBF_4, M 87.8, b 130°(dec), d^{25} 1.4g/cm^3(of 48% aqueous solution), pK^{25} -4.9.** Crystallise fluoroboric acid several times from conductivity water. It can be stored in a glass vessel at room temperature. It is available commercially as ~48% aqueous solution. It is most useful for preparing ***tetrafluoroborate salts*** which are generally insoluble. For example, addition of the acid to aryldiazonium salt solutions precipitates the more stable aryldiazonium tetrafluoroborate salts which can be washed with H_2O to remove impurities, followed by EtOH and Et_2O, and stored for short periods of time before further use. It is a catalyst for preparing acetals. [Mathers et al. *J Am Chem Soc* **37** 1515 *1915*, DOI: 10.1021/ja02171a012; Wamser *J Am Chem Soc* **70** 1209 *1940*, DOI: 10.1021/ja01183a101; Sharp *Adv Fluorine Chem* **1** 68-128 *1960,* Kwasnik in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** pp 221-222 *1963*.] **STRONG IRRITANT and is TOXIC.**

Gallium (metallic liquid) *[7440-55-3]* Ga, M 69.7, m 29.78°, b 2403°/atm, $d^{29.6}$ 5.904, $d^{29.8}$ 6.095.

Dissolve the metal in dilute HCl and extract it with Et_2O. Bubbling H_2S through the solution removes many metals, and a second extraction with Et_2O frees Ga further from metal impurities, except for Mo, Th(III) and Fe which are largely removed by precipitation with NaOH. The solution is then electrolysed in 10% NaOH with a Pt anode and cathode (2-5A at 4-5V) to deposit Ga, In, Zn and Pb, from which Ga was obtained by fractional crystallisation of the melt [Hoffman *J Res Nat Bur Stand* **13** 665 *1934*]. Ga is also purified by heating to boiling in 0.5-1M HCl, then heating to 40° in water and pouring the molten Ga with water under vacuum through a glass filter (30-50 μ pore size), to remove any unmelted metals or oxide film. The Ga is then fractionally crystallised from the melt under water. [Dönges in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 837 *1963*.]

Gallium (III) Chloride *[13450-90-3]* **$GaCl_3$, M 176.1, m 77.8°, b 133°/100mm, 197.7°/700mm, d $^{20}_4$ 2.47, pK $^{25}_1$ 2.91, pK $^{25}_2$ 3.70, pK $^{20}_3$ 4.42 (for Ga^{3+}).** The pure compound can be obtained by redistillation in a stream of Cl_2 or Cl_2/N_2 followed by vacuum sublimation or zone refining. It forms colourless needles which give ***gallium dichloride [$Ga(GaCl_4)$],*** **m** 172.4°] on heating. It dissolves in H_2O with liberation of heat. It is soluble in Et_2O and can be extracted from an HCl solution with Et_2O. Also commercially available in a 0.5M solution in pentane. [Laubengayer & Schirmer *J Am Chem Soc* **62** 1578 1940, DOI: 10.1021/ja01863a070; Dönges in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 846 *1963*.] $GaCl_3$ has been used as a mediator and catalyst in organic bond formation reactions [Barman *Synlett* 2440 *2003*, DOI: 10.1055/s-2003-43340]; and with NaN_3 [Grocholl et al. *Chem Mater* **13** 4290 *2001*, DOI: 10.1021/cm010342j] and Li_3N [Xie et al. *Science* **272** 1926 *1996*, DOI: jstor.org/stable/2890619] was used in lower-temperature solvothermal techniques for preparing nanocrystalline GaN.

Gallium (III) nitrate nonahydrate *[69365-72-6]* **$Ga(NO_3)_3$, M 255.7, 417.9, m *ca* 65°.** Recrystallise the nitrate from H_2O (solubility is 295g/100ml at 20°). It forms a white ***deliquescent***, colourless powder soluble in H_2O, absolute EtOH and Et_2O. It loses HNO_3 upon heating at 40°. Addition of Et_2O to a warm ethanolic solution (40-50°) of $Ga(NO_3)_3$ $9H_2O$ precipitates $Ga(OH)_2NO_3.Ga(OH)_3.2H_2O$. If the salt has partly hydrolysed, dissolve it in concentrated HNO_3, reflux, dilute with H_2O and concentrate on a sand bath. Wash the solid several times by adding H_2O and evaporating until there is no odour of acid. Dilute the residue to a Ga concentration of 26g/100ml. At this concentration, ***spongy*** $Ga(NO_3)_3.xH_2O$ separates from the viscous solution. After standing for several days the crystals are collected and dried in a stream of dry air first at room temperature, then at 40°. ***Dehydration*** is complete after 2 days. Recrystallise it from H_2O and dry it at water pump vacuum at room temperature. [Reimmann & Tanner *Z Naturforsch* **20B** 71 *1965*, Dönges in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 856 *1963*; Hendsbee et al. '$[Ga(H_2O)_6](NO_3)_3.3H_2O$' *Acta Cryst E***65** i65 *2009*, DOI: 10.1107/S1600536809028086 /mg2076sup1.cif.]

Gallium (III) sulfate *[13494-91-2 (anhydrous), 13780-42-2 (hydrate)]* **$Ga_2(SO_4)_3$, M 427.6(anhydr), m 105-110°, d ^{25} 3.86g/cm^3(xH_2O),** Recrystallisation from H_2O gives the 16-18H_2O hydrate (solubility at 20° is 170g/100ml). *Alternatively*, dissolve it in 50% H_2SO_4 and evaporate (60-70°), cool and precipitate it by adding EtOH/Et_2O. On heating at 165° it provides the ***anhydrous*** salt, which is a white ***hygroscopic*** solid. [Reimmann & Tanner *Z Naturforsch* **20B** 71 *1965*.]

Germanium *[7440-56-4]* **Ge, M 72.6, m 937°, 925-975°, b 2700°/atm, 2830°/atm, d $^{20}_4$ 5.3.** Copper contamination on the surface and in the bulk of single crystals of Ge can be removed by immersion in molten alkali cyanide under N_2. The Ge is placed in dry K and/or Na cyanide powder in a graphite holder in a quartz or porcelain boat. The boat is then inserted into a heated furnace which, after a suitable time, is left to cool to room temperature. At 750°, a 1mm thickness of metal requires about 1 minute, whereas 0.5cm needs about half hour. The boat is removed from the furnace, and the solid samples are taken out with plastic-coated tweezers, carefully rinsed in hot water and dried in air [Wang *J Phys Chem* **60** 45 *1956*, DOI: 10.1021/j150535a012; Schenk in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 712 *1963*]. **Care with the use of cyanide.**

Germanium (IV) oxide (germanium dioxide) *[1310-53-8]* **GeO_2, M 104.6, m 1080°(soluble form), d^{25} 6.239; m 1116°(insoluble form) d^{25} 4.228, pK$_1^{25}$ 9.02, pK$_2^{25}$ 12.82 (for germanic acid H_2GeO_3).** The oxide (GeO_2) is usually prepared by hydrolysing redistilled $GeCl_4$ and igniting it in order to remove H_2O and chloride.

It can be further purified by dissolving in hot H_2O (solubility is 4g/L cold) evaporating and drying the residual crystalline solid. When the ***soluble form*** (which is produced in H_2O at 355°) is heated for 100 hours, it is converted to the ***insoluble form***. This form is stable at temperatures up to 1033°, and fusion at 1080° for 4 hours causes complete de-vitrification and it reverts to the ***soluble form***. [Müller & Blank *J Am Chem Soc* **46** 2358 *1924*, DOI: 10.1021/ja01676a002; Dennis & Laubengayer *J Am Chem Soc* **47** 1945 *1925*, DOI: 10.1021/ja01684a504; Laubengayer & Morton *J Am Chem Soc* **54** 2303 *1932*, DOI: 10.1021/ja01345a019; Schenk in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol I p 706 *1963*.] The oxide is used for the synthesis of ultra-high refractive index and ultra-low loss wave guides [Imoto *Optromics* **260** 116 *2004*], and as a building block for inorganic nanowires [Rao et al. *J Mater Chem* **14** 440 *2004*, DOI: 10.1039/B310387K],

Germanium (IV) tetrabromide *[13450-92-5]* **$GeBr_4$, M392.2, m 26.1°, b 185.9°/atm, d_4^{29} 3.123.** Purify it by simple distillation or fractionation depending on purity. It is soluble in EtOH, $CHCl_3$, $*C_6H_6$ and Et_2O. It ***fumes*** in moist air and is readily hydrolysed by water. [Schenk in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 718 *1963*]. **LACHRYMATORY.**

Germanium tetrachloride *[10038-98-9]* **$GeCl_4$, M 214.4, m -49.5° (α), -52.0° (β), b 83.1°/760mm, 86.5°/760mm corr, d_4^{20} 1.84.** Traces of Cl_2 and HCl can be removed from the liquid by blowing dry air through it for a few hours at room temperature or by shaking it with Hg or Hg_2Cl_2 and then fractionating it in a vacuum. It decomposes on heating at 950°. It has a sharp penetrating odour and ***fumes*** in moist air to give a chalky coat of GeO_2. It is slowly hydrolysed by H_2O to give GeO_2, but distils from concentrated HCl. [Foster et al. *Inorg Synth* **2** 109 *1946*, DOI: 10.1002/9780470132333.ch30; Dennis & Hance *J Am Chem Soc* **44** 299 *1922*, DOI: 10.1021/ja01423a008; Schenk in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 715 *1963*.] **LACHRYMATORY.**

Glass Powder (100-300 mesh). Washed with 10% HNO_3, water and dry in air.

Glass Spheres*[65997-17-3]* **SiO_2, M 60.08,** (mean particle size 9-13μm), **d^{25} 1.1g/ml.** These are hollow spherical non-porous glass beads with an alkalinity of <0.5 meq/g. If too alkaline for the purpose then wash with 10% HNO_3, water and dry in air.

Gold powder *[7440-57-5]* **Au, M 196.97, m 1064.79°, b 2808° (2700°)/atm, d_4^{20} 19.3, resistivity at 0° is 2.05 μΩ-cm.** Massive gold reacts very slowly and it is best converted to the powder that is more readily reactive. While working in a well vented fume cupboard, solid gold (10g, 51mmol) is dissolved in ***Aqua Regia*****,** made from concentrated hydrochloric acid (12M HCl, 50ml) and concentrated nitric acid (16M HNO_3, 13ml), by heating to 90° which will hasten dissolution, but will require topping up with ***Aqua Regia***. *Alternatively*, the suspension is allowed to stand at ~25° until the solid has dissolved. The solution is evaporated to *ca* 10ml, concentrated hydrochloric acid (30ml) is added and evaporation is repeated. The solution is diluted with H_2O (20ml), filtered through a medium sintered-glass funnel, and the filter is washed with small volumes of H_2O. The filtrate and washings, which contain ***$HAuCl_4$***, are heated to boiling and hydroquinone (10g, 91mmol) in hot H_2O (100ml) is slowly added. The mixture is kept at 90° for 1 hour (sufficient time to reduce all the $HAuCl_4$ to Au), cooled and filtered through an extraction thimble. The thimble is placed in a Soxhlet apparatus and extracted with MeOH. Afer 15 minutes, when the circulating MeOH in the thimble is colourless, the thimble is removed and the contents are collected and dried in air to give Au powder quantitatively. [Block et al. *Inorg Synth* **4** 14 *1953*, DOI: 10.1002/9780470132357.ch4.] Also available in slugs, mica, beads and wires of various thicknesses, diameters or lengths.

Gold (III) bromide (gold tribromide) *[10294-28-7]* **$AuBr_3$. xH_2O, M 436.7, m 150°(dec).** Purify it by adding pure Br_2 to the dark powder, securely stopper the container, warm a little and shake while keeping away from light for *ca* 48 hours. Remove the stopper and place it over NaOH until free Br_2 is no longer in the apparatus (48-60 hours). The bright yellow needles of the tribromide are stable over NaOH in the dark. It is soluble in H_2O and in EtOH where it is slowly reduced. Keep it in a cooled, closed container and protect it from light as decomposition causes free gold to be formed. ***Auribromic acid*** can be obtained by adding the calculated amount of concentrated HBr to $AuBr_3$ (actually Au_2Br_6) until all dissolves, whereby the acid crystallises out as

$HAuBr_4.5H_2O$; a ***deliquescent*** solid soluble in EtOH with **m *ca* 27°**, and store it as above. [Gibson & Colles *J Chem Soc* 2407 *1931*, DOI: 10.1039/JR9310002407; Burawoy & Gibson *J Chem Soc* 217 *1935*, DOI: 10.1039/JR9350000217; Burawoy & Gibson *J Chem Soc* 219 *1935*, DOI: 10.1039/JR9350000219.]

Gold (I) chloride [aurous chloride, Au(I)Cl] *[10294-29-8]* **AuCl, M 232.4, m 289°(dec), d^{25} 7.57.** It is best prepared by heating $AuCl_3.\sim 3H_2O$, or $HAuCl_4$ (see next entry) at 100° in a high vacuum until the vapour pressure drops considerably when most of the H_2O has been expelled. As the $HAuCl_4$ liquefies again in this process much spluttering will occur. The solid residue (mostly anhydrous $AuCl_3$) is then heated to 156° (bromobenzene bath) and further to 170-205° when decomposition to AuCl is complete. Another preparation includes heating $AuCl_3$ in air at 185° [Thomsen *J Prakt Chem* **13** 337 *1876*, DOI: 10.1002/prac.18760130120], but purer salt is obtained by heating $AuCl_3$ in a stream of dry HCl at 175° [Diemer *J Am Chem Soc* **35** 552 *1913*, DOI: 10.1021/ja02194a006]. It forms pale yellow crystals which are not deliquescent, slightly soluble in cold EtOH, dissolve in alkali chloride solutions to form chloroaurates(I), e.g. $KAuCl_2$, but it decompose in H_2O to give gold and hydrolysed Au(III) species. [Blitz & Wein *Z Anorg Allgem Chem* **148** 192 *1925*, DOI: 10.1002/zaac.19251480121; Glemser & Sauer *Handbook of Preparative Inorganic Chemistry (Ed. Brauer* Academic Press Vol **II** p 1055 *1965*.]

Gold (III) chloride (hydrate) *[13453-07-1 (anhydrous), 16961-25-4 ($3H_2O$), 16903-35-8 (30w% in dil HCl]* **$AuCl_3$ (anhydrous), $HAuCl_4$. xH_2O, M 339.8 + xH_2O, x ~3, m 229°, b 354°(dec), d_4^{20} 3.9.** It is obtained as a dark red crystalline mass by dissolving Au in ***aqua regia*** and evaporating. When sublimed at 180°, the ***anhydrous*** crystals are ruby red. The anhydrous salt is ***hygroscopic***, soluble in H_2O but sparingly soluble in EtOH and Et_2O. ***Aurichloric acid*** (chloroauric acid, $HAuCl_4$) is formed when $AuCl_3$ is dissolved in HCl. [Diemer *J Am Chem Soc* **35** 552 *1913*, DOI: 10.1021/ja02194a006; Block *Inorg Chem* **4** 14 *1953*, Glemser & Sauer *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **II** p 1056 *1965*.] The trihydrate is commonly used for the preparation of ***Au nanoparticles*** [Bhattacharjee et al. *J Phys Chem B* **110 (13)** 6768 *2006*, DOI: 10.1021/jp056675b; Wang et al. *Biomacro* **7(4)** 1203 *2006*, DOI: 10.1021/bm060030f]; and for preparing stable nanosized and underivatised ***colloidal Au*** particles in solution [Fink et al. *Chem Mater* **10** 922 *1998*, DOI: 10.1021/cm970702w].

Gold (I) cyanide *[506-65-0]* **AuCN, M 223.0, m dec on heating, d^{25} 7.14g/ml.** The lemon yellow powder is sparingly soluble in H_2O and EtOH but soluble in aqueous NH_3. It is obtained by heating $H[Au(CN)_2]$ at 110°. Wash it well with H_2O and EtOH and dry it at 110°. It has an IR band at ν_{max} 2239 cm^{-1} typical for C≡N stretching vibration. [Glemser & Sauer *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **II** p 1064 *1965*.] **CARE**: may evolve HCN.

Gold (I) iodide *[10294-31-2]* **AuI, M 323.9, m 120°(dec), d_4^{20} 8.25.** It has been prepared by heating gold and iodine in a tube at 120° for 4 months. Since it decomposes to Au and I_2 in the presence of UV light and heat, then the main impurity is Au. The salt is therefore purified by heating it at 120° with I_2 for several weeks. The crystals should be kept dry and in a cool place in the dark. [Weiss & Weiss *Z Naturforsch* **11B** 604 *1956*.]

Gold (III) oxide hydrate *[1303-58-8]* **Au_2O_3. xH_2O, AuH_3O_3, M 441.9 + xH_2O, evolves O_2 at 110°, pK_1^{25} <11.7, pK_2^{25} 13.36, pK_3^{25} >15.3 [for $Au(OH)_3$].** The most probable impurities are SO_4^{2-} and Cl^- ions. Dissolve the brown powder in strong boiling KOH solution (*ca* 5M) and precipitate (**care**) with excess of 3N H_2SO_4. Then shake and centrifuge, resuspend in H_2O and repeat the washing several times until free from SO_4 and Cl ions. This gives a ***wet oxide*** that is dried in air, but decomposes to free gold in sunlight. It is advisable to ***keep it wet*** as it decomposes on drying (analyse wet sample). Store it away from light in the presence of H_2O vapour. It evolves O_2 at 110° to provide gold, being completed at 250°. It is insoluble in H_2O but soluble in HCl and concentrated HNO_3. [Roseveare & Buehrer *J Am Chem Soc* **49** 1221 *1927*, DOI: 10.1021/ja01404a011.] The ***wet oxide*** solutions are used to decorate porcelain, and the decorations become gold in colour when fired.

Graphite (black lead, mineral carbon, plumbago) *[7782-42-5]* **C, M 12,01, m 3652-3697°, d^{25} 2.09, 2.23.** This carbon allotrope is obtained by mining (e.g. in Shrilanka, Canada). It is normally soft, forms black/grey scales, and although even small crystals of it are rare it is composed of crystallised carbon containing traces of

SiO_2, Fe and other minerals. Treat graphite with hot 1:1 HCl. Then filter, wash and the dried powdered is heated in an evacuated quartz tube at 1000° until a high vacuum is obtained. Cool this and store it in an atmosphere of helium [Craig et al. *J Phys Chem* **60** 1225 *1956*, DOI: 10.1021/j150543a019; Ubbelohde & Lewis *Graphite and Its Crystals* Oxford *1960*, Holliday et al. *Comprehensive Inorganic Chemistry* Bailar Jr et al. eds, **vol 1** 1250-1294 *1973*]. Also available in flakes, rods, powder and nanofibers. It has been used in numerous applications viz: strengthened with Fe and SiO_2 in 'lead' pencils, polishing, cements, pigments, lubricants, matches, with $NaNO_3$ in explosives, commutator brushes, arc lamps, anodes, cathode coatings, electroplating, in nuclear piles as moderator etc. See also entry on *Graphene* in Chapter 7.

Helium *[7440-59-7]* **He, M 4.0, m –272.2°/26atm, b –268.93°/atm, $d^{-270.3}$ 0.147.** Dry the *inert* gas by passing it through a column of Linde 5A molecular sieves and $CaSO_4$, then through an activated-charcoal trap cooled in liquid N_2, to adsorb N_2, argon, xenon and krypton. Also pass it over CuO pellets at 300° to remove hydrogen and hydrocarbons, over Ca chips at 600° to remove oxygen, and then over titanium chips at 700° to remove N_2 [Arnold & Smith *JCS Faraday Trans 2* **77** 861 *1981*, DOI: 10.1039/F29817700861]. Its solubility in 100ml of H_2O is 0.94ml at 25°, 1.05ml at 50° and 1.21ml at 75°.

Hexachloroplatinic acid hydrate (chloroplatinic acid, platinum IV chloride soution) *[16941-12-1]* **H_2PtCl_6. xH_2O, M 409.8 + H_2O, m 60° (deliquescent solid).** If it is to be purified, or regenerated from Pt recovered from catalytic hydrogenations, it should be dissolved in ***aqua regia*** followed by evaporation to dryness and dissolution in the minimum volume of H_2O. Then the aqueous solution is treated with saturated ammonium chloride until all the ***ammonium hexachloroplatinate*** *[16919-58-7]* separates. This $(NH_4)_2PtCl_6$ is filtered off and dried at 100°. Igniting this salt gives **Pt *sponge***; dissolve the Pt sponge in ***aqua regia***, boil to dryness, dissolve the residue in concentrated HCl, boil to dryness again and repeat the process. Protect it from light. [Wichers *J Am Chem Soc* **43** 1268 *1921*, DOI: 10.1021/ja01439a008; Adams et al. *Org Synth* Coll Vol **1** 463, 466 *1941*, DOI: 10.15227/orgsyn.008.0092; Bruce *J Am Chem Soc* **58** 687 *1936*, DOI: 10.1021/ja01295a501.]

Hexammine cobalt(III) chloride *[10534-89-1]* **$[Co(NH_3)_6]Cl_3$, M 267.5, m 217°, d^{25} 1.71g/ml.** It crystallises from warm water (8ml/g) on cooling. It is soluble in NH_3. [Bjerrum et al. *Inorg Synth* **2** 216 *1946*, DOI: 10.1002/9780470132333.ch69.]

Hexammine ruthenium(III) chloride *[14282-91-8]* **$[Ru(NH_3)_6]Cl_3$, M 309.6.** Crystallise it twice from 1M HCl. In the presense of glucose oxidase (GOD) it is used as an electron mediator for the detection and estimation of glucose which is oxidised to D-glucono-δ-lactone.

Hydrazine (anhydrous) *[302-01-2]* **NH_2NH_2, M 32.1, m 1.4°, 1.5-2.0°, b 47°/26mm, 56°/71mm, 113-113.5°/atm, n_D^{20} 1.470, d^{25} 1.032g/ml, pK_1^{25} -0.88, pK_2^{25} 8.11.** Hydrazine hydrate is dried by refluxing with an equal weight of KOH pellets for 3 hours, then distilled from fresh solid NaOH or BaO in a current of dry N_2. Use stainless steel or copper equipment. Hydrazine and its hydrates have **VERY IRRITATING** and **TOXIC** vapours and should be used in an efficient fume cupboard. Store in a well-stoppered vessel, preferably under N_2. It is a useful ***reducing agent***. [Schenk in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** pp 469-472 *1963*, Fieser **1** 434, **2** 211, **3** 153, **4** 248, **5** 327, **6** 280, **7** 170, **8** 245, **9** 236, **11** 255, **12** 241, **13** 144, **16** 174.]

Hydrazine hydrate (N_2H_4. x H_2O) *[10217-52-4]* **NH_2NH_2. xH_2O, M 32.05(anhydr) + x 18.02, usually 50-60% N_2H_4 in H_2O, d^{25} 1.029g/ml.** Hydrated hydrazine can be obtained as above and diluted as required. Solutions containing various amounts of H_2O (e.g. 35 wt%), and a 1M solution in THF *[302-01-2]* are also available commercially.

Hydrazine monohydrate (N_2H_4. H_2O) *[7803-57-8]* **NH_2NH_2. H_2O, M 50.1, m -51.7°, b 120.1°/atm, d^{25} 1.032g/ml, n_D^{20} 1.428.** It is best obtained by heating hydrazine sulphate (200g), NaOH (160g) and H_2O (75ml, exothermic) in a copper flask under reflux for 1.5 hours then distilled off (using a flame to remove all the hydrazine). The distillate (175ml) is a clear liquid which contains ~40-45% of N_2H_4. ***Note*** that hydrazine

attacks glass, rubber and cork, and stainless steel equipment should be used. The percentage of hydrazine is determined by titration with standard acid (methyl orange indicator) or against standard iodine (starch indicator). ***Hydrazine monohydrate*** should contain 64% of N_2H_4. The ~40-45% solution may be concentrated by mixing it (144ml) with xylene (230ml) and distilling it through an efficient fractionating column (e.g. Hempel column). All the xylene passes over with about 85ml of H_2O. On distilling the residue, hydrated hydrazine (50ml) is obtained containing 80-85% of N_2H_4. This can be diluted with conductivity H_2O to 64% N_2H_4 to give the ***monohydrate***. ***Anhydrous*** hydrazine has also been obtained from mixtures of hydrazine monohydrohalides and NH_4Cl in four different ways [Sisler et al. *J Am Chem Soc* **76** 3914 *1954*, DOI: 10.1021/ja01644a013]. Hydrazine and its hydrates have **VERY IRRITATING** and **TOXIC** vapours and should be used in an efficient fume cupboard. [Schenk in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** pp 469-472 *1963*, Fieser **1** 434, **2** 211, **3** 153, **4** 248, **5** 327, **6** 280, **7** 170, **9** 236, **11** 255, **12** 241, **13** 144, **16** 174.]

Hydrazine dihydrochloride *[5341-61-7]* **NH_2NH_2. 2HCl, M 105.0, m 198°, 200°(dec) d ^{25} 1.42g/ml.** It is recrystallised from aqueous EtOH and dried under vacuum over $CaSO_4$.

Hydrazine monohydrochloride *[2644-70-4]* **NH_2NH_2. HCl, M 68.5, m 89°, 91-92.5°, 92.5°.** Prepare it by dropwise addition of cold concentrated HCl to cold liquid hydrazine in equimolar amounts. The crystals are harvested from water and are twice recrystallised from absolute MeOH and dried under a vacuum [Kovack et al. *J Am Chem Soc* **107** 7360 *1985*, DOI: 10.1021/ja00311a024]. *Alternatively*, NH_2NH_2. 2HCl is heated and the low melting product recrystallised from H_2O to give the ***monohydrochloride*** **m 92.5°** [Sisler et al. *J Am Chem Soc* **76** 3914 *1954*, DOI: 10.1021/ja01644a013.]

Hydrazine sulfate *[10034-93-2]* **NH_2NH_2. H_2SO_4, M 130.1, m 254°.** Crystallise it from H_2O. Its solubility in H_2O is 3% at room temperature, but is very soluble in hot H_2O. It is a suspected **carcinogen**. [Adams & Brown *Org Synth* Coll Vol **1** 309 *1941*, DOI: 10.15227/orgsyn.002.0037; Audrieth et al. *Inorg Synth* **I** 90 *1939*, DOI: 10.1002/ 9780470132326.ch31.]

Hydrazoic acid (hydrogen azide, triazoic acid) *[7782-79-8]* **H_3N, M 43.0, m -80°, b 37°/atm, d ^{25} 1.09g/ml. pK^{25} 4.72.** The free acid is **HIGHLY EXPLOSIVE** and **POISONOUS**, so it is prepared and used in solution, and in an **efficient fume cupboard**. It is a very useful reagent for Schmidt and related reactions [Wolff *Organic Reactions* **3** 307 *1946*, DOI: 10.1002/0471264180.or003.08]. Solutions in $*C_6H_6$ or $CHCl_3$ are prepared by making a paste from NaN_3 (65g, 1mole) in warm H_2O (65ml), and added to $*C_6H_6$ or $CHCl_3$ (400ml), cooled to 0°, and concentrated H_2SO_4 (26.6mls, 0.5mol) is dropped into the stirred mixture while carefully controlling the temperature between 0° and 5°. The organic layer is separated, dried (Na_2SO_4), and stored in a cold room. Its concentration is determined by shaking a small aliquot with ten times its volume of H_2O in a glass-stoppered flask, and titrating it against standard alkali. It can then be diluted to the desired concentration. [Audrieth et al. *Inorg Synth* **1** 77 *1939*, DOI: 10.1002/9780470132326.ch26; Frost et al. *J Am Chem Soc* **55** 3516 *1933*, DOI: 10.1021/ja01336a003; Schenk in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 472-474 *1963*.] The pure acid is a mobile, pungent explosive liquid, and ***poisonous*** compound, causing irritation of membranes, headaches, palpitation, lowering blood pressure and ataxia — *handle with* ***great care***.

Hydriodic acid *[10034-85-2]* **HI, M 127.9, b 127°(aqueous azeotrope), d $_4^{20}$ 1.701, pK^{25} -8.56.** Iodine can be removed from aqueous HI, probably as the amine hydrogen triiodide, by three successive extractions using a 4% solution of Amberlite LA-2 (a long-chain aliphatic amine) in CCl_4, toluene or petroleum ether (10ml per 100ml of acid). [Davidson & Jameson *Chem Ind (London)* 1686 *1963*.] Extraction with tributyl phosphate in $CHCl_3$ or other organic solvents is also suitable. *Alternatively*, a De-acidite FF anion-exchange resin column in the OH^--form using 2M NaOH, then into its I^--form by passing dilute KI solution through, can be used. Passage of an HI solution under CO_2 through such a column removes polyiodide. The column can be regenerated with NaOH. [Irving & Wilson *Chem Ind (London)* 653 *1964*]. The earlier method was to reflux with red phosphorus and distil in a stream of N_2. The colourless product is stored in ampoules in the dark [Bradbury *J Am Chem Soc* **74** 2709 *1952*, DOI: 10.1021/ja01131a005; Heisig et al. *Inorg Synth* **1** 157 *1939*, DOI: 10.1002/ 9780470132326.ch54]. It fumes in moist air. **HARMFUL VAPOURS.**

Hydrobromic acid *[10035-10-6]* **HBr, M 80.9, b 125°(aqueous azeotrope, 47.5% HBr)/atm, d $_4^{20}$ 1.38 (34%**

HBr), pK^{25} -8.69. A solution of aqueous HBr *ca* 48% (w/w, constant boiling) is purified by distilling twice with a little red phosphorus, and the middle half of the distillate is taken. (The azeotrope at 760mm contains 47.8% (w/w) HBr.) [Hetzer et al. *J Phys Chem* **66** 1423 *1962*, DOI: 10.1021/j100814a012]. Free bromine can be removed by Irvine and Wilson's method for HI (see above), except that the column is regenerated by washing with an ethanolic solution of aniline or styrene. Hydrobromic acid can also be purified by aerating with H_2S, distilling and collecting the fraction boiling at 125-127°. [Heisig & Andur *Inorg Synth* **1** 149(155) *1939*, DOI: 10.1002/9780470132326.ch53.] Also commercially available as a ~33% HBr solution in AcOH *[37348-16-6]*, M 80.1, d_4^{20} 1.40g/ml. **HARMFUL VAPOURS.**

Hydrochloric acid (muriatic acid) *[7647-01-0]* **HCl, M 36.5, b 108.6°(aqueous azeotrope, 20.2% HCl), d_4^{20} 1.09(20%), pK^{25} -6.1.** It is readily purified by fractional distillation as the constant boiling point acid, following dilution with H_2O. The constant-boiling fraction contains 1 mole of HCl in the following weights of distillate at the stated pressures: 179.555g (730mm), 179.766g (740mm), 179.979 (750mm), 180.193 (760mm), 180.407 (770mm). [Foulk & Hollingsworth *J Am Chem Soc* **45** 1220 *1923*, DOI: 10.1021/ja01658a016.] **Toxic**.

Hydrofluoric acid *[7664-39-3]* **HI, M 20.0, b 112.2°(aqueous azeotrope, 38.2% HF), d_4^{20} 1.15 (47-53% HF), pK^{25} 3.21.** It is freed from lead (Pb *ca* 0.002ppm) by co-precipitation with SrF_2, by addition of 10ml of 10% $SrCl_2$ solution per kilogram of the concentrated acid. After the precipitate has settled, the supernatant is decanted through a filter in a hard-rubber or paraffin lined-glass vessel [Rosenqvist *Am J Sci* **240** 356 *1942*, DOI: 10.2475/ajs.240.5.356]. An advantage of the method of Coppola and Hughes [*Anal Chem* **24** 768 *1952*, DOI: 10.1021/ac60064a047] is that the temperature of distillation (in a polyethylene still of special design) is 70° to 85°, and so boiling and entrapment of fine droplets by the vapour do not occur. Pure aqueous HF solutions (up to 25M) can be prepared by isothermal distillation in polyethylene, polypropylene or platinum apparatus. Thus: place in a polyethylene washing bowl two 250ml polyethylene beakers. Place in one beaker technical grade HF (150ml, 35M, 75% v/v). In the second beaker place de-mineralised water (150ml). Another washing bowl similar to the first one is then placed upside down on top of the first bowl making sure of a close fit. The de-mineralised water will absorb the HF vapour so that after a while pure HF will condense in the H_2O. After 2 days the pure HF is 12M, and by replenishing the technical acid beaker, pure 25M HF can be obtained. When ultra pure HF (50% v/v) obtained in this way was subjected to spectrochemical analysis, the concentrations of the 23 elements recorded were less than $10^{-3}\mu$g/ml. [Kwestroo & Visser *Analyst* **90** 297 *1965*, DOI: 10.1039/AN9659000297]. It attacks glass and is used for etching glass. **HIGHLY TOXIC do not inhale.**

Hydrogen *[1333-74-0]* **H_2, M 2.02, m -259.1°, b -252.9°/atm, d 0.08988g/L (gas at STP:** 0°/101.325kPa**), 0.07099g/L (liquid at b), d 0.0763g/ml (solid), 1 mole occupies 22.4L at STP.** It is usually purified by passing through a suitable absorption train of tubes. Carbon dioxide is removed with KOH pellets, soda-lime or NaOH pellets. Oxygen is removed with a 'De-oxo' unit or by passage over Cu heated to 450-500° and Cu on Kieselguhr at 250°. Passage over a mixture of MnO_2 and CuO (Hopcalite) oxidises any CO to CO_2 (which is removed as above). Hydrogen can be dried by passage through dried silica-alumina at -195°, through a dry-ice trap followed by a liquid-N_2 trap packed with glass wool, through $CaCl_2$ tubes, or through $Mg(ClO_4)_2$ or P_2O_5. Other purification steps include passage through a hot palladium thimble [Masson *J Am Chem Soc* **74** 4731 *1952*, DOI: 10.1021/ja01139a001], through an activated-charcoal trap at -195°, and through a non-absorbent cotton-wool filter or small glass spheres coated with a thin layer of silicone grease. *Potentially* **VERY EXPLOSIVE** *in air or with O_2.*

Hydrogen bromide (anhydrous) *[10035-10-6]* **HBr, M 80.9, m -67°, b -66.8°/atm.** Dry it by passing it through $Mg(ClO_4)_2$ towers. This procedure is **hazardous** [Stross & Zimmermann *Ind Eng Chem News* **17** 70 *1939*, Publication date: January 20, 1939]. *Alternatively*, shake it with mercury, distil it through a -78° trap and condense it at -195°/10^{-5}mm. It ***fumes*** in moist air. **HARMFUL VAPOURS**. It is soluble in H_2O. A constant boiling aqueous solution of HBr has **b 126°/760mm,** and its HBr concentration is 47.4% (see hydrobromic acid above). It is soluble in AcOH. [Schneider & Johnson *Inorg Synth* **1** 149 *1939*, DOI: 10.1002/9780470132326.ch53; Schmeisser in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** pp 282-286 *1963*.]

Hydrogen chloride *[7647-01-0]* **HCl, M 36.5, m -114°, b -85°/760mm, d ^{25} 1.2g/ml.** Pass it through concent-

rated H_2SO_4, then over activated charcoal and silica gel. It fumes in moist air. Hydrogen chloride in gas cylinders contains ethylene, 1,1-dichloroethane and ethyl chloride. The latter two may be removed by fractionating the HCl through a trap cooled to -112°. Ethylene is difficult to remove. HCl fumes in moist air. **HARMFUL VAPOURS.** Its solubility in H_2O is 82% at 0°. A constant boiling aqueous solution (azeotrope) has **b 108.6°/760mm** with an HCl concentration of ~20%, and is called ***Hydrochloric acid (muriatic acid)*** (see above). [Schmeisser in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** pp 280-282 *1963*.]

Hydrogen cyanide (anhydrous) [prussic acid, Blausäure (German)] *[74-90-8]* **HCN, M 27.0, m -14 to -15°, b 25.7°/760mm, d ^{25} 0.687g/ml, n $^{20}_{D}$ 1.2675, pK^{25} 9.21 (aqueous acid).** HCN is prepared from NaCN and H_2SO_4, and dried by passage through H_2SO_4 and over $CaCl_2$, then distilled in a vacuum system and degassed at 77°K before use [Arnold & Smith *JCS Faraday Trans 2* **77** 861 *1981*, DOI: 10.1039/F29817700861]. Cylinder HCN may contain stabilisers against explosive polymerisation, together with small amounts of H_3PO_4, H_2SO_4, SO_2, and water. It can be purified by distillaton over P_2O_5, then frozen in Pyrex bottles at Dry-ice temperature for storage. [Zeigler *Org Synth* Coll Vol **1** 314 *1941*, DOI: 10.15227/orgsyn.007.0050; cf. Glemser in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** pp 658-660 *1963*.] Liquid HCN, like liquid ammonia, evaporates very slowly since the latent heat of evaporation is high, and keeps it in the liquid state because the temperature of the liquid is lowered to below its boiling point. ***Note*** that some individuals (genetic variants) cannot smell this odour (the HCN molecule does not span across their olfactory sensors) so should take great care when working with compounds that liberate HCN. Earlier chemists with this olfactory deficiency smoked tobacco pipes near the equipment because the HCN vapours sucked through the pipes produced a foul taste in the mouth. Cyanides, and particularly HCN are extremely poisonous, readily absorbed in the mouth; the ***lethal dose*** is of the order of 150-300mg, depending on the individual. It is a respiratory inhibitor, blocks electron transport by acting on mitochondrial cytochrome oxidase, leading to anaerobic metabolism and lactic acidosis. The face and body become blue, hence the german name. **EXTREMELY POISONOUS; all due precautions should be taken.**

Hydrogen fluoride (anhydrous, hydrofluoric acid) *[7664-39-3]* **HF, M 20.0, m -83.55°, b 19.5°/atm, d ^{25} 1.15g/ml, pKa 3.17.** It can be purified by trap-to-trap distillation, followed by drying over CoF_2 at room temperature and further distillation. *Alternatively*, it can be absorbed on NaF to form $NaHF_2$ which is then heated under vacuum at 150° to remove volatile impurities. The HF is regenerated by heating at 300° and is stored with CoF_3 in a nickel vessel, being distilled as required. (Water content should be *ca* 0.01%.) To avoid contact with base metals, use can be made of nickel, polychlorotrifluoroethylene and gold-lined fittings [Hyman et al. *J Am Chem Soc* **79** 3668 *1957*, DOI: 10.1021/ja01571a016]. An aqueous solution is ***hydrofluoric acid*** (see above). It is **HIGHLY TOXIC and attacks glass.**

Hydrogen iodide (anhydrous, hydriodic acid) *[10034-85-2]* **HI, M 127.9, m -50.8°, b -35.36°, d ^{25} 1.701g/ml, d 2.85g/ml (-47°), pK$_{Est}$ -10 (H_2O), pKa 2.8 (MeCN)** After removal of free iodine from aqueous HI, the solution is frozen, then covered with P_2O_5 and allowed to melt under vacuum. The gas evolved is dried by passing through P_2O_5 on glass wool. It can be freed from iodine contamination by repeated fractional distillation at low temperatures. It ***fumes*** in moist air, and an aqueous solution is ***hydriodic acid*** (see above). **HARMFUL VAPOURS, CORROSIVE.**

Hydrogen peroxide *[7722-84-1]* **H_2O_2, M 34.0, d $^{20}_{4}$ 1.110, pK^{25} 11.65.** The 30% material has been steam distilled using distilled water. Gross and Taylor [*J Am Chem Soc* **72** 2075 *1950*, DOI: 10.1021/ja01161a055] made 90% H_2O_2 approximately 0.001M in NaOH and then distilled it under its own vapour pressure, keeping the temperature below 40°, the receiver being cooled with a Dry-ice/isopropyl alcohol slush. The 98% material has been rendered ***anhydrous*** by repeated fractional crystallisation in all-quartz vessels. **EXPLOSIVE IN CONTACT WITH ORGANIC MATERIAL.** Available as a 3, 30-32, 30 (ACS grade), 35 and 50 wt% in H_2O (some stabilised with ~200ppm of MeCN), as well as in various semiconductor PURANAL (Honeywell) grades.

Hydrogen peroxide urea adduct (UHP, urea hydrogen peroxide 1:1 complex, carbamide peroxide, Debrox, Hyperol) *[124-43-6]* **$CO(NH_2)_2.H_2O_2$, M 94.1, m. 85-90°(dec), 90°(dec).** It is a safe alternative to

H_2O_2 in various oxidation reactions. It is commercially available in tablets ('rapidly soluble', equivalent to ~30% H_2O_2) or as a white powder (with 15-17% active oxygen). It is usually used without purification after assaying for active oxygen. This is done by titration with potassium permanganate or by iodometry, i.e. titration of liberated iodine when glacial acetic acid containing Fe^{3+} and NaI are added. It can be recrystallised from 30% H_2O_2 in a molar ratio of ~2:3 by heating in a pyrex dish for a few minutes at ~60°, cooling and allowed to crystallise slowly by evaporation in a crystallising dish. It forms elongated white needles, but if the solution is seeded just before crystallisation and shaken gently for as few seconds, then small plates are formed. Preferably collect the crystals by centrifugation at low temperature and dry them at 0° *in vacuo*. When dry, it is stable at room temperature and it has been reported that the available oxygen content had not decreased noticeably after 12 months. However, it is best to store it dry at low temperature. It is soluble in organic solvents e.g. EtOH, Et_2O, $CHCl_3$, CH_2Cl_2 and Me_2CO with slow decomposition, and its solubility in H_2O is 40% where it also decomposes slowly. It decomposes slowly at 40-60°/20mm and at 55-70°/760mm in air, but decomposition appears to accelerate above 80°. It is very useful (and in many cases superior to *p*-chloroperbenzoic acid) in the oxidation of alkenes, (epoxides), aromatic hydrocarbons (to phenols), ketones (Baeyer-Villiger), sulfides (to sulfones) and N-heterocycles (to N-oxides) when using 5 to 10 molar ratios of oxidant in the presence of acetic or trifluoroacetic anhydrides. Care should be used with this reagent as it is **potentially explosive**. [Lu et al. *J Am Chem Soc* **63** 1507 *1941*, DOI: 10.1021/ja01161a055; Cooper et al. *Synlett* 533 *1990*, DOI: 10.1055/s-1990-21156; *Beilstein* **3** H 54, **3** I 25, **3** II 45, **3** III 105, **3** IV 102.]

Hydrogen sulfide *[7783-06-4]* **H_2S, M 34.1, m -59.6°, -60°, b -80°/atm, pK_1^{25} 7.05, pK_2^{25} 12.89.** Wash it through water, then pass the gas through a train of tubes containing saturated $Ba(OH)_2$ (2x), water (2x), and dilute HCl [Goates et al. *J Am Chem Soc* **73** 707 *1951*, DOI: 10.1021/ja01146a063]. It is available in gas cylinders. **HIGHLY POISONOUS.**

Hydroxylamine *[7803-49-8]* **NH_2OH, M 33.0, m 33.1°, b 56.5°/22mm, d_4^{20} 1.226, pK^{20} 5.96 (pK_b 7.97).** Crystallise it from *n*-butanol at -10°, collect it by vacuum filtration and wash it with cold diethyl ether. Also available as a 50wt % solution in H_2O. **Harmful vapours, and potentially explosive.** [Hurd et al. *Inorg Synth* **1** 87 *1939*, DOI: 10.1002/9780470132326.ch30; Semon in *Org Synth* Coll Vol **1** 318 *1932*, DOI: 10.15227/orgsyn.003.0061.]

Hydroxylamine hydrochloride *[5470-11-1]* **NH_2OH. HCl, M 69.5, m 151°, 155-157°(dec), d^{25} 1.67g/cm^3.** Crystallise the salt from aqueous 75% ethanol or boiling methanol, and dry it under vacuum over $CaSO_4$ or P_2O_5. It has also been dissolved in a minimum of water and saturated with HCl; after three such crystallisations, it is dried under a vacuum over $CaCl_2$ and NaOH. Its solubility at 20° is 85% in H_2O, 6% in EtOH and 12% in MeOH. [Hurd et al. *Inorg Synth* **1** 87 *1939*, DOI: 10.1002/9780470132326.ch30; Semon in *Org Synth* Coll Vol **1** 318 *1941*, DOI: 10.15227/orgsyn.003.0061; Fieser **1** 478, **2** 217, **7** 176, **9** 245, **11** 257, **15** 170.] It is a monoamine oxidase (MAO) inhibitor, inhibits platelet aggregation and is used in a simple assay for superoxide dismutase [Elstner & Heupel *Anal. Biochem.* **70** 616 *1976*, DOI: 10.1016/0003-2697(76)90488-7].

Hydroxylamine sulfate *[10039-54-0]* **$(NH_2OH)_2$. H_2SO_4, M 164.1, m 130°, 170°(dec), d^{25} 1.88g/cm^3.** Crystallise it from boiling H_2O by cooling to 0° (solubility:0.6g/ml at 20°). Strong ***reducing agent***, converts aldehydes and ketones to oximes, acid chlorides to hydroxamic acids, used as a catalyst, swelling agent and a co-polymerisation inhibitor.

Hydroxylamine-*O*-sulfonic acid *[2950-43-8]* **H_2NOSO_3H, M 113.1, m 210-211°, 215°(dec), pK^{45} 1.48.** Stir the solid vigorously with anhydrous Et_2O and filter it off using large volumes of dry Et_2O. Drain dry at the pump for 5 minutes and then for 12-14 hours in a vacuum. Store it in a vacuum desiccator over concentrated H_2SO_4. Determine the purity by oxidation of iodide to I_2. It must be stored in a dry atmosphere at 0-4°. It decomposes slowly in H_2O at 25° and more rapidly above this temperature. [Matsuguma et al. *Inorg Synth* **5** 122 *1957*, DOI: 10.1002/9780470132364.ch32; Fieser **1** 481, **2** 217, **3** 156, **4** 256, **5** 343, **6** 290, **8** 250, **9** 245, **10** 207, **15** 170.]

Hydroxyurea *[127-07-1]* **$NH_2CONHOH$, M 76.1, m 70-72° (unstable form), m 133-136°, 141° (stable form), pK^{25} 10.6.** Recrystallise hydroxyurea from absolute EtOH (10g in 150ml). Note that the rate of solution

in boiling EtOH is slow (15-30 minutes). It should be stored in a cool dry place, but some decomposition could occur after several weeks. [Deghenghi *Org Synth* Coll Vol **5** 645 *1973*, DOI: 10.15227/orgsyn.040.0060.] The solublility in H_2O is 50mg/ml at ~25° and it can be crystallised from Et_2O. [Kofod *Acta Chem Scand* **10** 256 *1956*, DOI: 10.3891/acta.chem.scand.10-0256; *Beilstein* **3** IV 170.]

Hypophosphorous acid (Phosphinic acid) *[6303-21-5]* **H_3PO_2, M 66.0, m 26.5°, d $_4^{30}$ 1.217, 1.13 and 1.04 for 50, 30-32, and 10% aqueous solutions resp, pK^{25} 1.31 (H_3PO_2).** Phosphorous acid is a common contaminant of commercial 50% hypophosphorous acid. Jenkins and Jones [*J Am Chem Soc* **74** 1353 *1952*, DOI: 10.1021/ja01125a514] purified this material by evaporating about 600ml in a 1L flask at 40°, under reduced pressure (in N_2), to a volume of about 300ml. After the solution was cooled, it was transferred to a wide-mouthed Erlenmeyer flask which was stoppered and left in a Dry-ice/acetone bath for several hours to freeze (if necessary, with scratching of the wall). When the flask was then left at *ca* 5° for 12 hours, about 30-40% of it liquefied, and was again filtered. This process was repeated, then the solid was stored over $Mg(ClO_4)_2$ in a vacuum desiccator in the cold. Subsequent crystallisations from *n*-butanol by dissolving it at room temperature and then cooling in an ice-salt bath at -20° did not appear to purify it further. The ***free acid*** forms ***deliquescent*** crystals **m 26.5°** and is soluble in H_2O and EtOH. The NaH_2PO_2 salt can be purified through an anion exchange resin [Klement *Z Anorg Allgem Chem* **260** 267 *1949*, DOI: 10.1002/zaac.19492600408.]

Indium *[7440-74-6]* **In, M 114.8, m 155-158°, 156.6°, b 2000°/atm, d $_4^{20}$ 7.31.** Before use, the metal surface is cleaned with dilute HNO_3, followed by thorough washing with water and an alcohol rinse. [Dönges in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 856 *1963*.] The metal is commercially available as rods, bars, wire, foil, granular form and powder in a large variety of sizes and purity.

Indium (III) chloride *[10025-82-8 (anhydrous)]* **$InCl_3$, M 211.2, m 586°, b 800°/atn, d ^{25} 3.46g/cm^3, pK$_1^{25}$ 3.54, pK$_2^{25}$ 4.28, pK$_3^{25}$ 5.16 (for aqueous In^{3+}).** The anhydrous salt forms yellow ***deliquescent*** crystals which can be sublimed at 500-600° in the presence of Cl_2/N_2 (1:1) [does not melt]. It is resublimed in the presence of Cl_2/N_2 (1:10) and finally heated to 150° to expel excess Cl_2. It is soluble in THF and H_2O (exothermically) and should be stored in a tightly closed container. [Baxter & Alter *J Am Chem Soc* **55** 1943 *1933*, DOI: 10.1021/ja01332a023.] It is a Lewis acid catalyst, e.g. in Friedel-Crafts and Diels-Alder reactions, and is the ***most available soluble salt of Indium*** [Araki & Hirashita 'Indium trichloride' in *Encyclopedia of Reagents for Organic Synthesis* Paquette ed *2004*, Wiley NY, DOI:10.1002/047084289]. It forms a ***tetrahydrate*** *[22519-64-8]* M 293.1, and a solution in H_2O (2 mol/mol) is also available commercially.

Indium (III) oxide *[1312-43-2]* **In_2O_3, M 277.6, d $_4^{20}$ 7.18, m sublimes at 850°.** Wash it with H_2O and dry it below 850°. It volatilises at 850° and dissolves in hot mineral acids to form salts. Store it away from light because it darkens due to the formation of free In.

Indium sulfate *[13464-82-9]* **$In_2(SO_4)_3$, M 517.8, d ^{25} 3.44g/cm^3.** Crystallise the white-grey powder from dilute aqueous H_2SO_4. It is ***hygroscopic***; store it in a well-stoppered vessel.

Indium (III) sulfate pentahydrate *[17069-79-3]* **$In_2(SO_4)_3$. $5H_2O$, M 607.9, d $_4^{20}$ 3.44.** Dissolve the salt in strong H_2SO_4 and slowly evaporate at *ca* 50°. Wash the crystals with glacial AcOH and then heat them in a furnace at a temperature of 450-500° for 6 hours. Its solubility in H_2O is 529g/L at 20°. The ***pentahydrate*** is converted to an ***anhydrous hygroscopic*** powder on heating at 500° for 6 hours; but heating above this temperature over N_2 yields the oxide-sulfate. Evaporation of neutral aqueous solutions provides basic sulfates. [Baxter & Alter *J Am Chem Soc* **55** 1943 *1933*, DOI: 10.1021/ja01332a023; Hattox & Vries *J Am Chem Soc* **58** 2126 *1936*, DOI: 10.1021/ja01302a012.] The ***hydrate is a complex*** in which the H_2O in the complex exchanges with warter at the rate of 10,000,000/sec, so the NMR cannot detect the difference between complexed and uncomplexed ion [Wolfram et al. *Physical Chemistry Chemical Physics* **6** 5145 *2004*, DOI: 10.1039/b407419j].

Iodic acid *[7782-68-5]* **HIO_3, M 175.9, m 118°(dec), d $_4^{20}$ 4.628, pK^{25} 0.75, 0.79.** Dissolve iodic acid in the minimum volume of hot dilute HNO_3, filter and evaporate in a vacuum desiccator until crystals are formed. Collect the crystals and wash them with a little cold H_2O, and dry them in air in the dark. It is soluble in H_2O:

269g/100ml at 20° and 295g/100ml at 40°. It is soluble in dilute EtOH and darkens on exposure to light. It is converted to $HIO_3.I_2O_5$ on heating at 70°, but at 220° complete conversion to HIO_3 occurs. [Lamb et al. *J Am Chem Soc* **42** 1636 *1920*, DOI: 10.1021/ja01453a014; Bray & Caulkins *J Am Chem Soc* **53** 44 *1931*, DOI: 10.1021/ja01352a007.]

Iodine *[7553-56-2]* **I_2, M 253.8, m 113.7°, b 184.3°/atm, d ^{25} 4.93g/cm^3(solid), d 3.960 (liquid at 120°).** The almost black crystals with violet vapour are usually purified by vacuum sublimation. Preliminary purifications include grinding with 25% by weight of KI, blending with 10% BaO and subliming, subliming with CaO, grinding to a powder and treating with successive portions of H_2O to remove dissolved salts, then drying, and recrystallising from *benzene. Barrer and Wasilewski [*Trans Faraday Soc* **57** 1140 *1961*, DOI: 10.1039/TF9615701140] dissolved I_2 in concentrated KI and distilled it, then steam distilled it three times and washed it with distilled H_2O. Organic material is removed by sublimation in a current of O_2 over platinum at about 700°, the iodine being finally sublimed under vacuum. It has a high vapour pressure, and Iodine crystals sometimes sublime on to the sides and top of its stoppered container. [Fieser **1** 495, **2** 200, **2** 220, **3** 159, **4** 258, **5** 346, **6** 293, **7** 179, **8** 256, **9** 248, **10 210, 11** 201, **11** 261, **12** 253, **13** 148, **14** 181, **15** 172, **16** 182, **17** 153.] **HARMFUL VAPOURS.** I_2 is slightly soluble in H_2O (0.0013moles/L at 25°), but more so in aqueous KI solution where it is in equilibrium with KI_3. It is soluble in organic solvents to varying amounts at 35° (g/100g solvent) solubilities are: *C_6H_6 (17.9), CCl_4 (6.2), heptane (4.29), CS_2 (21.6), 2,2-dimethylbutane (1.99), cyclohexane (3.90), EtOH (24.60), *p*-xylene (20.14), perfluoroheptane (0.019) and at 25°: *C_6H_6 (14.1), CS_2 (14.5), EtOH (21.4), Et_2O (25.2), cyclohexane (2.27) and heptane (1.70), and CCl_4 (16.4) [Hildebrand & Jenks *J Am Chem Soc* **42** 2180 *1920*, DOI: 10.1021/ja01456a008; Hildebrand et al. *J Am Chem Soc* **72** 1017 *1950*, DOI: 10.1021/ja01158a096]. It is a good and commonly used topical antiseptic.

Iodine monobromide *[7789-33-5]* **IBr, M 206.8, m 42°, 42-50°, d ^{25} 4.416g/cm^3.** The brown-black crystals are purified by repeated fractional crystallisation from its melt. The vapour dissociates on heating [Yost et al. *J Amer Chem Soc* **55** 552 *1933*, DOI: 10.1021/ja01329a016; Schmeisser in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** pp 291-292 *1963*]. A useful electrophile in a new preparation of polyketides synthons [Liu et al. *Org Lett* **8** 5393 *2006*, DOI: 10.1021/ol0623318].

Iodine monochloride *[7790-99-0]* **ICl, M 162.4, m 27.2°(α-form), 13.9°(β-form), b 97.4°/atm, d ^{25} 3.24g/cm^3.** Recrystallise repeatedly from its melt at low temperatures. The black crystals melt to a red-brown liquid. [Cornog et al. *Inorg Synth* **I** 165 *1939*, DOI: 10.1002/9780470132326.ch56.] A useful ***electrophile*** in a new preparation of polyketides synthons [Liu et al. *Org Lett* **8** 5393 *2006*, DOI: 10.1021/ol0623318].

Iodine pentafluoride *[7783-66-6]* **IF_5, M 221.9, m -9.3°, -8.0°, b 97.85°/760mm, d ^{25} 3.250g/cm^3.** Rogers et al. [*J Am Chem Soc* **76** 4843 *1954*, DOI: 10.1021/ja01648a022] removed dissolved iodine from IF_5 by agitating with a mixture of dry air and ClF_3 in a Fluorothene beaker using a magnetic stirrer. The mixture is transferred to a still, and the more volatile impurities are pumped off as the pressure is reduced below 40mm. The still is gradually heated (kept at 40mm) to remove the ClF_3 before IF_5 distilled. Stevens [*J Org Chem* **26** 3451 *1961*, DOI: 10.1021/jo01067a103] pumped IF_5 under vacuum from its cylinder, trapping it at -78°, then allowing it to melt in a stream of dry N_2. It ***reacts vigorously*** with H_2O to form HF, is a strong fluorinating agent, is strongly oxidative; and forms nitriles with primary amines after hydrolysis with H_2O [Stevens *J Org Chem* **31** 2025 *1966*, DOI:10.1021/jo01344a539]. **HARMFUL VAPOURS.** [Kwasnik in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** pp 159-160 *1963*, Booth & Pinkston Jr. 'The Halogen Fluorides' *Chem Rev* **41** 421–439 *1947*, DOI: 10.1021/cr60130a001.]

Iodine trichloride *[865-44-1]* **ICl_3, I_2Cl_6, M 233.3, m 33°, b 77°(dec).** Purify ICl_3 by sublimation at room temperature. At 77° it decomposes to ICl and Cl_2. It is stable as a 20% to 35% in hydrochloric acid. A strong chlorinating and oxidising agent. **Irritant, toxic vapours.** [Booth et al. *Inorg Synth* **1** 167 *1939*, DOI: 10.1002/9780470132326.ch57.] It is an interhalogen compound and is infact a ***dimer $Cl_2ICl_2ICl_2$*** [Boswijk & Wiebenga 'The crystal structure of I_2Cl_6 (ICl_3)' *Acta Cryst* **7** 417 *1954*, DOI: 10.1107/S0365110X54001260

Iridium *[7439-88-5]* **Ir, M 192.2, m 2450°, b ~4500°/atm, 4130°/atm, d ^{25} 22.65g/cm^3.** Iridium is a silver

white hard solid which oxidises on the surface in air. Scrape the outer tarnished layer until silver clear and store it under paraffin. It is stable to acids but dissolves in ***aqua regia***. Available as a black powder, foil, and wire. [Gilchrist *Chem Rev* **32** 277 *1943*, DOI: 10.1021/cr60103a002.]

Iridium (IV) chloride hydrate (hexachloroiridic acid) *[16941-92-7 ($6H_2O$), 207399-11-9 (xH_2O)]* **$IrCl_4.xH_2O$, M 334.0+H_2O.** If it contains nitrogen, then repeatedly concentrate a concentrated HCl solution until free from nitrogen, and dry free from HCl in a vacuum over CaO until crystals are formed. The olive-green solid (yellow at ~700°) is very ***hygroscopic***. [Woo & Yost *J Am Chem Soc* **53** 884 *1931*, DOI: 10.1021/ja01354a008; Grube in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **II** p1592 *1965*.]

Iron (wire) *[7439-89-6]* **Fe, M 55.9, m 1535°, 1538°, b 2750°/atm, 2862°/atm, d ^{25} 7.86g/cm^3.** Clean it in concentrated HCl, rinse in de-ionised water, then reagent grade acetone and dry it under vacuum. It reacts with mineral acids to give the respective iron salts and hydrogen. Available as chips, granular form, powder, rods, and wire. [Fieser **1** 519, **2** 229, **3** 167, **5** 357, **9** 257, **12** 263, **14** 184, **17** 157.]

Lanthanum *[7439-91-0]* **La, M 138.9, m 920°, b 3464°/atm, 3470°/atm, d ^{25} 6.19g/cm^3.** It is a shiny metal that slowly tarnishes in air due to oxidation. It slowly decomposes by H_2O in the cold and more rapidly on heating to form the hydroxide. The metal is cleaned by scraping off the tarnished areas until the shiny metal is revealed and stored under oil or paraffin. It burns in air at 450°. It exists in three forms: α-form, β-form and γ-form with transition temperatures of 310° and 864°, respectively. [Spedding et al. *Ind Eng Chem* **44** 553 *1952*, DOI: 10.1021/ie50507a034.]

Lead (II) bromide *[10031-22-8]* **$PbBr_2$, M 367.0, m 371°, 373°, b 892°/atm, d ^{25} 6.66g/cm^3.** Crystallise it from water containing a few drops of HBr (25ml of water per gram $PbBr_2$) between 100° and 0°. A neutral solution is evaporated at 110°, and the crystals that separate are collected by rapid filtration at 70° and dried at 105° (to give the ***monohydrate***). Its solubility in H_2O is 0.5% (at ~10°) and 5% (at ~ 100°), (solubility product at 20° is 7.9 x 10^{-5}). To prepare the ***anhydrous*** bromide, the hydrate is heated for several hours at 170° and then in a Pt boat at 200° in a stream of HBr and H_2. Finally it is fused [Clayton et al. *JCS Faraday Trans 1* **76** 2362 *1980*, DOI: 10.1039/ F19807602362]. **POISONOUS.**

Lead (II) chloride *[7758-95-4]* **$PbCl_2$, M 278.1, m 501°, b 950°/atm, d ^{25} 5.85g/cm^3.** Crystallise it from distilled water at 100° (33ml/g) after filtering through sintered-glass and adding a few drops of HCl, by cooling. After three crystallisations the solid is dried under vacuum or under anhydrous HCl vapour by heating slowly to 400°. The solubility in H_2O is 0.07% at ~10°, and 0.43% at ~ 100°, (solubility product at 20° is 2.4 x 10^{-4}). **POISONOUS.**

Lead (II) iodide *[10101-63-0]* **PbI_2, M 461.0, m 402°, b 954°/atm, d ^{25} 6.16g/cm^3.** It crystallises from a large volume of water. The solubility in H_2O is 1.1% at ~10°, and 3.3% at ~ 100°. **POISONOUS.**

Lead monoxide *[1317-36-8]* **PbO, M 223.2, m 886°, 888°, b 1477°/atm, d ^{25} 9.53g/cm^3.** Higher oxides are removed by heating under vacuum at 550° with subsequent cooling under vacuum. It is red at room temperature but becomes yellow at high temperatures (~480°) reversibly. It has low solubility in H_2O (0.017g/L at 25°), but is soluble in concentrated alkalies, HCl and NH_4Cl. [Ray & Ogg *J Am Chem Soc* **78** 5994 *1956*, DOI: 10.1021/ja01604a010; Kwestroo et al. *J Inorg Nucl Chem* **29** 39 *1967*, DOI: 10.1016/0022-1902(67)80141-6.] **POISONOUS.**

Lead sulfide (Galena) *[1314-87-0]* **PbS, M239.3, m 1112°, d ^{25} 7.5g/ml.** The sulfide is a black powder which is almost insoluble in H_2O (4.9g x 10^{-11}g/L at ~25°; solubility product at 20° is 4.2 x 10^{-29}) meaning that traces of lead can be detected in solution by bubbling H_2S through it or adding aqueous H_2S solution to it. Thus, lead can be detected in the supernatant of an aqueous solution of precipitated lead chloride (cf. above, solubility product at 20° is 2.4 x 10^{-4}). If PbS is required pure then it is best prepared by precipitating it by bubbling washed H_2S through a solution of pure recrystallised lead acetate, filtering off the sulfide, washing it thoroughly with H_2O and drying it in a vacuum. ***Note*** that the precipitate is often red in the presence of hydrochloric acid

due to the initial formation of ***red lead sulfochloride (PbS.PbCl$_2$)*** which decomposes on dilution, or by further passage of H_2S to form the black sulfide [Lenher *J Am Chem Soc* **23** 680 *1901*, DOI: 10.1021/ja02035a008]. Although PbS has a high melting point it will sublime under N_2 above 860°. It dissolves in boiling dilute HNO_3 with precipitation of S; and with concentrated HNO_3 it is completely converted to the insoluble white $PbSO_4$ (solubility product at 20° is 2.3 x 10^{-8}).
Lead sulfide paper test for H_2O_2. The paper is prepared by soaking filter paper in aqueous lead acetate solution and exposing it to a small amount of H_2S then drying it in a vacuum desiccator, and storing the brown paper in a stoppered container. A drop of a neutral or slightly acidic H_2O_2 solution on the paper will show up as a white spot on a brown background. The white spot is from $BaSO_4$ formed by oxidation. The sensitivity for H_2O_2 is 0.07μg with a concentration limit of 1 in 700,000.

Lead nitrate *[10099-74-8]* **Pb(NO$_3$)$_2$, M 331.2, m 270°(dec), d ^{20} 4.53g/cm^3.** Precipitate it twice from a hot (60°) concentrated aqueous solution by adding HNO_3. The precipitate is sucked dry on a sintered-glass funnel, then transferred to a crystallising dish which is covered by a clock glass and left in an electric oven at 110° for several hours [Beck et al. *Trans Faraday Soc* **55** 331 *1959*, DOI: 10.1039/TF9595500331]. Its solubility in H_2O is 0.38g/ml (0°), 0.52g/ml (20°), 1.27g/ml (100°); in EtOH it is 0.04g/100ml (~25°), in MeOH it is 1.3g/100ml (~25°), and virtually insoluble in HNO_3. After two recrystallisations of ACS grade, no metals above 0.001ppm were detected. **POISONOUS.**

Lithium (metal) *[7439-93-2]* **Li, M 6.9, m 180.5°, b 1342°/atm, d ^{25} 0.534g/cm^3.** After washing with petroleum ether to remove storage oil, lithium is fused at 400° and then forced through a 10-micron stainless-steel filter with argon pressure. It is again melted in a dry-box, skimmed, and poured into an iron distillation pot. After heating under a vacuum to 500°, cooling and returning it to the dry-box for a further cleaning of its surface, the lithium is distilled at 600° using an all-iron distillation apparatus [Gunn & Green *J Am Chem Soc* **80** 4782 *1958*, DOI: 10.1021/ja01551a008].

Lithium aluminium hydride *[16853-85-3]* **LiAlH$_4$, M 37.9, m 125°(dec).** Extract it with Et_2O, and, after filtering, the solvent is removed under vacuum. The residue is dried at 60° for 3 hours, under high vacuum [Ruff *J Am Chem Soc* **83** 1798 *1961*, DOI: 10.1021/ja01469a006]. It is a strong ***reducing agent***. Store it in aliquots in a strictly dry atmosphere, and use in these aliquoted quantities. **It IGNITES in the presence of a small amount of water and reacts with it EXPLOSIVELY.** [Becher in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 805 *1963*; Fieser **1** 581, **2** 242, **3** 176, **4** 291, **5** 382, **6** 325, **7** 196, **8** 286, **9** 274, **10** 236, **11** 289, **12** 272, **13** 158, **14** 190, **15** 184.] Also commercially available as a 1.0M solution in Et_2O, 0.5M solution in 2-methoxyethyl ether, 0.5M solution in ethylene glycol dimethyl ether, 1.0M and 2.0M solution in THF, and as a ~3.5M suspension in THF/toluene.

Lithium amide *[7782-89-0]* **LiNH$_2$, M 23.0, m 380-400°, d$^{17.5}$ 1.178, d ^{25} 1.178g/cm^3.** Purify it by heating at 400° while NH_3 is passed over it in the upper of two crucibles (the upper crucible is perforated). The $LiNH_2$ will drip into the lower crucible through the holes in the upper crucible. The product is cooled in a stream of NH_3. Protect it from air and moisture, store it under N_2 in a clear glass bottle sealed with paraffin. Store it in small quantities so that all the material is used once the bottle is opened. If the colour of the amide is yellow, it should be destroyed as it is likely to have oxidised and to **EXPLODE.** On heating above 450° it is decomposed to Li_2NH, which is stable up to 750-800°. [Schenk in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 463 *1963*, Greenlee et al. *Inorg Synth* **2** 128 *1953*, DOI: 10.1002/9780470132333.ch38.]

Lithium azide *[19597-69-4]* **LiN$_3$, M 49.0, m 115-298° (dec), pK^{25} 4.72 (HN$_3$).** Digest ~1g with 15ml of 96% EtOH at 35°, filter and dry it in air at temperatures below 80°. Store it in a cool place and treat it as **potentially explosive**. Its solubility in H_2O is 66.4% at 16°, and 20.26% at 16° in EtOH. [Hofmann-Bang *Acta Chem Scand* **11** 581 *1957*, DOI: 10.3891/acta.chem.scand.11-0581; Schenk in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 581 *1963*.] Also available as a 20wt % solution in H_2O. **Poisonous.**

Lithium borohydride *[16949-15-8]* **LiBH$_4$, M 21.8, m 268°, 275°(dec), b 380°(dec), d ^{25} 0.666g/cm^3.** It is crystallised from Et_2O, and pumped free of ether at 90-100° during 2 hours [Schaeffer et al. *J Am Chem Soc* **78**

729 *1956*, DOI: 10.1021/ja01585a011]. Store it dry as it decomposes slowly in moist air. [Becher in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 775 *1963*, Fieser **1** 603, **4** 296, **11** 293, **12** 276, **14** 191, **15** 186.] Also commercially available as a 2.0M solution in THF.

Lithium bromide *[7550-35-8]* **LiBr, M 86.8, m 550°.** Crystallise it several times from water or EtOH, then dry it under high vacuum for 2 days at room temperature, followed by drying at 100°. Its solubility in H_2O is 167% at ~20°, and 250% at ~100°. It is ***deliquescent*** and should be stored in a tightly stoppered vessel. [Fieser **1** 604, **2** 245, **4** 297, **13** 332.]

Lithium carbonate *[554-13-2]* **Li_2CO_3, M 73.9, m 552°, 618°, d ^{25} 2.11g/cm^3(powder).** Crystallise it from water. Its solubility decreases as the temperature is raised. The solubility in H_2O is 1.3% at ~10°, and 0.7% at ~100°. [Dönges in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 987 *1963*, Calby et al. *Inorg Synth* **1** 1 *1939*, DOI: 10.1002/9780470132326.ch1; Fieser **1** 606, **3** 183, **4** 192, **3** 396.]

Lithium chloride *[7447-41-8]* **LiCl, M 42.4, m 600°, 605°, 723°, d ^{25} 2.068g/cm^3, n $_D^{24}$ 1.662.** Crystallise the white powder from water (1ml/g) or MeOH and dry it for several hours at 130°. Other metal ions can be removed by preliminary crystallisation from hot aqueous 0.01M disodium EDTA. It has also been crystallised from concentrated HCl, fused in an atmosphere of dry HCl gas, cooled under dry N_2 and pulverised in a dry-box. Runner & Wagner [*J Am Chem Soc* **74** 2529 *1952*, DOI: 10.1021/ja01130a022] precipitated it with ammonium carbonate, washed it with Li_2CO_3 five times by decantation and finally with suction, then dissolved it in HCl. The LiCl solution is evaporated slowly with continuous stirring in a large evaporating dish, the dry powder being stored (while still hot) in a desiccator over $CaCl_2$. It has the following solubilities in H_2O: 0.68g/ml (0°), 0.84g/ml (25°), 1.23g/ml (100°); in EtOH: 0.14g/ml (0°), 0.25g/ml (30°), 0.23g/ml (60°); in HCOOH: 0.27g/ml (25°); in Me_2CO: 0.012g/ml (20°), 0.008g/ml (25°), 0.006g/ml (50°); in liquid NH_3: 0.0054g/ml (-34°) and 0.032g/ml (25°). [Fieser **1** 609, **2** 246, **4** 298, **5** 677, **13** 332, **16** 194.] It forms a ***hydrate*** *[85144-11-2]* LiCl. xH_2O [Fieser **13** 332, **16** 194.] **TOXIC, affects the nervous system**.

Lithium dimethylaminoborohydride (in 1M solution in THF) *[53042-33-4]* **Li(Me_2N)BH_3, M 64.8, d ^{25} 0.882g/cm^3 n $_D^{20}$ 1.423.** This reagent is prepared under a N_2 atmosphere by reacting 1mol of borane (BH_3) or borane-dimethylsulfide (BMS) in THF with 1 mol of Me_2NH (or other primary or secondary amine) at ~25° for 1 hour followed by addition of just under 1mol of *n*BuLi at 0° slowly, and the temperature allowed to rise to ~25° while stirring, and stirred for a further hour. These solutions are kept in vials with a *sure-fit* cap and are stable for at least 9 months. The solid reagent can be obtained by removing the solvent at 0°/1mm. ***Note*** that care should be taken that a slight excess of *n*BuLi will cause the solid to he highly ***pyrophoric***. The solid or solution retain their activity when kept under nitrogen as well as in a dry air atmosphere and are as stable as $NaBH_4$. It is however better to store the reagent as a solution. These ***LABs (lithium aminoborohydrides)*** are selective, air stable reducing agents capable of reducing a variety of functional groups [Fisher et al. *J Org Chem* **59** 6378 *1994*, DOI: 10.1021/jo00100a046; Review: Pasumansky et al *Aldrichimica Acta* **38** 61 *2005*, Saikai *Synlett* 995 *2007*, DOI: 10.1055/s-2007-973864]. They are also capable of transferring the amine group as in their reactions with halopyridines [Thomas et al *Org Lett* **5** 3867 *2003*, DOI: 10.1021/ol035430j] and primary alkyl methanesulfonates [Thomas et al. *Org Lett* **3** 3915 *2001*, DOI: 10.1021/ol0167659]

Lithium fluoride *[7789-24-4]* **LiF, M 25.9, m 842°, 845°, 848°, b 1676°, 1681°, d $_4^{20}$ 2.640.** Possible impurities are $LiCO_3$, H_2O and HF. These can be removed by calcining it at red heat, then pulverising it with a Pt pestle and storing it in a paraffin bottle. Its solubility in H_2O is 0.27% at 18°. It volatilises between 1100-1200°. [Kwasnik in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 235 *1963*].

Lithium hydride *[7580-67-8]* **LiH, M 7.95, m 680°, d $_4^{20}$ 0.76-0.77.** It should be a white powder; otherwise replace it. It darkens rapidly on exposure to air and is decomposed by H_2O to give H_2 and LiOH, and reacts with lower alcohols. One gram in H_2O liberates 2.8L of H_2 (could be explosive). [Dönges in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 987 *1963*, Fieser **4** 304, **13** 165.]

Lithium hydroxide monohydrate *[1310-66-3 (H_2O), 1310-65-2 (anhydrous)]* **LiOH. H_2O, M 42.0, m 470°**

(dec), 471°, d 1.51, pK^{25} 13.82. It crystallises from water (3ml/g) as the ***monohydrate***. It ***dehydrates*** at 150° in a stream of CO_2-free air, and sublimes at 220° with some decomposition [Cohen *Inorg Synth* **5** 1 *1957*, DOI: 10.1002/9780470132364.ch1; Bravo & Groot *Inorg Synth* **7** 1 *1963*, DOI: 10.1002/9780470132388.ch1].

Lithium iodate *[13765-03-2]* **$LiIO_3$, M 181.9, m 420-450°, d ^{25} 4.487g/cm^3, n $^{20}_D$ 1.8875.** Crystallise it from water and dry it in a vacuum oven at 60°. Its solubility in H_2O is 0.89g/ml (10°), 0.83g/ml (25°), 0.78g/ml (40°), and 0.73g/ml (75.6°). [Zachariasen & BartaLars 'Crystal Structure of Lithium Iodate'. *Physical Review Letters* **37** 1626 *1931*, DOI: 10.1103/PhysRev.37.1626.]

Lithium iodide *[10377-51-2, 85017-80-7 (hydrate)]* **LiI, M 133.8, m 73° ($3H_2O$), 446°, 469°, b 1171°, d ^{25} 3.49g/cm^3.** Crystallise it from hot water (0.5mL/g) by cooling in a $CaCl_2$/ice/EtOH or from an acetone/Dry-ice bath. Dry it under a vacuum over P_2O_5 for 1 hour at 60° and then at 120°. It is ***deliquescent*** and should be stored in dark tightly stoppered vessels. [Fieser **1** 615, **4** 304, **5** 410, **7** 208, **9** 283, **10** 245, **11** 300, **12** 282, **13** 322.]

Lithium nitrate *[7790-69-4]* **$LiNO_3$, M 68.9, m 253°, 255°, 264°, b 600°/atm(dec), d ^{25} 2.38g/cm^3, n $^{20}_D$ 1.735.** It crystallises from water [solubility: 0.52g/ml (20°), 0,9/ml (28°), 2.3g/ml (100°)] or EtOH. Dry it at 180° for several days by repeated melting under vacuum. If it is crystallised from water, and keeping the temperature above 70°, formation of ***trihydrate*** is avoided. The ***anhydrous*** salt is dried at 120° and stored in a vacuum desiccator over $CaSO_4$. After the 99% pure salt was recrystallised 3 times, it contained: metal (ppm) Ca (1.6), K (1.1), Mo (0.4), Na (2.2). [Donnan & Burt *J Chem Soc* **83** 335 *1903*, DOI: 10.1039/CT9038300335.]

Lithium nitrite monohydrate *[13568-33-7]* **$LiNO_2$. H_2O, M 71.0 m 222°.** Crystallise it from water by cooling from room temperature. The salt is very soluble in EtOH, so dissolve it in EtOH and allow to evaporate slowly which leaves white crystals on the side of the flask. On addition of a small amount to the saturated solution will provide larger needle-shaped crystals of the ***monohydrate***. [Ball & Abram 'The nitrites of thallium, lithium, caesium, and rubidium' *JCS Transactions* **103** 2130 *1913*, DOI: 10.1039/CT9130302130.]

Lithium perchlorate *[7791-03-9, 13453-78-6 ($2H_2O$)]* **$LiClO_4$, M 106.4, m 236°, pK^{25} -2.4 to -3.1 (for $HClO_4$).** Crystallise it from water or 50% aqueous MeOH. It is rendered ***anhydrous*** by heating the ***trihydrate*** at 170-180° in an air oven. It can then be recrystallised twice from acetonitrile and again dried under vacuum [Kosower & Mohammad *J Am Chem Soc* **93** 2713 *1971*, DOI: 10.1021/ja00740a022]. **SKIN IRRITANT.**

Lithium sulfate (anhydrous) *[10377-48-7]* **Li_2SO_4, M 109.9, loses H_2O at 130° and m 845°, 859°, d ^{25} 2.22g/cm^3(anhydr).** Crystallise it from H_2O (4ml/g) by partial evaporation, and dry it above 130° *in vacuo*.

Lithium tetrafluoroborate *[14283-07-9]* **$LiBF_4$, M 93.7, m 293-300°(dec), d ^{25} 0.852g/cm^3(1.0M in MeCN), pK^{25} 13.82 (Li^+), pK^{25} -4.9 (for HBF_4).** Dissolve it in THF just below its solubility, filter from insoluble material and evaporate it to dryness in a vacuum below 50°. Wash the residue with dry Et_2O, and pass dry N_2 gas over the solid and finally heat it in an oven at 80-90°. Its solubility in Et_2O is 1.3g in 100ml at 25°; in THF it is 71g in 100ml at 25°. It is ***hygroscopic*** and is an **IRRITANT.** [Elliott et al. *J Am Chem Soc* **74** 5211 *1952*, DOI: 10.1021/ja01140a507; **75** 1753 *1953*.]

Lithium thiocyanate (lithium rhodanide) *[556-65-0, 123333-85-7 (xH_2O)]* **LiSCN, M 65.0, pK^{25} -1.85 (for HSCN).** It crystallises from H_2O as the ***dihydrate***, but on drying at 38-42° it gives the ***monohydrate***. It can be purified by allowing an aqueous solution to crystallise in a vacuum over P_2O_5. The crystals are collected, dried out *in vacuo* at 80°/P_2O_5 in a stream of pure N_2 at 110°. [Coates & Taylor *J Chem Soc* 1245 *1936*, DOI: 10.1039/JR9360001245; *Beilstein* **3** III 251.]

Magnesium

[7439-95-4] **Mg, M 24.3, m 648°, 651°, b 1091°/atm, 1100°/atm, d $^{20}_4$ 1.739, d^{650} 1.584 g/cm^3(liquid).** It slowly oxidises in moist air and tarnishes. If too dark in colour, do not use it. The shiny solid should be degreased by washing with dry Et_2O, dry it *in vacuo* and keep it in a N_2 atmosphere. It can be activated by stirring it in Et_2O containing a crystal of I_2 then filtering it off, before drying and storing.

[Gmelin's Magnesium (8th edn) **27A** 121 *1937*; Amundsen et al. 'Magnesium'. *Ullmann's Encyclopedia of Industrial Chemistry 2002* Wiley-VCH. DOI:10.1002/14356007.a15_559; Fieser **1** 627, **2** 254, **3** 189, **3** 254, **4** 315, **5** 419, **6** 351, **7** 218, **10** 251, **11** 307, **12** 290, **13** 170, **16** 198.] It is used in flares as it burns with a very bright light; and used for making light alloys.

Magnesium bromide (anhydrous) *[7789-48-2]* **$MgBr_2$, M 184.1, m 711°, d $_4^{20}$ 3.72, d ^{25} 3.72g/cm^3.** Crystallise it from EtOH or H_2O (3.3g/ml). Dry it in a vacuum at ~150°, or heat the ***hydrate*** in a stream of HCl. It is very ***deliquescent***. It forms ***hexahydrate*** crystals *[13446-53-2]* with **d ^{25} 2.0g/cm^3.** [Ehrlich in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 909 *1963*.]

Magnesium chloride hexahydrate *[7791-18-6 ($6H_2O$), 7786-30-3 (anhydrous)]* **$MgCl_2$. $6H_2O$, M 203.3 ($6H_2O$), 95.2 (anhydr) m ~100°(dec), pK_1^{25} 10.3, pK_2^{25} 12.2 (for Mg^{2+} hydrolysis).** Crystallise it from hot water (3.3g/ml) by cooling. Dry it in a vacuum at ~175°, or heat the ***hydrate*** in a stream of HCl. When the hydrate is heated above 180° it is hydrolysed to the oxychloride (Mg_2OCl_2). It is ***deliquescent***; store it in a well-stoppered vessel. [Bryce-Smith & Hunt *Inorg Synth* **6** 9 *1960*, DOI: 10.1002/9780470132371.ch4; Ehrlich in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 908 *1963*.]

Magnesium iodate tetrahydrate *[13446-17-8 ($4H_2O$), 7790-32-1]* **$Mg(IO_3)_2$. $4H_2O$, M 446.2, m 210°(dec).** Crystallise from water (0.2g/ml) between 100° and 0°.

Magnesium iodide *[10377-58-9]* **MgI_2, M 278.1, m 634°, 637°(dec), d ^{25} 4.43g/cm^3.** Crystallise it from water (0.8g/ml) by partial evaporation in a desiccator. It is deliquescent and should be stored in the dark. [Ehrlich in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 910 *1963*.]

Magnesium nitrate hexahydrate *[13446-18-9]* **$Mg(NO_3)_2$. $6H_2O$, M 256.4, m 89°(dec), ~95°(dec).** Crystallise the nitrate from water (2.5mlg) by partial evaporation in a desiccator. It is ***deliquescent*** and is soluble in EtOH. After two recrystallisations, ACS grade salt has: metal (ppm) Ca (6.2), Fe (8.4), K (2), Mo (0.6), Na (0.8), Se (0.02).

Magnesium perchlorate (Anhydrone, Dehydrite) *[10034-81-8 (anhydrous)]* **$Mg(ClO_4)_2$, M 223.2(anhyd), m >250°, pK^{25} -2.4 to -3.1 (for $HClO_4$).** Crystallise it from water to give the ***hexahydrate*** **M 331.3** *[13346-19-0]*. Coll et al. [*J Am Chem Soc* **81** 1284 *1959*, DOI: 10.1021/ja01515a005] removed traces of unspecified contaminants by washing it with small portions of Et_2O and drying in a vacuum **(CARE)**. The anhydrous salt is commercially available as an ACS reagent, and is as efficient a dehydrating agent as P_2O_5 and is known as 'Dehydrite' or 'Anhydrone'. [Willard & Smith *J Am Chem Soc* **44** 2255 *1922*, DOI: 10.1021/ja01431a022; and Smith et al. *Ind Eng Chem* **16** 20 *1924*, DOI: 10.1021/ie50169a006.] It is ***hygroscopic***; keep it in a tightly closed container. It is **EXPLOSIVE** *in contact with organic materials, and is a* **SKIN IRRITANT**.

Magnesium sulfate (anhydrous) *[7487-88-9 (anhydrous), 14168-73-1 (H_2O), 17830-18-1 ($6H_2O$)]* **$MgSO_4$, M 120.4, m 1127°.** Crystallise it from warm H_2O (1g/ml) by cooling. Dry the ***heptahydrate (Epsom salt)*** [*10034-99-8* ($7H_2O$)] M 246.5, at ~250° until it loses 25% of its weight. Its solubility in H_2O is 36% at 20°, 55% at 60° and 74% at 100°; above 110° the solubility decreases with rise of temperature. Store it in a sealed container. [Fieser **1** 634, **4** 425, **5** 421.] Used as a purgative, in general anesthesia, local inflammation and septic wounds

Manganous(II) bromide (anhydrous) *[13446-03-2 (anhydrous), 10031-20-6 ($4H_2O$)]* **$MnBr_2$, M 214.8, m 695° ($4H_2O$)** *[10031-20-6]* **M 286.8, m 64°(dec).** It forms rose-red ***deliquescent*** crystals which are soluble in EtOH. The H_2O is removed by heating at 100° then in HBr gas at 725°, or dry it in an atmosphere of N_2 at 200°.

Manganous(II) chloride tetrahydrate *[13446-34-9 ($4H_2O$), 38639-72-4 ($2H_2O$), 7773-01-5 (anhydrous)]* **$MnCl_2$. $4H_2O$, M 197.9($4H_2O$), 125.8(anhydr), m 58°, 87.5°, 650°, 654°(anhydrous), b 1190°/atm (anhydrous), 1225°/atm, d ^{25} 2.977g/cm^3(anhydr), d ^{25} 2.27g/cm^3($2H_2O$), d ^{25} 2.01g/cm^3($4H_2O$).** It crystallises from water (0.3ml/g) on cooling. The red-rose ***tetrahydrate*** melts at **~52°** and forms the ***dihydrate salt*** which loses all its H_2O at 198° to give $MnCl_2$. It is soluble in EtOH. Another ***hydrate*** [*73913-06-1* (xH_2O)]

has **m 122°** and d ^{25} 1.193g/cm^3. It is soluble in EtOH and pyridine but insoluble in Et_2O. [Reidies 'Manganese Compounds', *Ullmann's Encyclopedia of Industrial Chemistry 2002* Weinheim: Wiley-VCH, DOI:10.1002/14356007.a16_123].

Manganous sulfate monohydrate *[10034-96-5 (H_2O), 10101-68-5 ($4H_2O$), 15244-36-7 (xH_2O), 7785-87-7 (anhydrous)]* **$MnSO_4$. H_2O, M 169.0, m 710°(anhydr), 27°($4H_2O$), b 850°/atm(anhydr), d ^{25} 3.25g/cm^3(anhydr), d ^{25} 2.95g/cm^3(H_2O), d ^{25} 2.107g/cm^3($4H_2O$).** Crystallise it from water (0.9ml/g) at 54-55° by evaporating about two-thirds of the water. It ***dehydrates*** above 400°. The anhydrous salt is soluble in EtOH but insoluble in Et_2O. [Reidies 'Manganese Compounds' *Ullmann's Encyclopedia of Chemical Technology 2007* Wiley-VCH, Weinheim, DOI:10.1002/14356007.a16_123.]

Mercuric bromide *[7789-47-1]* **$HgBr_2$, M 360.4, m 236°, b 320°/atm, 322°/atm, d ^{25} 6.03g/cm^3.** Crystallise it from hot saturated ethanolic solution, dry and keep it at 100° for several hours under a vacuum, then sublime it. [Garrett *J Am Chem Soc* **61** 2744 *1939*, DOI: 10.1021/ja01265a055.] Its solubility in H_2O is 0.6% at 20°, and 22% at 100°; in EtOH it is 30% at 25°; and in MeOH it is 69.6% at 25°. [Wagenknecht & Juza *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **II** p 1109 *1965*.] **POISONOUS**.

Mercuric chloride *[7487-94-7]* **$HgCl_2$, M 271.5, m 276°, b 304°/atm d ^{25} 5.43g/cm^3, n $^{25}_{D}$ 1.859, pKa 3.2 (0.2M solution).** Crystallise it twice from distilled water, dry it at 70° and sublime it under high vacuum. Its solubility in H_2O is 4.3% at ~0°, 6.6% at ~10° and 54% at ~100°. It is soluble in EtOH, Me_2CO, EtOAc, and is extracted into Et_2O (solubility: 4g/100ml at ~25°) from an aqueous solution. It is **very POISONOUS** and 0.2-0.4g is fatal. [Simon 'Mercury, Mercury Alloys, and Mercury Compounds' in *Ullmann's Encyclopedia of Industrial Chemistry 2006*, Wiley-VCH, Weinheim, DOI: 10.1002/14356007.a16_269.pub2]. The antidote is immediate administration of white of egg as an emetic.

Mercuric cyanide *[592-04-1]* **$Hg(CN)_2$, M 252.6, m 320°(dec), d ^{25} 3.996g/cm^3.** Crystallise it from water. The solubility in H_2O is 8% at ~20° and 33% at ~100°; in EtOH it is 8% at ~20° and in MeOH it is 25% at ~20°. [Blitz *Z Anorg Allgem Chem* **170** 161 *1928*, DOI: 10.1002/zaac.19281700123.] **POISONOUS.**

Mercuric iodide (red) *[7774-29-0]* **HgI_2, M 454.4, m 259°(yellow >130°), b ~350°(subl), 354°, d $^{20}_{4}$ 6.3.** Crystallise it from MeOH or EtOH and wash it repeatedly with distilled water (solubility is 0.006% at ~25°). It has also been mixed thoroughly with excess 0.001M iodine solution, filtered, washed with cold distilled water, rinsed with EtOH and Et_2O, and dried in air. It changes colour reversibly to yellow at ~130°. [Friend *Nature* **109** 341 *1922*, DOI: 10.1038/109341b0.] **POISONOUS.**

Mercuric nitrate monohydrate *[7783-34-8 (H_2O), 10045-94-0 (anhydrous)10415-75-5 (anhydrous)]* **$Hg(NO_3)_2$. H_2O, M 324.6(anhydr), m 79°, d ^{25} 4.30g/cm^3.** This salt is prepared by reacting concentrated HNO_3 with Hg, and under these conditions the HNO_3 is an oxidising agent. The ***anhydrous*** salt is ***deliquescent*** and is soluble in a small volume of H_2O, from which the ***monohydrate*** can be obtained by slow evaporation at room temperature *in vacuo*. A 0.14N solution in H_2O (d^{25}1.025g/cm^3) is also available commercially. However, with large volumes of H_2O, or on boiling, it is hydrolysed forming the insoluble basic salt. It is a strong ***oxidising agent***, is light sensitive and is explosive in contact with EtOH in which it is insoluble. It is poisonous if absorbed through the skin. [Fieser **3** 197, **10**, 254, **11** 317.] **Caution as this is a poisonous substance.**

Mercuric oxide (yellow) *[21908-53-2]* **HgO, M 216.6, m 500°(dec), d ^{25} 11.14g/cm^3, n $^{25}_{550nm}$ 2.5.** Dissolve it in $HClO_4$ and precipitate it with NaOH solution. It is yellow when cold and changes to red at ~130° reversibly. Its solubility in H_2O is quite low: 0.0053g/100ml (25°) and 0.0395g/100ml (100°), and is insoluble in EtOH, Et_2O, Me_2CO and NH_3. [Fieser **1** 655, **2** 267, **4** 323, **5** 428, **6** 360, **7** 224, **8** 316, **9** 293, **12** 305.] **POISONOUS.**

Mercuric thiocyanate *[592-85-8]* **$Hg(SCN)_2$, M 316.8, m 165°(dec), d ^{25} 3.71g/cm^3, pK^{25} -1.85 (for HSCN).** Recrystallise it from H_2O, and it can give various crystal forms depending on conditions. Its solubility in H_2O is 0.069% at 25°, but is more soluble at higher temperatures. It decomposes to Hg above 165°. **POISONOUS.** [Mason & Forgeng *J Phys Chem* **35** 1123 *1930*, DOI: 10.1021/j150322a017; Birckenbach & Kolb *Chem Ber* **68** 895 *1935*, DOI: 10.1002/cber.19350680532; *Beilstein* **3** IV 305.]

Mercurous nitrate dihydrate *[7782-86-7 ($2H_2O$)]* **$Hg_2(NO_3)_2$, M 561.2, m 70°(dec), d ^{25} 4.78g/cm^3, pK^{25} 2.68 (for Hg_2^{2+} hydrolysis).** Its solubility in H_2O containing 1% HNO_3 is 7.7%. Recrystallise it from a warm saturated solution of dilute HNO_3 and cool to room temperature slowly to give elongated prisms. Rapid cooling gives plates. The colourless crystals should be stored in the dark. **POISONOUS.** [For crystal structure see Grdenic *J Chem Soc* 1312 *1956*, DOI: 10.1039/JR9560001312]

Mercurous sulfate *[7783-36-0]* **Hg_2SO_4, M 497.3, d ^{25} 7.56g/cm^3.** The white-yellow powder is recrystallised from dilute H_2SO_4., dried in a vacuum under N_2, and stored in the dark. Its solubility in H_2O is 0.6% at 25°. It is hydrolysed by excessive washing with H_2O to form the greenish-yellow ***basic salt $Hg_2SO_4.Hg_2O.H_2O$***. Store it in the dark, as exposure to light decomposes it to Hg and $HgSO_4$. **POISONOUS.**

Mercury *[7439-97-6]* **Hg, M 200.6, m -38.9°, b 126°/1mm, 184°/10mm, 261°/100mm, 356.9°/atm, d $^{20}_{4}$ 13.534 g/cm^3.** After air has been bubbled through mercury for several hours to oxidise metallic impurities, it is filtered to remove coarser particles of oxide and dirt, then sprayed through a 4-ft column containing 10% HNO_3. It is washed with distilled water, dried with filter paper and distilled under vacuum. [Schenk in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 8 *1963*.] A **mercury absorption kit,** available commercially, which consists of a bottle of **Mercurisorb** (100g, which absorbs its own wt of Hg in 5 minutes), a brush, a minishovel, disposable gloves, a container for adsorbed mixture, disposable pipettes and a compact case.

Molybdenum *[7439-98-7]* **Mo, M 95.9, m 2622°, b ~4825°, d^{25} 10.3g/ml, resistivity of 5.0 $\mu\Omega$-cm at 20°.** The dark-grey metal is commercially available in varying degrees of purity from 98 to 99.99%, as foil with thickness from 0.025mm (5.8g 150 x 150mm) to 1.0mm (25.6g, 50mm x 50mm or 102.4g, 100mm x 100 mm), or black powder from <150μm to 1-2μm particle size as well in nanopowder form of <100nm (BET) size. It is also available as wire of 1.0mm in diameter. The metal is stable in air but is oxidised at red heat to MoO_3; is ureactive towards dilute acids or alkalies but reacts with strong HNO_3, H_2SO_4, fused $KClO_3$ or KNO_3, F_2 (at ~ 25°), Cl_2 and Br_2 (at red heat). [**CARE**: it is potentially quite toxic—particularly the nano sized particles.]

Molybdenum (VI) dichloride dioxide (MoO_2Cl_2) *[13637-68-8]* **MoO_2Cl_2, M 198.8, d^{25} 6.31g/cm^3.** It is prepared from MoO_2 (40.0g, 313mmol) by placing it in a test tube with a wide side arm and a central tube which ends ~2cm above the surface of the oxide. The side arm is connected to a large round bottomed flask which vents through a bubbler containing H_2SO_4. The apparatus is flushed with argon, and the tube containing the oxide is immersed in an oil bath which is kept at 140° for 12 hours to dry the oxide. The temperature of the tube is then raised to 160° and a stream of Cl_2 gas (pre-dried by bubbling through two H_2SO_4 traps) is allowed to flow over the hot oxide for 10 hours. The wide tube connecting the test tube and the flask is wrapped with a heating tape to encourage the MoO_2Cl_2 to sublime into the flask as it is formed. Stirring the contents of the flash (magnetic stirrer bar) hinders the clogging entry and exit tubes. MoO_2Cl_2 collects as ivory flakes that are quite pure for most purposes, but can be resublimed if necessary. All due **PRECAUTIONS** should be taken as chlorine is a **TOXIC GAS** and concentrated H_2SO_4 is used in the bubblers. [Schrock et al. *J Am Chem Soc* **112** 3875 *1990*, DOI: 10.1021/ja00166a023; Epperson et al. *Inorg Synth* **7** 163 *1963*, DOI: 10.1002/9780470132388.ch45.] Commercial fluffy MoO_2Cl_2 gives poor yields of substitution products (e.g. with $ArNHSiMe_3$), but the ***THF complex $MoO_2Cl_2(THF)_2$*** *[556907-19-8; 12081-12-8]* is easier to handle, reacts in a similar way, and gives much higher yields of substitution products. It is readily prepared in solution by carefully adding solid MoO_2Cl_2 to dry THF at -30°. Addition of THF to MoO_2Cl_2 is too exothermic to keep under control. [Schrock et al. *J Am Chem Soc* **112** 3875 *1990*, DOI: 10.1021/ja00166a023.] Krauss & Huber prepared it by adding MoO_2Cl_2 (2.0g, 10mmol) in four portions to THF (7ml. 6.5g, 90mmol) while shaking. The yellow solution is diluted with light petroleum (5ml), filtered, the filtrate is diluted further with light petroleum (10ml) when the complex crystallises out. The supernatant is decanted off, the solid is washed several times with light petroleum (10ml lots), and dried at room temperature in a stream of N_2 to give analytically ***pure $MoO_2Cl_2(THF)_2$*** (3.2g, 93%) as very pale yellow needles, **m > 50° (dec)**, that are soluble in THF, slightly soluble in Et_2O but insoluble in light petroleum [Krauss & Huber *Chem Ber* **94** 2864 *1961*, DOI: 10.1002/cber.19610941106]. It is very useful for preparing a variety of Mo complexes and catalysts.

Molybdenum hexafluoride *[7783-77-9]* **MoF_6, M 209.9, m 17.5°, b 35°/760mm, d $^{20}_{4}$ 2.543.** Purify the hexa-

fluoride by low-temperature trap-to-trap distillation over pre-dried NaF. It is ***hygroscopic***, fumes in moist air and is hydrolysed readily by H_2O. [Oppegard et al. *J Am Chem Soc* **82** 3835 *1960*, DOI: 10.1021/ja01500a011; Anderson & Winfield *JCS Dalton Trans* 337 *1986*, DOI: 10.1039/DT9860000337; Kwasnik in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 259 *1963*.] **Poisonous vapours, take necessary precaution.**

Molybdenum (IV) oxide [molybdenum (IV) dioxide] *[18868-43-4]* **MoO_2, M 127.9, m 1100°(dec), d^{25} 6.47g/cm^3.** It is prepared by grinding together ~10-15g of a mixture in a 2:1 ratio of MoO_3 (dried by heating in at 500° for 1 hour) and Mo metal powder in a quartz combustion tube under argon, or in an evacuated tube (CARE when opening), at 800° for 70 hours. It forms a brown-violet powder, oblong needles or thick platelets with a metallic lustre. It is insoluble H_2O, alkalies, HCl, HF, but only slightly soluble in hot HNO_3. [Conroy et al. *Inorg Synth* **14** 149 *1973*, DOI: 10.1002/9780470132456.ch31; **30** 105 *1997*, DOI: 10.1002/ 9780470132616.ch21; Herzog et al. in *Handbuch der Preparativen Anorganische Chemie (Ed. Brauer)* Enke Verlag Stuttgart Vol **3** p 1542 *1981*.] Beware of **TOXIC** vapours.

Molybdenum trichloride *[13478-18-7]* **$MoCl_3$, M 202.3, m 1027°, d_4^{20} 3.74.** Boil it with 12M HCl, wash it with absolute EtOH and dry it in a vacuum desiccator. It is a brown-red powder soluble in H_2O, EtOH or Et_2O and gives a blue solution in concentrated H_2SO_4. [Hein & Herzog *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **II** p 1404 *1965*, Larsonet al. *Inorg Synth* **12**, 165 *1970*, DOI: 10.1002/ 9780470132432.ch29.]

Molybdenum trioxide [molybdenum (VI) oxide, MoO_3] *[1313-27-5]* **MoO_3, M 143.9, m 795°, b 1155°/atm, d_4^{20} 4.60.** MoO_3 is prepared by adding HNO_3 to an aqueous solution of ammonium molybdate and stirring for several hours which precipitates H_2MoO_4. The acid is filtered off, washed with H_2O, heated at 150° for 1-2 hours and the hydrated oxide is dried at 450°. It recrystallises in rhombs from water (1g/50ml) between 70° and 0°, and is dried in air at ~500° for 1 hour before use. Its solubility in H_2O is 0.1% at 18°, and 2% at 70°. It is a white powder which turns yellow reversibly on heating. It sublimes readily at >780°/760mm in a quartz tube to give pure MoO_3. [Hein & Herzog *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **II** p 1412 *1965*, Herzog et al. in *Handbuch der Preparativen Anorganische Chemie (Ed. Brauer)* Enke Verlag Stuttgart Vol **3** p 1544 *1981*.] It is used in the synthesis of Mo compounds, and of the ternary reduced molybdenum oxide $Pr_4Mo_9O_{18}$, which contains the previously unknown Mo_7, Mo_{13}, and Mo_{19} clusters; and is a precursor for the preparation of fast ion conductors and superconductors [Arulraj et al. *Chem Mater* **14** 2492 *2002*, DOI: 10.1021/cm011239x ; Lacorre et al. *Nature* **404** 856 *2000*, DOI: 10.1038/35009069]. The oxide forms hydrates and alcoholates which have different IR spectra [Krauss & Huber *Chem Ber* **94** 2864 *1961*, DOI: 10.1002/cber.19610941106]. Beware of **TOXIC** vapours.

Molybdic acid *[7782-91-4]* **H_2MoO_4, M 162.0, 180.0 (monohydrate), d^{25} 3.124g/cm^3 (for monohydrate), pK_1^{25} 0.9 (proton addition), pK_2^{20} 4.00, pK_3^{20} 4.21.** Treatment of an aqueous solution of 0.4N Na_2MoO_4 [1L, or of $(NH_4)_2MoO_4$ as in the preceding entry] at 60° with 30% HNO_3 (1L, prepared from 300ml of concentrated acid, d 1.42, in 1L of H_2O with cooling) and allowing to stand at 25° for several days deposited the theoretical amount of canary yellow monoclinic crystals which are collected, washed with ice water and dried *in vacuo* over H_2SO_4 for 2 weeks to give $H_2MoO_4.H_2O$. This is referred to as ***α-molybdic acid*** which on warming in H_2O at 70° is transformed to the white anhydrous ***β-molybdic acid***. These acids have different X-Ray spectra and vapour pressures. ***Colloidal molybdic acid*** is obtained by dialysing an aqueous solution of $(NH_4)_2MoO_4$ and HCl, and forms a gum on evaporation. By heating these acids, or the ammonium salts, provide white MoO_3 which on heating further at 500° in the presence of H_2 gives reddish-brown MoO_2, and at 1200° a grey powder of metallic Mo is obtained (see preceding entries). Polymeric forms are known such as ***tetramolybdic acid*** **[$H_2Mo_4O_{16}$**, pK_1 1.4, pK_2 1.2, Chauveau et al. *Bull Soc Chim Fr* 1190 *1959***]** and ***heptamolybdic acid*** **[$H_6Mo_7O_{24}$**, pK_5^{25} ~3.7, pK_6^{25} 4.33, Sasaki et al *J Inorg Nucl Chem* **9** 93 *1959*, DOI: 10.1016/0022-1902(59)80016-6]. ***Note*** that in aqueous alkaline solution the main Mo(VI) acid species are MoO_4^{2-}, but in neutral and acidic media polynuclear species exist [cf. Sasaki & Sillén *Arkiv Kemi* **29** 253 *1968*, and Sasaki et al *J Inorg Nucl Chem* **9** 93 *1959*, DOI: 10.1016/0022-1902(59)80016-6]. [Herzog et al. in *Handbuch der Preparativen Anorganische Chemie (Ed. Brauer)* Enke Verlag Stuttgart Vol **3** p 1544 *1981*,

Rosenheim *Z Anorg Chem* **50** 320 *1906*, DOI: 10.1002/zaac.19060500131; Peters et al. *Z Anorg Allgem Chem* **365** 14 *1969*, DOI: 10.1002/zaac.19693650103; and for pKs see also Sasaki & Sillén *Acta Chem Scad* **18** 1014 *1964*, DOI: 10.3891/acta.chem.scand.18-1014; Rohwer & Cruywagen *J S African Chem Inst* **16** 26 *1963*, for first protonation constant of monomeric molybdic acid see Rohwer & Cruywagen *J S African Chem Inst* **17**(2) 145 *1964*, ISBN 03794350, http://hdl.handle.net/10520/AJA03794350_1072]

Monocalcium phosphate dihydrate (monobasic) *[7789-77-7 ($2H_2O$), 7757-93-9 (anhydrous)]* **$CaHPO_4.2H_2O$, M 154.1, m 200°(dec, loses H_2O at 100°), d ^{25} 2.31g/ ml.** Crystallise it from a near-saturated solution in 50% aqueous reagent grade phosphoric acid at 100° by filtering through fritted glass and cooling to room temperature. The crystals are filtered off, and this process is repeated three times using fresh acid. For the final crystallisation the solution is cooled slowly with constant stirring to give thin plate crystals that are filtered off on a fritted glass funnel, washed free of acid with anhydrous acetone and dry in a vacuum desiccator [Egan et al. *J Am Chem Soc* **78** 1811 *1956*, DOI: 10.1021/ja01590a009].

Neodynium chloride hexahydrate *[13477-89-9]* **$NdCl_3.6H_2O$, M 358.7, 250.6, m 124°, d ^{25} 4.13g/ cm^3(anhydr), d ^{25} 2.282g/cm^3(hydrate), pK_1^{25} 8.43 (for Nd^{3+} hydrolysis)**. Neodynium chloride forms large purple-pink prisms from concentrated solutions of dilute HCl. ***Hygroscopic***. The crystals are soluble in H_2O (2.46 parts in 1 part of H_2O) and EtOH, and lose H_2O at 160°. [Steele & Wertz 'Solvent effects on the coordination of neodymium(3+) ions in concentrated neodymium trichloride solutions' *Inorg Chem* **16** 1225 *1977*, DOI: 10.1021/ic50171a050.]

Neodymium(II) iodide *[61393-36-0, 61393-39-0]* **NdI_2, M 398.1, 395.7, m 562°, d ^{25} 5.85g/cm^3.** This one electron reductant can be prepared in large quantities (~40g) by direct reaction of the metal and iodine at 600° [Evans et al. *Inorg Chem* **42** 3097 *2003*, DOI: 10.1021/ic0300316]. The black solid NdI_2 can be kept at room temperature for months in the absence of solvent. Solutions can be stored under argon for several hours at -15° but should be used as soon as possible. The stability is considerably reduced if N_2 is used as inert atmosphere, instead of argon, even at -30°. In tetrahydrofuran under argon it promotes a ***pseudo-Barbier reaction***, i.e. rapid reductive coupling of primary and secondary (but not tertiary) halides with ketones, e.g. butylchloride and cyclohexanone provide almost quantitative yield of 1-butylhexan-1-ol [Evans et al. *Org Lett* **5** 2041 *2003i,* DOI: 10.1021/ol030033u]. Thus behaving somewhat like a Grignard reagent. This solution also has ***Birch reduction-type reactivity***, e.g. reduces naphthalene to 1,4-dihydronaphthalene.
NdI_2 $(THF)_x$ solution is prepared by transferring pre-cooled THF (45ml, at -15°) *via* a cannula into a septum-capped flask containing black NdI_2 (1.0g, 2.5mmol) and a magnetic stirrer bar at -15° whereby the colour of the solution becomes purple, and is stirred for 45 minutes. An aliquot should show the concentration to be 0.05M by complexiometric titration [method of Evans & Allen *J Am Chem Soc* **122** 2118 *2000*, DOI: 10.1021/ja992951m]. This solution is used for reactions that should be performed under argon.

Neodymium(III) iodide (anhydrous) *[13813-24-6]* **NdI_3, M 524.7. m 775°, b 1370°/atm, d ^{25} 5.85g/ml.** It is an almost black crystalline powder (green when ground) that is soluble in hot and cold H_2O. It can be prepared by the method of Bochkarev [Bochkarev & Fagin *Chem Eur J* **5** 2990 *1999*, DOI: 10.1002/(SICI)1521-3765(19991001)5:10<2990] where a small quantity of Nd metal is placed in a quartz crucible in a quartz reactor [see Evans et al. *Inorg Chem* **42** 3097 *2003*, DOI: 10.1021/ic0300316], heated to 600°, and I_2 is added, then small amounts of metal and I_2 are added alternately. Every addition of I_2 results in an orange glow in the mixture. When addition is complete (total ≥3 equivalents) the apparatus is cooled, and the crucible containing NdI_3 is transferred to an argon filled glovebox and the salt is ground (with a pestle and mortar) to a green powder. The metal content is analysed by titration (complexometric metal analysis is performed by dissolving the salt in H_2O at ~25°, evaporating, ashing the residue at 500°, dissolving in HCl and the analysis is carried out in hexamethylenetetramine buffer with xylenol orange as indicator and EDTA as titrant: Schwarzenbach & Flaschka 'Complexometric Titrations' Metheun, London p 194 *1969*; Evans et al. *J Am Chem Soc* **103** 6672 *1981*, DOI: 10.1021/ja00412a023). It should contain at least 27.5% Nd (theoretical is 29.5% Nd). [Evans & Workman *Organometallics* **24** 1989 *2005*, DOI: 10.1021/om050033t.]
Potassium graphite KC_8 with NdI_3 has also been used for reductive coupling and is prepared *in situ*. [Weitz & Rabinovitz *JCS Perkin Trans I* 117 *1993*, DOI: 10.1039/P19930000117]. KC_8 can be prepared in a Schlenk

line, or in a glove box, by adding K metal (0.541g, 13.8mmol) to a scintillating vial containing a Teflon stirbar then Graphite (1.242g, 12.9mmol), and the mixture is stirred and heated until a bronze-coloured powder results. The ***NdI_3/KC_8/THF*** is prepared by adding precooled (-15° *via* a cannula) THF into a septum-capped Schlenk flask (~25ml) containing NdI_3, KC_8 and a Teflon stirbar thus producing a purple solution which is stirred at -15° for 40 minutes and is ready for the reaction. The alkyl halide is injected, stirred for 1 minute, and is followed by the aldehyde or ketone. [Evans & Workman *Organometallics* **24** 1989 *2005*, DOI: 10.1021/om050033t.]

Neodynium nitrate hexahydrate *[16454-60-7 ($6H_2O$), 13746-96-8 (xH_2O)]* **$Nd(NO_3)_3$. $6H_2O$, M 438.4($6H_2O$), 330.3(anhydr), m 40°, 69-71°, 70-72°.** It crystallises (red-purple crystals) with 5 and 6 molecules of H_2O from concentrated solutions in dilute HNO_3 by slow evaporation; 1 part is soluble in 10 parts of H_2O. Used for colouring glass.

Neodymium oxide *[1313-97-9]* **Nd_2O_3, M 336.5, m 2320°, d^{20} 7.24g/cm^3.** Dissolve it in $HClO_4$, precipitate it as the oxalate with doubly recrystallised oxalic acid, wash it free of soluble impurities, dry it at room temperature and ignite it in a platinum crucible at higher than 850° in a stream of oxygen. It is a blue powder. [Tobias & Garrett *J Am Chem Soc* **80** 3532 *1958*, DOI: 10.1021/ja01547a011.]

Neon *[7440-01-9]* **Ne, M 20.2, m -248.6°, b -246.1°/atm, d 0.9002g/L (at STP: 0°/101.325), d 1.207g/L (at -246.1°).** Pass the gas through a copper coil packed with 60/80 mesh 13X molecular sieves, which is cooled in liquid N_2, or through a column of ***Ascarite*** (NaOH-coated silica/asbestos adsorbent).

Nickel bromide *[13462-88-9]* **$NiBr_2$, M 218.5, m 963°(loses H_2O at ~ 200°), d^{25} 5.098g/cm^3.** Crystallise it from dilute HBr (0.5ml/g) by partial evaporation in a desiccator. The ***anhydrous*** salt is yellow, but the ***trihydrate*** is green.

Nickel chloride hexahydrate *[7791-20-0 ($6H_2O$), 69098-15-3 (xH_2O), 7718-54-9 (anhydrous)]* **$NiCl_2$. $6H_2O$, M 237.7($6H_2O$), m 140°($6H_2O$), 1001°(anhydr), d^{25} 1.92g/cm^3($6H_2O$), d^{25} 3.55g/cm^3(anhydr).** It crystallises from dilute HCl to form the green ***hexahydrate***. At 70° this dehydrates to the ***tetrahydrate***, and at higher temperatures it forms the ***anhydrous*** salt. It sublimes in yellow hexagonal scales in a stream of HCl. Store it in a desiccator as it is ***deliquescent***. [Hart & Partington *J Chem Soc* 104 *1943*, DOI: 10.1039/JR9430000104.]

Nickel nitrate hexahydrate *[13478-00-7]* **$Ni(NO_3)_2$. $6H_2O$, M 290.8, m 56°, 57°, d^{25} 2.05g/cm^3($6H_2O$),** Crystallise it from water (3.3g/ml) by partial evaporation in a desiccator. Store it in a desiccator as it is ***deliquescent***.

Nickel(II) perchlorate hexahydrate *[13520-61-1]* **$Ni(ClO_4)_2$. $6H_2O$, M 365.7, m 140°, 200°, 209° (sealed tube), d^0 1.570, d^{20} 1.583, d^{40} 1.597, d^{50} 1.646, d^{60} 1.597.** The greenish blue hexagonal prisms of this salt are obtained by double decomposition between $NiSO_4$ and $Ca(ClO_4)_2$ in aqueous solution, filtering off the insoluble $BaSO_4$, and concentrating the filtrate. It recrystallises from H_2O, and drying the crystals in a vacuum desiccator over H_2SO_4 or $CaCl_2$ provides the ***hexahydrate***. *Alternatively*, it is prepared from freshly precipitated NiO or $NiCO_3$ and aqueous $HClO_4$, filtering off the excess of $NiCO_3$ and concentrating the filtrate to crystallisation. The solubility of $Ni(ClO_4)_2.6H_2O$ in H_2O (g/100ml) is 217 (0°), 236 (10°), 245 (20°), 267 (30°), 280 (35°), 273 (40°), 311 (50°), 295 (55°), 280 (60°). The salt form hydrates with 2, 4, 5, 6, 7, and 9 molecules of H_2O. The ***hexahydrate*** is normally obtained by crystallisation from H_2O and is the more stable hydrate. It forms the ***tetrahydrate*** at 110°/760mm/36 hours or 70°/1mm/66 hours, which yields the ***dihydrate*** at 130°/760mm/42 hours or 100°/1mm/72 hours. It should be kept in a desiccator over $CaCl_2$ as it is quite ***hygroscopic***. The UV in EtOH has λ_{max} (logε) at 395 (~0.68), 660 (~0.22), 720 (~0.25) nm. Evaporation of a solution in ether with dry air gives ***$Ni(ClO_4)_2.Et_2O$*** as a yellow powder, and with dioxane it forms ***$Ni(ClO_4)_2.2C_4H_8O_2$***. A solution in Me_2CO at ~2 x 10^{-4}M is green with a characteristic absorption at 410nm [Katzin *Nature* **182** 1013 *1958*, DOI: 10.1038/1821013a0]; it complexes also with acetylacetone [Izatt et al. *J Phys Chem* **59** 235 *1955*, DOI: 10.1021/j150525a010], ethylene, trimethylenediamine [Cotton & Harris *J Phys Chem* **59** 1203 *1955*, DOI: 10.1021/j150534a006], DMF [Pflaum, & Popov *Anal Chim Acta* **13** 165 *1955*, DOI: 10.1016/S0003-2670(00)87919-2], and with pyridine it forms blue crystals of ***$[Ni(C_5H_5N)_6](ClO_4)_2.4H_2O$*** [Weinland et al. *Arch*

Pharm **265** 352 *1927*, DOI: 10.1002/ardp.19272651026], ***$Ni(ClO_4)_2.4(C_5H_5N)$*** and ***$Ni(ClO_4)_2.6(C_5H_5N)$*** [Sinha *J Indian Chem Soc* **35** 865 *1958*, Sinha & Ray *J Indian Chem Soc* **20** 32 *1943*]. [Salvadori *Gazzetta* **42** I 458 *1912*, Veeraiah & Qureshi *J Indian Chem Soc* **21** 127 *1944*, Bernath et al. *J Prakt Chem* **143** 298 *1935*, DOI: 10.1002/prac.19351431004; Freund & Schneider *J Am Chem Soc* **81** 4780 *1959*, DOI: 10.1021/ja01527a006; Gmelin's *Handbuch der Anorganischen Chemie, Nickel Teil B-Lieferung 2I,* Verlag Chemie GMBH Weinheim, System 57, pp 596-601 *1966*.]

Nickel sulfate hexahydrate *[10101-97-0]* **$NiSO_4.6H_2O$, M 262.9, m loses $5H_2O$ at 100°, becomes anhydrous at ~280°, d^{25} 2.07.** It crystallises from H_2O in bluish-green tetragonal crystals of the α-form which undergo a transition at 53.3° to the β-form that has green transparent monoclinic crystals. The crystals are stable at ~40°, become blue in colour and then opaque in air due to slow efflorescence. Its solubility in H_2O is 0.6/ml at 0° and 3.4g/ml at 100°. It is sparingly soluble in EtOH, slightly more soluble in MeOH, soluble in aqueous NaOH, and very soluble in aqueous ammonia to give the bluish-green ***monoclinic $(NH_4)_2Ni(SO_4)_2\ 6H_2O$ double salt***. The pH of an aqueous solution is about 4.5, i.e. weakly acidic. (See also the heptahydate below).

Nickel sulfate heptahydrate *[10101-98-1, 7786-81-4 (anhydrous)]* **$NiSO_4.7H_2O$, M 280.9, 154.8(anhydr), m loses $5H_2O$ at 100°, anhydrous m at ~280°, d^{25} 1.948 g/cm^3.** The sulfate crystallises from warm water (4g/ml) or dilute H_2SO_4 as bright green monoclinic crystals on cooling. It is isomorphous with Epsom salt (see $MgSO_4\ 7H_2O$ above). Prolonged exposure to air gives the blue ***tetrahydrate***. On heating above 118°, it is converted to the ***dihydrate***, which at >280° is converted to the ***yellow anhydrous $NiSO_4$*** which does not react with HCl.

Nickel(II) sulfide M 90.8 (NiS, *Mellirite*, bronze-yellow, d^{25} 5.3-5.6), 240.2 (Ni_3S_2 *[12035-72-2]* ***Heazelwoodite***, **d^{25} 5.8 g/cm^3) and (Ni_3S_2/NiS black powder** *[16812-54-7]* **d^{25} 5.3-5.6 g/cm^3), m 790°, 797°.** The sulfide is generally obtained as a highly insoluble black precipitate by adding NH_4OH and NH_4SH to a nickel salt. It dissolves slowly in excess of $(NH_4)_2S_x$ and re-precipitates on boiling, exposure to air or addition of acid. A black dense sulfide is also obtained by boiling a nickel salt with $Na_2S_2O_3$. It is insoluble in dilute HCl, slowly soluble in concentrated HCl, readily in HNO_3 and ***aqua regia***. The sulfides should be washed well with H_2O, dried, and analysed for Ni. Various forms have been prepared [Dunn & Rideal *J Chem Soc* **123** 1242 *1923*, DOI: 10.1039/CT9232301242.]

Niobium (Colombium) (V) chloride *[10026-12-7]* **$NbCl_5$, M 270.2, m 204.7-209.5°, b ~250°/atm(begins to sublime at 125°), d^{25} 2.75g/cm^3.** It forms yellow, very deliquescent crystals which decompose in moist air to liberate HCl. Keep it in a dry box flushed with N_2 in the presence of P_2O_5. Wash it with CCl_4 and dry it over P_2O_5. The yellow crystals can contain a few small, dirty white pellets among the yellow needles. These should be easily picked out. Upon grinding in a dry box, however, they turn yellow. $NbCl_5$ has been sublimed and fractionated in an electric furnace. It forms complexes with Lewis bases. [Epperson et al. *Inorg Synth* **7** 163 *1963*, DOI: 10.1002/9780470132388.ch45; Alexander & Fairbrother *J Chem Soc* suppl 233 *1949*, DOI: 10.1039/JR949000S223.]

Nitric acid (*Aqua fortis*) *[7697-37-2]* **HNO_3, M 63.0, m -42°, b 83°, d^{25} 1.5027, [Constant boiling acid has composition w/w of 68% HNO_3 + 32% H_2O, b 120.5°, d_4^{20} 1.41], pK^{25} -1.27 (1.19).** The acid is obtained colourless (approx. 92%) by direct distillation of fuming HNO_3 under reduced pressure at 40-50° with an air leak at the head of the fractionating column. ***Concentrated nitric acid*** is an aqueous solution containing 70-71% of HNO_3 (**d_4^{20} 1.4134**). Store it in a desiccator that is kept in a refrigerator away from light which causes the formation of NO_2. Nitrite-free HNO_3 can be obtained by vacuum distillation from urea. [Ward et al. *Inorg Synth* **3** 11 *1950*, DOI: 10.1002/9780470132340.ch4; Kaplan et al. *Inorg Synth* **4** 52 *1953*, DOI: 10.1002/9780470132340.ch4.] If ***'fuming nitric acid'*** (90%) is yellow in colour (due to the presence of oxides of nitrogen), then treat 100mls with urea (0.5g) and bubble dry air through it until it is colourless (~20 minutes) [Freeman & Shepard *Org Synth* **43** 83 *1963*, DOI: 10.15227/orgsyn.043.0083]. Acid that is free from oxides does not discolour drops of 1N $KMnO_4$. ***Anhydrous*** **HNO_3 (100%, d_4^{20} 1.5129)** is obtained on distilling a mixture of equal volumes of ***'fuming nitric acid'*** and concentrated H_2SO_4 [Liang *Org Synth* Coll Vol **3** 803 *1955*, DOI: 10.15227/orgsyn.021.0105]. It is an oxidising agent, its vapours irritate and cauterise tissues, and cause the skin to turn yellow in colour. The ***'fuming acid'*** is particularly dangerous, should be handled in an efficient fume cupboard, and is used more as an oxidant than for acidification — use EYE PROTECTION.

Nitric oxide *[10102-43-9]* **NO, M 30.0, m -163.6°, b -151.8°/atm, d^{25} 1.3402g/ml, n_D^{25} 1.0002697.** Bubble the gas through 10M NaOH which removes NO_2. It can also be freed from NO_2 by passage through a column of ***Ascarite*** followed by a column of silica gel held at -197°K. The gas is dried with solid NaOH pellets or by passing through silica gel cooled at -78°, followed by fractional distillation from a liquid N_2 trap. This purification does not eliminate nitrous oxide. Other gas scrubbers sometimes used include one containing concentrated H_2SO_4 and another containing mercury. It is freed from traces of NO_2 by the freeze and thaw method. The solubility of the gas in H_2O is 0.0098g/100ml (0°) and 0.0056g/ml (20°). [Blanchard et al. *Inorg Synth* **2** 126 *1946*, DOI: 10.1002/9780470132333.ch37; Schenk in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** pp 485-487 *1963*.] **TOXIC.**

Nitrogen *[7727-37-9]* **N_2, M 28.0, m -210.00°/, b -195.8°/atm, -195.795°/atm, d 1.3402g/L(STP: 0°/101.325kPa), d 0.808g/L(at b -195.8°).** Cylinder N_2 can be freed from oxygen by passage through ***Fieser's solution*** [which comprises 2g sodium anthraquinone-2-sulfonate and 15g sodium hydrosulfite dissolved in 100ml of 20% KOH; see Fieser, *J Am Chem Soc* **46** 2639 *1924*, DOI: 10.1021/ja01677a005] followed by scrubbing with saturated lead acetate solution (to remove any H_2S generated by the Fieser solution), concentrated H_2SO_4 (to remove moisture), then soda-lime (to remove any H_2SO_4 and CO_2). *Alternatively*, after passage through ***Fieser's solution***, N_2 can be dried by washing with a solution of the metal ketyl from benzophenone and Na wire in absolute diethyl ether. [If ether vapour in N_2 is undesirable, the ketyl from liquid Na-K alloy under xylene can be used.]
Another method for removing O_2 is to pass the nitrogen through a long, tightly packed column of Cu turnings, the surface of which is constantly renewed by scrubbing it with aqueous ammonia (sg 0.880) solution. The gas is then passed through a column packed with glass beads moistened with concentrated H_2SO_4 (to remove ammonia), through a column of packed KOH pellets (to remove H_2SO_4 and to dry the N_2), and finally through a glass trap packed with chemically clean glass wool immersed in liquid N_2. Nitrogen has also been purified by passage over Cu wool at 723°K and Cu(II) oxide [prepared by heating $Cu(NO_3)_2.6H_2O$ at 903°K for 24 hours] and then into a cold trap at 77°K.
A typical dry purification method consists of a mercury bubbler (as trap), followed by a small column of silver and gold turnings to remove any mercury vapour, towers containing anhydrous $CaSO_4$, dry molecular sieves or $Mg(ClO_4)_2$, a tube filled with fine Cu turnings and heated to 400° by an electric furnace, a tower containing soda-lime, and finally a plug of glass wool as filter. Variations include tubes of silica gel, traps containing activated charcoal cooled in a Dry-ice bath, copper on Kieselguhr heated to 250°, and Cu and Fe filings at 400°. [Schenk in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** pp 458-460 *1963*.]

Nitrosyl chloride *[2696-92-6]* **NOCl, M 65.5, m -59.4°, b -5.55°/atm, d^{25} 2.872mg/L.** It is an orange gas with a suffocating odour. It has been fractionally distilled at atmospheric pressure in an all-glass, low-temperature still, taking the fraction boiling at -4° and storing it in sealed tubes. *Alternatively*, the gas is dried by $CaCl_2$ and passed through H_2SO_4 when Cl_2 passes on, but NOCl is absorbed to form ***nitrososulfuric acid (NO.HSO$_4$)*** which on warming with NaCl evolves pure NOCl [Tilden *J Chem Soc* **27** 630 *1874*, DOI: 10.1039/JS8742700630.] It is decomposed by H_2O and alkali, and forms compounds with metal chlorides e.g. $FeCl_3$.NOCl. [Coleman et al. *Inorg Synth* **1** 55 *1939*, DOI: 10.1002/9780470132326.ch20; Morton, Wilcox et al. *Inorg Synth* **4** 48 *1953*, DOI: 10.1002/9780470132357.ch16; Beckham et al. 'Nitrosyl Chloride' *Chem Rev* **48** 319 *1951*, DOI: 10.1021/ cr60151a001]

Nitrous oxide (laughing gas) *[10024-97-2]* **N_2O, M 44.0, m -90.86°, b -88.5°/atm, d^{25} 1.977g/L(gas), n 1.000516(STP: 0°/101.325kPa).** Wash the gas with concentrated alkaline pyrogallol solution, to remove O_2, CO_2, and NO_2, then dry it by passing it through columns of P_2O_5 or Drierite, and collecting in a dry trap cooled in liquid N_2. It is further purified by freeze-pump-thaw and distillation cycles under vacuum [Ryan & Freeman *J Phys Chem* **81** 1455 *1977*, DOI: 10.1021/j100530a005; Schenk in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** pp 484-485 *1963*].

Osmium(VIII) tetroxide (osmic acid) *[20816-12-0]* **OsO_4. $2H_2O$, H_4OsO_6, M 524.2, m 40.6°, b**

59.4°/60mm, 71.5°/100mm, 109.3°/400mm, 130°/760mm, d $^{20}_{D}$ 5.10, pK$_1^{25}$ 7.2, pK$_2^{25}$ 12.2, pK$_3^{25}$ 13.95, pK$_4^{25}$ 14.17. It is **VERY TOXIC** and should be manipulated in a very efficient fume cupboard. *It attacks the eyes severely* **(use also eye and face protection)** and is a good oxidising agent. It is volatile and has a high vapour pressure (11mm) at room temperature. It sublimes and volatilises well below its boiling point. It is soluble in *C_6H_6, H_2O (7.24% at 25°), CCl_4 (375% at 25°), EtOH and Et_2O. It is estimated by dissolving a sample in a glass-stoppered flask containing 25ml of a solution of KI (previously saturated with CO_2) and acidified with 0.35M HCl. After gentle shaking in the dark for 30 minutes, the solution is diluted to 200ml with distilled H_2O saturated with CO_2 and titrated with standard thiosulfate using starch as indicator. This method is not as good as the gravimetric method. Hydrazine hydrochloride (0.1 to 0.3g) is dissolved in 3M HCl (10ml) in a glass-stoppered bottle. After warming to 55-65°, a weighed sample of OsO_4 solution is introduced, and the mixture is digested on a water bath for 1 hour. The mixture is transferred to a weighed glazed crucible and evaporated to dryness on a hot plate. A stream of H_2 is started through the crucible, and the crucible is heated over a burner for 20-30 minutes. The stream of H_2 is continued until the crucible is cooled to room temperature, and then the H_2 is displaced by CO_2 in order to avoid rapid combustion of H_2. Finally the crucible is weighed. [Grube in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **II** pp 1603 *1965*, Anderson & Yost *J Am Chem Soc* **60** 1822 *1938*, DOI: 10.1021/ja01275a031; Fieser **1** 759, **10** 290, **12** 258, **13** 222, **14** 235, **15** 240, **16** 249.] § Available commercially on a variety of polymer support.

Oxygen *[7782-44-7]* **O_2, M 32.00, m -218.79°, b -182.96°/atm, d^{-183} 1.149g/L(liquid), d 1.429(STP: 0°/101.325kPa).** Purify it by passing the gas over finely divided platinum at 673°K and Cu(II) oxide (see under nitrogen) at 973°, then condensed in a liquid N_2-cooled trap. **HIGHLY EXPLOSIVE with organic matter.**

Palladium (II) chloride *[7647-10-1]* **$PdCl_2$, M 177.3, m 678-680°, d^{25} 4.0g/cm^3.** The ***anhydrous salt*** is insoluble in H_2O and dissolves in HCl with difficulty. The ***dihydrate*** forms red ***hygroscopic*** crystals that are readily reduced to Pd. Dissolve it in concentrated HCl through which dry Cl_2 is bubbled. Filter this solution which contains H_2PdCl_4 and H_2PdCl_6 and on evaporation it yields a residue of pure $PdCl_2$. [Grube in *Handbook of Preparative Inorganic Chemistry (Ed Brauer)* Academic Press Vol **II** p 1582 *1965*, Mozingo *Org Synth* Coll Vol **3** 685 1955, DOI: 10.15227/orgsyn.026.0077.] *Alternatively*, (fume cupboard), Pd metal is dissolved in ***aqua regia***, and converted to the chloride by repeated evaporation with concentrated HCl. The dark red palladous chloride is dried at 150-180° in a stream of dry chlorine gas to give the ***anhydrous*** salt. [Kharasch et al. *J Am Chem Soc* **60** 882 *1938*, DOI: 10.1021/ja01271a035; for use as catalyst see Fieser **1** 782, **2** 303, **4** 369, **5** 500, **6** 447, **7** 277, **8** 384, **9** 352, **10** 300, **11** 393, **12** 371, **13** 234, **15** 248, **16** 268.]

Palladium (II) cyanide *[2035-66-7]* **$Pd(CN)_2$, M 158.5.** The yellow solid should be washed well with H_2O and dry in air. Its solubility in H_2O is low with a logK_{sp} of -42. [Bigelow et al. *Inorg Synth* **2** 245 *1946*, DOI: 10.1002/9780470132333.ch78; Hibble et al. 'Structures of $Pd(CN)_2$ and $Pt(CN)_2$: Intrinsically Nanocrystaline Materials'. *Inorg. Chem.* **50** 104 *2011*, DOI: 10.1021/ic101358q]. It is an effective catalyst for the stereospecific ring opening of oxiranes in almost quatitative yields [Imi et al. *J Org Chem* **52** 1013 *1987*, DOI: 10.1021/jo00382a008]. **POISONOUS.**

Perchloric acid *[7601-90-3]* **$HClO_4$, M 100.5, d^{25} 1.665g/cm^3, pK^{25} -2.4 to -3.1 ($HClO_4$).** The 72% acid has been purified by double distillation from silver oxide under vacuum: this frees the acid from metal contamination. Distillation at atmospheric pressure is ***dangerous*** and ***explosive***. The ***anhydrous*** acid is obtained by adding gradually 400-500ml of oleum (20% fuming H_2SO_4) to 100-120ml of 72% $HClO_4$ in a reaction flask cooled in an ice-bath. The pressure is reduced to 1mm (or less), with the reaction mixture at 20-25°. The temperature is gradually raised during 2 hours to 85°; the distillate is collected in a receiver cooled in Dry-ice. For further details of the distillation apparatus see Smith [*J Am Chem Soc* **75** 184 *1953*, DOI: 10.1021/ja01097a048]. **It is HIGHLY EXPLOSIVE; a strong protective screen should be used at all times.** [Schmeisser in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** pp 318-320 *1963*, Fieser **1** 796, **2** 309, **3** 220, **5** 506, **6** 453, **7** 279, **11** 402.]

Perrhenic acid [hydrated rhenium(VII) oxide] *[13768-11-1]* **$HReO_4$(gas), $H_4Re_2O_9$(solid), M 251.2, m sublimes, d^{25} 2.16g/cm^3, pK^{25} -1.25.** The acid, which has the formula ***$[Re_2O_7(OH_2)_2]$***, is commercially

available as a 65-70% w/w solution in H_2O, from which it can be obtained by evaporation. It can be prepared freshly from a solution of pure finely powdered ***potassium perrhenate*** {*[10466-65-6]* $KReO_4$ M 289.3, **m 550° d ^{25} 4.887g/cm^3**} (10.0g, 35.6mmol) in hot H_2O (120ml) at 100° which is placed on the top of a Dowex 50W-X1 cation exchange resin column (40 x 20mm, 50g of 50-100 mesh with a 1cm layer of Pyrex wool). This resin is first washed with 6 M HCl (20ml) and flushed with pure hot H_2O at 100° until the effluent is colourless and does not become turbid on addition of $AgNO_3$ solution (i.e. chloride free). The hot solution of $KReO_4$ is applied to the resin in four 30ml portions (to keep the temperature high, boiling if necessary for the salt to remain in solution), and the hot column is rinsed with pure hot H_2O. The rate of flow should be kept at 15-20ml/minute, the first effluent (*ca* 50ml) is discarded and the acidic fraction (to litmus, *ca* 150ml) is collected. This solution is concentrated to as small a volume as possible, preferably *in vacuo* over P_2O_5, and an aliquot is diluted and titrated against standard alkali to determine the concentration of HRe_2O_4 in the residue. It is a strong acid (cf. pKa). It is then diluted with pure H_2O as required. The theoretical amount of acid in the residue should be 8.68g. [Watt et al. *Inorg Synth* **7** 189 *1963*, DOI: 10.1002/9780470132388.ch51.] It is also prepared by dissolving the ***anhydride*** rhenium heptoxide {**rhenium(VII) oxide** *[1314-68-7]* Re_2O_7 M484.4, **m 220°**, **b 360°/atm**, **d** ^{25} 6.103g/cm^3} in H_2O. [Smith & Long *J Am Chem Soc* **70** 354 *1948*, DOI: 10.1021/ja01181a110; Melaven et al. *Inorg Synth* **3** 188 *1950*, DOI: 10.1002/9780470132340.ch50.] When aqueous solutions of Re_2O_7 [i.e. Re_2O_7 $(OH_2)_2$ = $H_4Re_2O_9$] are kept for several months it breaks up, and crystals of ***$HReO_4.H_2O$*** separate which contain tetrahedral ReO_4^-. Generally perrhenic acid and rhenium(VII) oxide have been used interchangeably, from which organorhenium oxides are prepared that catalyse olefin oxidation, metathesis and other transformations [Herrmann et al. *Inorg Chem* **34** 4701 *1955*, DOI: 10.1021/ic00123a001].

Phosgene *[75-44-5]* **$COCl_2$, M 98.9, m -118°, b 8.2°/756mm.** Dry the gas with Linde 4A molecular sieves, de-gas it and distil it under vacuum at low temperature. This should be done in a closed system such as a vacuum line. It is hydrolysed slowly by H_2O, but does not fume in moist air. It is available in cylinders and as a ~20% solution in toluene (d^{20} 0.94g/ml); as well as in cartridges (of ***triphosgene*** *[32315-10-9]*) for generating phosgene and respective starter kits. **It is HIGHLY TOXIC and should not be inhaled. If it is inhaled, the operator should lie very still, and be made to breathe in ammonia vapour that reacts with phosgene to form urea.** [Atkinson et al. *J Chem Soc* **117** 1410 *1920*, DOI: 10.1039/CT9201701410; *Beilstein* **3** IV 41.]

Phosphine *[7803-51-2]* **PH_3, M 34.0, m -133°, b -87.7°, critical temp 51.3°, pK^{25} -14, pK_b 28**. PH_3 is best purified in a gas line (in a vacuum) in an efficient fume cupboard. It is spontaneously flammable, has a strong odour of decayed fish and is **POISONOUS**. The gas is distilled through solid KOH towers (two), through a Dry ice-acetone trap (-78°, to remove H_2O, and P_2H_4 which spontaneously ignites with O_2 to form oxides of phosphorus), then through two liquid N_2 traps (-196°), followed by distillation into a -126° trap (Dry-ice/methylcyclohexane slush), allowed to warm in the gas line and then sealed in ampoules preferably under N_2. Its IR as ν_{max} at 327 (m), 1121 (m) and 900 (m) cm^{-1}. [Klement in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** pp 525-530 *1963*, Gokhale et al. *Inorg Synth* **9** 56 *1967*, DOI: 10.1002/9780470132401.ch17.] PH_3 has also been absorbed into a solution of cuprous chloride in hydrochloric acid (when $CuCl.PH_3$ is formed). PH_3 gas is released when this solution is heated, and the gas is purified by passage through KOH pellets and then over P_2O_5. It ignites spontaneously in air with a luminous flame. Its solubility is 0.26ml/1 ml of H_2O at 20°, forming a crystalline ***hydrate*** on releasing the pressure on the aqueous solution. [For further detail see 'Miscellaneous As, B, P, Si, S, Se and Te Compounds' in Chapter 3.]

Phosphonitrilic chloride (cyclic tetramer) (octachloro-cyclotetraphosphazene) *[1832-07-1]* **$(NPCl_2)_4$, $N_4P_4Cl_8$, M 463.9.** Purify it by zone melting, then recrystallise it from petroleum ether (b 40-60°) or *n*-hexane. [Shaw et al. *Chem Rev* **62** 247 *1962*, DOI: 10.1021/cr60217a004; Crystal structure, ^{31}P, ^{1}HNMR and reactivity of Cl: van der Huizen et al. *JCS Dalton Trans* 1317 *1986*, DOI: 10.1039/DT9860001317.]

Phosphonitrilic chloride (cyclic trimer) (hexachloro-cyclotriphosphazene) *[940-71-6]* **$(NPCl_2)_3$, $N_3P_3Cl_6$, M 347.6, m 112.8°, 113-114°, 113-115°, 128.8°, b 127°/12mm, d ^{25} 1.98g/cm^3.** Purify it by zone melting, by crystallisation from petroleum ether, *n*-hexane or *benzene, and by sublimation. [Nielsen et al. *Inorg Synth* **6** 94 *1960*, DOI: 10.1002/9780470132371.ch28; Shaw et al. *Chem Rev* **62** 247 *1962*, DOI: 10.1021/cr60217a004; Paddock *Quart Rev* **18** 168 *1964*, DOI: 10.1039/QR9641800168; crystal structure, ^{31}P, ^{1}HNMR and reactivity

of Cl see van der Huizen et al. *JCS Dalton Trans* 1317 *1986*, DOI: 10.1039/DT9860001317; Meirovitch et al. *J Phys Chem* **88** 1522 *1984*, DOI: 10.1021/j150652a016; Alcock et al. *J Am Chem Soc* **106** 5561 *1984*, DOI: 10.1021/ja00331a028; ^{31}P, ^{1}HNMR and reactivity of Cl: Winter & van de Grampel *JCS Dalton Trans* 1269 *1986*, DOI: 10.1039/DT9860001269; Fieser **2** 206, **4** 386, **5** 322, **6** 469.] Useful for the synthesis of 'dandelion' (spherical) dendrimers [Labarre et al. *Synlett* 799 *1996*, DOI: 10.1055/s-1996-5584].

Phosphonous acid (phosphonic acid) *[13598-36-2]* **H-P=O(OH)$_2$, M 82.0, m 73.6°, d ^{25} 1.651, pK$_1$ 1.43, pK$_2$ 6.67.** Phosphonous acid is best prepared by adding PCl_3 to concentrated HCl, when HCl gas is liberated and the solution is evaporated (fume-cupboard) until the temperature reaches 180° (all HCl gas is driven off). On cooling the acid separates as white hygroscopic (and deliquescent) crystals. It has a garlic taste, melts at 73.6°, and decomposes at 200° to give phosphine and phosphoric acid (***note*** that PH_3 ignites in air with bright flashes, see above). It is a dibasic acid that slowly oxidises to phosphoric acid in air. Store it under dry N_2, or as a 20% aqueous solution under N_2. [Simon et al. *Z Anorg Allgem Chem* **230** 289 *1937*, DOI: 10.1002/zaac.19372300312; Voight et al. *Inorg Synth* **4** 55 *1953*, DOI: 10.1002/9780470132357.ch18.]
Tautomerism of phosphonous acid. This acid is tautomeric with trihydroxyphosphine with the latter tautomer being in extremely small concentrations, e.g. 1 in 10^{12}. The diester [e.g. $(MeO)_2P(H)=O$] has the H linked to the P atom. The tautomerism is not like that of keto-enol tautomerism in carbon chemistry, and dialkylphosphites $(RO)_2P(H)=O$ do *not* react with sulfur to form the corresponding P-SH derivatives, but they do form solid salts such as $(RO)_2PONa$ which *do* add sulfur readily. Also this acid does form triesters such as $(MeO)_3P$ which is trimethylphosphite or trimethoxyphosphine, and behave more like phosphines. [cf. F.A. Cotton, G, Wilkinson, C.A. Murillo and M. Bochmann, *Advanced Inorganic Chemistry*, 6th Edn, Interscience Publ, *1999*, ISBN 0-471-19957-5.]

Phosphoric acid (orthophosphoric acid) *[7664-38-2]* **H_3PO_4, M 98.0, m 41 to 44°, 42.3°, b 158°/atm, d ^{25} 1.685—1.830g/cm^3, pK$_1^{25}$ 2.15, pK$_2^{25}$ 7.21, pK$_3^{25}$ 12.37.** Pyrophosphate can be removed from phosphoric acid by diluting with distilled H_2O and refluxing overnight. By cooling to 11° and seeding with crystals obtained by cooling a few millilitres in a Dry-ice/acetone bath, 85% orthophosphoric acid crystallises as $H_3PO_4.H_2O$. The crystals are collected on a sintered glass filter. Concentrated acid is ~85% H_3PO_4. xH_2O. [Weber et al. *Inorg Synth* **I** 101 *1939*, DOI: 10.1002/9780470132326.ch35.]
When orthophosphoric acid (85%) is heated and liquefies (*ca* 350° and above) it is converted into ***meta-phosphoric acid*** *[37267-86-0]* **$(HPO_3)_n$** which cools to a ***hygroscopic*** transparent, glassy solid, or a soft silky mass. It is slowly soluble in H_2O (faster on boiling) to regenerate orthophosphoric acid. It is polymeric, consisting of cyclic trimer, tetramer or linear polymers (with 3 to 7 or more P atoms) depending on the heat treatment. It is soluble in EtOH, can be made into rods and is stabilised with $NaPO_3$ or sodium phosphate. It has been used as a phosphorylating agent as in the preparation of coenzyme phosphates and polyphospates. [Viscontini et al. *Helv Chim Acta* **32** 1482 *1949*, DOI: 10.1002/hlca.19490320515; Viscontini et al. *Helv Chim Acta* **34** 1834, 2198 *1951*, codecarboxylase DOI: 10.1002/hlca.19510340617, pyridoxal-5'-phosphate DOI: 10.1002/hlca.19510340712.] The sodium phosphate stabilised solid has been used in dentistry for making zinc oxyphosphate cement.

Phosphorus (red) *[7723-14-0]* **P, M 31.0, m 590°/43atm, ignites at 200°, d ^{25} 2.34g/ml.** Heat it for 15 minutes in boiling distilled H_2O, allow it to settle and wash it several times with boiling H_2O. Transfer it to a Büchner funnel, wash it with hot H_2O until the washings are neutral, then dry it at 100° and store it in a desiccator.

Phosphorus (white) *[7723-14-0]* **P, M 31.0, m 44.1°, b 287°, d ^{25} 1.82.** Purify white phosphorus by melting it under dilute H_2SO_4—dichromate (possible **carcinogen**) mixture and allow to stand for several days in the dark at room temperature. It remains liquid, and the initial milky appearance due to insoluble, oxidisable material gradually disappears. The phosphorus can then be distilled under vacuum in the dark [Holmes *Trans Faraday Soc* **58** 1916 *1962*, DOI: 10.1039/TF9625801916]. It sublimes *in vacuo*. Other methods of purification include extraction with dry CS_2 followed by evaporation of the solvent, or washing with 6M HNO_3, then H_2O, and drying under vacuum. It ignites in air at ~50°, or by friction if dry. Store and cut it under H_2O. **POISONOUS, use gloves.**

Phosphorus oxychloride (phosphoryl chloride) *[10025-87-3]* **$POCl_3$, M 153.3, m 1.25°, b 105.8°/atm, d $_4^{20}$ 1.675, n $_D^{20}$ 1.461.** Distil the liquid under reduced pressure to separate it from the bulk of the HCl and the phosphoric acid (from hydrolysis); the middle fraction is re-distilled into ampoules containing a little purified mercury. These ampoules are sealed and stored in the dark for 4-6weeks with occasional shaking to facilitate reaction of any free chloride with the mercury. The $POCl_3$ is then again fractionally distilled and stored in sealed ampoules in the dark until required [Herber *J Am Chem Soc* **82** 792 *1960*, DOI: 10.1021/ja01489a007]. Lewis and Sowerby [*J Chem Soc* 336 *1957*, DOI: 10.1039/JR9570000336] refluxed their distilled $POCl_3$ with Na wire for 4 hours, then removed the Na and again distilled. ***Use Na only with almost pure $POCl_3$ to avoid explosions.*** [Fieser **1** 876, **2** 330, **3** 228, **4** 390, **5** 535, **7** 292, **9** 374, **11** 429, **13** 249, **15** 267, **17** 288.] **HARMFUL VAPOURS; work in an efficient fume cupboard.**

Phosphorus pentabromide *[7789-69-7]* **PBr_5, M 430.6, m <100°, b 106°/atm(dec).** Dissolve it in pure nitrobenzene at 60°, filtering off any insoluble residue on to sintered glass funnel, then allow it to crystallise by cooling. Wash the collected solid with dry Et_2O and remove excess ether in a current of dry N_2. (All manipulations should be performed in a dry-box.) [Harris & Payne *J Chem Soc* 3715 3732 *1958*, DOI: 10.1039/JR9580003715,]. It ***fumes*** in moist air because of hydrolysis. **HARMFUL VAPOURS** (wash burning eyes with aqueous $NaHCO_3$)**.**

Phosphorus pentachloride *[10026-13-8]* **PCl_5, M 208.2, m 179-180°(sublimes).** [All operations should be carried out in an efficient fume cupboard.] Sublime it at 160-170° in an atmosphere of chlorine. Excess chlorine is then displaced by dry N_2 gas. All subsequent manipulations should be performed in a dry-box [Downs & Johnson *J Am Chem Soc* **77** 2098 *1955*, DOI: 10.1021/ja01613a019]. It fumes in moist air and attacks the eyes and the mucous membranes of the nose. It should not be breathed in and has very **HARMFUL VAPOURS** (wash burning eyes with aqueous $NaHCO_3$). A commercial polymer-bound version is available. [Fieser **1** 866, **4** 388, **5** 534, **7** 290.]

Phosphorus pentasulfide *[1314-80-3]* **P_2S_5, M 444.5, m 277-283°, 290°, b 513-515/atm, d ^{25} 2.09g/cm^3.** Purify P_2S_5 by extraction and crystallisation with CS_2, using a Soxhlet extractor, and is heated in a CO_2 atmosphere at 150° to remove solvent. It liberates H_2S in moist air. **HARMFUL VAPOURS.** [Klements in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 568 *1963*, Fieser **1** 870, **3** 226, **4** 389, **5** 534, **6** 470, **7** 290, **8** 401, **9** 374, **10** 320, **11** 428.]

Phosphorus pentoxide *[1314-56-3]* **P_2O_5, M 141.9, m 340°, 562°, b 605°/atm, d ^{25} 2.3g/ml.** It has been sublimed at 250° under vacuum into glass ampoules. It fumes in moist air and reacts violently with water. It is an excellent drying agent for use in desiccators. **HARMFUL VAPOURS and attacks skin, use gloves.** [Manley *J Chem Soc* **121** 331 *1922*, DOI: 10.1039/CT9222100331; Klements in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 541 *1963*, Fieser **1** 871, **7** 291, **10** 319.]

Phosphorus sesquisulfide *[1314-85-8]* **P_4S_3, M M 220.1, m 172°, b 408°/atm, d ^{25} 2.08g/ml.** Extract $P_4S_3$with CS_2, filter it and evaporate it to dryness. *Alternatively*, place it in H_2O, and pass steam through it for an hour. The H_2O is then removed, the solid is dried, and recrystallised from CS_2 (with the usual CS_2 precautions) [Rogers & Gross *J Am Chem Soc* **74** 5294 *1952*, DOI: 10.1021/ja01141a018].

Phosphorus sulfochloride (phosphorus thiochloride) *[3982-91-0]* **$PSCl_3$, M 169.4, m -35°, b 122-124°/atm, 125°(corr)/atm, d $_4^{30}$ 1.64, n $_D^{30}$ 1.556.** Possible impurities are PCl_5, H_3PO_4, HCl and $AlCl_3$. Gently mix it with H_2O to avoid a heavy emulsion; the product decolourises immediately and settles to the bottom layer. It is soluble in $*C_6H_6$ and CCl_4. [Moeller et al. *Inorg Synth* **4** 71 *1953*, DOI: 10.1002/9780470132357.ch24.] **HARMFUL VAPOURS.**

Phosphorus tribromide *[7789-60-8]* **PBr_3, M 270.7, m -41.5°, b 168-170°/725mm, 171-173°/atm, 172.9°(corr) /760mm, d$_4^{30}$ 2.852.** It is decomposed by moisture, it should be kept dry and is ***corrosive***. Purify it by distillation through an efficient fractionating column [see Whitmore & Lux *J Am Chem Soc* **54** 3451 *1932*, DOI: 10.1021/ja01347a071] in a slow stream of dry N_2, i.e. under strictly dry conditions. [Gay et al. *Inorg Synth* **2** 147 *1946*, DOI: 10.1002/9780470132333.ch43; Noller & Dismore *Org Synth* Coll Vol **2** 358 *1943*, DOI:

10.15227/orgsyn.013.0020.] Dissolve it in CCl_4, dry it over $CaCl_2$, filter and distil it. Store it in sealed ampoules under N_2 and keep it away from light. It is also commercially available as a 1.0M solution in CH_2Cl_2 (d ^{25} 1.488). [Fieser **1** 873, **2** 330, **7** 292, **8** 400.] **HARMFUL VAPOURS.**

Phosphorus trichloride *[7719-12-2]* **PCl_3, M 137.3, m -112°, b 76°/atm, d $_4^{20}$ 1.575, n $_D^{20}$ 1.574.** Heat it under reflux to expel dissolved HCl, then distil it. It has been further purified by vacuum fractionation several times through a -45° trap into a receiver at -78°. [Forbes et al. *Inorg Synth* **2** 145 *1946*, DOI: 10.1002/9780470132333.ch42.] Also commercially available as 2.0M solution in CH_2Cl_2. **HARMFUL VAPOURS.**

Phosphorus triiodide *[13455-01-1]* **PI_3, M 411.7, m 61°, d ^{25} 4.18g/cm^3.** It decomposes in moist air and must be kept in a desiccator over $CaCl_2$. It is crystallised from sulfur-free CS_2; otherwise the **m** decreases to *ca* 55°. It is best to prepare it freshly. [Germann & Traxler *J Am Chem Soc* **49** 307 *1927*, DOI: 10.1021/ja01401a001; Klement in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 541 *1963*.] **HARMFUL VAPOURS.**

12-Phosphotungstic acid hydrate *[12501-23-4]* **$H_3[P(W_3O_{10})_4$. xH_2O, M 2880.2(anhydr), m 89°(hydrate), 95°, ~96°.** A few drops of concentrated HNO_3 are added to 100g of phosphotungstic acid dissolved in 75ml of water, in a separating funnel, and the solution is extracted with diethyl ether. The lowest of the three layers, which contains a phosphotungstic acid-ether complex, is separated, washed several times with 2M HCl, then with water and again extracted with ether. Evaporation of the ether under vacuum with mild heating on a water bath gives crystals which are dried under vacuum and ground [Matijevic & Kerker, *J Am Chem Soc* **81** 1307 *1959*, DOI: 10.1021/ja01515a012]. [For gravimetric determination of potassium as phospho-12-tungstate see Rieben & Van Slyke *J Biol Chem* **156** 765 *1944*, http://www.jbc.org/content/156/2/765.citation.]

Platinum (IV) ammonium chloride [ammonium hexachloroplatinate (IV)] *[16919-58-7]* **$(NH_4)_2PtCl_6$, M 443.9, m 380°, d ^{25} 3.065g/ml.** This salt is a useful Pt compound and is a very good source for preparing many amine complexes. It provides ***spongy Pt*** at high temperature. It is prepared by dissolving the less expensive spongy Pt (9.76g, 50mmol) in ***aa*** (200ml, 1HNO_3:4HCl by volume, and allowed to stand for 30 minutes until orange-red in colour) by heating and concentrating in an evaporating dish (***use an efficient fume hood and care as it is a dangerous operation***) to a thick syrup which is then taken almost to dryness on a water bath. Avoid drying at higher temperatures as it becomes incompletely soluble in H_2O. The orange-red crusty residue is dissolved in H_2O (100ml), filtered; and to it is add slowly a solution of NH_4Cl (8g, 150mmol) in H_2O (100ml) with stirring, when a yellow finely crystalline precipitate separates. Set the mixture aside for 30 minutes in an ice bath. Filter off the platinate salt and wash it several times with 1% aqueous NH_4Cl (30ml portions), then with EtOH (which removes any corresponding Pd salt impurity) and Et_2O. Dry the salt first in air, powder the crystals and dry further at 120° for 1 hour to provide an almost quantitative yield. ***Note*** that although the filtrates may be yellow in colour they only contain minute traces of Pt as the colour can be imparted at as low concentrations as 1 part in 20,000 parts of H_2O. The salt is not hygroscopic. Its solubility (by weight) in H_2O is 0.5% at 20° and 3.37% at 100°, and it is still less soluble in 1M NH_4Cl (0.0028%). It decomposes above 185° and yields ***spongy Pt*** at higher temperatures. It is reduced to the metal by H_2 at 120° and yields H_2PtCl_6 with Cl_2. [Kauffman *Inorg Synth* **9** 182 *1967*, DOI: 10.1002/9780470132401.ch51]

Platinum (II) chloride *[10025-65-7]* **$PtCl_2$, M 266.0, m 581°(dec), d $_4^{20}$ 5.87.** It is purified by heating at 450° in a stream of Cl_2 for 2 hours. Some sublimation occurs because the $PtCl_2$ sublimes completely at 560° as red (almost black) needles. This sublimate can be combined to the bulk chloride, and while still at *ca* 450° it should be transferred to a container and cooled in a desiccator. A probable impurity is $PtCl_4$. To test for this add a few drops of H_2O (in which $PtCl_4$ is soluble) to the salt, filter and add an equal volume of saturated aqueous NH_4Cl to the filtrate. If no precipitate is formed within 1 minute, then the product is pure. If a precipitate appears, then the whole material should be washed with small volumes of H_2O until the soluble $PtCl_4$ is removed. The purified $PtCl_2$ is partly dried by suction and then dried in a vacuum desiccator over P_2O_5. It is insoluble in H_2O, but soluble in HCl to form ***chloroplatinic acid (H_2PtCl_4)*** by disproportionation. [Cohen & Ferrone *Inorg Synth* **6** 209 *1960*, DOI: 10.1002/9780470132371.ch67.]

Potassium bicarbonate *[298-14-6]* **$KHCO_3$, M 100.1.** It is crystallised from water at 65-70° (1.25ml/g) by filtering and then cooling to 15° (~0.4ml/g). During all operations, CO_2 is passed through the stirred mixture. The crystals are sucked dry at the pump, washed with distilled water, dried in air and then over H_2SO_4 in an atmosphere of CO_2. It is much less soluble than the carbonate in H_2O (see below).

Potassium biiodate *[13455-24-8]* **KIO_4. HIO_4, $KH(IO_4)_2$, M 389.9.** Crystallise the biiodate three times from hot water (3ml/g), and stirring continuously during each cooling. After drying at 100° for several hours, the crystals are suitable for use in volumetric analysis. A*lternatively*, dry it for 2 hours in an oven at 105° and allow to cool to ~25° in a desiccator before use (keep drying temperature below 120° or decomposition occurs).

Potassium bisulfate *[7646-93-7]* **$KHSO_4$, M 136.2, m 214°, 218°, d ^{25} 2.32g/cm^3.** Crystallise it from H_2O (1ml/g) between 100° and 0°. It is also formed when a warm solution of K_2SO_4 in conc H_2SO_4 is cooled down. It can be freshly fused at 400°, cool and ground before use.

Potassium borohydride *[13762-51-1]* **KBH_4, M 53.9, m ~500°(dec) d ^{25} 1.18g/cm^3.** Crystallise it from liquid ammonia. It is slowly hydrolysed by H_2O. Its solubility at ~20° in H_2O or liquid NH_3 is 20%, in MeOH it is 0.7%, in Me_2NCHO it is 15% and in MeOH/H_2O (1:4) it is 13%. [James & Wallbridge *Progr Inorg Chem* **11** 99-231 *1970*, DOI: 10.1002/9780470166123.ch3.]

Potassium bromate *[7758-01-2]* **$KBrO_3$, M 167.0, m 350°(dec at 370°), d $^{20}_4$ 3.27.** Crystallise $KBrO_3$ from distilled H_2O (2ml/g) between 100° and 0°. To remove bromide contamination, a 5% solution in distilled H_2O, cooled to 10°, is bubbled with gaseous chlorine for 2 hours, then filtered and extracted with reagent grade CCl_4 until colourless and odourless. After evaporating the aqueous phase to about half its volume, it is cooled again slowly to about 10°. The crystalline $KBrO_3$ that separates, is washed with 95% EtOH and dried in a vacuum [Boyd et al. *J Am Chem Soc* **74** 237 *1952*, DOI: 10.1021/ja01121a062]. Another way to remove Br^- ions is by stirring several times in MeOH and then drying at 150° [Field & Boyd *J Phys Chem* **89** 3707 *1985*, DOI: 10.1021/j100263a026]. $KBrO_3$ is a powerful brominating agent for deactivated aromatic compounds [Kosandal et al. *Org Prep Proc Int* **23** 395, 569 *1991*, DOI: 10.1080/ 00304949109458221; amendment: DOI: 10.1080/00304949109458242].

Potassium bromide *[7758-02-3]* **KBr, M 119.0, m 734°, d $^{20}_4$ 2.75.** Crystallise the bromide from distilled water (1ml/g) between 100° and 0°. Wash it with 95% EtOH, followed by Et_2O. Dry it in air, then heat it at 115° for 1 hour, pulverise it, then heat it in a vacuum oven at 130° for 4 hours. It has also been crystallised from aqueous 30% EtOH, or EtOH, and dried over P_2O_5 under vacuum before heating in an oven.

Potassium carbonate *[584-08-7]* **K_2CO_3, M 138.2, m 891°, 898°, d ^{25} 2.43g/cm^3.** It crystallises from water between 100° and 0°. The solubility in H_2O is 105% at 0°, 127% at 60° and 205% at 135° (the boiling point of a saturated solution). After two recrystallisations of technical grade material, it had B, Li and Fe at 1.0, 0.04 and 0.01 ppm, respectvely. [Dönges in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 987 *1963*.]

Potassium chlorate *[3811-04-9]* **$KClO_3$, M 122.6, m 356°, 368°.** It has been recrystallised from water (1.8ml/g) between 100° and 0°, and the crystals were filtered onto sintered glass. Keep away from organic material as it oxidises them readily.

Potassium chloride *[7447-40-7]* **KCl, M 74.6, m 770°, 771°, d ^{25} 1.98g/cm^3.** Dissolve it in conductivity water, filter it, and saturate it with chlorine (generated from concentrated HCl and $KMnO_4$). Excess chlorine is boiled off, and the KCl is precipitated by HCl (generated by dropping concentrted HCl into concentrated H_2SO_4). The precipitate is washed with water, dissolved in conductivity water at 90-95°, and crystallised by cooling to about -5°. The crystals are drained at the centrifuge, dried in a vacuum desiccator at room temperature, then fused in a platinum dish under N_2, cooled and stored in a desiccator. Potassium chloride has also been sublimed in a stream of pre-purified N_2 gas and collected by electrostatic discharge [Craig & McIntosh *Can J Chem* **30** 448 *1952*, DOI: 10.1139/v52-053].

Potassium chromate *[7789-00-6]* **K_2CrO_4, M 194.2, m 971°, 975°, d_4^{20} 2.72, pK_1^{25} 0.74, pK_2^{25} 6.49 (for H_2CrO_4).** Crystallise it from conductivity water (0.6g/ml at 20°), and dry it between 135° and 170°.

Potassium cobalticyanide [potassium hexacyanocobaltate(III)] *[13963-58-1]* **$K_3Co(CN)_6$, M 332.4, m dec on heating, d^{25} 1.878g/cm^3.** Crystallise it from water to remove traces of HCN. Its solubility in 87-88% EtOH is 1 in 7500 at 20°. [Glemser in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **II** p 1542 *1965*.]

Potassium cyanate *[590-28-3]* **KOCN, M 81.1, d^{25} 2.05g/cm^3, pK^{25} 3.46 (for HCNO).** Common impurities include ammonia and bicarbonate ion (from hydrolysis). Purify it by preparing a saturated aqueous solution at 50°, neutralising with acetic acid, filtering, adding two volumes of EtOH and keeping for 3-4 hours in an ice bath. (More EtOH can lead to co-precipitation of $KHCO_3$.) Filter, wash it with EtOH and dry it rapidly in a vacuum desiccator (P_2O_5). The process is repeated [Vanderzee & Meyers *J Phys Chem* **65** 153 *1961*, DOI: 10.1021/j100819a044].

Potassium cyanide *[151-50-8]* **KCN, M 65.1, m 634°, d_4^{20} 1.52, pK^{25} 9.216 (for HCN).** A saturated solution in H_2O-ethanol (1:3) at 60° is filtered and cooled to room temperature. Absolute EtOH is added, with stirring, until crystallisation ceases. The solution is again allowed to cool to room temperature (during 2-3 hours), then the crystals are filtered off, washed with absolute EtOH, and dried, first at 70-80° for 2-3 hours, then at 105° for 2 hours [Brown et al. *J Phys Chem* **66** 2426 *1962*, DOI: 10.1021/j100818a026]. It has also been purified by melting in a vacuum and by zone refining. Its solubility is 33% (H_2O), 66% (boiling H_2O), 33% (glycerol), 4% (MeOH) and 1% (EtOH). It hydrolyses in H_2O, and a 0.1M aqueous solution of KCN has a pH of 11, i.e. CO_2 in the H_2O makes it acidic enough to liberate a lot of the more poisonous HCN. To keep the HCN in solution it must be made quite alkaline (pH <11). LD_{50} oral toxicity in rat is ~10mg/Kg. [Fieser **5** 553, **7** 299, **8** 409, **10** 324, **11** 433, **12** 405.] **HIGHLY POISONOUS work in an efficient fume cupboard.**

Potassium dichromate *[7778-50-9]* **$K_2Cr_2O_7$, M 294.2, m 398°(dec), d_4^{20} 2.68.** Crystallise it from water (g/ml) between 100° and 0° and dry it under vacuum at 156°. [Fieser **8** 410, **9** 383, **10** 324, **12** 405.] Possible **CARCINOGEN**.

Potassium dihydrogen phosphate (moobasic) *[7778-77-0]* **KH_2PO_4, M 136.1, m 252.6°, d^{25} 2.338g/cm^3, pK_1^{25} 2.15, pK_2^{25} 6.82, pK_3^{25} 12.38.** Dissolve it in boiling distilled water (2ml/g), keep on a boiling water-bath for several hours, then filter it through paper pulp to remove any turbidity. Cool rapidly with constant stirring, and the crystals are collected on to hardened filter paper, using suction, washed twice with ice-cold water, once with 50% EtOH, and dried at 105°. Alternate recrystallisations are from water, then 50% EtOH, and again water, or from concentrated aqueous solution by addition of EtOH. It is freed from traces of Cu by extracting its aqueous solution with diphenylthiocarbazone in CCl_4, followed by repeated extraction with CCl_4 to remove traces of diphenylthiocarbazone.

Potassium dithionate *[13455-20-4]* **$K_2S_2O_6$, M 238.3, $pK_{Est(1)}$ -3.4, pK_2^{25} 0.49 (for dithionic acid).** Crystallise it from water (1.5ml/g) between 100° and 0°. [For crystal structure see Stanley *Acta Cryst* **9** 897 *1956*, DOI: 10.1107/S0365110X56002540.]

Potassium ferricyanide (Red prussiate) *[13746-66-2]* **$K_3Fe(CN)_6$, M 329.3, pK^{25} <1 (for ferricyanide).** It has been recrystallised repeatedly from hot water (1.3ml/g) and dried under vacuum in a desiccator. [For uses see Fieser **1** 929, **2** 345, **4** 406, **5** 554, **6** 480, **7** 300, **8** 410, **9** 385, **13** 255.]

Potassium ferrocyanide trihydrate *[14459-95-1]* **$K_4Fe(CN)_6.3H_2O$, M 422.4, m 70°, pK_3^{25} 2.57, pK_4^{25} 4.35 (for ferrocyanide).** It is purified by repeated crystallisation from distilled water, and never heating above 60°. The ***anhydrous*** salt is prepared by drying at 110° over P_2O_5 in a vacuum desiccator. To obtain the ***trihydrate***, it is necessary to equilibrate the salt in a desiccator over a saturated aqueous solution of sucrose and NaCl. It can also be precipitated from a saturated solution at 0° by adding an equal volume of cold 95% EtOH, setting aside for several hours, then centrifuge and wash with cold 95% EtOH. It is finally sucked air dry with water-pump vacuum. The ***anhydrous*** salt is obtained by drying the hydrate in a platinum boat at 90° in a slow stream of N_2

[Loftfield & Swift *J Am Chem Soc* **60** 3083 *1938*, DOI: 10.1021/ja01279a504]. [*Beilstein* **2** IV 67.]

Potassium fluorosilicate *[16871-90-2]* **K_2SiF_6, M 220.3, d ^{25} 2.665g/cm^3, pK^{25} 1.92 (for H_2SiF_6).** Crystallise it several times from conductivity water (100ml/g) between 100° and 0°.

Potassium hexachloroiridate (III) (K_3IrCl_6) *[14024-41-0]* **K_3IrCl_6, M 522.2.** Crystallise it from hot aqueous solution, and the solution should be olive-green in colour. If it has a tinge of red, then some would have oxidised to (K_2IrCl_6) [see following entry]. In this case make a concentrated solution in H_2O, and bubble H_2S through until the solution is clearly olive-green in colour due to Ir(III). Add KCl and ***$K_3IrCl_6.3H_2O$*** deposits on evaporating under N_2. Filter it off, wash it with a little H_2O, then EtOH and dry it *in vacuo* away from air. [Grube in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **II** pp 1595 *1965*.]

Potassium hexachloroiridate (IV) (K_2IrCl_6) *[16920-56-2]* **K_2IrCl_6, M 483.1, m >385°(dec), d ^{25} 3.42g/cm^3.** Crystallise it from hot aqueous solution containing a few drops of HNO_3 to keep it in the oxidised state. It forms small shiny red-black octahedral crystals which are dried at 100° and give a red powder on grinding [Grube in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **II** pp 1593-1594 *1965*].

Potassium hexachloroosmate (IV) *[16871-60-6]* **K_2OsCl_6, M 481.1, m 600°(dec), d ^{25} 3.546g/cm^3.** Crystallise it from hot dilute aqueous HCl. [Turner et al. *Anal Chem* **30** 1708 *1958*, DOI: 10.1021/ac60142a602.]

Potassium hexachloroplatinate (IV) *[16921-30-5]* **K_2PtCl_6, M 486.0, m 250°(dec), d ^{25} 3.50g/cm^3.** It crystallises in orange-yellow crystals from water (20ml/g) between 100° and 0°. Its solubility in H_2O is 0.7% at 0°, 1.12% at 20°, 2.16% at 50° and 5.13% at 100°. [Grube in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **II** p 1571 *1965*.]

Potassium hexacyanochromate (III) ($K_3[Cr(CN)_6]$ $3H_2O$) *[13601-11-1]* **$K_3Cr(CN)_6$, M 328.4, m >350°.** It forms yellow crystals from water. Recrystallise it two or three times from H_2O and dry it over H_2SO_4. Its solubility at 20° is 30.96g/100g H_2O, and it is insoluble in EtOH. Aqueous solutions tend to decompose especially in the presence of light or on heating when $Cr(OH)_3$ separates. [Hein & Herzog in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **II** pp 1373-1374 *1965*.]

Potassium hexafluorophosphate *[17084-13-8]* **KPF_6, M 184.1, m 575°, d ^{25} 2.75g/cm^3.** Crystallise it from alkaline aqueous solution, using polyethylene vessels, or from 95% EtOH, and dry it in a vacuum desiccator over KOH. [Kolditz *Z Anorg Allgem Chem* **284** 144 *1956*, DOI: 10.1002/zaac.19562840116; Kwasnik in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 196 *1963*.]

Potassium hexafluorozirconate *[16923-95-8]* **K_2ZrF_6, M 283.4, d $^{20}_{4}$ 3.48.** Recrystallise it from hot water (solubility is 0.78% at 2° and 25% at 100°).

Potassium hydrogen fluoride *[7789-29-9]* **KHF_2, M 78.1, m 225°(dec), 239°(dec), d ^{25} 2.37g/cm^3.** It crystallises from water. It is very soluble in hot H_2O and 41% at 21°. [Kwasnik in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 237 *1963*.] A 3.0M aqueous solution (d ^{25} 2.37g/cm^3) is also commercially available, and useful for preparing potassium organotrifluoroborates from their respective boronic acids [Molander & Ham *Org Lett* **8** 2031 *2006*, DOI: 10.1021/ol060375a].

Potassium hydroxide (solution) *[1310-58-3]* **KOH, M 56.1, pK^{25} 16 (for aquo K^+).** Its carbonate content can be reduced by rinsing KOH sticks rapidly with water prior to dissolving them in boiled out distilled water. *Alternatively*, a slight excess of saturated $BaCl_2$ or $Ba(OH)_2$ can be added to the solution which, after shaking well, is set aside so that the $BaCO_3$ is allowed to separate out. Davies and Nancollas [*Nature* **165** 237 *1950*, DOI: 10.1038/165237b0] rendered KOH solutions carbonate free by ion exchange using a column of Amberlite IR-100 in the OH^- form. [For applications see Fieser **1** 935, **2** 346, **3** 238, **4** 409, **5** 557, **6** 486, **7** 303, **8** 414, **9** 387, **11** 439, **12** 411, **13** 258.]

Potassium iodate *[7758-05-6]* **KIO_3, M 214.0, m 560°, d ^{25} 3.93g/cm^3, pK^{25} 0.80 (for HIO_3).** It has been crystallised twice from distilled water (3ml/g) between 100° and 0°, dried for 2 hours at 140° and cooled in a desiccator. Analytical reagent grade material dried in this way is suitable for use as an analytical standard.

Potassium iodide *[7681-11-0]* **KI, M 166.0, m 681°, b 1330°/atm, d ^{25} 3.12g/cm^3, pK^{25} -8.56 (for HI).** Crystallise it from distilled water (0.5ml/g) by filtering the near-boiling solution and cooling. To minimise oxidation to iodine, the process can be carried out under N_2 and the salt is dried under a vacuum over P_2O_5 at 70-100°. Before drying, the crystals can be washed with EtOH or with acetone followed by petroleum ether. It has also been recrystallised from water/ethanol. After 2 recrystallisations, ACS/USP grade had Li and Sb at <0.02 and <0.01 ppm respectively. [Lingane & Kolthoff *Inorg Synth* **I** 163 *1939*, DOI: 10.1002/ 9780470132326.ch55.]

Potassium nickel sulfate hexahydrate *[13842-46-1]* **K_2SO_4. $NiSO_4$. 7H_2O, M 437.1, m <100°(dec), d $^{20}_4$ 2.124.** Crystallise the blue-green solid from H_2O (1.7ml/g) between 75° and 0°. [For crystal growth see He et al. *J Cryst Growth* **233** 809 *2001*, DOI: 10.1016/S0022-0248(01)01564-0.]

Potassium nitrate (saltpetre) *[7757-79-1]* **KNO_3, M 101.1, m 334°, 336°, decomposes at 400°/atm, d ^{15}** 2.109 **g/cm^3, n $^{25}_D$ 1.335, 1.5056, 1.5604, pK_b 15.3.** It crystallises from hot H_2O (0.5ml/g) on cooling (cf. KNO_2 below). Dry it for 12 hours under vacuum at 70°. The solubility in H_2O is 13.3% at 0°, 110% at 60°, and 246% at 100°. After two recrystallisations, technical grade salt had <0.001 ppm of metals. The fused salt is a powerful oxidising agent. It decomposes between 550° and 790° to KNO_2 and O_2. Useful for making fireworks, explosives, blasting powders, in candle wicks as it burns evenly, as a flux, tempering steel and as a diuretic. [Spencer *Saltpeter:The Mother of Gunpowder* OUP, UK *2013* pp 256, ISBN 9780199695751.]

Potassium nitrite *[7758-09-0]* **KNO_2, M 85.1, m 350°(dec at ~441°), d ^{25} 1.915g/ml, pK^{20} 3.20 (for HNO_2).** A saturated solution at 0° is warmed and partially evaporated under vacuum. The crystals so obtained are filtered off from the warm solution. (This procedure is designed to reduce the level of nitrate impurity and is based on the effects of temperature on solubility. The solubility of KNO_3 in water is 13g/100ml at 0°, 247g/100ml at 100°; for KNO_2 the corresponding figures are 280g/100ml and 413g/100ml.) *Alternatively*, dissolve it in H_2O and precipitate by adding of EtOH. An aqueous solution is alkaline, and it reacts with dilute mineral acid to liberate nitrous acid (blue green colour nitrosating agent) which oxidises to give brown fumes of NO_2. [Young 'Potassium Nitrite' *J Chem Educ* **85** 779 *2008*, DOI: 10.1021/ed085p779.]

Potassium nitrosodisulfonate (Fremy's Salt) *[14293-70-0]* **$(K_2SO_3)_2NO$, M 268.3.** It forms yellow needles (dimeric) which dissolve in H_2O to give the violet monomeric free radical. It is purified by dissolving (~12g) in 2M KOH (600ml) at 45°, filtering the blue solution and keeping it in a refrigerator overnight. The golden yellow crystals (10g) are filtered off, washed with MeOH (3x), then Et_2O and stored in a glass container in a vacuum over KOH. It is stable indefinitely when dry. [Cram & Reeves *J Am Chem Soc* **80** 3094 *1958*, DOI: 10.1021/ja01545a048; Schenk *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 505 *1963*; preparation and use: Wehrli & Pigott *Org Synth* Coll Vol **6** 1010, *1988*, DOI: 10.15227/orgsyn.052.0083.] A useful ***radical oxidant***, e.g. for the oxidation of anilines and phenols to quinones [Teuber & Benz *Chem Ber* **100** 218 *1967*, DOI: 10.1002/ cber.19671000916; Teuber *Org Synth* Coll Vol **6** 480 *1988*, DOI: 10.15227/orgsyn.052.0088].

Potassium osmate (VI) dihydrate *[19718-36-6, 10022-66-9 ($2H_2O$)]* **K_2OsO_4. 2H_2O, M 368.4, m 332.4°(2H_2O), 368.4°(anhyr).** It forms ***hygroscopic*** **POISONOUS** purple crystals which are soluble in H_2O but insoluble in EtOH and Et_2O. It decomposes slowly in H_2O to form the ***tetroxide*** which ***attacks the eyes***. The solid should be kept dry and in this form it is relatively safe. [Lloyd et al. *Synthesis* 610 *1972*, DOI: 10.1055/s-1972-21948; Grube in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **II** p 1604 *1965*.] A reagent for the cleavage of olefins to ketones and carboxylic acids [Whitehead et al. *Tetrahedron Lett* **47** 3797 *2006*, DOI: 10.1016/j.tetlet.2006.03.087], and the intramolecular amidohydroxylation of carbamoyloxy-tethered olefins to give hydroxyoxazolidinones [Donohoe et al. *J Am Chem Soc* **128** 2514 *2006*, DOI: 10.1021/ja057389g]

Potassium perchlorate *[7778-74-7]* **$KClO_4$, M 138.6, m 400(dec), d $_4^{20}$ 2.52, pK^{25} -2.4 to -3.1 (for $HClO_4$).** It crystallises from boiling water (5ml/g) on cooling. Dry it under vacuum at 105°. **Potentially explosive.**

Potassium periodate (potassium metaperiodate) *[7790-21-8]* **KIO_4, M 230.0, m 582°, d $_4^{20}$ 3.62.** Crystallise it from distilled water. Its solubility in H_2O is 0.2% at 0°, 0.4% at 20°, 4.4% at 80°, and 7.9% at 100°. [Willard et al. *Inorg Synth* **I** 168 *1939*, DOI: 10.1002/9780470132326.ch58; Schmeisser in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 325 *1963*.] I is a powerful oxidant [Fieser **1** 809, **2** 311, **4** 373, **5** 507, **6** 455.]

Potassium permanganate *[7722-64-7]* **$KMnO_4$, M 158.0, m 240°(dec), d $_4^{20}$ 2.7, pK^{25} -2.25 (for $HMnO_4$).** Crystallise the purple-bronze solid from hot water (19ml/g at 15°, 4ml/g at 65°), then dry it in a vacuum desiccator over $CaSO_4$. Phillips and Taylor [*J Chem Soc* 4242 *1962*, DOI: 10.1039/JR9620004242] cooled an aqueous solution of $KMnO_4$, saturated at 60°, to room temperature in the dark, and filtered it through a No.4 porosity sintered-glass filter funnel. The solution was allowed to evaporate in air in the dark for 12 hours, and the supernatant liquid was decanted from the crystals, which were dried as quickly as possible with filter paper. It is a secondary analytical standard. It is a useful oxidant and is used as a topical antiseptic. [Fieser **1** 942, **2** 348, **4** 412, **5** 562, **8** 416, **9** 388, **10** 330, **11** 440, **12** 413, **13** 258, **14** 267, **15** 273.] Also commercially available on phosphate buffered silica gel (200-400 mesh).

Potassium peroxydisulfate (potassium persulfate) *[7727-21-1]* **$K_2S_2O_8$, M 270.3, m <100°(dec), d ^{25} 3.477g/cm^3, n $_D^{25}$ 1.467.** Crystallise the persulfate twice from distilled water (10ml/g) and dry it at 50° in a vacuum desiccator. Its solubility in H_2O is 1.6% at 0°, 4.5% at 20°, and 7.2% at 30°. An aqueous solution decomposes on long standing with evolution of O_2 and formation of $KHSO_4$. It is a powerful oxidising agent. Store it at ~10°. [Fehér in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 390 *1963*.]

Potassium peroxymonosulfate (Oxone, potassium monopersulfate triple salt; $2KHSO_5.KHSO_4.K_2SO_4$), *[37222-66-5, 70693-62-8 (triple salt)]* **$2KHSO_5.KHSO_4.K_2SO_4$, M 614.8.** This is a stable form of Caro's acid and should contain >4.7% of active oxygen. It can be used in EtOH/H_2O and EtOH/AcOH/H_2O solutions. If active oxygen is too low. it is best to prepare it afresh from 1mole of $KHSO_5$, 0.5mole of $KHSO_4$ and 0.5mole of K_2SO_4. [Kennedy & Stock *J Org Chem* **25** 1901 *1960*, DOI: 10.1021/jo01081a019; Stephenson US Patent 2,802,722 *1957*.] A rapid preparation of ***Caro's acid*** is made by stirring finely powdered potassium persulfate (**M** 270.3) into ice-cold concentrated H_2SO_4 (7ml) and when homogeneous add ice (40-50g). It is stable for several days if kept cold. Keep away from organic matter as it is a **STRONG OXIDANT**. A detailed preparation of **Caro's acid** (***hypersulfuric acid,*** **H_2SO_5,** *[7722-86-3]*) in crystalline form **m** ~45° from H_2O_2 and chlorosulfonic acid was described by Fehér in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 388 *1963*. [For applications see Fieser **1** 952, **11** 442, **12** 413, **13** 259, **14** 267.]

Potassium perrhenate *[10466-65-6]* **$KReO_4$, M 289.3, m 550°, b 1360-1370°/atm, d ^{25} 4.887g/cm^3, n $_D^{25}$ 1.643. pK^{25} -1.25 (for $HReO_4$).** It forms white tetrahedral crystals from H_2O where its solubility is 12.1g/L at 20° and 140g/L at 100°. The salt is then fused in a platinum crucible in air at 750°. [Smith & Long *J Am Chem Soc* **70** 354 *1948*, DOI: 10.1021/ja01181a110; Watt et al. *Inorg Synth* **7** 189 *1963*, DOI: 10.1002/9780470132388.ch51.]

Potassium reineckate *[34430-73-4]* **$K[Cr(NH_3)_2(SCN)_4].H_2O$, M 357.5.** Crystallise it from KNO_3 solution, then from warm water [Adamson *J Am Chem Soc* **80** 3183 *1958*, DOI: 10.1021/ja01546a004]. [Use as a chemical actinometer (photochemical reference): *Analyst* **114** 739 *1989*, DOI: 10.1039/AN9891400739; for charge transfer photochemistry see Mainusch et al. *Inorg Chim Acta* **255** 87 *1997*, DOI: 10.1016/S0020-1693(96)05343-1

Potassium ruthenate(VI) *[31111-21-4]* **$KRuO_4$, M 243.3.** Dissolve the ruthenate in H_2O and evaporate until crystals are formed. The crystals are iridescent green prisms which appear red in thin films. A possible impurity is RuO_4; in this case wash with CCl_4 (which dissolves RuO_4). The concentration of an aqueous solution of RuO_4^{2-} (orange colour) can be estimated from the absorbance at 385nm (ε 1030 M^{-1} cm^{-1}), or at 460nm (ε 1820

M^{-1} cm^{-1}). [Lee et al. *Can J Chem* **50** 3741 *1972*, DOI: 10.1139/v72-592; Connick & Hurley *J Am Chem Soc* **74** 5012 *1952*, DOI: 10.1021/ja01140a007; Grube et al. *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **II** p 1600 *1965*]. For the preparation of salts free of chloride ions see Kaziro et al. [*Inorg Chim Acta* **164** 85 *1989*, DOI: 10.1016/S0020-1693(00)80880-4].

Potassium selenocyanate *[3425-46-5]* **KSeCN, M 144.1.** Dissolve it in acetone, filter and precipitate it by adding Et_2O. For use in solid state NMR see Bowmaker et al. [*Inorg Chem* **37** 1734 *1998*, DOI: 10.1021/ic9700112]. A convenient reagent for selenocyanation [Block et al. *J Am Chem Soc* **128** 14949 *2006*, DOI: 10.1021/ja065037j], cyclocondensation [Köhler et al. *Tetrahedron* **46** 7735 *1990*, DOI: 10.1016/S0040-4020(01)90069-9] and heterocyclisation reactions [*Chem Commun 860 1991*, DOI: 10.1039/C39910000860].

Potassium sulfate *[7778-80-5]* **K_2SO_4, M 174.3, m 1069°, d $_4^{20}$ 2.67**. It crystallised from distilled water (4ml/g at 20°; 8ml/g at 100°) between 100° and 0°.

Potassium tetrachloroplatinate(II) *[10025-99-7]* **K_2PtCl_4, M 415.1, m 500°(dec), d ^{25} 3.38g/cm^3.** It forms crystals from aqueous 0.75M HCl (20ml/g) between 100° and 0°. Wash them with ice-cold water and dry. The solubility in HO is 0.93g/100ml (16°) and 5.3g/100ml (100°). [Keller & Moeller *Inorg Synth* **7** 247 *1963*, DOI:10.1002/9780470132333.]

Potassium tetracyanopalladate (II) trihydrate *[10025-98-6]* **$K_2Pd(CN)_4$. $3H_2O$, M 377.4.** *All operations should be carried out in an efficient fume cupboard.* ***Cyanide is very*** **POISONOUS**. Dissolve the complex (*ca* 5g) in a solution of KCN (4g) in H_2O (75ml) with warming and stirring, and evaporate hot till crystals appear. Cool, filter off the crystals and wash them with a few drops of cold H_2O. Further concentration of the mother liquors provides more crystals. The complex is recrystallised from H_2O as the colourless ***trihydrate***. It ***effloresces*** in dry air and dehydrates at 100° to the ***monohydrate***. The ***anhydrous salt*** is obtained by heating at 200°, but at higher temperatures it decomposes to $(CN)_2$, Pd and KCN. [Bigelow et al. *Inorg Synth* **2** 245 *1946*, DOI: 10.1002/9780470132333.ch78.]

Potassium tetrafluoroborate (potassium borofluoride) *[14075-53-7]* **KBF_4, M 125.9, m 530°, d $_4^{30}$ 2.505, pK^{25} -4.9 (for HBF_4).** Crystallise it from H_2O (solubility% (temperature): 0.3 (3°), 0.45 (20°), 1.4 (40°), 6.27 (100°), and dry it under vacuum. It is a non-hygroscopic salt. A 10% solution is transparent blue at 100°, green at 90° and yellow at 60°. [Vörlander et al. *Chem Ber* **65** 535 *1932*, DOI: 10.1002/cber.19320650406; Kwasnik in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 223 *1963*.]

Potassium thiocyanate (potassium rhodanide) *[333-20-0]* **KSCN, M 97.2, m 172°, 173°, pK^{25} -1.85 (for HSCN).** Crystallise it from H_2O if much chloride ion is present in the salt, otherwise from EtOH or MeOH (optionally by addition of Et_2O). Filter off on a Büchner funnel without paper, and dry it in a desiccator at room temperature before heating for 1 hour at 150°, with a final 10-20 minutes at 200° to remove the last traces of solvent [Kolthoff & Lingane *J Am Chem Soc* **57** 2126 *1935*, DOI: 10.1021/ja01314a025]. Store it in the dark. [Fieser **1** 954.]

Potassium thiosulfate hydrate *[13446-67-8, 10294-66-3 (75% aqueous solution)]* **$K_2S_2O_3$. xH_2O M 190.3, pK $_1^{25}$ 0.6, pK $_2^{25}$ 1.74 (for $H_2S_2O_3$)** Crystallise it from warm water (0.5ml/g) by cooling in an ice-salt mixture. It is a good reducing agent used in analytical chemistry. [Foerster & Mommsen *Chem Ber* **57** 258 *1924*, DOI: 10.1002/cber.19240570218.]

Potassium tungstate (*ortho* dihydrate) *[37349-36-3; 7790-60-5]* **K_2WO_4. $2H_2O$, M 362.1(anhydr), m 921°, d ^{25} 3.12g/cm^3, pK $_1^{25}$ 2.20, pK $_2^{25}$ 3.70 (for H_2WO_4).** Crystallise it from hot water (0.7ml/g).

Praseodymium trichloride hexahydrate *[10361-79-2, 19423-77-9 ($6H_2O$)]* **$PrCl_3$. $6H_2O$, M 247.3(anhydr), m 786°, d ^{25} 2.25g/cm^3(hydrate), pK $_1^{25}$ 8.55 (for Pr^{3+} hydrol).** Its 1M solution in 6M HCl is passed twice through a Dowex-1 anion-exchange column. The eluate is evaporated in a vacuum desiccator to half its volume and allowed to crystallise [Katzin & Gulyas *J Phys Chem* **66** 494 *1962*, DOI: 10.1021/j100809a029].

Praseodymium (III, IV) oxide *[12037-29-5]* **Pr_6O_{11}, M 1021.4.** Dissolve the oxide in acid (perchloric acid), precipitate it as the oxalate and the salt is ignited at 650° to give the oxide. The single valence ***praseodenium(III) oxide*** **Pr_2O_3, M 329.8,** has **m** 2183°, **b** 2760° and **d** ^{25} 6.9g/ml.

Reineckate salt See ammonium reineckate above.

Rhodium (III) chloride *[10049-07-7, 20765-98-4 (xH_2O)]* **$RhCl_3$, M 209.3, m >100°(dec), b 717°.** Probable impurities are KCl and HCl. Wash the chloride well with small volumes of H_2O to remove excess KCl and KOH and dissolve it in the minimum volume of concentrated HCl. Evaporate it to dryness on a steam bath to give wine-red coloured $RhCl_3.3H_2O$. Leave it on the steam bath until the odour of HCl is lost—do **not** try to dry further as it begins to decompose above 100° to the oxide and HCl. It is not soluble in H_2O but soluble in alkalies or CN solutions and forms double salts with alkali chlorides. [Anderson et al. *Inorg Synth* **7** 214 *1963*, DOI: 10.1002/9780470132388.ch57.] Catalyst for converting CH_4 to AcOH [Lin & Sen *Nature* **368** 613 *1994*, DOI: 10.1038/368613a0], and for conjugate reduction of cinnamaldehydes followed by cross-coupling with arylboronic acids [Wang et al. *Chem Commun* 1192 *2004*, DOI: 10.1039/B401511H]. [Fieser **6** 504, **7** 313, **16** 292.]

Rubidium bromide *[7789-39-1]* **$RbBr_3$, M 165.4, m 682°, b 1340°/atm, d ^{25} 3.35g/cm^3.** The bromide is a white crystalline powder which crystallises from H_2O (solubility: 50% in cold and 67% in boiling H_2O to give a neutral solution). It also crystallises from near-boiling water (0.5ml/g) by cooling to 0°.

Rubidium chlorate *[13446-71-4]* **$RbClO_3$, M 168.9, d $^{20}_4$ 3.19.** It crystallises from water (1.6ml/g) by cooling from 100°.

Rubidium chloride *[7791-11-9]* **$RbCl_3$, M 120.9, m 715°, m 1383°/atm, d ^{25} 2.80g/cm^3.** Crystallise it from water (0.7ml/g) by cooling to 0° from 100°. Its solubility in H_2O is 77.3% at 0.6°, 90.3% at 70° and 147% at boiling point. [Dönges in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 951-955 *1963*.]

Rubidium nitrate *[13126-12-0]* **$RbNO_3$, M 147.5, m 305°, d ^{25} 2.80g/cm^3.** Crystallise the nitrate from hot water (0.25ml/g) by cooling to room temperature.

Rubidium perchlorate *[13510-42-4]* **$RbClO_4$, M 184.9, m 281°, b 600°/atm(dec), d ^{25} 2.88g/cm^3, pK^{25} -2.4 to -3.1 (for $HClO_4$).** Crystallise the perchlorate from hot water by cooling to 0° [solubility in g/100ml: 1.09 (0°), 1.30 (25°), 3.44 (50°), 6.72 (70°) and 17.39 (99°)]. Oxidising agent.

Rubidium sulfate *[7488-54-2]* **Rb_2SO_4, M 267.0, m 530°, d ^{25} 3.61g/ml.** Crystallise the sulfate from water (1.2ml/g) between 100° and 0°.

Ruthenium (III) chloride dihydrate (β−form) *[10049-08-8 (anhydrous), 13815-94-6 ($3H_2O$), 14898-67-0 (xH_2O)]* **$RuCl_3.xH_2O$, M 207.4 + H_2O, m >500°(dec), d ^{25} 3.11g/ml, pK $^{25}_1$ 3.40 (for aquo Rh^{3+} hydrolysis).** Dissolve the black salt in H_2O, filter and concentrate to crystallisation in the absence of air to avoid oxidation. Evaporate the solution in a stream of HCl gas while being heated just below its boiling point until a syrup is formed and finally to dryness at 80-100° and dried in a vacuum over H_2SO_4. When heated at 700° in the presence of Cl_2 the insoluble ***α-form*** is obtained [Grube in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **II** p 1598 *1965*,]. A very useful catalyst particularly when coordinated with organic ligands, e.g. for oxidation reactions with an oxidant [Carlsen et al. *J Org Chem* **46** 3936 *1981*, DOI: 10.1021/jo00332a045; Hasegawa et al. *Chem Lett (Jpn)* **14** 1385 *1985*, DOI: 10.1246/cl.1985.1385], the oxidative cyclisation of 1,7-ienes to oxepane diols [Piccialli et al. *Tetrahedron Lett* **48** 5131 *2007*, DOI: 10.1016/j.tetlet.2007.05.078] and hydroxylation of tertiary carbon-hydrogen bonds of cyclic ethers with periodate or bromate [Lee et al. *J Org Chem* **72** 5820 *2007*, DOI: 10.1021/jo070382s]. A kit of ruthenium metathesis catalysts kit is available commercially [see Schrodi & Pederson *Aldrichimica Acta* **40** 45 *2007*].

Ruthenium (IV) oxide *[12036-10-1, 32740-79-7 (xH_2O)]* **RuO_2, M 133.1, b 1200°/atm(sublimes), d ^{25} 6.97g/cm^3.** Free the black oxide from nitrates by boiling in distilled water and filtering. A more complete purification is based on fusion in a KOH/KNO_3 mix to form the soluble ruthenate and perruthenate salts. The melt is dissolved in water, and filtered, then acetone is added to reduce the ruthenates to the insoluble hydrated oxide which, after making a slurry with paper pulp, is filtered and ignited in air to form the ***anhydrous*** oxide [Campbell et al. *Anal Chem* **33** 58 *1961*, DOI: 10.1021/ac60169a016]. It is an electrocatalyst for producing chlorine, its oxides and oxygen [Mills 'Heterogeneous redox catalysts for oxygen and chlorine evolution' *Chem Soc Rev* **18** 285 *1989*, DOI: 10.1039/CS9891800285], and hydration of the oxide strongly affects its catalytic activity [Mills & Davies, *Inorg Chim Acta*, **189** 149 *1991*, DOI: a10.1016/S0020-1693(00)80183-8].

Samarium (II) iodide *[32248-43-4]* **SmI_2, M 404.2, m 520°, b 1580, d ^{25} 6.97g/cm^3.** A possible impurity is SmI_3, *[13813-25-7]* M 531.1, from which it is made. If present, grind the solid to a powder and heat it in a stream of pure H_2. The temperature (~ 500-600°) should be below the **m (~ 628°)** of SmI_3, since the molten compounds react very slowly. [Wetzel in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **II** pp 1149, 1150 *1965*.] It promotes a ***pseudo-Barbier reaction*** between aldehydes and ketones with aliphatic or alycyclic halides (see NdI_2) [Namy et al. *J Organomet Chem* **328** 81 *1987*, DOI: 10.1016/S0022-328X(00)99769-9.] It is a ***one-electron reducing agent*** [Brendt et al. *Aldrichimica Acta* **24** 15 *1991*.]

SmI_2 in THF (0.1M, d ^{25} 0.99g/cm^3) is available commercially for reactions can also be prepared in a dry box, or dry gloves, filled with N_2 (not generally necessary for synthetic purposes, but should be used for Grignard-type conditions, i.e. exclusion of moisture) from samarium powder (3g, 20mmol, or distilled metal or ingot), placed in a flask fitted with a dropping funnel containing 1,2-diiodoethane (22.82g, 10mmol) in THF (250ml) which is added dropwise. The reaction has no induction period if the solvent is pure. [Excess metal can be re-used later.] An intense blue-green solution results with a SmI_2 concentration of 4 x 10^{-2} M in THF that can be diluted to 10^{-1} M. These solutions can be stored for a long time without loss of Sm^{2+} concentration if kept in an inert atmosphere in the presence of a small amount of metal. However, it is best to use them within a few days to ensure reproducible results. In addition to promoting coupling reactions, it is also a powerful and selective reducing agent for olefins [Girard et al. *J Am Chem Soc* **102** 2693 *1980*, DOI: 10.1021/ja00528a029DOI: 10.1021/ja00528a029; see also Asano et al. *Synthesis* 1309 *2007*, DOI: 10.1055/s-2007-966006], promotes the reaction of chlorofluoroacetonitrile *[359-05-7]* with aldehydes to form cyanofluorohydrins in the presence of HMPA [Asano et al. *Synthesis* 1309 *2007*, DOI: 10.1055/s-2007-966006], intramolecular cyclisation reactions [Molander & McKie *J Org Chem* **59** 3186 *1994*, DOI: 10.1021/jo00090a041], and intermolecular ketone-olefin coupling reactions [Kawatsura et al. *J Org Chem* **59** 6900 *1994*, DOI: 10.1021/jo00102a010]. [See also Fieser **10** 344, **11** 464, **12** 429, **13** 270, **14** 276, **15** 282, **16** 294, **17** 307.]

Selenous acid *[7783-00-8]* **H_2SeO_3, M 129.0, m 70°(dec), d ^{25} 3.004g/cm^3, pK_1^{25} 2.62, pK_2^{25} 8.32 (H_2SeO_3).** Recrystallise the acid from water. On heating it loses water and SeO_2 sublimes. [Waitkins & Clark *Chem Rev* **36** 235 *1945*, DOI: 10.1021/cr60115a001; for use see Fieser **1** 992.]

Selenium *[7782-49-2]* **Se, M 79.0, m 217.4°, 220.85°, b 684.1°/atm, d ^{25} 4.81g/cm^3.** Dissolve selenium in small portions in hot concentrated HNO_3 (2ml/g), filter and evaporate to dryness to give selenious acid which is then dissolved in concentrated HCl. Pass SO_2 gas through the solution whereby selenium (but not tellurium) precipitates. It is filtered off and washed with concentrated HCl. This purification process is repeated. The selenium is then converted twice to the selenocyanate by treating with a 10% excess of 3M aqueous KCN (CARE), heated for half an hour on a sand-bath and filtered. Add an equal weight of crushed ice to the cold solution, followed by an excess of cold, concentrated HCl, with stirring (in an efficient fume cupboard as HCN is evolved) which precipitates selenium powder. This is washed with water until colourless, and then with MeOH and is heated in an oven at 105°. Finally it is fused for 2 hours *in vacuo*. It is cooled, crushed and stored in a desiccator [Tideswell & McCullough *J Am Chem Soc* **78** 3026 *1956*, DOI: 10.1021/ja01594a025].

Selenium dioxide *[7446-08-4]* **SeO_2, M 111.0, m 315°(sublimes), 340°, d ^{25} 3.95g/cm^3.** Purify it by sublimation at 315°, or by solution in HNO_3, precipitation of selenium which, after standing for several hours or

boiling, is filtered off, then re-oxidised by HNO_3 and cautiously evaporated to dryness below 200°. The dioxide is dissolved in H_2O and again evaporated to dryness. In H_2O it forms selenious acid (see selenious acid above). Its solubility in H_2O in g/100ml is 38.4 (20°), 39.5 (25°) and 82.5 (65°), and it is soluble in EtOH (6.7g/100ml at 15°), in Me_2CO (4.4g/100ml at 15°) in MeOH (10.16/100ml at 12°) and in AcOH (1.11/100ml at 14°). It is a useful and selective oxidant. [Waitkins & Clark *Chem Rev* **36** 235 *1945*, DOI: 10.1021/cr60115a001; Fehér in *Handbook of Preparative Inorganic Chemistry (Ed Brauer)* Academic Press Vol **I** p 421 *1963*, Rabjohn *Org Reactions* **5** 331 *1949*.]

Silica *[7631-86-9 (colloidal), 60676-86-0 (Quartz, Cristobalite, sand), 112945-52-5 (fumed)]* **SiO_2, M 60.1, m >1600°, b 2230°.** Purification of silica for high technology applications uses isopiestic vapour distillation from concentrated volatile acids and is absorbed in high purity water. The impurities remain behind. Preliminary cleaning to remove surface contaminants uses dip etching in HF or a mixture of HCl, H_2O_2 and deionised water [Phelan & Powell *Analyst* **109** 1269 *1984*, DOI: 10.1039/AN9840901269].

Silica gel *[63231-67-4, 112926-00-8].* Before use as a drying agent, silica gel is heated in an oven, then cooled in a desiccator. Conditions in the literature range from heating at 110° for 15 hours to 250° for 2-3 hours. Silica gel has been purified by washing with hot acid (in one case successively with ***aqua regia***, concentrated HNO_3, then concentrated HCl; in another case it was digested overnight with hot concentrated H_2SO_4), followed by exhaustive washing with distilled water (one week in a Soxhlet apparatus has also been used), and prolonged oven drying. *Alternatively*, silica gel has been extracted with acetone until all soluble material was removed, then dried in a current of air, washed with distilled water and oven dried. Silica gel has also been washed successively with water, M HCl, water, and acetone, then activated at 110° for 15 hours. Commercially available in various grades. [For applications see also Fieser **9** 410, **10** 346, **11** 466, **12** 431.]

Silicon monoxide *[10097-28-6]* **SiO, M 44.1, m > 1700°, d ^{25} 2.18g/cm^3.** Purify the monoxide by sublimation in a porcelain tube in a furnace at 1250° (4 hours) in a high vacuum (10^{-4}mm) in a stream of N_2. It is obtained as brownish black scales. [Schenk in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 696 *1963*.]

Silicon tetrachloride *[10026-04-7]* **$SiCl_4$, M 169.9, m -70°, b 57.6°/atm, d ^{25} 1.483g/cm^3.** Distil it under vacuum and store it in sealed ampoules under N_2. It fumes in moist air and is very sensitive to moisture. It is soluble in organic solvents. It is a **strong irritant**. [Schenk in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** pp 682-683 *1963*.] Also available as a 1.0M solution in CH_2Cl_2 (d ^{25} 1.34g/cm^3). Useful for preparing silicon compounds.

12-Silicotungstic acid (tungstosilicic acid;) *[12027-43-9, 11130-20-4]* **$H_4SiW_{12}O_{40}$, M 2878.2.** Extract the acid with diethyl ether from a solution acidified with HCl. The diethyl ether is evaporated under vacuum, and the free acid is crystallised twice [Matijevic & Kerker *J Phys Chem* **62** 1271 *1958*, DOI: 10.1021/j150568a026].

Silver (metal) *[7440-22-4]* **Ag, M 107.9, m 961.9°, b 2212°/atm, d ^{25} 10.49g/cm^3.** For purification by electrolysis, see Craig et al. [*J Res Nat Bur Stand* **64A** 381 *1960*]. For purification of crude, or silver residues to pure silver see Glemser & Sauer in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** pp 1028-1030 *1963*, and for the preparation of *colloidal silver* see *ibid (Ed. Brauer)* p 1034.

Silver acetate *[563-63-3]* **AgOAc, M 166.9, dec on heating, d^{25} 3.259.** The salt is a white (or slightly grey if exposed to light) crystalline powder or lustrous needles, which should not be exposed to light for long periods. It can be purified by recrystallisation from H_2O (preferably containing a little AcOH) as its solubility (w/v) in cold H_2O is 1% and in boiling H_2O it is 35%. *Alternatively*, it is boiled with Ac_2O, the insoluble salt is collected and recrystallised from glacial AcOH. It is freely soluble in dilute HNO_3. Store in dark bottles away from light. [*Beilstein* **2** H 110, **2** I 48, **2** II 116, **2** III 189, **2** IV 112.]
It oxidises a green solution of U(IV) acetate in liquid NH_3 to the yellow U(VI) in a few hours with the formation of the tris complex $(NH_4)U(VI)O_2(AcO)_3$ [isolated], acetamide and Ag metal [Kline & Kershner *Inorg Chem* **5** 932 *1966*, DOI: 10.1021/ic50039a047].
At a 0.2-2 mole%, AgOAc catalyses efficient cycloaddition reactions of methyl isocyanoacetate with olefin

Michael-acceptors at ambient temperature to produce Δ^1- or Δ^2-pyrrolines in good yields. Isocyanoacetates undergo AgOAc catalysed cyclodimerisation to imidazoles in excellent yields in the absence of a suitable olefin. Also, when combined with azomethine ylide, AgOAc catalyses a 1,3-dipolar cycloaddition reaction in a one-pot sequential cascade process to yield the 7-azabicyclo[2.2.1]heptane ring system which is characteristic of the naturally occurring potent non-opioid analgesic epibatidine [originally isolated from the skin of the Ecuadoran poison frog *Epipedobates tricolor*, Spande et al. *J Am Chem Soc* **114** 3475 *1992*, DOI: 10.1021/ja00035a048]. [Grigg et al. *Tetrahedron* **55** 2025 *1999*, DOI: 10.1016/S0040-4020(98)01216-2.]
When combined with I_2, AgOAc in aqueous or anhydrous AcOH reacts with olefins to form ***vicinal diols*** (glycols). The hydroxylations are not always *cis* [Woodward & Brutcher *J Am Chem Soc* **80** 209 *1958*, DOI: 10.1021/ja01534a053; Ginsberg *J Am Chem Soc* **75** 5746 *1953*, DOI: 10.1021/ja01118a515; Barkley et al. *J Am Chem Soc* **76** 5014 *1954*, DOI: 10.1021/ja01649a003; Klass et al. *J Am Chem Soc* **77** 3829 *1955*, DOI: 10.1021/ja01619a04; Slates & Wendler *J Am Chem Soc* **78** 3749 *1956*, DOI: 10.1021/ja01596a054; Jefferies & Milligan *J Chem Soc* 2363 *1956*, DOI: 10.1039/JR9560002363; Gunstone & Morris *J Chem Soc* 487 *1957*, DOI: 10.1039/JR9570000487; Ellington et al. *J Chem Soc* 1327 *1966*, DOI: 10.1039/J39660001327], but can produce *cis/trans* diol mixtures depending on the olefin [Bunton & Carr *J Chem Soc* 770 *1963*, DOI: 10.1039/JR9630000770]. It was used in a novel preparation of highly reflective and conductive silvered polymeric films [Southward et al. *Chem Mater* **11** 501 *1999*, DOI: 10.1021/cm981014v].

Silver bromate *[7783-89-3]* **$AgBrO_3$, M 235.8, m dec on heating, d^{25} 5.28g/cm^3.** It crystallises from hot water (80ml/g). It reacts with bromine water to form bromic acid ($HBrO_3$) which is a strong oxidising agent. Store it in the dark.

Silver bromide *[7785-23-1]* **AgBr, M 187.8, m 432°, d^{25} 6.473g/cm^3, n_D^{25} 2.253.** Purify it from Fe, Mn, Ni and Zn by zone melting in a quartz vessel under vacuum. It is insoluble in dilute HNO_3 or dilute NH_3 but is soluble in concentrated NH_3. Its solubility product in H_2O at 20° is 3.5 x 10^{-13}. Store it in the dark as it is affected by light. Used in photography and as antiseptic.

Silver chlorate *[7783-92-8]* **$AgClO_3$, M 191.3, m 230°, b 250°/atm(dec), d^{25} 4.43g/cm^3.** Recrystallise the chlorate three times from water (10ml/g at 15°; 2ml/g at 80°). Also soluble in EtOH. Store it in the dark. [Nicholson et al. *Inorg Synth* **2** 4 *1946*, DOI: 10.1002/9780470132333.ch2; Glemser & Sauer in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 1037 *1963*.]

Silver chloride *[7783-90-6]* **AgCl, M 143.3, m 455°, b 1547°/atm, d^{25} 5.56g/cm^3, n_D^{25} 2.071.** Recrystallise it from conc NH_3 solution by acidifying with HCl, filtering off the solid, washing it with H_2O and drying it in a vacuum. Its solubility product in H_2O at 20° is 1.2 x 10^{-10}. It is soluble in NH_3 and should be kept in the dark as light decomposes it.

Silver chromate *[7784-01-2]* **Ag_2CrO_4, M 331.8, d^{25} 5.625g/cm^3, pK_1^{25} 0.74, pK_2^{25} 6.49 (for H_2CrO_4), K_{sp} 1.1 x 10^{-12}.** Wash the red-brown powder with H_2O, dry it in a vacuum, then powder well and dry again in a vacuum at 90°/5 hours. Its solubility in H_2O is 0.0014% at 10°, and its solubility product in H_2O at 20° is 1.7 x 10^{-12}. Store it in the dark. [Cardillo & Shimizu *J Org Chem* **42** 4268 *1977*, DOI: 10.1021/jo00862a023.]

Silver cyanide *[506-64-9]* **AgCN, M 133.9, m dec at 320°, d^{25} 3.95g/cm^3.** It is a **POISONOUS** white or greyish white powder. Stir it thoroughly with H_2O, filter, wash well with EtOH and dry it in air in the dark. It is very insoluble in H_2O (0.000023g in 100ml H_2O), but is soluble in HCN or aqueous KCN to form the soluble ***$Ag(CN)_2^{2-}$ complex***. [Schnitz-Dumont *Chem Ber* **72** 298 *1939*, DOI: 10.1002/cber.19390720210; Randall & Halford *J Am Chem Soc* **52** 178 *1930*, DOI: 10.1021/ja01364a026.]

Silver (II) difluoride *[7783-95-1]* **AgF_2, M 145.9, m 690°, b 700°/atm(dec) d^{25} 4.58g/cm^3.** It is highly **TOXIC** because it liberates HF and F_2. It is very ***hygroscopic*** and reacts **violently** with H_2O. It is a powerful oxidising agent and liberates O_3 from dilute acids, and I_2 from I^- solution. Store it in quartz or iron ampoules. It is white when pure; otherwise it is brown-tinged. It is thermally stable up to 700°. [Kwasnik in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 241 *1963*.] [For surface characterization see Wolan & Hoflund *Appl Surf Sci* **125** 251 *1998*, DOI: 10.1016/S0169-4332(97)00498-4].

Silver (I) fluoride *[7775-41-9]* **AgF, M 126.9, m >300°, 435°, b *ca* 1150°, d^{25} 5.855g/cm^3.** The fluoride is a ***hygroscopic*** solid with a solubility in H_2O (g/100ml) of 65.78 (0°), 179.1 (25°) and 213.4 (50°); in MeOH of 1.5 (25°) and 83 (12°), and forms an insoluble basic fluoride in moist air. Purify it by washing with AcOH and dry $*C_6H_6$, then keep it in a vacuum desiccator at room temperature to remove $*C_6H_6$, and store it in opaque glass bottles. The flaky ***hygroscopic*** crystals darken on exposure to light. It *attacks* bone and teeth. [Sharpe *J Chem Soc* 4518 4538 *1952*, DOI: 10.1039/JR9520004518; Kwasnik in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 240 *1963*.]

Silver iodate *[7783-97-3]* **$AgIO_3$, M 282.8, m >200°, b 1150°, d^{25} 5.525g/cm^3.** Wash the iodate with warm dilute HNO_3, then H_2O and dry it at 100°, or recrystallise it from NH_3 solution by adding HNO_3, filtering, washing with H_2O and drying at 100°. It is poorly soluble in H_2O: 0.003g/100ml at 10° and 0.019g/100ml at 50°; and soluble in ammonia.

Silver nitrate *[7761-88-8]* **$AgNO_3$, M 169.9, m 212°, b 444°/atm(dec), d^{25} 4.35g/cm^3, n_D^{25} 1.744.** Purify it by recrystallisation from hot water (solubility of $AgNO_3$ in water is 912g/100ml at 100° and 122g/100ml at 0°). It has also been purified by crystallisation from hot conductivity water by slow addition of freshly distilled EtOH. **CAUTION: avoid using EtOH for washing the precipitate; and avoid concentrating the filtrate to obtain further crops of $AgNO_3$ owing to the risk of EXPLOSION (as has been reported to us) caused by the presence of silver fulminate. When using EtOH in the purification, the apparatus should be enveloped in a strong protective shield.** [Tully, *News Ed (Am Chem Soc)* **19** 3092 *1941*; Henderson & Garin *J Chem Educ* **47** 741 *1970*, DOI: 10.1021/ed047p741; Bretherick, *Handbook of Reactive Chemical Hazards* 4th edn, Butterworths, London, 1985, pp 13-14.] Before being used as a standard in volumetric analysis, analytical reagent grade $AgNO_3$ should be finely powdered, dried at 120° for 2 hours, then cooled in a desiccator. Its solubility in AcOH is 0.776g/Kg (30°), 1.244g/Kg (40°), 5.503g/Kg (93°); in EtOH is 1.3g/100g (19°); in EtOAc is 2.7g/100g (20°); in Me_2CO is 0.35g/100g (14°), 0.44g/100g (18°); and in $*C_6H_6$ is 0.22g/Kg (35°) and 0.44g/Kg (40.5°). [For applications see Fieser **1** 1008, **2** 366, **3** 252, **4** 427, **5** 528, **7** 321, **9** 411, **10** 350, **12** 433.] Recovery of silver residues as $AgNO_3$ **[use protective shield during the whole of this procedure]** can be achieved by washing with hot water and adding 16M HNO_3 to dissolve the solid. Filter this through glass wool and concentrate the filtrate on a steam bath until precipitation commences. Cool the solution in an ice-bath and filter the precipitated $AgNO_3$. Dry it at 120° for 2 hours, then cool it in a desiccator in a vacuum. Store it over P_2O_5 in a vacuum in the dark. ***AVOID contact with hands due to formation of black stains***. It is a standard in volumetric analysis, and is used as a precursor for preparing silver-containing nanomaterials [Zhou et al. *Ind Eng Chem Res* **45(10)** 3503 *2006*, DOI: 10.1021/ie051098z] and complexes [Konno et al. *Chem Lett (Jpn)* **35(3)** 316 *2006*, DOI: 10.1246/cl.2006.316]. Also available as a loading of ~10 wt% on silica gel (+230 mesh).

Silver nitrite *[7783-99-5]* **$AgNO_2$, M 153.9, m 141°(dec), d^{25} 4.45g/cm^3.** Crystallise the salt from hot conductivity water (0.0142g/ml) in the dark. It solubility in H_2O (g/100ml) is 0.155 (0°), 0.275 (15°) and 1.363 (60°). Dry it in the dark under vacuum. [Glemser & Sauer in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 1048 *1963*.] Used in Meyer-type nucleophilic substitution with organic bromides and iodides to form nitro compounds [Kornblum & Ungnade *Org Synth* **38** 75 *1958*, DOI: 10.15227/orgsyn.038.0075], and nitroalkene synthesis with nitryl iodide [Sy & By *Tetrahedron Lett* **26** 1193 *1985*, DOI: 10.1016/S0040-4039(00)98431-4] generated *in situ* from $AgNO_3$ and I_2 [Waldman et al. *Tetrahedron Lett* **37** 7889 *1996*, DOI: 10.1016/0040-4039(96)01807-2].

Silver(I) oxide *[20667-12-3]* **Ag_2O, M 231.7, m >200°(dec), d^{25} 7.13g/cm^3, K_{sp} 1.52 x 10^{-8}(20° AgOH).** Leach the oxide with hot water in a Soxhlet apparatus for several hours to remove any entrained electrolytes. Its solubility in H_2O is 0.013g/L (20°), 0.025g/L (40°) and 0.053g/L. [Glemser & Sauer in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **II** p 1037 *1965*, for applications see Fieser **1** 1011, **2** 368, **3** 252, **4** 430, **5** 583, **6** 515, **7** 321, **8** 442, **10** 350, **11** 468.]

Silver (I, III) oxide *[1301-96-8]* **AgO, M 123.9, m >100°(dec), d^{25} 7.48g/cm^3.** It is soluble in 40,000 parts of H_2O, and should be protected from light. Stir it with an alkaline solution of potassium peroxysulfate ($K_2S_2O_8$) at 85-90°. The black AgO is collected, washed free from sulfate with H_2O made slightly alkaline and dried in air in the dark. [Hammer et al. *Inorg Synth* **4** 12 *1953*, DOI: 10.1002/9780470132357.ch3.]

Silver perchlorate monohydrate *[14242-05-8 (H_2O)*, 331717-44-3 *(xH_2O), 7783-93-9 (anhydrous)]* **$AgClO_4$, M 207.3, pK^{25} -2.4 to -3.1 (for $HClO_4$).** Reflux it with *benzene (6ml/g) in a flask fitted with a Dean and Stark trap until all the water is removed azeotropically (*ca* 4 hours). The solution is cooled and diluted with dry pentane (4ml/g of $AgClO_4$). The precipitated $AgClO_4$ is filtered off and dried in a desiccator over P_2O_5 at 1mm for 24 hours [Radell et al. *J Am Chem Soc* **83** 3958 *1961*, DOI: 10.1021/ja01480a007]. It has also been recrystallised from perchloric acid. [**Caution** *due to its* **EXPLOSIVE** *nature in the presence of organic matter*.] Store it in the dark. [For applications see Fieser **2** 369, **3** 121, **4** 432, **5** 585, **6** 69, **6** 518, **7** 142, **9** 413, **10** 354, **11** 469, **15** 121, **16** 300.]

Silver permanganate *[7783-98-4]* **$AgMnO_4$, M 226.8, m >160°(dec), d^{25} 4.27/cm^3.** The salt forms violet crystals which can be recrystallised from hot H_2O (solubility is 5.5g/L at 0° and 16.9g/L at 30°. Store it in the dark. This oxidising agent is decomposed by light. [Lux in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 1463 *1963*, for crystal structure see Boonstra *Acta Cryst Section B* **24** (8) 1053 *1968*, DOI: 10.1107/S0567740868003699]

Silver perrhenate (silver tetraoxorhenate) *[20654-56-2]* **$Ag(ReO_4)$, M 358.1, m 430°, d^{25} 7.05/cm^3, pKa -1.25.** It is prepared by adding slowly, with ice cooling, H_2O_2 (35%, 100ml) to a stirred suspension of Re powder (10g, 54mmol) in H_2O (20ml) during 4 hours, stirring at ~25° for 30 minutes, and then at 80° for 3 hours. The mixture is filtered from a small amount of insoluble material, and the clear solution is treated with $Ag(NO_3)$ (10g, 59mmol), when $Ag(ReO_4)$ immediately separates as a white precipitate which is filtered off, washed with Et_2O (3 x 25ml) to remove H_2O and H_2O_2, and dried *in vacuo* to give the silver salt (18.7g, 97%). [Herrmann & Kratzer *Inorg Synth* **33** 111 *2002*, DOI: 10.1002/0471224502.ch2; Herrmann et al. *Angew Chem Int Ed* **36** 2652 *1997*, DOI: 10.1002/anie.199726521.]

Silver sulfate *[10294-26-5]* **Ag_2SO_4, M 311.8, m 652°, b 1085°/atm(dec), d^{25} 5.45/cm^3.** Crystallise the sulfate form hot concentrated H_2SO_4 containing a trace of HNO_3, and dilute with H_2O while being strongly cooled. The precipitate is filtered off, washed with H_2O and dried at 120°. Its solubility in H_2O is 0.8% at 17°, and 1.46% at 100°. Store it in the dark. [Glemser & Sauer in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **II** p 1042 *1965*.] [Fieser **1** 1015, **3** 254, **4** 435.]

Silver thiocyanate *[1701-93-5]* **AgSCN, M 165.9, m 265°(dec), d_4^{20} 3.746, pK^{25} -1.85 (for HSCN).** Digest the solid salt with dilute aqueous NH_4NCS, filter, wash it thoroughly with H_2O and dry it at 110° in the dark. It is soluble in dilute aqueous NH_3. *Alternatively*, dissolve it in strong aqueous NH_4NCS solution, filter and dilute with large volumes of H_2O when the Ag salt separates. The solid is washed with H_2O by decantation until free from NCS^- ions, collected, washed with H_2O, EtOH and dried in an air oven at 120°. It has also been purified by dissolving in dilute aqueous NH_3 when single crystals are formed by free evaporation of the solution in air. Store it in the dark. [Garrick & Wilson *J Chem Soc* 835 *1932*, DOI: 10.1039/JR9320000835; Occleshaw *J Chem Soc* 2404 *1932*, DOI: 10.1039/JR9320002404; IR and Raman: Kinell & Strandberg *Acta Chem Scand* **13** 1607 *1957*, DOI: 10.3891/acta.chem.scand.13-1607; Lindqvist *Acta Cryst* **10** 29 *1957*, DOI: 10.1107/S0365110X57000067; *Beilstein* **3** IV 303.]

Sodium (metal) *[7440-23-5]* **Na, M 23.0, m 97.5°, 97.794°, 97.8°, b 882.94°/atm, d^{25} 0.968/cm^3.** The metal is placed on a coarse grade of sintered-glass filter, melted under vacuum and forced through the filter using argon. The Pyrex apparatus is then re-evacuated and sealed off below the filter, so that the sodium could be distilled at 460° through a side arm and condenser into a receiver bulb which is then sealed off [Gunn & Green *J Am Chem Soc* **80** 4782 *1958*, DOI: 10.1021/ja01551a008]. [Fieser **1** 1022, **4** 437, **5** 589, **7** 324, **13** 277.] **EXPLODES and IGNITES in water.**

Sodium amide *[7782-92-5]* **$NaNH_2$, M 39.0, m 210°, b 400°/atm, d^{25} 1.39/cm^3, pKa 38 (conjugate acid).** It reacts *violently* with H_2O and is soluble in liquid NH_3 (1% at 20°). It should be stored in wax-sealed containers in small batches. It is very ***hygroscopic*** and absorbs CO_2 and H_2O. If the solid is discoloured by being yellow or brown in colour, then it should be destroyed as it can be highly **EXPLOSIVE.** It should be replaced if discoloured. It is best destroyed by covering it with much toluene and slowly adding dilute EtOH with stirring until all the ammonia is liberated (FUME CUPBOARD). [Dennis et al. *Inorg Synth* **1** 74 *1939*, DOI: 10.1002/

9780470132326.ch25; Schenk in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 465 *1963*, Bergstrom *Org Synth* Coll Vol **3** 778 *1955*, DOI: 10.15227/orgsyn.020.0086; Fieser **1** 1034, **2** 373, **4** 439, **5** 591, **6** 525, **8** 446, **13** 278, **14** 284, **15** 288.]

Sodium ammonium hydrogen phosphate *[13011-54-6, 7783-13-3 (4H_2O)]* **$NaNH_4HPO_4$, M 209.1(anhydr), m 79°(dec), 80°(dec), d^{25} 1.544/cm^3.** Crystallise it from hot water (1ml/g).

Sodium arsenate heptahydrate *[10048-95-0]* **Na_2HAsO_4. 7H_2O, M 312.0(hydrate), m 50° (loses 5H_2O), m 130°, d_4^{20} 1.88 pK_1^{25} 2.22, pK_2^{25} 6.98 (for H_3AsO_4).** Crystallise it from water (2ml/g). [For arsenic and arsenic compounds see Grund et al. *Ullmann's Encyclopedia of Industrial Chemistry 2005,* Wiley-VCH, Weinheim, DOI: 10.1002/14356007.a03_113].

Sodium azide *[26628-22-8]* **NaN_3, M 65.0, m 300°(dec, explosive), pK^{25} 4.72 (for HN_3).** Crystallise sodium azide from hot water or from water by adding absolute EtOH or acetone. Also purify it by repeated crystallisation from an aqueous solution saturated at 90° by cooling it to 10°, and adding an equal volume of EtOH. The crystals are washed with acetone, and the azide is dried at room temperature under vacuum for several hours in an Abderhalden pistol. Its solubility in H_2O is 42% at 18°, and in EtOH it is 0.22% at 0°. [Das et al. *JCS Faraday Trans 1* **78** 3485 *1982*, DOI: 10.1039/F19827803485; Schenk in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** pp 474-475 *1963*, Browne et al. *Inorg Synth* **1** 79 *1939*, DOI: 10.1002/9780470132326.ch27; Miller et al. *Inorg Synth* **2** 139 *1946*, DOI: 10.1002/9780470132333.ch40.] Used also for the efficient 1,4-addition of azide to a α,β-unsaturated aldehydes in the presence of tertiary amines [Kim & Park *Synth Commun* **37** 1027 *2007*, DOI: 10.1080/00397910601168306]. **HIGHLY POISONOUS and potentially explosive.**

Sodium bicarbonate *[144-55-8]* **$NaHCO_3$, M 84.0, m ~50°(dec, -CO_2),), b 851°, d^{25} 2.20/cm^3, n_D^{25} 1.3344. pK_1^{25} 6.35, pK_2^{25} 10.33 (for carbonic acid).** Crystallise it from hot water. Its solubility in H_2O is 69g/L (0°), 165g/L (60°) and 236g/L (100°); and 0.02 %wt in Me_2CO; 2.13 %wt in MeOH, and insoluble in EtOH. The solid should not be heated above 40° due to the formation of carbonate. [For the solubilities of sodium carbonate and sodium bicarbonate in acetone-water and methanol-water mixtures see Ellingboe & Runnels *J Chem Eng Data* **11**(3) 323 *1966*, DOI: 10.1021/je60030a009.]

Sodium bisulfite *[7631-90-5]* **$NaHSO_3$, M 104.1, d^{25} 1.48/cm^3.** Crystallise it from hot H_2O (1ml/g). Dry it at 100° under vacuum for 4 hours. It dehydrates on warming to give a solid which is sodium metabisulfite $Na_2S_2O_5$ ($2NaHSO_3 - 2H_2O$). An aqueous solution of ***sodium metabisulfite*** is in fact a solution of ***sodium bisulfite***.

Sodium borate (borax) *[1330-43-4]* **$Na_2B_4O_7$, M 201.2, m 741°, d^{25} 2.367/cm^3.** Most of the water of hydration is removed from the ***decahydrate*** (see below) by evacuation at 25° for three days, followed by heating to 100° and evacuation with a high-speed diffusion pump. The dried sample is then heated gradually to fusion (above 966°), allowed to cool gradually to 200°, then transferred to a desiccator containing P_2O_5 [Grenier & Westrum *J Am Chem Soc* **78** 6226 *1956*, DOI: 10.1021/ja01605a004]. [Becher in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** pp 794-795 *1963*, Fieser **4** 461, **15** 295.]

Sodium borate (decahydrate, hydrated borax) *[1303-96-4]* **$Na_2B_4O_7$. 10H_2O, M 381.2, m 75°(loses 5H_2O at 60°), d^{25} 1.73/cm^3.** Crystallise the borate from water (3.3ml/g), keeping below 55° to avoid formation of the pentahydrate. Filter it off at the pump, wash it with water and equilibrate it for several days in a desiccator containing an aqueous solution saturated with respect to sucrose and NaCl. Borax can be prepared more quickly (but its water content is somewhat variable) by washing the recrystallised material at the pump with water, followed by 95% EtOH, then Et_2O, and dried in air at room temperature for 12-18 hours on a clock glass. [Becher in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** pp 794-795 *1963*.]

Sodium borohydride *[16940-66-2]* **$NaBH_4$, M 37.8, m ~400°(dec), b 500°/atm(dec), d^{25} 1.0740/cm^3.** After adding $NaBH_4$ (10g) to freshly distilled diglyme (120ml) in a dry three-necked flask fitted with a stirrer, nitrogen inlet and outlet, the mixture is stirred for 30 minutes at 50° until almost all of the solid has dissolved. Stirring is

stopped, and, after the solid has settled, the supernatant liquid is forced under N_2 pressure through a sintered-glass filter into a dry flask. [The residue is centrifuged to obtain more of the solution which is added to the bulk.] The solution is cooled slowly to 0° and then decanted from the white needles that separated. The crystals are dried by evacuating for 4 hours to give anhydrous $NaBH_4$. *Alternatively*, after the filtration at 50° the solution is heated at 80° for 2 hours to give a white precipitate of substantially anhydrous $NaBH_4$ which is collected on a sintered-glass filter under N_2, then evacuated at 60° for 2 hours [Brown et al. *J Am Chem Soc* **77** 6209 *1955*, DOI: 10.1021/ja01628a044].
$NaBH_4$ has also been crystallised from isopropylamine by dissolving it in the solvent at reflux, cooling, filtering and allowing the solution to stand in a filter flask connected to a Dry-ice/acetone trap. After most of the solvent has passed over into the cold trap, crystals are removed with forceps, washed with dry diethyl ether and dried under vacuum. [Kim & Itoh *J Phys Chem* **91** 126 *1987*, DOI: 10.1021/j100285a029.] Somewhat less pure crystals were obtained more rapidly by using Soxhlet extraction with only a small amount of solvent and extracting for about 8 hours. The crystals that formed in the flask are filtered off, then washed and dried as before. [Stockmayer et al. *J Am Chem Soc* **77** 1980 *1955*, DOI: 10.1021/ja01612a082.] Other solvents in which it is soluble include H_2O (but reacts vigorously with it, but less if alkaline, stable at ~pH 14), MeOH (13g/100ml, but reacts slowly with it), EtOH (3.16g/100ml, reacts very slowly with it), diglyme (5.15g/100ml), liquid NH_3, amines and pyridine, but is almost insoluble in Et_2O. It is destroyed by acids and liberates H_2. [Banfi et al. Sodium Borohydride in *Encyclopedia of Reagents for Organic Synthesis* (L. Paquette ed) *2004*, J. Wiley & Sons, NY, DOI:10.1002/047084289X.rs052.] Also commercially available in 2-methoxyethyl ether (0.5M), ~12 wt% in 14M NaOH, in tetraglyme (3.0M), in triethylene glycol dimethyl ether (2.0M) and on alumina (~10 wt% loading).

Sodium bromate *[7789-38-0]* **$NaBrO_3$, M 150.9, m 381°, d^{25} 3.339/cm^3.** It is crystallised from hot water (1.1ml/g) to decrease contamination by NaBr, bromine and hypobromite. [Noszticzius et al. *J Am Chem Soc* **107** 2314 *1985*, DOI: 10.1021/ja00294a019; Fieser **1** 1055.]

Sodium bromide *[7647-15-6]* **NaBr, M 102.9, m 747°, 755°, b 1390°/atm, d_4^{20} 3.2.** Crystallise the bromide from water (0.86ml/g) between 50° and 0°, and dry it at 140° under vacuum (this purification may not eliminate chloride ion). [Fieser **12** 445.]

Sodium carbonate (soda ash) *[497-19-8 (anhydrous), 5968-11-6 (H_2O), 6132-02-1 ($10H_2O$)]* **Na_2CO_3, M 106.0, m 851°(anhydr, dec), 858°(anhydr, dec), 100°(H_2O, dec), 33.5°($7H_2O$, dec), 34°($10H_2O$, dec), d^{25} 2.54/cm^3(anhydr), n_D^{25} 1.487 (anhydrous), n_D^{25} 1.420 (H_2O), n_D^{25} 1.405 ($10H_2O$), pK_1^{25} 6.35, pK_2^{25} 10.33 (for carbonic acid).** It crystallises from water as the ***decahydrate*** which is redissolved in water to give a near-saturated solution. By bubbling CO_2, $NaHCO_3$ is precipitated. It is filtered off, washed and ignited for 2 hours at 280° [MacLaren & Swinehart *J Am Chem Soc* **73** 1822 *1951*, DOI: 10.1021/ja01148a121]. Before being used as a volumetric standard, analytical grade material should be dried by heating at 260-270° for 0.5 hour and allowed to cool in a desiccator. It has a transition point at 450°, and its solubility in water is 21.58% at 20° (***decahydrate*** in solid phase), 49.25% at 35° (***heptahydrate*** in solid phase) and 44.88% at 75° (***monohydrate*** in solid phase) [Dönges in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 987-988 *1963*]. After three recrystallisations, technical grade Na_2CO_3 had Cr, Mg, K, P, Al, W, Sc and Ti at 32, 9.4, 6.6, 3.6, 2.4, 0.6, 0.2 and 0.2 ppm respectively; another technical source had Cr, Mg, Mo, P, Si, Sn and Ti at 2.6, 0.4, 4.2, 13.4, 32, 0.6, 0.8 ppm respectively.

Sodium chlorate *[7775-09-9]* **$NaClO_3$, M 106.5, m 248°, 248-261°, b >300°(dec), d^{25} 2.50g/cm^3, n_D^{20} 1.515.** It is crystallised from hot water [solubility: 0.79g/ml (0°), 1.06g/ml (25°), 1.25g/ml (40°) and 2.20g/ml (100°)]. A strong oxidising agent, and should be kept clear from organic matter. [Preparation: Scott & Allen *Org Synth* Coll Vol **2** 128 *1943*, DOI: 10.15227/orgsyn.018.0015; Fieser **1** 1056.] It is used for tanning leather, as a herbicide and a sulfation biosynthesis inhibitor.

Sodium chloride (Rock salt) *[7647-14-5]* **NaCl, M 58.4, m 800.7°, b 1413°/atm, d^{25} 2.165g/cm^3, n_{589}^{25} 1.5442.** Recrystallise from a saturated aqueous solution (2.7ml/g) by passing in HCl gas, or by adding EtOH or acetone. It can be freed from bromide and iodide impurities by adding chlorine water to an aqueous solution and boiling it for some time to expel free bromine and iodine. Traces of iron can be removed by prolonged boiling

of solid NaCl in 6M HCl; the crystals are then washed with EtOH and dried at *ca* 100°. Sodium chloride has been purified by sublimation in a stream of pre-purified N_2 and collected by electrostatic discharge [Ross & Winkler *J Am Chem Soc* **76** 2637 *1954*, DOI: 10.1021/ja01639a010]. For use as a primary analytical standard, analytical reagent grade NaCl should be finely ground, dried in an electric furnace at 500-600° in a platinum crucible, and allowed to cool in a desiccator. For most purposes, however, drying at 110-120° is satisfactory. Its solubility (g/kg at 25°) in H_2O is 360, in formamide is 94.0, in glycerine is 83.0, in propylene glycol is 71.0, in formic acid is 52.0, in liq NH_3 is 30.2, in MeOH is 14.0, in EtOH is 0.65, in DMF is 0.4, in *n*-PrOH is 0.124, in sulfolane is 0.05, in *n*-BuOH is 0.05, in 2-PrOH is 0.03, in 1-pentanol is 0.018, in MeCN is 0.003 and in Me_2CO is 0.00042.

Sodium chlorite *[7758-19-2, 49658-21-1 ($3H_2O$)]* **$NaClO_2$, M 90.4(anhydr), m 180-200°(dec), d ^{25} 2.468g/cm^3, pKa 10.11 ($HClO_2$)**. Crystallise the chlorite from hot water and store it in a cool place. It has also been crystallised from MeOH by counter-current extraction with liquid ammonia [Curti & Locchi *Anal Chem* **29** 534 *1957*, DOI: 10.1021/ac50162a033]. A major impurity is chloride ion which can be removed by recrystallisation from 0.001M NaOH. [Schmeisser in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 312 *1963*, for applications see Fieser **9** 423, **11** 481, **13** 280.]

Sodium chromate tetrahydrate *[10034-82-9 ($4H_2O$), 7775-11-3]* **Na_2CrO_4, M 234.0($4H_2O$), 162.0(anhydr), m ~20°(for $10H_2O$), 792°(anhydr), d ^{25} 2.698g/cm^3, pK $_1^{25}$ 0.74, pK $_2^{25}$ 6.49 (for H_2CrO_4).** Crystallise the yellow chromate from hot water [solubility is 0.32g/ml (0°), 0.85g/ml (25°) and 1.27g/ml (100°)]. It is ***deliquescent***. [Fieser **5** 605.] Useful anti-rust in paints.

Sodium cyanate *[917-61-3]* **NaOCN, M 65.0, m 550°, d ^{25} 1.893g/cm^3, pK^{25} 3.47 (for HCNO).** It forms colourless needles from EtOH (0.22g/100ml at 0°). Its solubility in EtOH is 0.22g/100g at 0°. It is soluble in H_2O (11.6g/100ml at 25°), but can be recrystallised from small volumes of it. [*Beilstein* **3** IV 80.]

Sodium cyanide *[143-33-9]* **NaCN, M 49.0, m 563.7°, b 1496°/atm, d ^{25} 1.5955g/cm^3, n $_D^{25}$ 1.452, pK^{25} 9.216 (for HCN).** NaCN can be purified in the same way as KCN (*[151-50-8]* above). It has also been prepared by bubbling HCN gas through an alcoholic solution of NaOH. This white solid is slightly ***more soluble*** in H_2O ***than KCN***, with solubilities of 48.15g/100ml at 10° and 63.7g/100ml at 25°. It has some solublility in MeOH, EtOH and NH_3, is slightly soluble in DMF and SO_2 but is insoluble in DMSO. Because it is the salt of a weak acid it hydrolyses in aqueous solution generating HCN (***prussic acid*** see *[74-90-8]*) in the equilibrium, which is liberated into the air, consequently it has the odour of HCN (bitter almonds). ***Note*** that some individuals (genetic varients) cannot smell this odour (the HCN molecule does not span across their olfactory sensors) so should take great care when working with compounds that liberate HCN. Earlier chemists with this olfactory deficiency smoked tobacco pipes near the equipment because the HCN vapours sucked through the pipes produced a foul taste in the mouth. Cyanides, and particularly HCN are extremely poisonous, readily absorbed in the mouth, the lethal dose is of the order of 150-300mg, depending on the individual. It is a repiratory inhibitor, blocks electron transport by acting on mitochondrial cytochrome oxidase, leading to anaerobic metabolism and lactic acidosis. This is evidenced by the blue colouration of the face and body. NaCN (and KCN) is used in gold mining as it forms water soluble ***Na[Au(CN_2)] complex***, in fumigation for insects and vermin by releasing HCN, in electroplating baths and in case hardening of steel. [For applications see Fieser **4** 446, **5** 606, **6** 535, **7** 333, **8** 453, **13** 185.]

Sodium cyanoborohydride *[25895-60-7]* **$NaBH_3CN$, M 62.8, m 240-242°(dec), d^{28} 1.199 g/cm^3.** It is a very ***hygroscopic*** solid, soluble in H_2O (212g/100ml at 29°, 121g/100ml at 88°), tetrahydrofuran (37g/100ml at 28°, 42.2g/100ml at 62°), very soluble in MeOH, slightly soluble in EtOH, but insoluble in Et_2O, *C_6H_6 and hexane. It is stable to acid up to pH 3 but is hydrolysed in 12N HCl. The rate of hydrolysis at pH 3 is 10^{-8} times that of $NaBH_4$. The fresh commercially available material is usually sufficiently pure. If very pure material is required, one of the following procedures can be used [Lane *Synthesis* 135 *1975*, DOI: 10.1055/s-1975-23685]: **(a)** The $NaBH_3CN$ is dissolved in tetrahydrofuran (20% w/v), filtered and the filtrate is treated with a fourfold volume of CH_2Cl_2. The solid is collected and dried in a vacuum [Wade et al. *Inorg Chem* **9** 2146 *1970*, DOI: 10.1021/ic50091a036]. **(b)** $NaBH_3CN$ is dissolved in dry $MeNO_2$, filtered, and the filtrate is poured into a 10-fold volume of CCl_4 with vigorous stirring; the white precipitate is collected, washed several times with CCl_4

and dried in a vacuum (yield 75%) [Berschied & Purcell *Inorg Chem* **9** 624 *1970*, DOI: 10.1021/ic50085a039].
(c) When the above procedures fail to give a clean product, then dissolve $NaBH_3CN$ (10g) in tetrahydrofuran (80ml) and add N MeOH/HCl until the pH is 9. Pour the solution with stirring into dioxane (250ml). The solution is filtered and heated to reflux. A further volume of dioxane (150ml) is added slowly with swirling. The solution is cooled slowly to room temperature, then chilled in ice and the crystalline dioxane complex is collected, dried in a vacuum for 4 hours at 25°, then 4 hours at 80° to yield the amorphous dioxane-free powder (6.7g) with purity >98% [Borch et al. *J Am Chem Soc* **93** 2897 *1971*, DOI: 10.1021/ja00741a013]. The purity can be checked by iodometric titration [Lyttle et al. *Anal Chem* **24** 1843 *1952*, DOI: 10.1021/ac60071a041].
$NaBH_3CN$ is a selective reducing agent [Boesch et al. *J Am Chem Soc* **93** 2897 *1971*, DOI: 10.1021/ja00741a013; Lane *Aldichimica Acta* **8** 3 *1975*], albeit **less powerful than $NaBH_4$** due to the electron withdrawing CN group, but is more stable in aqueous acidic solutions up to pH~3.0. In 12*N* HCl however, it decomposes very rapidly, but at a rate of *ca* 10^{-8} that of $NaBH_4$. It has been used for the reductive amination of aldehydes [Manescalchi et al. *Tetrahedron Lett* **35** 2775 *1994*, DOI: 10.1016/S0040-4039(00)77030-4], ketones [Mattson et al. *J Org Chem* **55** 2552 *1990*, DOI: 10.1021/jo00295a060], reductive alkylation of amines [Balogh et al. *Synth Commun* **24** 701 *1994*, DOI: 10.1080/00397919408012649], and used in the synthesis of a new phenolate-bridged dilanthanum (III) complex [Wang et al. *Inorg Chem* **36** 629 *1997*, DOI: 10.1021/ic960665v]. [See also Fieser, **4** 448, **5** 607, **6** 537, **7** 334, **8** 454, **9** 424, **10** 360, **11** 481, **12** 445, **13** 287, **14** 286, **16** 305.] **POISONOUS, FATAL if swallowed due to cyanide.**

Sodium dichromate *[7789-12-0]* **$Na_2Cr_2O_7$, M 298.0, m 84.6°, 91°($2H_2O$), 356° (anhydrous); b 400°/atm(dec), d $_4^{25}$ 2.348.** Crystallise the dichromate from small volumes of H_2O by evaporation to crystallisation. Its solubility in H_2O is 238% at 0° and 508% at boiling. The red ***dihydrate*** is slowly dehydrated by heating at 100° for long periods. It is ***deliquescent*** and is a powerful oxidising agent—*do not place it in contact with skin— wash immediately as it is* ***caustic.*** (Possible **carcinogen**.)

Sodium dihydrogen orthophosphate dihydrate *[13472-35-0 ($2H_2O$), 10049-21-5 (H_2O), 7558-80-7 (anhydrous)]* **NaH_2PO_4, M 120.0, m 60°(dec), d $_4^{20}$ 1.91.** Crystallise it from warm water (0.5ml/g) by chilling.

Sodium dithionite dihydrate (Reductone, sodium hydrosulfite, hydrolin) *[7631-94-9 ($2H_2O$), 7775-14-6 (anhydrous)]* **$Na_2S_2O_4$, M 174.1(nhydr), 210.1 ($2H_2O$), m 110°(loses $2H_2O$), 267°(dec), d ^{25} 2.38g/cm^3(anhydr), $pK_{Est(1)}$ -3.4, pK $_2^{25}$ 0.49 (for dithionic acid).** Crystallise it from hot water (1.1ml/g) by cooling (solubility at 20°:18.2g/100ml for anhydrous salt and 21.9g/100ml for dihydrate). [Fieser **3** 266, **11** 487.]

Sodium ferricyanide monohydrate *[14217-21-1, 13601-19-9 (anhydrous)]* **$Na_3Fe(CN)_6.H_2O$, M 298.9, pK^{25} <1 (for ferricyanide).** Crystallise the ferricyanide from hot water (1.5ml/g) or by precipitation from 95% EtOH. Solubility in H_2O is 18.9g/100g at 0° and 67g/100g at 100°, and is insoluble in EtOH.

Sodium ferrocyanide decahydrate *[13601-19-9]* **$Na_4Fe(CN)_6.10H_2O$, M 484.1, m 50-80° (loses $10H_2O$), 435°(anhydr, dec), d ^{25} 1.458g/cm^3, n $_D^{25}$ 1.530, pK$_3^{25}$ 2.57, pK$_4^{25}$ 4.35 (for ferrocyanide).** Crystallise the pale yellow solid from hot water until free of ferricyanide as shown by the absence of formation of Prussian Blue colour with ferrous sulfate solution. Its solubility in H_2O is 10.2g/100ml at (10°), 17.6g/100ml at (20°), and 39.7g/100ml at (96.6°).

Sodium fluoride *[7681-49-4]* **NaF, M 42.0, m 993°, 996°, b 1695°/atm, d ^{25} 2.558g/cm^3, n $_D^{25}$ 1.3252.** Crystallise NaF from water by partial evaporation in a vacuum desiccator, or dissolve it in water, and precipitate *ca* half of it by adding EtOH. The precipitate is dried in an air oven at 130° for one day, and then stored in a desiccator over KOH. Its solubility in H_2O is 4% at 15° and 4.3% at 25°. [Kwasnik in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 235 *1963*, Fieser **1** 1073, **2** 382.]

Sodium fluoroborate *[13755-29-8]* **$NaBF_4$, M 109.8, m 384°, d ^{25} 2.47g/cm^3, pK^{25} -4.9 (for fluoroboric acid $H_3O^+BF_4^-$).** Crystallise the fluoroborate from hot water (50ml/g) by cooling to 0°. *Alternatively*, free it from insoluble material by dissolving it in a minimum amount of water; then fluoride ions are removed by adding concentrated lanthanum nitrate in excess. After removing lanthanum fluoride by centrifugation, the supernatant is passed through a cation-exchange column (Dowex 50, Na^+-form) to remove any remaining lanthanum [Anbar

& Guttman *J Phys Chem* **64** 1896 *1960*, DOI: 10.1021/j100841a021]. It has also been recrystallised from anhydrous MeOH and dried in a vacuum at 70° for 16 hours. Keep it dry as it is ***hygroscopic***. [Delville et al. *J Am Chem Soc* **109** 7293 *1987*, DOI: 10.1021/ja00258a008.]

Sodium hexafluorophosphate *[21324-39-0]* **$NaPF_6$, M 167.9, m >200°, d ^{25} 2.369g/cm^3, pK $_1^{25}$ ~0.5, pK $_2^{25}$ 5.12 (for fluoro-phosphoric acid H_2PO_3F).** Recrystallise it from acetonitrile and dry it in a vacuum for 2 days at room temperature. It is an **irritant** and is ***hygroscopic***. [Delville et al. *J Am Chem Soc* **109** 7293 *1987*, DOI: 10.1021/ja00258a008.].]

Sodium hexafluorosilicate *[16893-85-9]* **Na_2SiF_6, M 188.1, d ^{25} 2.7g/cm^3, n $_D^{25}$ 1.312.** Crystallise it from hot water by cooling. Its solubility in H_2O is 0.64g/100ml at (20°), 1.27g/100ml at (50°), and 2.45g/100ml at (100°).

Sodium hexanitrocobaltate III *[13600-98-1]* **$Na_3[Co(NO_2)_6]$, M 403.9, m >220°(dec).** Dissolve the salt (*ca* 60g) in H_2O (300ml), filter to obtain a clear solution, add 96% EtOH (250ml) with vigorous stirring. Allow the precipitate to settle for 2 hours, filter it off, wash it with EtOH (4 x 25ml), twice with Et_2O and dry it in air [Glemser in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **II** p 1541 *1965*]. It forms yellow to brown crystals which are very soluble in H_2O, are decomposed by acid and form an insoluble K salt. Used for estimating potassium.

Sodium hydride *[7646-69-7]* **NaH, M 24.00, m 300°(dec), ~425°(dec), 800°(dec), d ^{25} 1.396g/cm^3, n $_D^{25}$ 1.470.** NaH is a granular grey powder which **ignites** in moist air and should be stored in an inert atmosphere. It is prepared in the laboratory by passing H_2 through a dispersion of Na in an industrial white oil at *ca* 250°. [Mattson et al. *Inorg Synth* **5** 10 *1957*, DOI: 10.1002/9780470132364.ch3]. Like sodium it is very reactive with H_2O liberating hydrogen and NaOH. Fortunately it is commercially available as a 50% to 60% (w/w) dispersion in oil, which protects the NaH from the atmosphere, moderates its reaction with moisture, and can be handled routinely without recourse to using dry box techniques. In this form its reaction with H_2O (and alcohols) can be controlled safely, unlike the dry solid. The oil is freely soluble in petroleum ethers, hexanes, Et_2O, $*C_6H_6$, toluene and THF without affecting NaH reactivity. Removal of the oil is achieved by adding any of these solvents, decanting them off, repeating the process, then adding the desired reaction solvent to cover the NaH. NaH is insoluble in inert organic solvents and in liquid NH_3. When the dispersion is kept for long periods, or if the lid of the container in which it is kept is removed a considerable number of times, the NaH may have deteriorated and the mixture will contain a high percentage of NaOH and/or $NaHCO_3$ or Na_2CO_3. In this case a new batch should be used as laboratory purification is not practicable. The NaH content can, however, be determined by carefully adding H_2O to a known weight of the dispersion oil in a flask and measuring the volume of H_2 released using a manometer. The aqueous solution can then be titrated with standard acid (phenolphthalein indicator) to provide the total Na content. [For many examples of the use of NaH in organic synthesis see Fieser **1** 1075, **2** 382, **4** 452, **5** 610, **6** 541, **7** 335, **8** 458, **9** 427, **12** 447, **14** 288, **16** 307.]

Sodium hydroxide (anhydrous, 'caustic soda') *[1310-73-2]* **NaOH, M 40.0, m 318°, 323°, b 1390°/atm, d ^{25} 2.13g/cm^3, n $_D^{25}$ 1.3576, pK_b 0.2.** Common impurities are water and sodium carbonate. Sodium hydroxide can be purified by dissolving 100g in 1L of pure EtOH, filtering the solution under vacuum through a fine sintered-glass disc to remove insoluble carbonates and halides. (This and subsequent operations should be performed in a dry, CO_2-free box.) The solution is concentrated under vacuum, using mild heating, to give a thick slurry of the mono-alcoholate which is transferred to a coarse sintered-glass disc and evacuated free of mother liquor. After washing the crystals several times with purified alcohol to remove traces of water, they are dried in a vacuum, with mild heating, for about 30 hours to decompose the alcoholate, leaving a fine white crystalline powder [Kelly & Snyder *J Am Chem Soc* **73** 4114 *1951*, DOI: 10.1021/ja01153a019]. **CAUSTIC.**

Sodium hydroxide solutions (*caustic*), NaOH aq, pK^{25} 14.77. Carbonate ion can be removed by passage through an anion-exchange column (such as Amberlite IRA-400; OH^--form). The column should be freshly prepared from the chloride form by slow prior passage of sodium hydroxide solution until the effluent gives no test for chloride ions. After use, the column can be regenerated by washing with dilute HCl, then water. Similarly, other metal ions are removed when a 1M (or more dilute) NaOH solution is passed through a column

of Dowex ion-exchange A-1 resin in its Na^+-form.
Alternatively, carbonate contamination can be reduced by rinsing sticks of NaOH (analytical reagent quality) rapidly with H_2O, then dissolving in distilled H_2O, or by preparing a concentrated aqueous solution of NaOH and drawing off the clear supernatant liquid. (Insoluble Na_2CO_3 is left behind.) Carbonate contamination can be reduced by adding a slight excess of concentrated $BaCl_2$ or $Ba(OH)_2$ to a NaOH solution, shaking well and allowing the $BaCO_3$ precipitate to settle. If the presence of Ba in the solution is unacceptable, an electrolytic purification can be used. For example, sodium amalgam is prepared by the electrolysis of 3L of 30% NaOH with 500ml of pure mercury for cathode, and a platinum anode, passing 15 Faradays at 4Amps, in a thick-walled polyethylene bottle. The bottle is then fitted with inlet and outlet tubes, the spent solution being flushed out by CO_2-free N_2. The amalgam is then washed thoroughly with a large volume of deionised water (with the electrolysis current switched on to minimise loss of Na). Finally, a clean steel rod is placed in contact in the solution with the amalgam (to facilitate hydrogen evolution), reaction being allowed to proceed until a suitable concentration is reached, before being transferred to a storage vessel and diluted as required [Marsh & Stokes *Aust J Chem* **17** 740 *1964*, DOI: 10.1071/CH9640740].

Sodium hypophosphite monohydrate *[10039-56-2]* **$NaH_2PO_2.H_2O$, M 106.0 (see pK of hypophosphorous acid).** Dissolve it in boiling EtOH, cool and add dry Et_2O till all the salt separates. Collect and dry it in vacuum. It is soluble in 1 part of H_2O. It liberates PH_3 on heating and can ***ignite*** spontaneously when heated. The anhydrous salt is soluble in ethylene glycol (33% w/w) and propylene glycol (9.7%) at 25°.

Sodium iodate *[7681-55-2]* **$NaIO_3$, M 197.9, m dec on heating >425°, d^{25} 4.28g/cm^3.** Crystallise sodium iodate from water by cooling. Its solubility in H_2O is 2.5g/100ml at (0°), 9.47g/100ml at (25°), and 32.59g/100ml at (100°); and it is soluble in AcOH, poorly soluble in DMF (0.5g/kg) and insoluble in EtOH.

Sodium iodide *[7681-82-5]* **NaI, M 149.9, m 660°, b 1304°/atm, d_4^{20} 3.67.** Crystallise NaI from water/ethanol solution and dry it for 12 hours under vacuum, at 70°. *Alternatively*, dissolve it in acetone, filter it and cool it to -20°; the resulting yellow crystals are filtered off and heated in a vacuum oven at 70° for 6 hours to remove acetone. The NaI is then crystallised from very dilute NaOH, dried under vacuum, and stored in a vacuum desiccator [Verdin *Trans Faraday Soc* **57** 484 *1961*, DOI: 10.1039/TF9615700484]. [For applications see Fieser **1** 1087, **2** 384, **3** 267, **4** 456, **6** 543, **7** 338, **10** 365, **12** 449, **13** 282, **14** 289.] **Sodium iodide dihydrate** *[13517-06-1]* **NaI. $2H_2O$, M 185.9,** crystallises from concentrated H_2O solution by evaporation and has **d^{25} 2.448g/ml.**

Sodium-mercury amalgam (sodium amalgam) *[11110-52-4]* **Na/Hg, M depends on Na%, m (Na-Hg/m): 0.5%/0°, 1.0%/50°, 1.5%/100°, 2.0%/130°, 2.5%/156°, 3.3%/250°, 4.0%/320°.** The composition of the amalgam depends on the amount of Na added to the Hg. The reaction is exothermic and can be violent on first mixing. Generally 1-3% of Na in Hg is used, but higher amalgams can be obtained or prepared. Amalgams with more than 1% are solids with melting points that increase with the percentage of Na reaching > 360° at > 5% Na.
Unless it has been prepared recently, it is always best to prepare the amalgam afresh. Three general procedures can be adopted. Use a fume cupboard as Hg vapour is **TOXIC**.
Method 1: For a ~1.2% amalgam, clean dry Na (9g) is placed in a 500ml flask with a reflux condenser, covered with dry toluene (20ml), and warmed gently until the Na has melted. Hg is added dropwise (separating funnel) with swirling. The ***exothermic reaction*** during the addition of the first few mls of Hg will cause the toluene to reflux, and Hg is added at such a rate as to keep the toluene refluxing gently. When addition is complete, allow the solvent to evaporate and the amalgam will solidify. ***Note*** that it is low melting (~50°) but will solidify on cooling. The solid amalgam is pulverised in a mortar (under N_2; to avoid spluttering of small quatities of solid Na-Hg, the mortar is covered with a thick filter paper, or cardboard, with a hole in the centre to allow the pestle to go through), and stored away from moisture in a tightly stoppered container. Up to a ~2%Na amalgam can be prepared by this method and using 15.2g Na and 750ml of Hg.
Method 2: To a flask with dry N_2 or argon flushing continuously through it, clean freshly cut Na (22.8g) is added followed by Hg (10ml) from a separating funnel. The flask is warmed gently until the reaction commences then more Hg (total 750g) is added, with shaking, at such a rate as to keep the amalgam molten. After half the Hg is added, the amalgam begins to solidify and should be kept liquid by external heating. When addition is complete,

the molten amalgam is poured (under N_2 or Argon) into a cold mortar and powdered (see Method 1 above). This provides a 3% amalgam. It should be stored as before. A 5%Na amalgam corresponds to a composition of $NaHg_2$, and a 20% amalgam corresponds to a composition of Na_2Hg.
Method 3: This method is convenient and commonly used. To the required volume of Hg in a wide-necked flask continuously flushed with N_2 or Argon, is added Na which is cut into small cubes, *ca* 5mm, and each cube is speared with a pointed glass rod and pushed into the liquid Hg. If traces of metal are not a concern, then it is better to use a stainless steel spike or a long tweezers to pick the Na cubes. A vigorous reaction occurs (perhaps with a flash of light occasionally) as each piece of Na dissolves into the Hg or amalgam. The temperature rises and the amalgam is kept in liquid form by the heat released on adding the Na. Do not allow the amalgam to solidify before all the Na is added. If it does, then heat the flask with a burner to keep the amalgam in a liquid state. To avoid damage from flying pieces of Na resulting from the vigorous reaction, the glass rod or metal pick spearing the Na cubes is inserted through a hole in the centre of a thick cardboard sheet which is placed over the mouth of the flask. The amalgam is then powdered and stored as above.
The amalgams are good reducing agents, and react with H_2O releasing 'nascent H' and H_2, but much less vigorously than Na metal. [Brauer in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **II** p 1802 *1965*, Audrieth *Inorg Synth* Vol **I** 5 *1939*, DOI: 10.1002/9780470132326.ch3; Babcock et al. *Inorg Synth* **1** 10 *1939*, DOI: 10.1002/9780470132326.ch4; Holleman *Org Synth* Coll Vol **1** 554 *1941*, DOI: 10.15227/orgsyn.007.0088; Renfrow & Hauser *Org Synth* Coll Vol **2** 607 *1943*, DOI: 10.15227/org syn.019.0083; Deulofeu & Guerrero *Org Synth* Coll Vol **3** 586 *1955*, DOI: 10.15227/orgsyn.022.0089.]

Sodium metaperiodate (sodium periodate) *[7790-28-5]* **$NaIO_4$, M 213.9, m ~300°(anhydr, dec), d^{25} 3.865g/cm^3(anhydr).** Recrystallise it from hot water. [Willard et al. *Inorg Synth* **I** 168 *1939*, DOI: 10.1002/9780470132326.ch58; Bernays et al. *Inorg Synth* **2** 212 *1946*, DOI: 10.1002/ 9780470132333.ch66.] Useful oxidant; generates quinones *via* glycol cleavage and oxidation of hydroquinones [Daumas et al. *Synthesis* 64 *1989*, DOI: 10.1055/s-1989-27155].

Sodium metasilicate pentahydrate *[10213-79-3 ($5H_2O$), 6834-92-0 (anhydrous)]* **Na_2SiO_3. $5H_2O$, M 122.1 (anhydr), 212.1($5H_2O$), m 1088°, d_4^{20} 2.4.** Crystallise it from aqueous 5% NaOH solution. [Schwartz & Mathis *Z Anorg Allgem Chem* **126** 55 *1923*, DOI: 10.1002/zaac.19231260105.]

Sodium molybdate dihydrate *[10102-40-6]* **Na_2MoO_4. $2H_2O$, M 241.9, m 100°(loses $2H_2O$), 687°(anhydr), d^{25} 3.78g/cm^3, n_D^{25} 1.714, pK^{25} 4.08 (for H_2MoO_4).** Crystallise the white powder from hot water (solubility is 84g/100ml at 100°) by cooling to 0°. It is incompatible with alkali metals and oxidisng agents, e.g. will ***explode*** when in contact with molten Mg, and its reaction with hot Na, K or Li is ***incandescent***. Used in agriculture as a necessary Mo trace element, and in the metal industry as a corrosion inhibitor. [Braithwaite & Haber *Molybdenum: An outline of its Chemistry and Uses. 1994*, Elsevier Science Amsterdam, The Netherlands.]

Sodium nitrate (Chile saltpeter) *[7631-99-4]* **$NaNO_3$, M 85.0, m 307°, b 380°/atm, d^{25} 2.257g/cm^3, n_D^{25} 1.587(trigonal).** Crystallise $NaNO_3$ from hot water (0.6ml/g) by cooling to 0°, or from a concentrated aqueous solution by adding MeOH. Its solubility in H_2O is 73g/100ml at (0°), 91.2g/100ml at (25°), and 180g/100ml at (100°). Dry it under a vacuum at 140°. After two recrystallisations, technical grade sodium nitrate had K, Mg, B, Fe Al, and Li at 100, 29, 0.6, 0.4, 0.2 and 0.2 ppm respectively. (See KNO_3.)

Sodium nitrite *[7632-00-0]* **$NaNO_2$, M 69.0, m 271°, b 320°/atm, d^{25} 2.168g/cm^3, n_D^{25} 1.65.** Crystallise $NaNO_2$ from hot water by cooling to 0°, or from its own melt. Its solubility in H_2O is 71.4g/100ml at (0°), 84.8g/100ml at (25°), and 160g/100ml at (100°); in MeOH it is 4.4g/100ml (25°), in Et_2O it is 0.3g/100ml (25°). Dry it over P_2O_5. (See KNO_2.)

Sodium perborate monohydrate and tetrahydrate (PBS, hydrogen peroxide sodium borate adduct) *[7632-04-4 and 90568-23-3 (anhydrous), 10332-33-9 (H_2O), 10486-00-7 ($4H_2O$)]* **$NaBO_3$. nH_2O, M 99.81 (PBS-1, H_2O), 153.9 (PBS-4, $4H_2O$), m dec (anhydr), 60-65°, 63° ($4H_2O$, melts in its own H_2O then dec at 130-150°), pK^{25} 7.91 [for hypothetical $(H_3BO_3, H_2O_2)^-$ H^+].** The ***perborate*** is prepared by reaction of borax ($Na_2B_4O_7$. $5H_2O$), H_2O_2 and NaOH; and upon recrystallisation from H_2O provides the ***tetrahydrate*** (solubility of 2.3w/v% at 20°) which on gentle heating dehydrates to the ***monohydrate*** (solubility of 1.6w/v% at 20°). They

hydrolyse slowly in H_2O producing H_2O_2 and borate, liberating ~10% and ~15% w/w of oxygen respectively. Oxygen release is rapid >60°, but they are active at lower temperatures (40-60°) in the presence of additives, e.g. acid or tetraacetylethylenediamine. X-ray crystallography showed that the structural unit consists of a cyclic ***dimer anion*** $B_2O_4(OH)_4^{2-}$ where the two boron atoms are joined by two oxo bridges in a chair-shaped 6-membered ring [Carrondo & Skapski *Acta Crystallogr* **34B** 3551 *1978*, DOI: 10.1107/S0567740878011565]. The perborate has oxidising properties and is used in industry as a disinfectant, a bleach in detergents (laundry), cleaning products, dental products, eye drops and is less aggressive than hypochloride in degrading dyes and textiles. [Greenwood & Earnshaw *Chemistry of the Elements* (2nd ed.) *1997*, Butterworth-Heinemann. ISBN 0080379419; JRC European Commission, Institute for Health and Consumer Protection (IHPC), Toxicology and Chemical Substance (TCS), European Chemicals Bureau (ECB), 1-21027 Ispra (VA) Italy, *2007* EUR 22973 EN/2]. [For applications see Fieser **1** 1102, **2** 387, **4** 59, **12** 452, **14** 290, **16** 310.]
Also used as a chemical oxidising agent, e.g. in AcOH as solvent it oxidises *p*-substituted anilines to the respective 4,4'-disubstituted azobenzenes [Mehta & Vakilwala *J Am Chem Soc* **74** 563 *1952*, DOI: 10.1021/ja01122a514; Santurri et al. *Org Synth* **40** 18 *1960*, DOI: 10.15227/orgsyn.040.0018], and shown to be a useful epoxidising agent for quinones including (±) terric acid in high yields [Rashid & Read *J Chem Soc C* 1323 *1967*, DOI: 10.1039/ J39670001323]. **IRRITANT** on skin and if inhaled.

Sodium percarbonate ($Na_2CO_3.\ 1.5H_2O_2$, hydrogen peroxide sodium carbonate adduct) *[15630-89-4]* **$Na_2CO_3.\ 1.5H_2O_2$, M 157.0, dec >120°.** This is not a per-salt, but is crystalline Na_2CO_3 with H_2O_2 of crystallisation with a specific composition. The crystals are consistent in having 1.5 molecules of H_2O_2 for each molecule of Na_2CO_3. It is a stable, inexpensive, a non-toxic source of H_2O_2 that is easily handled in the laboratory. It is prepared by the addition of excess of H_2O_2 (~3 to 15%) to a saturated aqueous solution of analytically pure Na_2CO_3 or $NaHCO_3$ at room temperature, stirring for 30 minutes then absolute EtOH is added. The percarbonate separates as white needle-shaped crystals. These are filtered off, washed with EtOH then Et_2O and dried in air. Its available oxygen content is determined by titration with standard $KMnO_4$ after acidification, and is ~13-15%. [Galwey & Hood *J Phys Chem* **83** 1810 *1979*, DOI: 10.1021/j100477a003.] Its solubility in H_2O at ~25° is ~1 mol/L and the pH is ~10.5. The ***kinetics of thermal decomposition*** have been studied in detail and are autocatalytic, and best represented by the equation $Na_2CO_3.1.5H_2O_2 = Na_2CO_3 + 1.5\ H_2O + 0.75O_2$. [Galwey & Hood *JCS Faraday Trans 1* **78** 2815 *1982*, DOI: 10.1039/F19827802815.] It is a useful oxidising agent; converting nitriles to amides [Kabalka et al. *Synth Commun* **20** 1445 *1990*, DOI: 10.1080/00397919008052860], oxidises α-diketones to dicarboxylic acids [Yang et al. *Synth Commun* **23** 1183 *1993*, DOI: 10.1080/00397919308018595], it promotes the Baeyer-Villiger reaction in TFA at 0° [Olah et al. *Synthesis* 739 *1991*], forms epoxides with olefins, hydroxylates arenes, forms *N*-oxides, and converts sulfides into sulfones [Review: Muzart *Synthesis* 1325 *1995*, DOI: 10.1055/s-1995-4128], and converts selectively primary and secondary alcohols to their respective carbonyl compounds in the presence of catalytic amounts of $K_2Cr_2O_7$ and Adogen 464 [see *72749-59-8*] [Muzart et al. *Tetrahedron Lett* **35** 1989 *1994*, DOI: 10.1016/S0040-4039(00)73029-2; Mohand & Muzart *Synth Commun* **25** 2373 *1995*, DOI: 10.1080/00397919508015440]. It is a useful disinfectant and antiseptic, and is best stored below 10°.
For X-ray crystallography, the crystals were prepared by slowly evaporating in air a solution of Na_2CO_3 in 10% H_2O_2, or in an excess of 15% H_2O_2 or D_2O_2 by standing for 1 hour at -5° before precipitating with EtOH, washing with EtOH and Et_2O, and drying in air. $Na_2{}^{13}CO_3$ was similarly used. The X-ray structure revealed the presence of H_2O_2 molecules hydrogen bonded to the CO_3 ions in the crystal, with two types of H_2O_2 molecules. The IR and Raman spectra of the normal, ^{13}C and ^{2}H isotopically substituted 'percarbonates' are consistent with the X-ray data where the two H_2O_2 sites are different. The IR (nujol, 25°) of $Na_2CO_3.1.5H_2O_2$ has ν_{max} at 3050w, 2900m, 2720sh, 2490s, 2350m, 1550m, 985m, 960s, 973vw, 868w cm^{-1}, and $Na_2CO_3.1.5^2H_2O_2$ has ν_{max} at 2470w, 2210m, 1940sh, 1890s, 1820m, 1130m, 1040s, 1035m, 873vw, 869w, 660m, 635s cm^{-1} [Carrondo et al. *JCS Dalton Trans* 2323 *1977*, DOI: 10.1039/DT9770002323.]

Sodium perchlorate (anhydrous) *[7601-89-0 (anhydrous), 7791-07-3 (H_2O)]* **$NaClO_4$, M 122.4, m 130°(for monohydrate), 468°(anhydrous), d^{25} 2.4994g/cm^3, n_D^{25} 1.4618, pK^{25} -2.4 to -3.1 (for $HClO_4$).** Because its solubility in water is high (2.1g/ml at 15°) and it has a rather low-temperature coefficient of solubility, sodium perchlorate is usually crystallised from acetone, MeOH, water/ethanol or dioxane/water (33g dissolved in 36ml of water and 200ml of dioxane is added). After filtering and recrystallising, the solid is dried under vacuum at

140-150° to remove solvent of crystallisation. Basic impurities can be removed by crystallisation from hot acetic acid, followed by heating at 150°. If $NaClO_4$ is precipitated from distilled water by adding $HClO_4$ to the chilled solution, the precipitate contains some free acid. **EXPLOSIVE.**

Sodium phosphoamidate *[3076-34-4]* **H_2N-P(ONa)$_2$O, M 121.0.** Dissolve it in water below 10°, and acetic acid is added dropwise to pH 4.0 so that the monosodium salt is precipitated. The precipitate is washed with water and Et_2O, then dried in air. Addition of the stoichiometric amount of NaOH to the solution gives the disodium salt, the solution being adjusted to pH 6.0 before use [Rose & Heald *Biochem J* **81** 339 *1961*, DOI: 10.1042/bj0810339].

Sodium-potassium alloy *[11135-81-2]* **Na/K, M depends on composition, liquid.** This is generally in the form of a liquid globule from which an aliquot can be pipetted under dry N_2. It is available commercially in two ratios, *viz* K (78wt%), Na (22 wt%) and K (56 wt%), Na (44 wt%), in ampoules. A fresh *ca* ~5:1 $NaK_{2.8}$ liquid alloy can be prepared from clean K metal (77g, 2.0mol) and clean Na (16g, 0.7mol) by heating gently in xylene (100ml, freshly distilled from Na) until the metals coalesce, then dry oxygen-free diglyme (50ml) is added in order to keep the alloy in one globule (stir with a glass rod). Small globules of the alloy can be united by adding a few drops of *iso*-PrOH to the mixture. Cool to room temperature, and this can be stored under dry N_2 indefinitely. An aliquot can be safely pipetted out from the central globule by syringe equipped with a metal stopcock. The alloy can be more safely disposed of than the Na/Hg alloy, but must be handled carefully as it ignites in moist air. Residues are readily destroyed by a 1:1 muxture of *iso*-PrOH/petroleum ether (b 60-100°). [Ellis & Flom *J Organomet Chem* **99** 263 *1975*, DOI: 10.1016/S0022-328X(00)88455-7; Gilman & Young *J Org Chem* **1**, 315 *1936*, DOI: 10.1021/jo01233a001.] When it reacts, e.g. in THF, to form metal carbonyl anions, and with some hydrocarbons, e.g. cyclopentadienes, diphenyl ether, it always forms the K-metallide, i.e. cyclopentadienylpotassium and C_6H_5K, and not the Na-metallide [Bryce-Smith & Turner *J Chem Soc* 861 *1953*, DOI: 10.1039/JR9530000861; Ziegler & Schnell *Justus Liebigs Ann Chem* **437** 227 *1924*, DOI: 10.1002/jlac.19244370114; Müller & Bunge *Chem Ber* **69** 2164 *1936*, DOI: 10.1002/cber.19360690929].

Sodium pyrophosphate decahydrate (tetrasodium pyrophosphate) *[13472-36-1 ($10H_2O$), 7722-88-5 (anhydrous)]* **$Na_4P_2O_7$. $10H_2O$, M 446.1($10H_2O$), 265.9(anhydr), d ^{25} 2.534g/cm^3, n$_D^{25}$ 1.425, m 988°(anhydr), 79.5°($10H_2O$), pK$_1^{25}$ 1.52, pK$_2^{25}$ 2.36, pK$_3^{25}$ 6.60, pK$_4^{25}$ 9.25 (for pyrophosphoric acid, $H_4P_2O_7$).** Crystallise the salt from hot H_2O and dry it in air at room temperature. Its solubility in H_2O is 2.61g/100ml at (0°), 6.7g/100ml at (25°), and 42.2g/100ml at (100°). Useful buffer, and a laxative.

Sodium selenate *[13410-01-0, 10102-23-5 ($10H_2O$)]* **Na_2SeO_4, M 188.9(anhydr), d ^{25} 3.098g/cm^3, pK$_1^{25}$ ~0, pK$_2^{25}$ 1.66 (for selenic acid, H_2SeO_4).** Crystallise sodium selenate from hot water. [Fehér in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 433 *1963*]. Used in the glass industry to produce a red hue. Also used as a fungicide and insecticide. TOXIC.

Sodium selenite *[10102-18-8]* **Na_2SeO_3, M 172.9, m >350°, 710°(dec), d ^{25} 3.1g/cm^3, pK$_1^{25}$ 2.62, pK$_2^{25}$ 8.32 (for H_2SeO_3).** Crystallise sodium selenite from a saturated aqueous solution where its solubility is 68% at 20° to give the ***pentahydrate*** salt. The solubility at 20° is 85g/100ml of H_2O. This yields the ***anhydrous*** salt on heating at 40°. [Fehér in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 431 *1963*]. It imparts a pink colour to glass which cancels the green colour from Fe impurities. Used as a trace element supplement. TOXIC.

Sodium silicate solution (water glass, sodium trisilicate) *[1344-09-8, 6834-92-0]* **$Na_2Si_3O_7$, M 242.2, d ^{25} 3.1g/cm^3, n$_D^{25}$ 1.52, pK$_1^{25}$ 9.51, pK$_2^{25}$ 11.77 (for silicic acid, H_4SiO_4)** Purify by contact filtration through activated charcoal. Its solubility in H_2O is 2.2g/100ml at (25°) and 160.6g/100ml at (80°). Used to preserve food and eggs; as an adhesive in concrete, stucco, caulking and plasters, automotive repair leaks, e.g. exhaust pipes, as an abrasive in drilling, in detergents and waterproofing.

Sodium sulfate decahydrate (Glauber's salt) *[7727-73-3 ($10H_2O$), 7757-82-6 (anhydrous)]* **Na_2SO_4. $10H_2O$, M 140.0(anhydr), m 32.3°(hydrate, dec), 884° (anhydrous), d ^{25} 2.664g/cm^3 (anhydrous), d ^{25} 1.464 g/cm^3, ($10H_2O$), n$_D^{25}$ 1.468(anhydr), n$_D^{25}$ 1.394($10H_2O$).** Crystallise sodium sulfate from water at 30° (1.1ml/g) by

cooling to 0°. It becomes anhydrous at 32°. The solubility of the ***anhydrous salt*** in H_2O is 4.76g/100ml at (0°), 13.9g/100ml at (20°), and 42.7g/100ml at (100°); and the ***heptahydrate*** is 2.19.5g/100ml at (0°) and 44g/100ml at (20°). Useful for the manufacture of wood pulp, glass industry as a fining agent (removes air bubbles), in textiles, as an inert drying agent for solvents when anhydrous, and for heat storage in solar panels. The ***decahydrate*** was historically used as a laxative. [Fieser **1** 1103.]

Sodium sulfide nonahydrate *[1313-84-4 ($9H_2O$), 1313-82-2 (anhydrous)]* **Na_2S $10H_2O$, M 240.2($9H_2O$), 78.0(anhydr), m ~50(loses H_2O), 950(anhydrous), d ^{25} 1.856g/cm^3 (anhydrous), d ^{25} 1.58g/cm^3 (anhydrous), ($5H_2O$), d ^{25} 1.43g/cm^3 ($9H_2O$), m 50°($9H_2O$, dec), 100°($5H_2O$, dec), 1176° (anhydrous), pK $_1^{25}$ 7.04, pK $_2^{25}$ 11.96 (for H_2S).** Some purification of the pale yellow hydrated salt can be achieved by selecting large crystals and removing the surface layer (contaminated with oxidation products) by washing with distilled water. Other metal ions can be removed from Na_2S solutions by passage through a column of Dowex ion-exchange A-1 resin, Na^+-form. The hydrated salt can be rendered ***anhydrous*** by heating it in a stream of H_2 or N_2 until water is no longer evolved. (The resulting cake should not be heated to fusion because it is readily oxidised.) Recrystallise it from distilled water [Andersson & Azoulay *JCS Dalton Trans* 469 *1986*, DOI: 10.1039/DT9860000469]. ***Note*** that sodium sulfide hydrolyses in H_2O to form NaHS + H_2O, and is therefore alkaline and the solution has the odour of rotten eggs, as does the solid. A 0.1N solution in H_2O is 86% hydrolysed at room temperature. Its solubility in H_2O is 12.4% at 0°, 18.6% at 20° and 39% at 50°. The ***anhydrous*** salt is obtained by allowing it to stand in a vacuum over concentrated H_2SO_4 or P_2O_5 at 45° to start with, then at 30-35° when the salt contains 4% of water. The last traces of water are removed by heating to 700° in a glass or porcelain tube in a stream of H_2 to give pure H_2S. [Fehér in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** pp 358-360 *1963*, for applications see Fieser **1** 1104, **11** 492, **12** 543.] It has found use in the pulp and paper industry, in water treatment to scavange O_2 and precipitate heavy metals, and used in the leather rubber industry.

Sodium sulfite *[7757-83-7]* **Na_2SO_3, M 126.0, m 33.4°($7H_2O$, dec), 500°(anhydr, dec), d ^{25} 2.633g/cm^3, n $_D^{25}$ 1.565, pK $_1^{25}$ 1.82, pK $_2^{25}$ 7.205 (for H_2SO_3).** Crystallise the sulfite from warm water (solubility at 20° is 27%) by cooling to 0°. Also purify it by repeated crystallisation from deoxygenated water inside a glove-box, and finally drying it under vacuum. [Rhee & Dasgupta *J Phys Chem* **89** 1799 *1985*, DOI: 10.1021/j100255a052.] It is a useful reagent for particular photochemical reductions [see Fieser **2** 387]. Used in the pulp and paper industry, as a preservative; also useful in photography to protect developer solutions and for the production of SO_2 by addition of dilute acid.

Sodium tetrametaphosphate *[13396-41-3, 77489-25-9]* **$Na_4P_4O_{12}$, M 429.9, pK $_1^{25}$ 2.60, pK $_2^{25}$ 6.4, pK $_3^{25}$ 8.22, pK $_4^{25}$ 11.4 (tetrametaphosphoric acid, $H_4P_4O_{12}$).** Crystallise it twice from water at room temperature by adding EtOH (300g of $Na_4P_4O_{12}.H_2O$, 2L of water, and 1L of EtOH), wash it first with 20% EtOH then with 50% EtOH and dry it in air [Quimby *J Phys Chem* **58** 603 *1954*, DOI: 10.1021/j150518a006].

Sodium thioantimonate (Schlippe's salt) *[13776-84-6]* **Na_3SbS_4. $9H_2O$, M 481.1, m 87°, b 234°/atm, d ^{25} 1.806g/cm^3.** Crystallise the pale yellow solid from warm water (2ml/g made weakly alkaline with a few drops of dilute aqueous NaOH) by cooling to 0°. It forms a yellow ***nonahydrate*** which readily ***effloresces*** in air. The salt was used for preparing antimony quinsulfide Sb_2S_5 (gold sulfur) on acidification which is used to vulcanise rubber. The antimony (V) sulfide was used as an ***amplifier*** in Ag-based photography, as a flammable component of matches and for the electrodeposition of zinc. [Schenk in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 619 *1963*, and for the crystal structure see Mereiter et al. *Acta Cryst* **35B** 19 *1979*, DOI: 10.1107/S0567740879002442].

Sodium thiocyanate (sodium rhodanate) *[540-72-7]* **NaSCN, M 81.1, m 300°, pK^{25} -1.85 (for HSCN)**. It is recrystallised from EtOH or Me_2CO, and the mother liquor is removed from the crystals by centrifugation. It is very ***deliquescent*** and should be kept in an oven at 130° before use. It can be dried in a vacuum at 120°/P_2O_5 [Partington & Winterton *Trans Faraday Soc* **30** 1104 *1934*, DOI: 10.1039/TF9343001104]. Its solubility in H_2O is 113% at 10°, 178% at 46°, 225.6% at 101.4°; in MeOH 35% at 15.8°, 51% at 48°, 53.5% at 52.3°; in EtOH 18.4% at 18.8°, 24.4% at 70.9°; and in Me_2CO 6.85% at 18.8° and 21.4% at 56° [Hughes & Mead *J Chem Soc* 2282 *1929*, DOI: 10.1039/JR9290002282].
Sodium thiocyanate has also been recrystallised from water, acetonitrile or from MeOH using Et_2O for washing,

then dried at 130°, or dried under vacuum at 60° for 2 days. [Strasser et al. *J Am Chem Soc* **107** 789 *1985*, DOI: 10.1021/ja00290a009.] (The latter purification removes material reacting with iodine.) Sodium thiocyanate solutions can be freed from traces of iron by repeated batch extractions with Et_2O. [For preparation of ***isopropylthiocyanate*** *[625-59-2]* **b 152-153°/atm**, see Shriner *Org Synth* Coll Vol **2** 366 *1943*, DOI: 10.1002/0471264180.os011.27; and for the synthesis of thiaza heterocycles see Allen and van Allan *Org Synth* Coll Vol **3** *76 1955*, DOI: 10.15227/orgsyn.022.0016.]

Sodium thiosulfate pentahydrate (hypo, hydrosulfite) *[10102-17-7 (5HO), 7772-98-7 (anhydrous)]* **$Na_2S_2O_3$. $5H_2O$, M 248.2(H_2O), 158.1°(anhydrous), m 48°(rapid heat), d ^{25} 1.667g/cm^3 (anhydrous), n $_D^{25}$ 1.489, pK $_1^{25}$ 0.6, pK $_2^{25}$ 1.74 (for $H_2S_2O_3$).** Crystallise it from EtOH/H_2O solutions or from water (solubility is 70.1g/100ml at 20° and 231g/100ml at 100°) below 60° by cooling to 0°, and dry it at 35° over P_2O_5 under vacuum. [Foerster & Mommsen *Chem Ber* **57** 258 *1924*, DOI: 10.1002/cber.19240570218.] This salt is used as a secondary standard in volumetric analysis (iodometry) [Kilpatrick *J Am Chem Soc* **45** 2132 *1923*, DOI: 10.1021/ja01662a014], and is used as '**Hypo**' in photography [Hargreaves & Dunningham *J Soc Chem Ind* **42** 147T *1923*, DOI: 10.1002/jctb.5000421517]. The reaction of $Na_2S_2O_3$ with HCl which produces NaCl + S + SO_2 + H_2O is known as the ***Clock Reaction*** because when the S reaches a certain concentration, the solution changes from colourless to pale yellow.

Sodium trimetaphosphate hexahydrate *[7785-84-4]* **$Na_3P_3O_9$. $6H_2O$, M 305.9(anhydr), m 53°($6H_2O$), d ^{25} 2.49g/cm^3 (anhydrous), d ^{25} 1.786g/cm^3 ($6H_2O$), n $_D^{25}$ 1.489 ($6H_2O$), pK $_2^{25}$ 1.64, pK $_3^{25}$ 2.07 (for trimetaphosphoric acid, $H_3P_3O_9$).** It is precipitated from an aqueous solution at 40° by adding EtOH. Its solubility in HO is 22% at ~25°. It is dried in air.

Sodium tripolyphosphate (STPP, tripolyphosphate TPP, sodium triphosphate STP) *[7758-29-4]* **$Na_5P_3O_{10}$, M 367.9, m 622°, pK $_1^{25}$ ~1, pK $_2^{25}$ 2.0, pK $_3^{25}$ 2.13, pK $_4^{25}$ 5.78, pK $_5^{25}$ 8.56 (for tripolyphosphoric acid, $H_5P_3O_{10}$).** Purify it by repeated precipitation from aqueous solution by slow addition of MeOH and dried in air. Also a solution of anhydrous sodium tripolyphosphate (840g) in water (3.8L) is filtered, MeOH (1.4L) is added with vigorous stirring to precipitate $Na_5P_3O_{10}.6H_2O$. The precipitate is collected on a filter, air dried by suction, then left to dry in air overnight. It is crystallised twice more in this way, using a 13% aqueous solution (w/w), and leaching the crystals with 200ml portions of water [Watters et al. *J Am Chem Soc* **78** 4855 *1956*, DOI: 10.1021/ja01600a011]. Similarly, EtOH can be added to precipitate the salt from a filtered 12-15% aqueous solution, the final solution containing *ca* 25% EtOH (v/v). Air drying should be at a relative humidity of 40-60%. Heat and vacuum drying should be avoided. Its solubility in H_2O is 14.5g/100ml at (25°). [Quimby *J Phys Chem* **58** 603 *1954*, DOI: 10.1021/j150518a006; Klement in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 547 *1963*.] This phosphate is used in detergents, ceramics, leather tanning, anti-caking, anticorrosion, antifreeze, textiles, and fermentation.

Sodium tungstate dihydrate *[10213-10-2 ($2H_2O$), 13472-45-2]* **Na_2WO_4. $2H_2O$, M 329.9, m 698°, d ^{25} 4.172g/cm^3 (anhydrous), d ^{25} 3.25g/cm^3 ($2H_2O$), pK $_1^{25}$ 2.20, pK $_2^{25}$ 3.70 (for tungstic acid, H_2WO_4).** The salt crystallises from hot water (0.8ml/g) on cooling to 0°. Its solubility in H_2O is 57.5g/100ml at (0°), 74.2g/100ml at (25°), 96.9g/100ml at (100°). [Grüttner & Jender in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **II** p 1727 *1965*; for applications see Fieser **6** 455, **13** 145, **15** 295.] The oxidation of alkenes and alcohols are catalysed by this salt. Sodium tungstate is known also for its anti-diabetic properties [Dominiguez et al. *J Biol Chem* **278** 42785 *2003*, DOI: 10.1074/jbc.M308334200].

Stannic chloride (tin IV chloride, stannic tetrachloride) *[7646-78-8, 10026-06-9 ($5H_2O$)]* **$SnCl_4$, M 260.5, m -33°, -30.2°, b 114°/760mm, d ^{25} 2.226g/cm^3(anhydrous), d ^{25} 2.04g/cm^3 ($5H_2O$), n $_D^{25}$ 1.512, pK^{25} 14.15 (for aquo Sn^{4+} hydrolysis).** $SnCl_4$ fumes in moist air due to formation of a ***hydrate***. Fractionate it in a ground glass still and store it in the absence of air. Possible impurities are SO_2 and HCl [Baudler in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 729 *1963*]. It forms a solid ***pentahydrate*** *[10026-06-9]* which smells of HCl and is obtained when the ***anhydrous salt*** is dissolved in a small volume of H_2O. Also reflux it with clean mercury or P_2O_5 for several hours, then distil it under (reduced) N_2 pressure into a receiver containing P_2O_5. Finally redistil it. *Alternatively*, distil it from Sn metal under vacuum in an all-glass system and seal off in large ampoules. $SnCl_4$ is available commercially as 1M solutions in CH_2Cl_2 or hexane. It

is a Lewis acid catalyst [Hirabayashi et al. *Chem Lett (Jpn)* **36** 826 *2007*, DOI: 10.1246/cl.2007.826], and stabilises polyaniline (by doping) allowing it to be processed in $MeNO_2$ solution [Kulszewicz-Bajer et al. *Chem Mater* **11** 552 *1999*, DOI: 10.1021/cm980727a]. [Also see Fieser **1** 1111, **3** 269, **5** 627, **6** 553, **7** 342, **9** 436, **10** 370, **11** 522, **12** 486, **13** 300, **14** 304, **15** 311.] **HARMFUL VAPOURS.**

Stannic iodide *[7790-47-8]* **SnI_4, M 626.3, m 144°, b 340°/atm, d ^{25} 4.47g/cm^3.** It is recrystallised from anhydrous $CHCl_3$, dry it under vacuum and store it in a vacuum desiccator. It sublimes at 180°.

Stannic oxide (SnO_2) *[18282-10-5]* **SnO_2, M 150.7, m 1630°, d ^{25} 6.95g/cm^3.** Reflux it repeatedly with fresh HCl until the acid shows no tinge of yellow. The oxide is then dried at 110°. It is abrasive and used for polishing glass, ceramic and metal, and as a mordant in dyeing and textile printing.

Stannous chloride (anhydrous) *[7772-99-8, 10025-69-1 ($2H_2O$)]* **$SnCl_2$, M 189.6, m 247°(anhydr), 37.7°($2H_2O$), b 606°/atm, b 652°/atm,(dec), d ^{25} 3.94g/cm^3(anhydrous), d ^{25} 2.71g/cm^3 ($2H_2O$), pK $_1^{25}$ 1.7, pK $_2^{25}$ 3.7 (for aquo Sn^{2+} hydrolysis).** Analytical reagent grade stannous chloride ***dihydrate*** is dehydrated by adding it slowly to vigorously stirred, redistilled acetic anhydride (120g salt per 100g of anhydride) in a fume cupboard. After *ca* an hour, the ***anhydrous*** $SnCl_2$ is filtered on to a sintered-glass or Büchner funnel, washed free from acetic acid with dry Et_2O (2 x 30ml), and dried under vacuum. It is stored in a sealed container. [Stephen *J Chem Soc* 2783 2786 *1930*, DOI: 10.1039/JR9300002783; Williams *Org Synth* Coll Vol **3** 626 *1955*, DOI: 10.15227/orgsyn.023.0063; Fieser **1** 1113, **3** 389, **5** 631, **6** 554, **11** 521, **13** 298, **15** 309, **16** 329.] Used in tin-plating, dyeing, as a reducing agent, and for many chemical reactions.

Strontium bromide *[10476-81-0, 7789-53-9 ($6H_2O$)]* **$SrBr_2$, M 247.4, m 643°/atm, d ^{25} 4.216g/cm^3(anhydrous), d ^{25} 2.386g/cm^3 ($6H_2O$).** Crystallise the bromide from water (0.5ml/g). It is soluble in EtOH and is *deliquescent*. [Ehrlich in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 930 *1963*.] It is a white crystalline powder that burns bright red in air and is used in flares. [For cystal structure see Sass; et al. *J Phys Chem* **67** 2862 *1963*, DOI: 10.1021/j100806a516].

Strontium chloride hexahydrate *[10025-70-4 ($6H_2O$), 10476-85-4]* **$SrBr_2$. $6H_2O$, M 266.6($6H_2O$), 158.5(anhydr), m 61°(rapid heating), 114-150°(loses $5H_2O$), 868°(anhydrous), b 1250°/atm, d ^{25} 3.052g/cm^3(anhydrous), d ^{25} 1.930g/cm^3 ($6H_2O$), n $_D^{25}$ 1.650(anhydrous), n $_D^{25}$ 1.536 ($6H_2O$).** It crystallises from warm water (solubility of ***hexahydrate*** is 106g/100ml at 0° and 206g/100ml at 40°, and for ***anhydrous salt*** it is 53.8g/100ml at 20°) and cooling to 0°. It ***dehydrates*** at 150-160° in a vacuum. [Ehrlich in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 930 *1963*.] It is used in dental care.

Strontium chromate *[7789-06-2]* **$SrCrO_4$, M 203.6, d ^{25} 3.353g/cm^3, pK $_1^{25}$ 0.74, pK $_2^{25}$ 6.49 (for H_2CrO_4).** Crystallise yellow strontium chromate from water (solubility is 0.12g/100ml at 15° and 3.0g/100ml at 100°) by cooling. The salt is used as a colorant, an inhibitor in pigments, anti-corrosion primer for Zn, Mg, Al and alloys in aircrafts, and in pyrotechnics.

Strontium hydroxide octahydrate *[1311-10-0 ($8H_2O$), 18480-07-4 (anhydrous)]* **$Sr(OH)_2$. $8H_2O$, M 121.6(anhydr), m >100°(loses H_2O), 375°(anhydr), b 710°/atm(anhydr, dec), d ^{25} 3.625g/cm^3(anhydr), d ^{25} 1.90g/cm^3 ($8H_2O$), pK$_b$ -2.19.** Crystallise the hydroxide from hot water (solubility is 0.41g/100ml at 0°, and 1.77g/100ml at 20°, and 21.8g/100ml at 100°) by cooling to 0°. Readily absorbs CO_2 to form $SrCO_3$. ***Deliquescent***. [Georg in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 935 *1963*.] Used in refining beet sugar and as a plastic stabiliser. **IRRITANT.**

Strontium nitrate *[10042-76-9]* **$Sr(NO_3)_2$, M 211.6, m 570°, b 645°/atm (dec), d ^{25} 2.986g/cm^3.** Crystallise it from hot water (solubility of ***tetrahydrate*** is 60.43g/100ml at 0° and 206.5g/100ml at 100°; and of the ***anhydrous*** salt is 71.0g/100ml at 18° and 66.0g/100ml at 20°) by cooling to 0°. Its physiological effects are similar to those of Ca^{2+}, and lessens skin irritations. It burns with a rich red flame in fireworks and road flares.

Sulfamic acid *[5329-14-6]* **NH_2SO_3H, M 97.1, m 205°(dec), pK^{25} 0.99 (NH_2SO_3H).** Crystallise the white

solid from water at 70° (300ml per 25g), after filtering, by cooling a little and discarding the first batch of crystals (about 2.5g) before standing in an ice-salt mixture for 20 minutes. The crystals are filtered off by suction, washed with a small quantity of ice cold water, then twice with cold EtOH and finally with Et_2O. Dry it in air for 1 hour, then store it in a desiccator over $Mg(ClO_4)_2$ [Sisler et al. *Inorg Synth* **2** 176 *1946*, DOI: 10.1002/9780470132333.ch52; for use as standard of reference in acidimitry see Butler et al. *Ind Eng Chem (Anal Ed)* **10** 690 *1938*, DOI: 10.1021/ac50128a011]. For the preparation of primary standard material see *Pure Appl Chem* **25** 459 *1969*. Aqueous solutions are unstable and hydrolyse to ammonium bisulfate, but the crystals are indefinitely stable on normal storage. It is moderately soluble in DMF, slightly soluble in MeOH but insoluble in hydrocarbon solvents. Used for cleaning metals, removing rust and limescale, and household cleaning. [For sulfamic acid and its *N*-substituted derivatives see Benson & Spillane *Chem Rev* **80** 151 *1980*, DOI: 10.1021/cr60324a002.]

Sulfamide *[7803-58-9]* **$(NH_2)_2SO_2$, M 96.1, m 91.5°, 93°, b 250°/atm (dec), d ^{25} 1.611g/cm^3.** Crystallise sulfamide from absolute EtOH. It decomposes at 250°. [Schenk in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** pp 482-483 *1963*, for the role of sulfamide derivatives in Medicinal Chemistry see Reitz et al. A Patent Review (2006 – 2008) *Expert Opinion on Therapeutic Patents* **19** 1449–1453 *2009*, DOI: 10.1517/13543770903185920.]

Sulfur *[7704-34-9]* **S, M 32.1, m between 112.8° and 120°, depending on form.** Murphy, Clabaugh & Gilchrist [*J Res Nat Bur Stand* **64A** 355 *1960*] have obtained sulfur of about 99.999% purity by the following procedure: Roll sulfur was melted and filtered through a coarse-porosity glass filter funnel into a 2L round-bottomed Pyrex flask with two necks. Conc H_2SO_4 (300ml) was added to the sulfur (2.5kg), and the mixture was heated to 150°, stirring continuously for 2 hours. Over the next 6 hours, conc HNO_3 was added in about 2ml portions at 10-15 minutes intervals to the heated mixture. It was then allowed to cool to room temperature and the acid was poured off. The sulfur was rinsed several times with distilled water, then remelted, cooled, and rinsed several times with distilled water again, this process being repeated four or five times to remove most of the acid entrapped in the sulfur. An air-cooled reflux tube (*ca* 40cm long) was attached to one of the necks of the flask, and a gas delivery tube (the lower end about 2.5cm above the bottom of the flask) was inserted into the other. While the sulfur was boiled under reflux, a stream of helium or N_2 was passed through to remove any water, HNO_3 or H_2SO_4, as vapours. After 4 hours, the sulfur was cooled so that the reflux tube could be replaced by a bent air-cooled condenser. The sulfur was then distilled, rejecting the first and the final 100ml portions, and transferred in 200ml portions to 400ml glass cylinder ampoules (which were placed on their sides during solidification). After adding about 80ml of water, displacing the air with N_2, the ampoule was cooled, and the water was titrated with 0.02M NaOH, the process being repeated until the acid content was negligible. Finally, entrapped water was removed by alternate evacuation to 10mm Hg and refilling with N_2 while the sulfur was kept molten. The ampoules were then sealed. Other purifications include crystallisation from CS_2 (which is less satisfactory because the sulfur retains appreciable amounts of organic material), *benzene or *benzene/acetone, followed by melting and degassing. It has also been boiled with 1% MgO, then decanted, and dried under a vacuum at 40° for 2days over P_2O_5. [For the purification of ***S_6***, ***'recrystallised S_8'*** and ***'Bacon-Fanelli sulfur'*** see Bartlett et al. *J Am Chem Soc* **83** 103, 109 *1961*, DOI: 10.1021/ja01462a020.] [For applications see Fieser **1** 1118, **3** 273, **5** 632, **6** 556, **15** 297.]

Sulfur dichloride (sulfur chloride) *[10545-99-0]* **SCl_2, M 103.0, m -121°, -78°, b 59°/760mm(dec), d ^{25} 1.621g/cm^3, n $^{25}_D$ 1.5570.** Distil the red sulfur chloride twice in the presence of a small amount of PCl_3 through a 12in Vigreux column, the fraction boiling between 55-61° being redistilled (in the presence of PCl_3), and the fraction distilling between 58-61° retained. (The PCl_3 is added to inhibit the decomposition of SCl_2 into S_2Cl_2 and Cl_2). The SCl_2 must be used as quickly as possible after distillation — within 1 hour at room temperature. The sample contains 4% of S_2Cl_2. On long standing this reaches 16-18%. [Fehér in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** pp 370-372 *1963*.] It hydrolyses with release of HCl, and old samples contain Cl_2. **HARMFUL VAPOURS.**

Sulfur dioxide *[7446-09-5]* **SO_2, M 64.1, m -73°, -72°, b -10°/atm, d ^{25} 2.6288g/cm^3.** Dry the pungent irritating gas by bubbling through conc H_2SO_4 and by passage over P_2O_5, then through a glass-wool plug. Freeze it with liquid air and pump it to a high vacuum to remove dissolved gases. It is easily liquefied by

compression (2.5 atmospheres at 15°), or by passing it through a glass spiral column in a freezing mixture of ice and salt. It is a colourless liquid with a density of 1.434 at 0°, which on rapid evaporation forms a snow white solid. It has been used as a solvent in certain reactions, a reducing agent, a refrigerant, in wine making, and is a physiologically active compound and an air pollutant. **HARMFUL SUFFOCATING VAPOURS.**

Sulfurous acid *[7782-99-2]* **H_2SO_3, M 82.0, d ^{25} 1.03g/cm^3, pK $_1^{25}$ 1.857, pK $_2^{25}$ 7.172,** is a weak acid obtained by bubbling SO_2 through H_2O, and a *ca* 6% solution is available commercially. It is a reducing agent (e.g. reducing I_2 to iodide), used for making sulfites and bisulfites, a disinfectant and a mild bleaching agent. [For 'Generation and Characterization of Sulfurous Acid (H_2SO_3) and of Its Radical Cation as Stable Species in the Gas Phase' see Sülzle et al. *Angew Chem Int Ed* **27** 1533 *1988*, DOI: 10.1002/anie.198815331.]

Sulfuric acid (oil of vitriol) *[7664-93-9]* **H_2SO_4, M 98.08, d $_4^{20}$ 1.836 (96-98%), 1.805 (100%), m 3.0° (98%), 10.36° (100%), b 330.0 ±0.5°/atm (100%), dec > 340.0°, *dihydrate* M 134.11, m -38.9°, b 167°/atm, d ^{25} 1.84g/cm^3, pK $_1^{25}$ ~ -8.3, pK $_2^{25}$ 1.99.** Sulfuric acid, and also 30% fuming H_2SO_4, can be distilled in an all-Pyrex system, optionally from potassium persulfate. It has been purified by fractional crystallisation of the ***monohydrate*** from the liquid. It has a very strong dehydrating action and attacks skin—wash immediately with cold H_2O ***and protect eyes***; otherwise the skin can be scarred for life ***and could be blinding***. It causes tissues and paper to char. It is very ***hygroscopic*** and has been used as a desiccant in desiccators. *Dilution with H_2O is highly exothermic, and because the concentrated acid is much more dense than H_2O it is diluted by running the concentrated acid down the side of the container of H_2O with slow stirring while cooling the outside of the container in an ice bath. If these precautions are not taken, the H_2O is likely to splatter and boil vigorously over.* **CORROSIVE.**

Sulfuric acid (fuming) (oleum) *[8014-95-7]* **H_2SO_4, M 98.08 (+ *x* SO_3).** This is sulfuric acid with various amounts of SO_3 dissolved in it up to 80% free SO_3. The specific gravities, **Sp gr $_4^{20}$**, of oleums (% free SO_3) are: 1.899 (15%), 1.915 (20%), 1.952 (30%), 2.001 (50%), 2.102 (60% maximum density) and 1.949 (80%). They are an almost colourless viscous liquids which emit choking fumes of SO_3, and should be handled with great care: **use eye and body protection**. It reacts explosively with H_2O to form strong sulfuric acid, and is a strong sulfonating agent.

Sulfur monochloride (sulfur chloride) *[10025-67-9, 12771-08-3]* **S_2Cl_2, M 135.0, m -80°, -77°, b 19.1°, 29-30°/12mm, 72°/100mm, 138°/760mm, d ^{25} 1.688g/cm^3, n $_D^{20}$ 1.658.** It is a *pungent, irritating golden yellow liquid*. When impure its colour is orange to red due to SCl_2 formed. It fumes in moist air and liberates HCl, SO_2 and H_2S in the presence of H_2O. Distil it and collect the fraction boiling above 137° at atmospheric pressure. Fractionate this fraction over sulfur at *ca* 12mm using a ground glass apparatus (**b** 29-30°). *Alternatively*, purify it by distillation below 60° from a mixture containing sulfur (2%) and activated charcoal (1%), under reduced pressure (e.g. 50mm). It is soluble in EtOH, *C_6H_6, Et_2O, CS_2 and CCl_4. Store it in a closed container in the dark in a refrigerator. [Fehér in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 371 *1963*, see also Fieser **1** 1122, **3** 275, **6** 560, **9** 442, **11** 495.] **VERY HARMFUL VAPOURS.**

Sulfuryl chloride *[7791-25-5]* **SO_2Cl_2, M 135.0, m -54.1°, b 69.3°/760mm, d ^{25} 1.67g/cm^3, n $_D^{20}$ 1.4473.** It is a *pungent, irritating colourless liquid*. It becomes yellow with time due to decomposition to SO_2 and HCl. Distil it and collect fraction boiling below 75°/atm which is mainly SO_2Cl_2. To remove HSO_3Cl and H_2SO_4 impurities, the distillate is poured into a separating funnel filled with crushed ice and *briefly* shaken. The lower cloudy layer is removed, dried for some time in a desiccator over P_2O_5 and finally fractionate it at atmospheric pressure. The middle fraction boils at 69-70° and is pure SO_2Cl_2. It decomposes gradually in H_2O to H_2SO_4 and HCl. It reacts **violently** with EtOH and MeOH and is soluble in *C_6H_6, toluene, Et_2O and acetic acid. [Fehér in *Handbook of Preparative Inorganic Chemistry (Ed Brauer)* Academic Press Vol **I** p 383 *1963*, Allen et al. *Inorg Synth* **1** 114 *1939*, DOI: 10.1002/9780470132326.ch42; Maynard *Encyclopedia of Reagents for Organic Synthesis* John Wiley *2001* DOI: 10.1002/047084289X.rs140; for a versatile alternative to chlorine see Moussa *Aust J Chem* **65** 95 *2012*, DOI: 10.1071/CH11367.] **HARMFUL VAPOURS, LACHRYMATOR.**

Tantalium (V) chloride (tantalium pentachloride) *[7721-01-9]* **$TaCl_5$, M 358.2, m 216.2°, 216.5-220°,**

b 239°/atm, d ^{25} 3.68g/cm^3. Purify it by sublimation in a stream of Cl_2. It forms colourless needles when pure (yellow when contaminated with even less than 1% of $NbCl_5$). It is sensitive to H_2O forming $TaOCl_3$; even in conc HCl it decomposes to tantalic acid. It is soluble in EtOH, Et_2O and CCl_4. [Rolsten *J Am Chem Soc* **80** 2952 *1958*, DOI: 10.1021/ja01545a011; Brauer in *Handbook of Preparative Inorganic Chemistry (Ed Brauer)* Academic Press Vol **II** p 1302 *1965*.]

Telluric acid *[7803-68-1]* **H_6TeO_6, M 229.6, m 136°, d ^{25} 3.07g/cm^3, pK $^{25}_1$ 7.68, pK $^{25}_2$ 11.04 (H_6TaO_6).** Crystallise it once from nitric acid, then repeatedly from hot water (0.4ml/g). [Fehér in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** pp 451-453 *1963*.] It has a strong tendency to polymerise, e.g. dehydrates to *polymetatellutic acid* $(H_2TeO_4)_{10}$ on heating >100°.

Tellurium *[13494-80-9]* **Te, M 127.6, m 450°, 722.6°, b 990°/atm, 1261°/atm, d ^{25} 6.24g/cm^3.** Purify the silver white tellurium by zone refining and repeated sublimation to an impurity of less than 1 part in 10^8 (except for surface contamination by TeO_2). [Machol & Westrum *J Am Chem Soc* **80** 2950 *1958*, DOI: 10.1021/ja01545a010.] Tellurium is volatile at 500°/0.2mm. It has also been purified by electrode deposition [Mathers & Turner *Trans Amer Electrochem Soc* **54** 293 *1928*]. [Fieser **11** 498.] With KOH, it promotes the pinacolisation of aromatic carbonyl compounds quantitatively [Khan et al. *Synth Commun* **27** 2193 *1997*, DOI: 10.1080/00397919708003371].

Tellurium dioxide *[7446-07-3]* **TeO_2, M 159.6, m 733°, b 1245°/atm, d ^{25} 5.67g/cm^3, n $^{20}_D$ 1.24.** Dissolve the cream coloured solid in 5M NaOH, filter it and precipitate it by adding 10M HNO_3 (CARE) to the filtrate until the solution is acid to phenolphthalein. After decanting the supernatant, the precipitate is washed five times with distilled water, then dried for 24 hours at 110° [Horner & Leonhard *J Am Chem Soc* **74** 3694 *1952*, DOI: 10.1021/ja01134a508]. It is soluble in acid and alkali.

Terbium (III, IV) oxide *[12037-01-3]* **Tb_4O_7, M 747.7, d ^{25} 7.3g/cm^3, pK^{25} 8.16 (for Tb^{3+} hydrolysis).** Dissolve the dark brown-black hygroscopic solid in acid (e.g. perchloric acid), precipitate it as its oxalate and ignite the oxalate at 650°.

Thallium (III) nitrate trihydrate [TTN, thallic nitrate trihydrate, $Tl(NO_3)_3\ 3H_2O$] *[13453-38-8]* **$Tl(NO_3)_3.3H_2O$, M 444.4, m 102-105°, 103°.** It is prepared from Tl(III)oxide (45g, [1314-32-5]) by stirring it in hot concentrated HNO_3 (120ml) at ~50° for 30 minutes when all the oxide dissolves to give a clear colourless solution. On cooling to 0°, a white solid crystallises out. It is filtered off, washed with a little cold H_2O, dilute HNO_3, dried in a vacuum desiccator over P_2O_5 to give TTN (75g, 85%) as hard, colourless crystals which should be stored in a cold tightly sealed container. It has reducing properties. Treat carefully as it is **POISONOUS**. [McKillop et al. *J Am Chem Soc* **95** 3635 *1973*, DOI: 10.1021/ja00792a028.] [For applications see Fieser **4** 492, **5** 656, **6** 578, **7** 362, **8** 476, **9** 460, **10** 395, **12** 481, **14** 302, **16** 326.]

Thallous bromide *[7789-40-4]* **TlBr, M 284.3, m 460°, 480°, b 815°/atm, d ^{25} 7.557g/cm^3.** Thallous bromide (20g) is purified by refluxing for 2-3 hours with water (200ml) containing 3ml of 47% HBr. It is then washed until acid-free, heated to 300° for 2-3 hours and stored in brown bottles. It solubility in H_2O (w/w) is 0.034% at 0°, 0.048% at 20°, and 0.204% at 100°. [Dönges in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 870 *1963*, for applications see Fieser **2** 405, **3** 286, **5** 655, **7** 361.] **POISONOUS.**

Thallous carbonate *[6533-73-9]* **$TlCO_3$, M 468.7, m 268-270°, 272°, d ^{25} 7.11g/cm^3.** It crystallises from hot water (solubility is 5.2g/100ml at 25° and 27.2g/100ml at 100°) on cooling. It is soluble in EtOH, Et_2O and Me_2CO. **POISONOUS.**

Thallous chlorate *[13453-30-0]* **$TlClO_3$, M 287.8, d $^{20}_4$ 5.05.** It crystallises from hot water (2ml/g) on cooling. Its solubility in H_2O (w/w) is 0.17% at 0°, 0.32% at 20°, and 2.4% at 100°. [Dönges in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 870 *1963*]. **POISONOUS.**

Thallous chloride *[7791-12-0]* **TlCl, M 239.8, m 429.9°, b 806°/atm, d ^{25} 7.004g/cm^3, n $^{20}_D$ 1.2.247.** Recrystallise it from 1% HCl and wash it until acid-free, or crystallise it from hot water (50ml/g), then dry it at

140° and store it in brown bottles. Also purify it by subliming it in a vacuum, followed by treatment with dry HCl gas and filtering while molten. (It is soluble in 260 parts of cold water and 70 parts of boiling water). It is soluble in EtOH, Me_2CO and NH_4OH. **POISONOUS.**

Thallous hydroxide *[12026-06-1]* **TlOH, M 221.4, m 139°(dec), d ^{25} 7.44g/cm^3, pK^{25} 13.2 (for Tl$^+$).** Crystallises the yellow solid from hot water (0.6ml/g) on cooling. It is a strong base. **POISONOUS.**

Thallous iodide *[7790-30-9]* **TlI, M 331.3, m 440°, 441.8°, b 824°/atm, d ^{25} 7.29g/cm^3.** Reflux the yellow solid (red above 170°) for 2-3 hours with water containing HI, then wash it until acid-free, and dry it at 120°. Store it in brown bottles. Almost insoluble in H_2O. [Dönges in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 870 *1963*]. **POISONOUS.**

Thallous nitrate *[10102-45-1]* **$TlNO_3$, M 266.4, m 206°, b 430°/atm, 450°/atm (dec), d $^{20}_4$ 5.55.** The nitrate crystallises from warm water (1ml/g) on cooling to 0°. [Fieser **12** 481.] **POISONOUS.**

Thallous perchlorate *[13453-40-2]* **M 303.8, d^{20} 4.8g/cm^3, pK^{25} -2.4 to -3.1 (for $HClO_4$).** It crystallises from hot water (0.6ml/g) on cooling. Dry it under vacuum for 12 hours at 100° (protect from possible **EXPLOSION**). [For thermal behavior see Udupa *Thermochim Acta* **16** 128 *1976*, DOI: 10.1016/0040-6031(76)85051-4.]

Thallous sulfate *[7446-18-6]* **Tl_2SO_4, M 504.8, m 633°, d ^{25} 6.77g/cm^3, n $^{25}_D$ 1.860.** The sulfate crystallises from hot water (solubility is 2.70g/100ml at 0°, 4.87g/100ml at 20°, and 18.45g/100ml at 100°) by cooling; then dry it under vacuum over P_2O_5. The salt inhibits plant growth. **POISONOUS.** It is the precursor of **Tl_2S** *[1314-97-2]* M 440.8, (precipitated by bubbling H_2S through an aqueous solution of the sulfate) which exhibits high electrical conductivity on exposure to infrared light. [For the 'Thalofide Cell—a New Photo-Electric Substance' see Case *Phys Rev* **15** 289 *1920*, DOI: 10.1103/PhysRev.15.289; and for the Case thallous sulfide cell see Kaplan *J Opt Soc Am* **14**(3) 251 *1927*, DOI: 10.1364/JOSA.14.000251.]

Thionyl chloride *[7719-09-7]* **$SOCl_2$, M 119.0, m -105°, b 74.6°/atm, 77°/atm, d ^{25} 1.638g/cm^3, n $^{20}_D$ 1.517.** Crude $SOCl_2$ can be freed from sulfuryl chloride, sulfur monochloride and sulfur dichloride by refluxing it with sulfur and then fractionally distilling twice. [The $SOCl_2$ is converted to SO_2 and sulfur chlorides. The S_2Cl_2 (**b** 135.6°) is left in the residue, whereas SCl_2 (**b** 59°) passes over in the forerun.] The usual purification is to distil it from quinoline (50g $SOCl_2$ to 10g quinoline) to remove acid impurities, followed by distillation from boiled linseed oil (50g $SOCl_2$ to 20g of oil). Precautions must be taken to exclude moisture. Thionyl chloride is used extensively in organic syntheses and can be prepared by distillation of technical $SOCl_2$ in the presence of ***diterpene*** (12g/250ml $SOCl_2$), and avoiding overheating. Further purification is achieved by redistillation from ***linseed oil*** (1-2%) [Rigby *Chem Ind (London)* 1508 *1969*]. Gas chromatographically pure material is obtained by distillation from 10% (w/w) triphenyl phosphite [Friedman & Wetter *J Chem Soc (A)* 36 *1967*, DOI: 10.1039/J19670000036; Larsen et al. *J Am Chem Soc* **108** 6950 *1986*, DOI: 10.1021/ja00282a020]. It is soluble in most aprotic solvents, e.g. toluene, $CHCl_3$, Et_2O, but reacts with protic solvents, e.g. H_2O, MeOH etc. **HARMFUL VAPOURS.**

Thorium (IV) chloride *[10026-08-1]* **$ThCl_4$, M 373.8, m 770°, b 921°/atm, d ^{25} 4.59g/cm^3, pK $^{25}_1$ 10.45, pK $^{25}_2$ 10.62, pK $^{25}_3$ 10.80, pK $^{25}_4$ 11.64 (for aquo Th^{4+}).** It is freed from anionic impurities by passing a 2M solution of $ThCl_4$ in 3M HCl through a Dowex-1 anion-resin column. The eluate is partially evaporated to give crystals which are filtered off, washed with Et_2O and stored in a desiccator over H_2SO_4 to dry. *Alternatively*, a saturated solution of $ThCl_4$ in 6M HCl is filtered through quartz wool and extracted twice with ethyl, or isopropyl ether (to remove iron), then evaporated to a small volume on a hot plate. (Excess silica precipitates and is filtered off. The filtrate is cooled to 0° and saturated with dry HCl gas.) It is shaken with an equal volume of Et_2O, shaken with HCl gas, until the mixture becomes homogeneous. On standing, $ThCl_4.8H_2O$ precipitates out and is filtered off, washed with Et_2O and dried [Kremer *J Am Chem Soc* **64** 1009 *1942*, DOI: 10.1021/ja01256a505].

Thorium sulfate tetrahydrate *[33088-16-3 ($4H_2O$), 10381-37-0 ($9H_2O$)]* **$Th(NO_3)_4.4H_2O$, M 496.2($4H_2O$),**

M 424.2 (anhydr), m 42°(loses H_2O), 500°(anhydr, dec), d ^{20} 2.80g/cm^3. Crystallise it from water. The solubility of the ***decahydrate*** increases with increase in temperature, whereas the solubility of the ***tetrahydrate*** decreases with increase of temperature.

Tin (powder) *[7440-31-5]* **Sn, M 118.7, m 231.9°, b 2603°/atm, d ^{25} 5.769g/cm^3(grey, α form, diamagnetic), d ^{25} 7.365g/cm^3(white, β form, paramagnetic).** The melting point varies with the form of the metal. Tin powder is purified by adding it to about twice its weight of 10% aqueous NaOH and shaking vigorously for 10 minutes. (This removes oxide film and stearic acid or similar material that is sometimes added for pulverisation.) It is then filtered, washed with water until the washings are no longer alkaline to litmus, rinsed with MeOH and dried in air. [Sisido et al. *J Am Chem Soc* **83** 538 *1961*, DOI: 10.1021/ja01464a008; for applications see Fieser **1** 1168, **2** 414, **13** 298, **17** 333.]

Titanium tetrabromide *[7789-68-6]* **$TiBr_4$, M 367.5, m 28.3°, 39°, b 233.5°/atm, d ^{25} 3.25g/cm^3.** Purify it by distillation. The distillate forms light orange hygroscopic crystals. Store it in the dark under N_2 preferably in sealed brown glass ampoules. It is soluble in chlorocarbons and *C_6H_6 but reacts ***violently*** with H_2O to liberate HBr. [Olsen & Ryan *J Am Chem Soc* **54** 2215 *1932*, DOI: 10.1021/ja01345a008.] It has been used as a Lewis acid catalyst in organic synthesis.

Titanium tetrachloride *[7550-45-0]* **$TiCl_4$, M 189.7, m -24°, b 136.4°/atm 154°, d ^{25} 1.726g/cm^3, n $_D^{10.5}$ 1.61. pK $_1^{25}$ 0.3, pK $_2^{25}$ 1.8, pK $_3^{25}$ 2.1, pK $_4^{25}$ 2.4 (for aquo Ti^{4+} hydrolysis).** Reflux it with mercury or a small amount of pure copper turnings to remove the last traces of colour [due to $FeCl_3$ and VCl_4], then distil it under N_2 in an all-glass system, taking precautions to exclude moisture. Clabaugh et al. [*J Res Nat Bur Stand* **55** 261 *1955*] removed organic material by adding aluminium chloride hexahydrate as a slurry with an equal amount of water (the slurry being *ca* one-fiftieth the weight of $TiCl_4$), refluxed it for 2-6 hours while bubbling in chlorine, the excess of which is subsequently removed by passing a stream of clean dry air. The $TiCl_4$ is then distilled, refluxed with copper and again distilled, taking precautions to exclude moisture. Volatile impurities are then removed using a technique of freezing, pumping and melting. The ***titanium tetrachloride 2-tetrahydrofuran complex, $TiCl_4(THF)_2$*** *[31011-57-1]* **M 333.9,** has **m 126-128°** and is easier to handle than $TiCl_4$ [Hamilton et al. *J Am Chem Soc* **75** 2881 *1953*, DOI: 10.1021/ja01108a027; Abrahamson et al. *Organometallics* **3** 1379 *1984*, DOI: 10.1021/om00087a010; *Beilstein* **17/1** V 33]. [Baxter & Fertig *J Am Chem Soc* ***45*** 1228 *1923*, DOI: 10.1021/ja01658a017; Baxter & Butler *J Am Chem Soc* ***48*** 3117 *1926*, DOI: 10.1021/ja01691a014.] It is useful as a Lewis acid in organic synthesis, in the formation of organometallic complexes with useful properties, reacts with H_2O to form a white smoke screen of TiO_2, and with THF it forms yellow crystals of $TiCl_4(THF)_2$. [For applications see Fieser **1** 1169, **2** 414, **3** 291, **4** 507 **5** 671, **6** 590, **7** 370, **8** 483, **9** 468, **10** 401, **11** 529, **11** 261, **12** 494, **13** 304, **14** 309, **15** 317, **16** 332, **17** 344.] It is also available as a 0.09M solution in 10% HCl; a 1.0M solution in CH_2Cl_2; 1.0M in toluene; and a $TiCl_4$.2THF complex *[31011-57-1]* M 333.9, m 126-128°. A **low valent titanium reagent** which can be prepared *in situ* by adding Mg powder (25mmol, 50 mesh) to $TiCl_4$ (15mmol) in THF (60ml) and activated by addition of 1,2-dibromomethane (10mmol) during 5 minutes at 0° under N_2. This reagent was shown to reduced Schiffs bases as well as dimerise them to provide imidazolines in moderate to good yields with come control in the stereochemistry [Periasamy et al. *Tetrahedron Lett* **37** 4767 *1996*, DOI: 10.1016/0040-4039(96)00930-6], and low valent titanium for carbonyl coupling [McMurry *Chem Rev* **89** 1513 *1989*, DOI: 10.1021/cr00097a007]. $TiCl_4$ vapours are **HARMFUL** and head and body protection should be used.

Titanium trichloride *[7705-07-9]* **$TiCl_3$, M 154.3, m 425°(dec), 440°(dec), b 960°/atm (dec), d ^{25} 2.64g/cm^3, n $_D^{25}$ 1.4854, pK $_1^{25}$ 2.55 (for hydrolysis of Ti^{3+} to $TiOH^{2+}$).** It is a brown purple powder that is very reactive to H_2O and pyrophoric when dry. It should be manipulated in a dry box. It is soluble in CH_2Cl_2 and tetrahydrofuran, and is used as a M solution in these solvents in the ratio of 2:1, and stored under N_2. It is a powerful reducing agent. [Ingraham et al. *Inorg Synth* **6** 52 *1960*, DOI: 10.1002/9780470132371.ch16.] In alcoholic solvent, with *tert*-butylhydroperoxide it mediates the reductive coupling of aryl aldehydes to form 1,2-diols [Clerici et al. *Eur J Org Chem* 4050 *2007*, DOI: 10.1002/ejoc.200700252]. [Fieser **2** 415, **4** 506, **5** 669, **6** 587, **7** 369, **8** 482, **9** 467, **10** 400, **11** 529, **11** 529, **12** 492, **13** 302, **15** 316, **16** 330.] Also commercially available

is a ~10wt% in 20-30wt% in hydrochloric acid for the quantitative titration of NO_2 groups to NH_2 groups.
Titanium trichloride—aluminium chlorde *[12003-13-3]* **3:1 $(TiCl_3)_3.AlCl_3$ complex, M 596.0, m >250°**, which is a useful reducing agent for catalysis. A 1:3 complex **$TiCl_3$/3THF** *[18039-90-2]* **M 370.5, >250**, for making bis(β-diketone) ligands of bimetallic Ti(III) complexes with a triple-helix structures is commercially available [Grillo et al. *JCS Chem Commun* 1561 *1997*, DOI: 10.1039/A702971C].

Titanyl (IV) sulfate *[13825-74-6]* **$TiOSO_4$. $2H_2O$, M 160.0, d ^{25} 1.361g/cm^3(~15 wt% in dil H_2SO_4).** Dissolve it in water, filter and crystallise it three times from boiling 45% H_2SO_4, washing with EtOH to remove excess acid, then with Et_2O. Dry it in air for several hours, then in an oven at 105-110°. [Hixson & Fredrickson *Ind Eng Chem* **37** 678 *1945*, DOI: 10.1021/ie50427a021.]

Trisodium orthophosphate dodecahydrate *[10101-89-0]* **Na_3PO_4. $12H_2O$, M 380.1, m 75°(dec), b 100°/atm, ($12H_2O$, dec), d ^{25} 1.62g/cm^3 ($12H_2O$), pK $_1^{25}$ 2.15, pK $_2^{25}$ 7.21, pK $_3^{25}$ 12.33 (for H_3PO_4).** It crystallises from warm dilute aqueous NaOH (1ml/g) on cooling to 0°. The solubility of the ***dodecahydrate*** in H_2O is 25.8g/100ml at 25°, and the ***anhydrous*** salt is 5.4g/100ml at 0°, 14.5g/100ml at 25°, 23.3g/100ml at 40°, and 94.6g/100ml at 100°.

Tritium *[10028-17-8]* **$^3H_2$, M 6.0.** Purify tritium from hydrocarbons and ^3H by diffusion through the wall of a hot nickel tube, as well as diffusion of H_2 and D_2 [Landecker & Gray *Rev Sci Instrum* **25** 1151 *1954*, http://dx.doi.org/10.1063/1.1770969]. Its half life is 12.32 years. **RADIOACTIVE.**

Tungsten (rod) *[7440-33-7]* **W, M 183.8, m 3410°, 3695°, b 5900°/atm, 6203°/atm, d ^{25} 19.25g/cm^3.** Clean the solid with concentrated NaOH solution, rub it with very fine emery paper until its surface is bright, wash it with previously boiled and cooled conductivity water and dry it with filter paper. [Hein & Herzog in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **II** p 1417 *1965*.] It has many radioactive isotopes.

Tungsten (VI) trichloride (tungsten hexachloride) *[13283-01-7]* **WCl_6, M 396.6, m 265°(dec), 275°, b 346.7°/atm, d ^{25} 3.52g/cm^3, pK$_1^{25}$ 2.20, pK$_2^{25}$ 3.70 (for tungstic acid, H_2WO_4).** Sublime the dark blue solid in a stream of Cl_2 in a high temperature furnace and collect it in a receiver cooled in a Dry-ice/acetone bath in an inert atmosphere because it is sensitive to moisture. At low temperatures its colour becomes red-wine. The red form can be produced also by condensing the vapour, but reverts to the blue-black form on gentle heating. It is soluble in CS_2, CCl_4, $CHCl_3$, $POCl_3$, *C_6H_6, petroleum ether and Me_2CO. Its solutions decompose on standing. Good crystals can be obtained by heating WCl_6 in CCl_4 to 100° in a sealed tube, followed by slow cooling (tablets of four-sided prisms). Store it in a desiccator over H_2SO_4 in the dark as it [Leitzke et al. *Inorg Synth* **3** 163 *1950*, DOI: 10.1002/9780470132340.ch44; Porterfield et al. *Inorg Synth* **9** 133 *1967*, DOI: 10.1002/9780470132401.ch36; Hein & Herzog in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **II** p 1420 *1965*.] The trichloride mediates the conversion of 1,3-dithiolanes and 1,3-dithianes to chlorinated dihydro-1,4-dithiins and dihydro-1,4-dithiepines [Firouzabadi et al. *Synlett* 413 *1999*, DOI: 10.1055/s-1999-2628], and is a precursor to tungsten-based carbenes which catalyse the olefin metathesis reactions of 1- and 2-octene [Düz et al. *Tetrahedron Lett* **47** 5167 *2006*, DOI: 10.1016/j.tetlet.2006.05.054].

Uranium hexafluoride *[7783-81-5]* **UF_6, M 352.0, m 64.0°, 64.8° (sealed tube??), b 0°/17.4mm, 56.2°/765mm(sublimes), d ^{25} 5.02g/cm^3, pK^{25} 1.68 (for hydrolysis of U^{4+} to UOH^{3+}).** Purify uranium hexafluoride by fractional distillation to remove HF. Also purify it by low-temperature trap-to-trap distillation over pre-dried NaF, and it sublimes at 56.5°/atm. [Anderson & Winfield *JCS Dalton Trans* 337 *1986*, DOI: 10.1039/DT9860000337].

Uranium trioxide *[1344-58-7]* **UO_3, M 286.0, m ~200-650°(dec), d ^{25} 5.5—8.7g/cm^3.** The yellow-orange oxide is dissolved in $HClO_4$ (to give a uranium content of 5%), and the solution is adjusted to pH 2 by addition of dilute ammonia. Dropwise addition of 30% H_2O_2, with rapid stirring, precipitated U(VI) peroxide, the pH being held constant during the precipitation, by addition of small amounts of the ammonia solution. Then H_2O_2

is added until further quantities caused no change in pH. After stirring for 1 hour, the slurry is filtered through coarse filter paper in a Büchner funnel, washed with 1% H_2O_2 acidified to pH 2 with $HClO_4$, then heated at 350° for three days in a large platinum dish [Baes *J Phys Chem* **60** 878 *1956*, DOI: 10.1021/j150541a011]. It is **POISONOUS** and **RADIOACTIVE** and should not be inhaled, ingested or be in contact with the skin — take extreme precautions.

Uranyl nitrate ($UO_2(NO_3)_2$ $6H_2O$) *[13520-83-7, 10102-06-4]* **$UO_2(UO_3)_2$. $6H_2O$, M 394.0, 502.1, m 60.2°, b 118°/atm (dec), d ^{25} 2.81g/cm^3, pK^{25} 5.82 (for aquo UO_2^{2+}).** Crystallise the nitrate from water by cooling to -5°, taking only the middle fraction of the solid which separates. Its solubility in H_2O is 98g/100g at 0° and 122g/100g at 20°, and 474g/100g at 100°, and is soluble in tributyl phosphate. Dry the ***deliquescent*** rhombic yellow crystals of the ***hexahydrate*** over 35-40% H_2SO_4 in a vacuum desiccator. The crystals reflect a greenish lustre. They are remarkable because on crushing, rubbing or shaking they show ***triboluminescence*** with occasional detonation. They are very soluble in EtOH, and solutions of the nitrate in Et_2O can explode in the presence of sunlight. **HIGHLY TOXIC see previous entry.**

Vanadium (metal) *[7440-62-2]* **V, M 50.9, m 1910°, b 3407°/atm, d ^{25} 6.0g/cm^3(solid), 5.5g/cm^3(melt).** Clean the blue-silver-grey metal by rapid exposure consecutively to HNO_3, HCl, HF, de-ionised water and reagent grade acetone, then dry it in a vacuum desiccator. [Brauer in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **II** pp 1252-1255 *1965*.] Used in hardening steel, trace metal in some enzymes, e.g. vanadium nitrogenases and haloperoxidases contain vanadium.

Vanadyl trichloride ($VOCl_3$) *[7727-18-6]* **$VOCl_3$, M 173.3, m -79.5°, b 124.5-125.5°/744mm, 127.16°/760mm, d^0 1.854g/cm^3, d^{32} 1.826 g/cm^3, d^{32} 1.811 g/cm^3.** $VOCl_3$ should be lemon yellow in colour. If it is red, it may contain VCl_4 and Cl_2. Fractionally distil it, and then redistil it over metallic Na, but be careful to leave some residue because the residue can become **EXPLOSIVE** in the presence of the metal. **USE A SAFETY SHIELD** *and avoid contact with moisture*. It readily hydrolyses to vanadic acid and HCl. Store it in a tightly closed container or in sealed ampoules under N_2. [Brown et al. *Inorg Synth* **1** 106 *1939*, DOI: 10.1002/9780470132326.ch38; Brown et al. *Inorg Synth* **4** 80 *1953*; DOI: 10.1002/9780470132357.ch28; Oppermann 'Untersuchungen an Vanadinoxidchloriden und Vanadinchloriden. I. Gleichgewichte mit $VOCl_3$, VO_2Cl und $VOCl_2$'. *Z Anorg Allgem Chem* **351** 113 *1967*, DOI: 10.1002/zaac.19673510302.]

Water *[7732-18-5]* **H_2O, M 18.0, m 0°, b 100°/atm, d$^{3.98}$ 1.000000g/ml (0.999972g/cm^3, n_D^{20} 1.33335. pK^{25} 14.00.** Conductivity water (specific conductance *ca* 10^{-7} mho) can be obtained by distilling water in a steam-heated tin-lined still, then, after adding 0.25% of solid NaOH and 0.05% of $KMnO_4$, distilling once more from an electrically heated Barnstead-type still, taking the middle fraction into a Jena glass bottle. During these operations suitable traps must be used to protect against entry of CO_2 and NH_3. Water, only a little less satisfactory for conductivity measurements (but containing traces of organic material) can be obtained by passing ordinary distilled water through a mixed bed ion-exchange column containing, for example, Amberlite resins IR 120 (cation exchange) and IRA 400 (anion exchange), or Amberlite MB-1. This treatment is also a convenient one for removing traces of heavy metals. (The metals Cu, Zn, Pb, Cd and Hg can be tested for by adding pure concentrated ammonia to 10ml of sample and shaking vigorously with 1.2ml of 0.001% dithizone in CCl_4. Less than 0.1μg of metal ion will impart a faint colour to the CCl_4 layer.) For almost all laboratory purposes, simple distillation yields water of adequate purity, and most of the volatile contaminants such as ammonia and CO_2 are removed if the first fraction of distillate is discarded. Most laboratories have glass stills that 'doubly' or 'triple' distil water for chemical and biological purposes. [See 'water' in Chapter 1.] Water also has **d_4^{25} 0.997**, **d_4^0 0.999868** (liq) and **d^0** (ice) **0/917g/cm^3**.

Wood's Metal *[76093-98-6]* **Bi,Pb,Sn,Cd, M ~1486, m ~75°, 73-77° (low melting granular)** It is a fusible alloy of Bi,Pb,Sn,Cd with the atomic composition of 4:2:1:1 (**m 71°**) It is commonly used as a metal bath for heating reaction flasks as it melts at a convenient temperature. Its temperature rises rather rapidly when heated with a Bunsen burner in a crucible (e.g. steel or nickel), so care should be taken when heating a reaction or distilling flask containing chemical reactants immersed into it. Heating should be applied slowly, and the temp-

erature should be monitored continuously with a thermometer immersed in the molten metal. The temperature of the metal can be taken up to ~350°, and it is better to work in an efficient fume cupboard as the vapours are toxic. At higher temperature some oxidation of the metal takes place. A bath that has been heated at high temperaures and then the metal cooled back to the solid, and melted again has a solid scum of the oxides on its surface. These can be easily removed with a nickel spatula to leave a nice clean surface. The melting point of the re-used alloy is not seriously affected, and the alloy can be used over and over again without considerable loss in weight. It is commercially available in a *low melting* **granular** form, or as **sticks** with the composition of Bi(50 wt%), Pb (25 wt%), Sn (12.5 wt%) and Cd (12.5 wt%). Other such alloys are **Rose's metal** (**m 93.75°**) with the composition of Bi (50%), Pb (25-28%), Sn (22-25%), i.e. in the ratio of *ca* 2:1:1; **Lipowitz alloy [60° (soft) to 70° (melt)**] with the composition of Bi, Pb, Sn, Cd in the ratio 15:8:4:3; **Cerrolow alloy (m 47.2°**) with the composition Bi (44.7%), Pb (22.6%), Sn (8.3%) In (19.1%) and Cd (5.3%) but they are not very commonly used in the laboratory probably because they contain Cd. Alloys of Bi, Pb and Sn which melt slightly above 100° have been used as melting plugs in sprinkler alarms.

Zinc (dust) *[7440-66-6]* **Zn, M 65.4. m 419.5°, m 420°, b 907°/atm, d ^{25} 7.14g/cm^3, d ^{420} 6.57g/cm^3(melt), n $^{25}_{D}$ 1.4854.** Commercial zinc dust (1.2kg) is stirred with 2% HCl (3L) for 1 minute, then the acid is removed by filtration, and washed in a 4L beaker with a 3L portion of 2% HCl, three 1L portions of distilled water, two 2L portions of 95% EtOH, and finally with 2L of absolute Et_2O. (Wash solutions were removed by filtration.) The material is dried thoroughly, and break lumps in a mortar. [Wagenknecht & Juza *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **II** p 1067 *1965*.] Or, fuse it *in vacuo*, cool, and wash it with acid to remove any oxide. Used in galvanising, in alloys, batteries, brass and bronze production, mineral supplements, zinc ointments; as antibacterial, and is an efficient Lewis acid. ***Zinc nano metallic powder*** is available in 75-125nm p.size with high surface area. It is very reactive and forms organo-Zn compounds with halides and used in azo couplings. Sonicate to de-agglomerise to 35nm size. ZnNP is available in <50nm p.size.

Zinc bromide *[7699-45-8, 18921-13-6 ($2H_2O$)]* **$ZnBr_2$, M 225.2(anhydr), m 384°, 394°(anhydr), b 697°/atm, d ^{25} 4.22g/cm^3, n $^{25}_{D}$ 1.5452.** Heat $ZnBr_2$ to 300° under vacuum ($2x10^{-2}$ mm) for 1 hour, then sublime it. Its solubility in H_2O is 311g/100ml at 0°, 447g/100ml at 20°, and 538g/100ml at 100°; and it is soluble in EtOH, Et_2O, Me_2CO and THF. [Wagenknecht & Juza *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **II** p 1072 *1965*; Fieser **2** 463, **5** 762, **8** 535, **9** 520, **10** 461, **11** 600, **13** 349, **15** 368, **16** 389.] The ***anhydrous salt*** is a Lewis acid which catalyses stereo and region selective reactions.

Zinc chloride *[7646-85-7]* **$ZnCl_2$, M 136.3(anhydr), m 283°, 290°, 293°, b 732°/atm, d ^{25} 2.907g/cm^3, n $^{25}_{D}$ 1.5452.** The anhydrous white material can be sublimed under a stream of dry HCl, followed by heating to 400° in a stream of dry N_2. It sublimes at high vacuum. Also purify it by refluxing (50g) in dioxane (400ml) with 5g zinc dust, filtering hot and cooling to precipitate $ZnCl_2$. Crystallise it from dioxane and store it in a desiccator over P_2O_5. It has also been dried by refluxing in thionyl chloride. [Weberg et al. *J Am Chem Soc* **108** 6242 *1986*, DOI: 10.1021/ja00280a022.] *Hygroscopic: minimal exposure to the atmosphere is necessary*. However, its solubility in H_2O is 43.2g/100ml at 25°, and is soluble in EtOH (43g/100ml), Me_2CO and glycerol. [Wagenknecht & Juza *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **II** p 1070 *1965*, Fieser **1** 1289, **2** 464, **3** 338, **5** 763, **6** 676, **8** 536, **9** 522, **10** 461, **11** 601, **12** 574, **13** 349, **15** 368, **16** 391.] Also available commercially as a 1M solution in Et_2O (**d ^{25} 0.835g/ml**).

Zinc-Copper Couple *[53801-63-1]* **Zn/Cu, m 419-420°.** It is available in the form of a powder made of Zn and Cu. If the Zn contains some ZnO, then it should be treated with dilute HCl for a very short period, washed H_2O, a little EtOH then Et_2O, and dried *in vacuo* (see also zinc dust above). The ***couple*** can be prepared in either of the following ways. **(1)** Zinc dust [(120g, MW of Zn is 65.4) and powdered copper oxide (10g, MW of Cu is 63.6) in a round-bottomed flask (~200ml) are heated gently over a flame in a current of H_2 and N_2 with stirring or rotating the flask until the CuO is reduced, and a uniformly grey mixture is obtained. The temperature should be maintained below the point of fusion during heating (~500°) and the mixture is stored in a desiccator. **(2)** Zinc powder (24.6g) is stirred with 3% aqueous HCl (20ml) for 1 minute, washed by decantation with 3% aqueous HCl (3 x 20ml), with H_2O (5 x 20ml), 2% aqueous $CuSO_4$ (2 x 40ml), distilled H_2O (5 x 20ml), with EtOH (4 x 20ml), with Et_2O (2 x 20ml), filtered off on a Büchner funnel, sucked dry then stored in a desiccator over P_2O_5

overnight. [Corbin et al. *Org Synth* Coll Vol **5** 328 *1973*; DOI: 10.15227/orgsyn.044.0030 Smith & Simmons *Org Synth* Coll Vol **5** 855 *1973*, DOI: 10.15227/orgsyn.041.0072.] (3) A suitable zinc/copper alloy with 5—8% of Cu can be prepared by melting zinc (m 419.5°) with clean brass turnings (*ca* 2Cu/1Zn) and casting into bars, which can be turned into fine shavings prior to use. [Noller *Org Synth* Coll Vol **2** 184 *1943*, DOI: 10.15227/orgsyn.012.0086.] Note that the couple loses activity in moist air, so it should be kept dry, and used as soon as possible after it is prepared for best results. When it is required to reduce organic halides to the respective hydrocarbon or deuterated derivative, it is best to prepare the Zn-Cu couple in an oxygen-free system. Thus Zn dust (6.5g, 100mmol) suspended in H_2O (10ml) is vigorously stirred with acidic cupric chloride solution (15ml of 0.15M in 5% hydrochloric acid) until evolution of gas ceases, the black solid is filtered off, and washed with H_2O until the filtrate gives a negative chloride test with 6% $AgNO_3$ solution. The ***couple*** is washed twice with Me_2CO, and in order to obtain the highest deuterium incorporation, the Me_2CO wash should be followed by a D_2O wash, two Me_2CO washes, two Et_2O washes and dried *in vacuo* at ~25°. This preparation of the ***couple*** is exceptional for replacing the halogen in a variety of organic halides by H or D in water-containing ether solvents, under mild conditions, and in reproducibly moderate to high yields (e.g. 1,4-dideuterobutadiene from 1,4-dichloro-1,3-butadiene, or 2-butanone-3-d_1 from 3-bromo-2-butanone). The deuterium derivatives provide a convenient ^{13}C NMR method for deuterium analysis. [Stephenson et al. *J Org Chem* **42** 212 *1977*, DOI: 10.1021/jo00422a006.]

Zinc cyanide *[557-21-1]* **$Zn(CN)_2$, M 117.4, m 800°(dec), d ^{25} 1.852g/ml.** It is a **POISONOUS** white powder which becomes black on standing if $Mg(OH)_2$ and carbonate are not removed in the preparation. Thus, wash it well with H_2O, then well with EtOH, Et_2O and dry it in air at 50°. Analyse it by titrating the cyanide with standard $AgNO_3$. Other likely impurities are $ZnCl_2$, $MgCl_2$ and traces of basic zinc cyanide; the first two salts can be washed out. It is soluble in aqueous KCN solutions. However, if purified in this way $Zn(CN)_2$ is not reactive in the Gattermann synthesis. For this, the salt should contain at least 0.33 mols of KCl or NaCl which will allow the reaction to proceed faster. Its solubility in H_2O is 0.00005g/100ml at 20°, and it reacts with alkalies, KCN and NH_4OH. [Adams & Levine *J Am Chem Soc* **45** 2373 *1923,* DOI: 10.1021/ja01663a020; Arnold & Sprung *J Am Chem Soc* **60** 1699 *1938*, DOI: 10.1021/ja01274a501; Fuson et al. *Org Synth* Coll Vol **3** 549 *1955*, DOI: 10.15227/orgsyn.023.0057; Fieser **1** 1293, *Beilstein* **2** III 86.]

Zinc fluoride *[7783-49-5, 13986-18-0 ($4H_2O$)]* **ZnF_2, M 103.4(anhydr), m 872°(anhydr), 100°(anhydr, dec), b 1500°/atm, d ^{25} 4.95g/ml.** A possible impurity is H_2O which can be removed by heating at 100° or by heating to 800° in a dry atmosphere. Heating in the presence of NH_4F produces larger crystals. It is sparingly soluble in H_2O (***anhydrous*** 0.00005g/100ml at 20°; ***tetrahydrate*** 1.52g/100ml at 20°), but is slightly more soluble in HCl, HNO_3 and NH_4OH. It can be stored in glass bottles. [Kwasnik in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 242 *1963*, for application see Fieser **6** 514.]

Zinc iodide *[1314-13-2]* **ZnI_2, M 319.2, m 445°, 446°, b 1150°(dec), d ^{25} 4.74g/ml.** Heat the iodide to 300°/2 x 10^{-2}mm) for 1 hour, then sublime it. Its solubility in H_2O is 450g/100ml at 20°, and it is soluble in EtOH. Store it in the dark. It is an X-ray opaque material in radiology, electrolyte and with OsO is a stain in electron microscopy. [For applications see Fieser **1** 1294, **5** 765, **10** 462, **11** 604, **12** 576, **13** 350.]

Zinc oxide *[10139-47-6]* **ZnO, M 81.4 m 1975°(dec), b 1975°(dec), d ^{25} 5.606g/ml, n $^{25}_{D}$ 2.0041.** Zinc oxide, obtained by burning zinc vapour (at > 907°) in air with emission of bright luminescence and lowering temperature, is called ***zinc white*** and used as a pigment. For pharmaceutical purposes it is prepared by treating an aqueous solution of $ZnSO_4$ with Na_2CO_3, and heating the basic zinc carbonate which is precipitated. When pure salts are used then pure ZnO thus obtained is used. The oxide is white and is ***thermochromic*** as it changes colour to yellow on heating reversibly, i.e. changes back to white on cooling. This is apparently due to a very small loss of some oxygen at *ca* 800° which is re-absorbed on cooling. The oxide is ***amphoteric***: dissolving in acids to form ***salts*** containing Zn^+ or Zn^{2+} ions and in alklalies to form ***zincates*** containing $[ZnO_2]^{2-}$ ions. The oxide has numerous applications which include pigments (paints), ceramic industry, rubber manufacture, food additives, pharmaceutical industry, UV absorbers, coatings, corrosion prevention electronics, and sensors among many applications. [De Liedekerke '2.3. Zinc Oxide (Zinc White): Pigments, Inorganic, 1' in *Ullmann's Encyclopdia of Industrial Chemistry* 2006 Wiley-VCH, Weinheim, DOI:10.1002/14356007.a20_243.pub2; Özgür et al. A comprehensive review of ZnO materials and devices *J Appl Phys* **98** 041301 *2005*, DOI: 10.1063/

1.1992666; Klingshirn 'ZnO: Material, Physics and Applications' *Chem Phys Chem* **8** 782 *2007*, DOI: 10.1002/cphc.200700002.] [For applications see Fieser **1** 1294, **5** 622.] The oxide is also used to prepare ***$NaZnSiO_3OH$*** which is a novel chiral zincosilicate framework material with potential application in ion exchange for adsorption or catalysis [Healey et al. *Inorg Chem* **38** 455 *1999*, DOI: 10.1021/ic9810135].
Zinc oxide hydrate *[55204-38-1]* **ZnO. xH_2O, M 81.4 (anhyd), m >390°, d^{25} 3.05g/ml,** a ***hydrated form*** of the oxide, is also available commercially.

Zinc perchlorate hexahydrate *[13637-61-1 (anhydrous), 10025-64-6 ($6H_2O$)]* **$Zn(ClO_4)_2$. $6H_2O$, M 372.4, m 105-107°, 106°, b 200°/atm, d^{25} 2.252g/cm^3, n_D^{25} 1.50, pK^{25} -2.4 to -3.1 (for $HClO_4$).** Crystallise the white solid from a small volume of H_2O. It is soluble in EtOH. Useful catalyst for epoxide ring opening by amines [Shivani & Chakraborti *J Org Chem* **72** 3713 *2007*, DOI: 10.1021/jo062674j] **Corrosive and Potentially EXPLOSIVE.**

Zinc-Silver Couple *[37350-66-6]* **Zn/Ag.** It is best to prepare the couple fresh when used to replace a vinylic bromine atom in organic compounds by a hydrogen atom, deuterium atom or a tritium atom. The zinc dust to be used should first be cleaned from any zinc oxide or greasy material. Zinc dust (22g) is stirred under N_2 at ~25° as a suspension in 10% aqueous HCl (110ml) for 20 minutes. Acetone (50ml) is added to the mixture, the liquid is decanted from the metal, and the grey slurry is washed thoroughly with Me_2CO (6 x 50ml) by decantation. The residual Zn is treated with a boiling suspension of AgOAc (~6.6g) in AcOH (125ml), stirred rapidly without further heating, the liquid is decanted off and the black granular solid that is formed is washed with AcOH (2 x 60ml), Me_2CO (2 x 20ml), and finally dry THF (2 x 50ml). Store it under N_2 in the dark. If it is used for deuterium replacement of bromine it is best to stir the couple with D_2O (5ml) in dry THF (50ml) for 15 minutes, decant, repeat the process a second time and then wash the solid with dry THF (50ml). This reduces the amount of proton incorporation while maximising deuterium incorporation. [Fryzuk & Bosnich *J Am Chem Soc* **101** 3043 *1979*, DOI: 10.1021/ja00505a035; Clark & Heathcock *J Org Chem* **41** 636 *1976*, DOI: 10.1021/jo00866a012.] It is a mild and convenient reagent for reductive dehalogenation of aryl halides to arenes [Chung et al. *Synth Commun* **18**(5) 507 *1988*, DOI: 10.1080/ 00397918808060744].

Zinc sulfate heptahydrate (white vitriol) *[7446-20-0 ($7H_2O$), 13786-24-8 ($6H_2O$), 7446-19-7 (H_2O), 7733-02-0 (anhydrous)]* **$ZnSO_4$. $7H_2O$, M 287.5($7H_2O$), 161.5(anhydr), m 100°($7H_2O$, dec), 280°(loses all $7H_2O$), >680°(anhydrous), d^{25} 3.54g/cm^3(anhydr), d^{25} 2.072g/cm^3($7H_2O$), n_D^{25} 1.658(anhydr), n_D^{25} 1.4357($7H_2O$).** Crystallise it from aqueous EtOH or dilute H_2SO_4 below 39° when it forms the ***heptahydrate***, and between 39° and 70° it forms the ***hexahydrate***, and above 70° the ***monohydrate*** is stable. The ***anhydrous salt*** is obtained from the hydrates by heating at 280° or lower temperatures in a current of dry air. It decomposes to ZnO and SO_2 at 767°. The solubility of the ***heptahydrate*** in H_2O is 5.88% at 0°, 61.92% at 30°, 66.61% at 35° and 70.05% at 39°. [Rohe & Wolf 'Zinc Compounds' in *Ullmann's Encyclopedia of Industrial Chemistry 2005,* Wiley-VCH, Weinheim. DOI: 10.1002/14356007.a28 537].

Zirconium tetrachloride *[10026-11-6]* **$ZrCl_4$, M 233.0, m >300°(sublimes), d^{25} 2.80g/cm^3, pK_1^{25} -0.32, pK_2^{25} 0.06, pK_3^{25} 0.35, pK_4^{25} 0.46 (for hydrolysis of aquo Zr^{4-}).** Crystallise the white solid repeatedly from concentrated HCl. It is hydrolysed by H_2O to form white $ZrOCl_2$ (see below) and HCl. [Krebs *Z Anorg Allgem Chem* **378** 263 *1970*, DOI: 10.1002/zaac.19703780306; Bora 'Zirconium Tetrachloride' *Synlett* (7) 1073 *2003*, DOI: 10.1055/s-2003-39323.]

Zirconyl chloride hexahydrate *[7699-43-6 (30% in HCl), 15461-27-5 (xH_2O)]* **$ZrOCl_2$. $6H_2O$, M 286.2, m 150°(loses $6H_2O$).** Crystallise it repeatedly from 8M HCl to give $ZrOCl_2.8H_2O$ (see below). On drying, $ZrOCl_2.6H_2O$, **m** 150°, is formed. The product is not free from hafnium. [Blumenthal *J Chem Ed* **39** 604 *1962*, DOI: 10.1021/ed039p604.] ***Zirconyl chloride octahydrate*** *[13520-92-8]* **$ZrOCl_2$. $8H_2O$, M 322.3, m 150°(loses $6H_2O$), 210°(loses all H_2O). 400°(anhydrous dec), d^{25} 1.91g/cm^3.** Recrystallise the chloride several times from water [Ferragina et al. *JCS Dalton Trans* 265 *1986*, DOI: 10.1039/DT9860000265]. Recrystallisation from 8M HCl gives the ***octahydrate*** as white needles on concentrating. It is also formed by hydrolysing $ZrCl_4$ with water. After one recrystallisation from H_2O, 99+% grade zirconyl chloride had Ag, Al, As, Cd, Cu, Hf, Mg, Na, Sc and V at 20, 1.8, 0.6, 0.6, 0.4, 8.4, 0.4, 2.4, 80 and 3 ppm, respectively. (See above.) [For structure see Mak 'Refinement of the crystal structure of zirconyl chloride octahydrate' *Can J Chem* **46**, 3491 *1968*, DOI: 10.1139/v68-579.]

METAL-ORGANIC COMPOUNDS

This section contains metal-organic compounds, ammonium and metal derivatives of organic alcohols, amines and carboxylic acids (salts), as well as ionophores that form complexes with metal ions. Note that there are a large number of metal-organic catalysts, and reagents for preparing some of these catalysts, in Chapter 5, that can be considered as an extension of this section. (For Introduction to this section see p 635.)

Acetylenedicarboxylic acid monopotassium salt *[928-04-1]* **C_4HO_4K, M 152.2, m 133°.** The white powder is very soluble in H_2O, but can be crystallised from a small volume of H_2O in small crystals. These are washed with EtOH and dried over H_2SO_4 at 125°. [Bandrowski *Chem Ber* **10** 838 *1877*, DOI: 10.1002/ cber.187701001231; Lossen *Justus Liebigs Ann Chem* **272** 127 *1893*, DOI: 10.1002/jlac.18932720202; *Beilstein* **2** H 801, **2** I 317, **2** II 670, **2** III 1991, **2** IV 2290.]

Acetylferrocene (ferrocenyl methylketone) *[1271-55-2]* **$C_{12}H_{12}OFe$, M 228.1, m 86°, 86-87°, b 161-163°/4mm, 369.2-373.5°/760mm.** Orange-red (red-brown) crystals are obtained when it is recrystallised from isooctane or *C_6H_6, and then sublimed at 100°/1mm. Insoluble in H_2O, but soluble in most organic solvents. The ***oxime*** has **m 167-170°** (from Et_2O or aqueous EtOH). The ***semicarbazone*** has **m 198-201°** (from EtOH). [Richmond & Freiser *J Am Chem Soc* **77** 2022 *1955*, DOI: 10.1021/ja01612a100; Weinmayr *J Am Chem Soc* **77** 3009 *1955*, DOI: 10.1021/ja01616a026; Broadhead et al. *J Chem Soc* 650 *1958*, DOI: 10.1039/JR9580000650; Donahue & Donahue 'Beyond Acetylferrocene: The Synthesis and NMR Spectra of a Series of Alkanoylferrocene Derivatives' *J Chem Edu* **90** 1688 *2013*, DOI: 10.1021/ed300544n; *Beilstein* **16** IV 1798.]

Allylpalladium(II) chloride dimer *[12012-95-2]* **$C_6H_{10}Cl_2Pd_2$, M 365.9, m 120°(dec), ~160°, 155-156°(dec).** Recrystallise the pale yellow solid from benzene. It is soluble in MeOH, Et_2O and $CHCl_3$. [Hüttel et al. *Chem Ber* **94** 766 *1961*, DOI: 10.1002/cber.19610940329; Dent et al. *J Chem Soc* 1585 *1964*, DOI: 10.1039/JR9640001585; Armstrong *J Org Chem* **31** 618 *1966*, DOI: 10.1021/jo01340a522; Tatsuno et al. '(η^3-allyl)palladium(II) Complexes' *Inorg Synth* **28** 342 *1990*, DOI: 10.1002/9780470132593.ch88; for applications see Feiser **2** 109, **5** 189, **7** 5, **9** 132.] Useful catalyst for efficient and accelerated Suzuki cross-coupling reactions [Wallow & Novak *J Org Chem* **59** 5034 *1994*, DOI: 10.1021/jo00096a056], Heck coupling of aryl halides with simple olefins [Fall et al. *Synthesis* 1683 *2007*, DOI: 10.1055/s-2007-966063], and enol ethers with aryl bromides [Battace et al. *Eur J Org Chem* 3122 *2007*, DOI: 10.1002/ejoc.200700152].

Allyl tri-*n*-butylstannane (allyl tributyl tin) *[24850-33-7]* **$C_{15}H_{33}Sn$, M 331.1, b 88-92°/0.2mm, 115°/17mm, d ^{20} 1.068g/ml, n $^{20}_D$ 1.487.** A possible impurity is tributylchlorostannane — test for Cl as Cl ion after hydrolysing. Dissolve it in *C_6H_6 (or toluene), shake this with dilute aqueous NaOH, dry ($CaCl_2$), filter, evaporate and distil the residue in a vacuum [Jones et al. *J Chem Soc* 1446 *1947*, DOI: 10.1039/JR9470001446; Bristow *Aldrichimica Acta* **17** 75 *1984*, Yamamoto *Aldrichimica Acta* **20** 45 *1987*]. [*Beilstein* **4** IV 4317; for applications see Fieser **9** 8, **11** 15, **12** 21, **13** 10, **14** 14, **16** 7, **17** 12.] Used in an efficient synthesis of homoallylic alcohols and amines from 2,4,6-trichloro-1,3,5-triazine [Das et al. *Tetrahedron Lett* **47** 9103 *2006*, DOI: 10.1016/j.tetlet.2006.10.068].

Aluminum acetylacetonate (tris[2,4-pentandionate]aluminium, $Al(acac)_3$) *[13963-57-0]* **$C_{15}H_{21}O_6Al$, M 324.3, m 192-194°, 195°, b 315°/atm, d ^{20} 1.42g/ml.** Recrystallise the white solid several times from *benzene or aqueous MeOH, λ_{max} 216 and 286mn. [Charles & Pawlikowski *J Phys Chem* **62** 440 *1958*, DOI: 10.1021/j150562a017.] It can be purified by sublimation and has the following solubilities in g percent: *C_6H_6 35.9 (20°), 47.6 (40°), toluene 15.9 (20°), 22.0 (40°) and acetylacetone 6.6 (20°), 10.4 (40°). [Fernelius & Bryant *Inorg Synth* **5** 105 *1957*, DOI: 10.1002/9780470132364.ch29; *Beilstein* **1** IV 3668.]

Aluminum ethoxide *[555-75-9]* **$C_6H_{15}O_3Al$, M 162.2, m 154-159°, 146-151°, b 187-190°/7mm, 210-214°/13mm, d ^{20} 1.142g/ml.** Crystallise the white powder from CS_2 [**m** 139°, CS_2 complex] and distil it in a vacuum. It reacts violently with H_2O, but is slightly soluble in xylene and PhCl. The molecular weight

corresponds to $[Al(OEt)_3]_4$ [Robinson & Peak *J Phys Chem* **39** 1125 *1935*, DOI: 10.1021/j150368a009; Vilani & Nord *J Am Chem Soc* **69** 2605 *1947*, DOI: 10.1021/ja01203a011]. [*Beilstein* **1** III 1284, **1** IV 1289.]

Aluminium isopropoxide *[555-31-7]* **$C_9H_{21}O_3Al$, M 204.3, m 119°(98%+purity), 138-142°(99.99%+ purity), b 94°/0.5mm, 135°/10mm, d^{20} 1.035g/ml.** Redistil the white solid under vacuum. *Hygroscopic*, decomposes in H_2O, but is soluble in *iso*-PrOH. [Robinson & Peak *J Phys Chem* **39** 1125 *1935*, DOI: 10.1021/j150368a009; *Beilstein* **1** IV 1468; Fieser **1** 35, **3** 10, **4** 15, **5** 14, **6** 19, **8** 15, **9** 14, **11** 29.] Commonly used in the preparation of Al_2O_3 [Sim *J Korean Ceram Soc* **52(1)** 56 *2015*, DOI: 10.4191/kcers.2015.52.1.56].

Aluminum triethyl (triethyl aluminum) *[97-93-8]* **$C_6H_{15}Al$, M 114.2, m -50°, b 69°/1.5mm, 76°/2.5mm, 129-131°/55mm, d_4^{20} 0.695, n_D^{20} 1.394.** Purify $Al(Et)_3$ by fractionation in an inert atmosphere under a vacuum in a 50cm column containing a heated nichrome spiral, taking the fraction **b 112-114°/27mm**. It is very sensitive to H_2O and should be stored under N_2. It should not contain chloride ions which can be shown by hydrolysis and testing with $AgNO_3$. [Baker & Sisler *J Am Chem Soc* **75** 4828 5193 *1953*, DOI: 10.1021/ja01115a502, DOI: 10.1021/ja01117a013; NMR: Brownstein et al. *J Am Chem Soc* **81** 3826 *1959*, DOI: 10.1021/ja01524a006; *Beilstein* **4** IV 4398; for applications see Fieser **1** 1197, **2** 427, **3** 299, **4** 526, **5** 688, **10** 415, **17** 367.] Also available commercially as solutions in heptane (1M), in hexanes (1M) and in toluene (25 wt%).

Aluminium tri-*tert*-butoxide *[556-91-2]* **$C_{12}H_{27}O_3Al$, M 246.3, m 208-210°(dec), >300°.** Crystallise pale yellow $Al(O\text{-}tBu)_3$ from $*C_6H_6$ and sublime it at 180°. [McElvain & Davie *J Am Chem Soc* **73** 1400 *1951*, DOI: 10.1021/ja01148a002; *Beilstein* **1** IV 1612; for applications see Fieser **1** 23, **2** 21.]

Aluminium trimethanide (trimethyl aluminium, TMA) *[75-24-1]* **C_3H_9Al, M 72.1, m 15.2°, b 111.5°/488.2mm, 124.5°/atm, d^{20} 0.752g/ml.** Distil $Al(Me)_3$ through a 10-20 theoretical plates column under 1 atmosphere pressure of N_2 (better with very slow take-off). It attacks grease (use glass joints). It has been distilled over Al in absence of grease, into small glass vials and sealed under N_2. The purity is measured by its freezing point. It reacts with H_2O, is non-conducting in $*C_6H_6$ and is **HIGHLY FLAMMABLE**. [Bamford et al. *J Chem Soc* 468 *1946*, DOI: 10.1039/JR9460000468; Pitzer & Gutowsky *J Am Chem Soc* **68** 2204 *1946*, DOI: 10.1021/ja01215a027; *Beilstein* **4** IV 4397; for applications see Fieser **8** 506, **15** 341, **17** 371.]

4-Aminophenylmercuric acetate (APMA) *[6283-24-5]* **$C_8H_9NO_2Hg$, M 371.8, m 163-165°, 168°, 175°(dec), 180°(dec).** Recrystallise it from hot dilute AcOH and dry it in air. Highly **TOXIC**. [Mahapatra et al. *J Indian Chem Soc* **32** 613 *1955*, Albert & Schneider *Justus Liebigs Ann Chem* **465** 257 *1928*, DOI: 10.1002/jlac.19284650113; *Beilstein* **16** III 1411, **16** IV 1754.]

Ammonium acetate *[631-61-8]* **$C_2H_3NO_2$, M 77.1, m 112-114°, 114°, d^{20} 1.17g/ml.** Crystallise it twice from anhydrous acetic acid, and dry under vacuum for 24 hours at 100° [Proll & Sutcliffe *Trans Faraday Soc* **57** 1078 *1961*, DOI: 10.1039/TF9615701078]. Its solubility in H_2O in g/100ml is 102 (0°), 148 (4°), 143 (20°) and 533 (80°); in MeOH it is 7.89 (15°) and 131.2 (94.2°); and 0.1 (25°) in DMF. [*Beilstein* **2** IV 121; Fieser **1** 38, **7** 11.]

Ammonium benzoate *[1863-63-4]* **$C_7H_9NO_2$, M 139.2, m 198°, 200°(dec), d^{20} 1.26g/cm^{-3}.** Crystallise it from EtOH. Its solubility in H_2O in w/v% is 21.3 (2°) and 83 (100°); and soluble in MeOH [*Beilstein* **9** IV 273.]

Ammonium dodecylsulfate (ammonium laurylsulfate) *[2235-54-3]* **$C_{12}H_{29}NO_4S$, M 283.4, b 418°/atm, d^{20} 1.02g/cm^{-3}** and **n_D^{20} 1.374 (for a ~30 wt% in H_2O).** Recrystallise it first from 90% EtOH and then twice from absolute EtOH, and finally dry it in a vacuum. [*Beilstein* **1** III 1786.] Useful anionic surfactant. **IRRITANT.**

Ammonium ferric oxalate trihydrate *[13268-42-3]* **$C_6H_{12}N_3O_{12}Fe.\ 3H_2O$, M 428.1, m ~160°(dec), d^{20} 1.77g/ml.** Crystallise it from hot water (0.5ml/g). [*Beilstein* **3** III 1103.]

Ammonium formate *[540-69-2]* **CH_5NO_2, M 63.1, m 116°, 117.3°, b 180°/atm (dec), d^{25} 1.26g/cm^3, d_4^{45} 1.280.** Heat the white solid in NH_3 vapour and dry it in a vacuum till the NH_3 odour is faint (***note*** that it can evaporate completely in a vacuum). Recrystallise it from absolute EtOH and then keep it in a desiccator over 99% H_2SO_4 *in vacuo*. It is very ***hygroscopic***. It exists in two forms, stable needles and less stable plates. It also

forms acid salts, i.e. $HCO_2NH_4.3HCO_2H$ and $HCO_2NH_4.HCO_2H$. [Kendall & Adler *J Am Chem Soc* **43** 1470 *1921*, DOI: 10.1021/ja01440a010; *Beilstein* **2** IV 18.] Its solubility in H_2O in g/100ml is 102 (0°), 142.7 (20°), 202.4 (40°) and 516 (80°); and is soluble in liquid NH_3. HCO_2NH_4, in the presence of microencapsulated Pd(0) under microwave irradiation, removes phenolic benzyl protecting groups rapidly [Quai et al. *Tetrahedron Lett* **48** 1241 *2007*, DOI: 10.1016/ j.tetlet.2006.12.041].

Ammonium ionophore I (Nonactin) *[6833-84-7]* **$C_{40}H_{64}O_{12}$, M 736.9, m 147-148°, $[\alpha]_D^{20}$ 0 (c 1.2, $CHCl_3$).** Crystallise it from MeOH (colourless needles), and dry at 20° in high a vacuum. It is a selectophore with high sensitivity for transporting NH_4^+ ions through biological membranes. [Corbaz et al. *Helv Chim Acta* **38** 1445 *1955*, DOI: 10.1002/hlca.19550380617; Dominguez et al. *Helv Chim Acta* **45** 129 *1962*, DOI: 10.1002/hlca.19620450117; Dobler *Helv Chim Acta* **55** 1371 *1972*, DOI: 10.1002/ hlca.19720550504; *Beilstein* **19/12** V 751.] Used for preparing potentiometric electrodes for determination of K^+ and NH_4^+ ions.

Ammonium oxalate dihydrate *[6009-70-7 (H_2O), 1113-38-8 (anhydrous)]* **$C_2H_8N_2O_4.H_2O$, M 142.1, m 70°(H_2O), 133°(anhydr, dec), b 365.1°/760mm, d^{20} 1.50g/cm^3.** Crystallise it from water (10ml/g) at 50°. [*Beilstein* **2** IV 1846.] It is a constituent of kidney stones.

Ammonium picrate (Dunnite explosive) *[131-74-8]* **$C_6H_6N_4O_7$, M 246.1, m EXPLODES above 200°, d^{25} 1.719g/cm^3.** Crystallise it from EtOH and acetone. Its solubility in H_2O at ~20° is 1g/100ml. [Mitchell & Bryant *J Am Chem Soc* **65** 128 *1943*, DOI: 10.1021/ja01242a001; *Beilstein* **6** II 262, **16** III 879, **16** IV 1392.]

n*-Amylmercuric chloride (pentylmercuric chloride)** *[544-15-0]* **$C_5H_{11}HgCl$, M 307.2, m 110°.** Crystallise it from EtOH. The ***bromide has **m 122°**. [Larock & Brown *J Am Chem Soc* **92** 2467 *1970*, DOI: 10.1021/ja00711a043; Marvel et al. *J Am Chem Soc* **47** 3009 *1925*, DOI: 10.1021/ja01689a026; *Beilstein* **14** H 706, 725.]

Aurothioglucose (gold thioglucose, Solganal) *[12192-57-3]* **$C_6H_{11}AuO_5S$, M 392.2.** Purify it by dissolving it in H_2O (0.05g in 1ml) and precipitating it by adding EtOH. It yields yellow crystals with a slight mercaptan odour. It decomposes slowly in H_2O, and is soluble in propylene glycol but insoluble in EtOH and other common organic solvents. [Caterson & Taylor *FEBS Lett* **98** 351 *1979*; DOI: 10.1016/0014-5793(79)80215-X; Cooney et al. *Biochem J* **259** 651 *1989*; DOI: 10.1042/bj2590651; Shaw 'Gold-Based Therapeutic Agents' *Chem Rev* **99** 2589 *1999*, DOI: 10.1021/cr980431o.]

Barium acetate *[543-80-6]* **$C_4H_6O_4Ba$, M 255.4, m 450°, d^{25} 2.468g/cm^3(anhydr).** Crystallise the white salt twice from anhydrous acetic acid and dry it under vacuum for 24 hours at 100°. Its solubility in H_2O in w/v% is 55.8 (0°) and 72 (20°), but it is only slightly soluble in EtOH. It decomposes to $BaCO_3$ upon heating in air. [*Beilstein* **2** III 192, **2** IV 114.] Used as a mordant for printing fabrics, drying paints and varnishes, and in lubricating oil.

Barium ionophore I [*N,N,N',N'*-tetracyclohexyloxy-bis-(*o*-phenyleneoxy)diacetamide] *[96476-01-6]* **$C_{40}H_{56}N_2O_5$, M644.9, m 156-158°.** Purify the ionophore by chromatography on a Kieselgel column, elute it with CH_2Cl_2/EtOAc (5:1), and recrystallise the residue from the evaporated effluent from EtOH/Me_2CO to give colourless crystals. It is an electrically neutral ionophore with high selectivity for Ba^{2+} ions and with high lipophilicity. [Kleiner et al. *Chem Ber* **118** 1071 *1985*, DOI: 10.1002/cber.19851180324; Läeubli et al. *Anal Chem* **57** 2756 *1985*, DOI: 10.1021/ac00291a005; Peshkova et al. *Electroanalysis* **22(19)** 2147 *2010*, DOI: 10.1002/elan.201000222.]

Barium propionate (H_2O) *[5908-77-0]* **$C_6H_{10}O_4Ba.H_2O$, M 301.5, 283.5(anhydr), m 300°, d_4^{27} 1.44, pK^{24} 4.88 (for propionic acid).** Crystallise the white powder from warm water (50ml/g) by adding EtOH and cooling. [*Beilstein* **2** III 517, **2** IV 702.]

Benzenechromium(0) tricarbonyl *[12082-08-5]* **$(C_6H_6)(CO)_3Cr$ M 214.1, m 162-163°, 163-166°.** Purify the yellow complex by sublimation *in vacuo*. A possible impurity is 2-picoline which can be removed by washing

with pentane and drying. It is then purified further by sublimation at 80-85°/10^{-3}mm, or by recrystallisation from Et_2O to give yellow crystals. ^1H NMR in $CDCl_3$ should give a single peak at τ 4.68. Soluble in THF, Et_2O and $*C_6H_6$, but insoluble in H_2O. [Rausch *J Org Chem* **39** 1787 *1974*, DOI: 10.1021/jo00925a052; Fischer & Őfele *Chem Ber* **90** 2532 *1957*, DOI: 10.1002/cber.19570901117; Pauson in Houben-Weyl *Meth Org Chem* V, E 18 Pt I p226 Theme Verlag, Stuttgart *1986*, *Beilstein* **5** IV 625; for applications see Fieser **6** 27, **13** 19.]

Beryllium acetate [$Be(OAc)_2$] *[543-81-7]* **$C_4H_6O_4Be$, M 127.1, m 65-100° (slow heating), 155-180° (rapid heating).** It is obtained by dissolving the *basic acetate* (4g, see below) in boiling glacial AcOH containing acetyl chloride (4.5g) and refluxing for ~15 minutes. The $Be(OAc)_2$ which separates during this time, is filtered off, washed with AcOH, cold $CHCl_3$ and dried *in vacuo* to give 90-94% yield of the salt. It is stable for several weeks in a tightly stoppered container at ~ 25°. It slowly loses Ac_2O**,** and more rapidly on heating, to give the basic acetate which sublimes out. Strong heating partially decomposes it to give Ac_2O and BeO. It is not readily attacked by cold H_2O but forms a hydrate on warming, and is insoluble in most solvents. Used in the ceramic industry. [Ehrlich in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 901 *1963*, Besson & Hardt *Z Anorg Allgem Chem* **277** 188 *1954*, DOI: 10.1002/zaac.19542770310.] Beryllium compounds are potentially **carcinogenic**.

Beryllium acetate (basic) [$Be_4O(OAc)_6$] *[1332-52-1, 19049-40-2]* **$C_{12}H_{18}O_{13}Be_4$, M 406.3, m 283°, 285-286°, b 330-331°/atm.** On evaporating $Be(OH)_2$ with AcOH this covalent basic acetate is produced. *Alternatively*, $BeCO_3$ (40g, see *[744998-97-8]*) and AcOH (80ml) are heated with stiring until evolution of CO_2 ceases. When the reaction is complete, white semi-translucent crystals separate. After cooling to ~ 25°, the basic acetate crystals are filtered off and dried in air. These are treated with warm $CHCl_3$ (60-80ml), any insoluble material is filtered off, and the colourless octahedral crystals of the basic acetate which separate on cooling (with partial evaporation) are collected and freed from any $CHCl_3$ *in vacuo* to give pure basic salt (28g, ~47%, **m 284°**). It is readily volatile, it can be distilled, and it sublimes in a vacuum leaving a small residue of 0.3-0.5% of BeO. It is very soluble in $CHCl_3$, soluble in non-polar organic solvents such as boiling $*C_6H_6$, toluene, xylene, tetralin, and in AcOH; less so in CCl_4, Ac_2O and AcCl, but is sparingly soluble (~0.3%) in Et_2O. It dissolves in anhydrous boiling MeOH but soon liberates Ac_2O to form highly aggregated basic acetates. It is quite stable in cold H_2O, but is rapidly hydrolysed in hot H_2O. [Moeller et al. *Inorg Synth* **3** 9 *1950*, DOI: 10.1002/9780470132340.ch3; Ehrlich in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 901 *1963*, and for the basic formate or propionate salts see Besson & Hardt *Z Anorg Allgem Chem* **277** 188 *1954*, DOI: 10.1002/zaac.19542770310; Hendus & Hardt *Z Anorg Allgem Chem* **277** 127 *1954*, DOI: 10.1002/zaac.19542770303; Hendus & Hardt *Z Anorg Allgem Chem* **286** 265 *1956*, DOI: 10.1002/zaac.19562860511; and Hardt *Z Anorg Allgem Chem* **286** 254 *1956*, DOI: 10.1002/zaac.19562860510; *Beilstein* **2** H 111, **2** I 48, **2** II 116, **2** III 190, **2** IV 112.] The X-ray crystal structure shows that the four beryllium atoms are arranged at the corners of a regular tetrahedron with oxygen at the centre, and the six edges are occupied by acetate groups. Thus the four Be atoms at the apexes of the tetrahedron are coordinated to the carboxyl oxygen atoms of the six acetate groups, i.e. each Be atom is coordinated to three oxygen atoms. [Bragg & Morgan *Proc Roy Soc* **104** 437 *1923*, DOI: 10.1098/rspa.1923.0119; for partial structure see also F.A. Cotton and G. Wilkinson *Advanced Inorganic Chemistry (A Comprehensive Text)* p. 175, Interscience Publ. *1962*, Library of Congress Catalog Number 62-14818.] Beryllium compounds are potentially **carcinogenic**.

Beryllium acetylacetonate [$Be(acac)_2$] *[10210-64-7]* **$C_{10}H_{14}O_4Be$, M 207.2, m 108°, 108.5-109°, b 270°/atm, d^{25} 1.168g/ml.** This complex has been prepared by adding 3M aqueous NaOH (100ml) to a solution of $BeSO_4$ $4H_2O$ (10g, see *[7787-50-0]*) in distilled H_2O (100ml) to give a strong basic solution to which is added freshly distilled acetylacetone (30ml) dropwise with stirring, and a white precipitate separates. This is collected, washed with H_2O and dried *in vacuo* to give the complex (5.1g 43%) which is recrystallised by dissolving in a small volume of $*C_6H_6$ and adding gradually petroleum ether until crystallisation is complete. The crystals are collected, washed with petroleum ether and dried *in* vacuo. It can be recrystallised further from a small volume of $*C_6H_6$ or a large volume of petroleum ether. It has also been prepared in 70% yield from basic beryllium carbonate (3g) in H_2O (45ml) by conversion to the chloride with 6N aqueous HCl (*ca* 20ml) until slightly acidic. To this is added dropwise a clear solution of acetylacetone (10g suspended in 45ml of H_2O to which is added 6N ammonia until completely clear) and stirred until precipitation of the complex is complete (pH should be near neutral). The solid is collected washed with H_2O, dried, and crystallised as before. It is also sublimed through a

plug of glass wool at a vacuum of 0.1mm by heating in a bath at 80 to100°. It is very soluble in most organic solvents such as EtOH, Et_2O, Me_2CO, $*C_6H_6$ and in CS_2 but considerably less in petroleum ethers. However, it is practically insoluble in H_2O which hydrolyses it on boiling; and it is also hydrolysed by acids and alkalis. [Jones *J Am Chem Soc* **81** 3188 *1959*, DOI: 10.1021/ja01522a005; Arch et al. *Inorg Synth* **2** 17 *1946*, DOI: 10.1002/9780470132333.ch5.] Berylluim compounds are potentially **carcinogenic**.

Bicyclo[2.2.1]hepta-2,5-diene rhodium (I) chloride dimer (norbornadiene rhodium chloride complex dimer) *[12257-42-0]* **$C_{14}H_{16}Cl_2Rh_2$, M 461, m 239-241°(dec), 240°(dec).** It recrystallises from hot $CHCl_3$/petroleum ether as fine crystals soluble in $CHCl_3$ and $*C_6H_6$ but is almost insoluble in Et_2O or petroleum ether. [Abel et al. *J Chem Soc* 3178 *1959*, DOI: 10.1039/JR9590003178.] It is a **pre-catalyst** for asymmetric and cross-coupling reactions, and is a catalyst for hydrosilylation. [cf. Ngai et al. *J Am Chem Soc* **129** 280 *2007*, DOI: 10.1021/ja0670815.]

2,2'-Bipyridinium chlorochromate *[76899-34-8]* **$C_{10}H_9N_2CrO_3Cl$, M 292.6.** Wash it with cold conc HCl, then H_2O (sintered glass funnel) and dry it in a vacuum ($CaCl_2$) to give a free-flowing yellow-brown powder. Store it in the dark. [Guziec & Luzzio *Synthesis* 691 *1980*, DOI: 10.1055/s-1980-29172; Chakraborty & Chandrasekaran *Synth Commun* **10** 951 *1980*, DOI: 10.1080/00397918008061857; Fieser **10** 30, **11** 44.] Useful oxidant. Together with *m*-chloroperbenzoic acid it mediates the cleavage of benzylidene acetals [Luzzio & Bobb *Tetrahedron Lett* **38** 1733 *1997*, DOI: 10.1016/S0040-4039(97)00203-7]. **SUSPECTED CARCINOGEN.**

2,2'-Biquinolin-4,4'-dicarboxylic acid dipotassium salt *[63451-34-3, 207124-63-8 ($3H_2O$)]* **$C_{20}H_{10}N_2O_4K_2$, M 420.51(anhydr), m >300°.** Recrystallise it from H_2O. The ***Cu salt*** has UV with λ_{max} at 562nm. [Mopper & Gindler *Anal Biochem* **56** 440 *1973*, DOI: 10.1016/0003-2697(73)90210-8; *Beilstein* **25** IV 1148.] Useful charged ligand for catalyst immobilisation and analysis [Review: Chisholm & McIndoe *JCS Dalton Trans* **30** 3933 *2008*, DOI: 10.1039/B800371H].

Bis(1,2,3,4,5-η-cyclooctadienyl)ruthenium [$Ru(COD)_2$] *[63395-36-8]* **$C_{16}H_{22}Ru$, M 315.4, m 89-90°, 113-114°.** The bis-complex is prepared by adding a solution of $RuCl_3$. $3H_2O$ (624mg, 1.33mol) in EtOH (20ml) under argon (or N_2) slowly over 30 minutes to a stirred suspension of Zn powder (7g), EtOH (5ml) and redistilled 1,2-5,6-cyclooctadiene (11ml, 80mol, COD see [*111-78-4*, *1552-12-1*], then stirring at room temperature for 2 hours, and filtering the mixture under N_2. The filtrate is concentrated on a vacuum line to remove volatiles, and the residual brown oil is placed on top of an Al_2O_3 column in hexane after flushing with N_2. The yellow band is eluted with hexane, concentrated *in vacuo*, the eluate is evaporated, pentane is added to dissolve the residue and the solution is cooled at -78° for several hours, to provide very pale yellow (almost colourless) crystals of the analytically ***pure complex*** (283mg, 35%). The ^1H NMR (60MHz, C_6D_6, TMS) has τ at 4.42 (t, 2H), 6.15 (dd, 4H), 6.45 (m, 4H) and 7.49-8.95 (m, 12H); and the ^{13}C NMR (22.6MHz, C_6D_6, TMS) has δ at 22.5, 27.3, 36.7, 35.3, 38.9, 62.4, 76.7, 87.6. [Preparation: Pertici et al. *JCS Dalton Trans* 1961 *1980* (gave m 89-90°), DOI: 10.1039/DT9800001961; Itoh et al. *J Organomet Chem* **272** 179 *1984* (gave m 113-114°), DOI: 10.1016/0022-328X(84)80465-9.]

Bis(η^5-2,4-cyclopentadien-1-yl)samarium II [$SmCp_2$, samarocene] *[80695-16-5]* **$C_{10}H_{10}Sm$, M 280.5, decomposes at high temperatures.** Samarium dicyclopentadienyl can be prepared in Schlenk equipment under argon by adding SmI_2 (0.1M in THF, 60ml, 6mmol) to a 0.4M solution of sodium pentadienide in THF (30ml, 12mmol) when the complex separates immediately and is decanted within 1 hour. The red powder of $SmCp_2$ is collected, washed twice with THF to remove NaI, dried *in vacuo* and stored under argon. The red powder and the purple solid THF complex (**M 352.6**) are ***pyrophoric*** in air. $SmCp_2$ can also be stored for a few days in a Schlenk tube under THF without decomposition. Freshly prepared suspensions of $SmCp_2$ have been used in ***pseudo-Barbier couplings*** between carbonyl compounds and aliphatic or allylic halides and are more efficient than SmI_2 [Namy et al. *J Organometal Chem* **328** 81 *1986*, DOI: 10.1016/S0022-328X(00)99769-9].
$SmCp_2$-THF has been prepared in one arm of a U-tube by stirring in an anhydrous oxygen-free helium atmosphere) tris(cyclopentadienyl)samarium III ($SmCp_3$, 0.499g), K metal (0.527g, naphthalene (0.128g, 25% molar deficiency) and THF (25ml, freshly distilled under reduced pressure from Na-benzophenone) for 48 hours. Purple $SmCp_2$-furanate was separated by decantation, washed by successive back-distillation with THF and the solvent is removed at 24°/10^{-3}mm during 18 hours. It is ***pyrophoric*** and should be handled in an anhydrous

oxygen-free atmosphere. Its IR has ν_{max} (Nujol) at 3080 (C-H stretch), 1475, 1347, 1308, 1263, 1163, 1070, 1008 (C-H bend parallel), 775, 740 (C-H bend perpendicular) and 350 (antisym metal-ring vibration) cm^{-1}, and other bands at 2980, 2880, 1375, 725 and 565 cm^{-1} due to coordinated THF with intensities similar to the weaker metallocene bands. On exposure to traces of air this complex immediately changes in colour from deep purple to yellow-grey with drastic reduction in the paramagnetism. [Watt & Gillow *J Am Chem Soc* **91** 775 *1969*, DOI: 10.1021/ja01031a061.]

Bis(2,9-dimethyl-1,10-phenanthroline) copper(I) perchlorate (Cuproine) *[54816-44-5]* **$C_{28}H_{24}N_4Cu.ClO_4$, M 579.6, pK^{25} -2.4 to -3.1 (for $HClO_4$) and 6.15 (for dimethylphenanthroline).** Crystallise it from acetone. It has UV with λ_{max} in isopentanol or hexan-1-ol at 454nm. [Smith & McCurdy *Anal Chem* **24** 371 *1952*, DOI: 10.1021/ac60062a029; Gahler *Anal Chem* **26** 577 *1954*, DOI: 10.1021/ac60087a052; *Beilstein* **23** III/IV 1737.]

1,1'-Bis(diphenylphosphino)ferrocene (DPPF) *[12150-46-8]* **$C_{34}H_{28}FeP_2$, M 554.4, m 181-182°(dec), 184-194°.** Wash the ferrocene with distilled H_2O and dry it in a vacuum. Dissolve it in *ca* 5 parts of hot dioxane and cool to give orange crystals **m 181-183°**. Recrystallisation from $*C_6H_6$/heptane (1:2) gives a product with **m 183-184°**. [Bishop et al. *J Organomet Chem* **27** 241 *1971*, DOI: 10.1016/S0022-328X(00)80571-9.] This ligand, *via* Pd-phosphine, is used to prepare new functionalised furan derivatives by sequential C-C and C-O bond formation [Tanimori et al. *Synthesis* **5** 865 *2006*, DOI: 10.1055/s-2006-926321], and when complexed with Pd(II), catalyses cross-coupling synthesis of oxazepine ring systems [Ma et al. *Tetrahedron* **62** 9002 *2006*, DOI: 10.1016/j.tet.2006.07.009].

Bis(ethyl)titanium(IV) chloride *[2247-00-9]* **$C_4H_{10}Cl_2Ti$, M 176.9.** Recrystallise it from boiling toluene. [Original paper: Pfeiffer et al. *Justus Liebigs Ann Chem* **503** 84 *1933*, DOI: 10.1002/jlac.19335030106] **VERY TOXIC.**

Bis(tetrabutylammonium) dichromate *[56660-19-6]* **$C_{32}H_{72}N_2O_7Cr_2$, M 700.9, m 139-142°, 139-143°.** Wash the dichromate with water and dry it in a vacuum. Recrystallise it from hexane (**m 79-80°**). Useful oxididant. [Santaniello & Ferraboschi *Synth Commun* **10** 75 *1980*, DOI: 10.1080/00397918008080055; *Beilstein* **4** IV 556.] (Possible **CARCINOGEN**.)

***n*-Butylmercuric chloride** *[543-63-5]* **$C_4H_9N_2ClHg$, M 293.1, m 130°.** Crystallise it from 95% EtOH (white needles or leaflets). Its solubility (g/100ml) in H_2O is 1 x 10^{-4} at 18° and 3.3 x 10^{-4} at 100°; in EtOH is 1.5 at 18° and 9.0 at 70°; and in $CHCl_3$ is 5.6 at 18°. [Larock & Brown *J Am Chem Soc* **92** 2467 *1970*, DOI: 10.1021/ja00711a043; Marvel et al. *J Am Chem Soc* **47** 3009 *1925*, DOI: 10.1021/ja01689a026.]

***n*-Butylstannoic acid [*n*-BuSnO(OH)$_n$, *n*-butyltinhydroxy oxide hydrate]** *[2273-43-0, 22719-01-3]* **$C_4H_{10}O_2Sn$, M 208.8(anhydr), d^{25} 1.46g/cm^3.** Purify it by adding excess KOH in $CHCl_3$ to remove small

amounts of *n*-BuSn(OH)Cl_2 and *n*-BuSn(OH)$_2$Cl, and isolate it by acidification. It is soluble in acetone and dries as an infusible white powder and is ***polymeric***. Its Mössbauer parameters are δ.68 and 0.70mm/sec for C, and its $H\Delta E_Q$ are 1.52 and 1.65mm/sec (see Davies et al. below). It forms a ***hexameric*** (by Xray, see Holmes et al. below) ***n*-butyloxy *o*-nitrobenzoate ester** [*n*-BuSn(O)$O_2CC_6H_4NO_2$-2]$_6$.3C_6H_6, thus: *n*-BuSnO(OH) (2.17g, 10.4mmol) is added to a stirred solution of $C_2H_2Cl_2$ (50ml) and *C_6H_6 (80ml) followed by *o*-nitrobenzoic acid (1.74, 11.4mmol), and refluxed for 18 hours under a Dean-Stark trap to remove H_2O azeotropically. The original clear yellow solution changes to a cream-white suspension, and after 24 hours standing a white powder containing small clear crystals result, which is filtered off and washed with *C_6H_6. On standing larger crystals separate in the filtrate. Both the white powder and the crystals have the same **m 295-305°** (total yield is 3.65g, 98%). They have IR (Nujol) with ν at 1530, 1550 (COO), 563 and 530 (Sn-O) cm^{-1}, and analyse correctly after drying. It forms ***hexameric esters*** with other acids, e.g. with cyclopentane carboxylic acid [see Chandrasekhar et al. *Inorg Chem* **26** 1050 *1987*, DOI: 10.1021/ic00254a017]. [Holmes et al. *J Am Chem Soc* **109** 1408 *1987*, DOI: 10.1021/ja00239a022; Luijten *Recl Trav Chim Pays-Bas* **85** 873 *1966*, DOI: 10.1002/recl.19660850904; for Mössbauer and NMR spectra see Davies et al. *J Organomet Chem* **39** 279 *1792*, DOI: 10.1016/S0022-328X(00)80452-0; Pfeiffer *Z Anorg Chem* **68** 102 *1910*, DOI: 10.1002/zaac.19100680111].

Cadion [1-(4-nitrophenyl)-3-(4-phenylazophenyl)-triazene] *[5392-67-6]* **$C_{18}H_{14}N_6O_2$, M 346.3, m 189°(dec), d ^{25} 1.30g/cm^3.** Commercial cadion is purified by recrystallisation from 95% EtOH and is dried *in vacuo*. It is stable in 0.2 N KOH (in 20% aqueous EtOH) at 25°. It is a sensitive reagent for ***Cd***, and the ***Cd complex*** has UV with λ_{max} (EtOH) at 475nm. [Chavanne & Geronimi *Anal Chim Acta* **19** 377 *1958*, DOI: 10.1016/S0003-2670(00)88180-5; *Beilstein* **16** III 664.] The method uses a dual-wavelength spectrophotometric assay and the difference value in absorbance in the λ_{max} (at 475nm) of the Cd chelate and that of Cadion (at 566nm) [Watanabi & Ohmori *Talanta* **26** 959 *1979*, DOI: 10.1016/0039-9140(79)80133-2].

Cadmium acetate dihydrate *[543-90-8(anhydr), 5743-04-4(2H_2O), 89759-80-8(xH_2O),]* **$C_4H_6O_4Cd$, M 230.5(anhydr), m 130° (hydrate, dec), 255°(anhydr), d ^{25} 2.01g/cm^3 (hydrate), 2.341g/cm^3 (anhydr), pK_1^{25} 9.7, pK_2^{25} ~11.0 (for Cd^{2+}).** Recrystallise it twice from anhydrous acetic acid and dry it under vacuum for 24 hours at 100°. The salts are soluble in MeOH and EtOH, and very soluble in H_2O. [*Beilstein* **2** IV 114.] **Cd compounds are considered Group 1 carcinogens by the IARC.**

Cadmium ionophore I [*N,N,N',N'*-tetramethyl-3,6-dioxooctanedi-(thioamide)] *[73487-00-0]* **$C_{22}H_{44}N_2O_2S_2$, M 432.7, m 35-36°.** Wash it well with petroleum ether, then several times with 2N HCl (if it has a slight odour of pyridine), then H_2O and dry it in a vacuum over H_2SO_4. It is a ***polar selectrophore*** for Cd. [Schneider et al. *Helv Chim Acta* **63** 217 *1980*, DOI: 10.1002/hlca.19800630121; Simon & Carafoli *Methods Enzymol* **56** 439 *1979*, DOI: 10.1016/0076-6879(79)56043-1.]

Cadmium lactate *[16039-55-7]* **$C_6H_{10}O_6Cd$, M 290.6. b 227.6°/760mm.** Recrystallise the lactate from water (10ml/g) by partial evaporation in a desiccator. [*Beilstein* **3** H 277, **3** III 465, **2** IV 637.] **Cd compounds are considered Group 1 carcinogens by the IARC.**

Cadmium salicylate monohydrate *[19010-79-8]* **$C_{14}H_{10}O_6Cd$, H_2O, M 386.6(anhydr), m 242°(dec).** Recrystallise the white solid from distilled Prasad et al. *J Indian Chem Soc* **35** 267 *1958*, H_2O by evaporation in a desiccator. It is readily soluble in acids and NH_4OH, slightly soluble in cold H_2O, MeOH and EtOH, but freely soluble in hot H_2O. It has been used as a pesticide, and as an antiseptic. [*Beilstein* **10** H 60, **10** I 25, **10** II 33, **10** III 94, **10** IV 128.] **Cd compounds are considered Group 1 carcinogens by the IARC.**

Calcein sodium salt [2',7'-bis-{*N,N*-di(carboxymethyl)aminomethyl}fluorescein Na salt, Fluorexon, Fluorescein Complexon] *[108750-13-6 diNa salt, 1461-15-0 free acid]* **$C_{30}H_{24}N_2O_{13}Na_2$, M 666.5, $pK_{Est(1)}$~ 1.9, $pK_{Est(2)}$~ 2.5, $pK_{Est(3)}$~ 8.0, $pK_{Est(4)}$ ~ 10.5 (all for N-CH_2COOH), and $pK_{Est(5)}$ ~ 3.5 (for benzoic COOH).** Dissolve it in distilled H_2O and acidify with dilute HCl to pH 3.5. Filter off the solid acid and wash it well with H_2O. Redissolve *ca* 10g in 300ml H_2O containing 12g of NaOAc. Precipitate it again by adding HCl, filtering and washing with H_2O. Add the solid to 200ml of EtOH stir for 1 hour and filter. Repeat the EtOH

wash and dry the bright yellow solid in a vacuum. This acid decomposes on heating at *ca* 180°. See below for the preparation of the Na salt. [Diehl & Ellingboe *Anal Chem* **28** 882 *1956*, DOI: 10.1021/ac60113a030].
Alternatively, dissolve it in H_2O and acidify with 3N HCl to pH 3.5. Collect the solid and wash it with H_2O. The air-dried precipitate is extracted with 70% aqueous EtOH, filtered hot and cooled slowly. Fine yellow needles of the acid crystallise out; they are filtered off and dissolved in the minimum quantity of 0.01N NaOH and re-precipitated by adding N HCl to pH 3.5. It is then recrystallised from 70% aqueous EtOH (3x). The final product (***acid***) is dried at 80° in a vacuum for 24 hours, **m >300°(dec)**. It contains one molecule of water per molecule of ***acid*** (***$C_{30}H_{36}N_4O_{13}.H_2O$***). The product is pure ***acid*** as revealed by electrophoresis at pH 5.6 and 8.6, and by TLC in *i*-BuOH/*i*-PrOH/AcOH/H_2O (60:60:5:5 by volume) or *i*-PrOH or pH 8.0 borate buffer. [Wallach et al. *Anal Chem* **31** 456 *1959*, DOI: 10.1021/ac60147a041.] The ***Na salt*** is prepared by dissolving the pure acid in H_2O containing 2 mols of NaOH per mol of acid reagent and lyophilising. It complexes with Ca and Mg ions [Pribil *Analyst* **83** 188 *1958*, DOI: 10.1039/ AN9588300188]. [*Beilstein* **19** III/IV 4338.]

Calcium acetate monohydrate *[5743-26-0 (H_2O), 62-54-4 (xH_2O)]* **$C_4H_6O_4Ca$, M 176.2 (H_2O), m 150° (loses H_2O), 150°(dec to $CaCO_3$ + Me_2CO), d ^{25} 2.01g/cm^3, n $^{25}_D$ 1.55, pK^{25} 12.7 (for Ca_2^+).** Recrystallise the acetate from water (3ml/g) by partial evaporation in a desiccator. Its solubility in H_2O in g/100ml is 37.4 (0°), 34.7 (20°), and 29.7 (100°); it is slightly soluble in MeOH and hydrazine but insoluble in Me_2CO, EtOH and hydrocarbon solvents. [*Beilstein* **2** IV 113, for applications see Fieser **13** 60.]

Calcium benzoate trihydrate *[2090-05-3, 5743-30-6]* **$C_{14}H_{16}O_7Ca.\ 3H_2O$, M 336.4($3H_2O$).** Recrystallise the benzoate from water (10ml/g) between 90° and 0°. Dry it in a crucible for 2 hours at 105° and cool in a dessicator. [*Beilstein* **9** I 60, **9** H 85, **9** III 377, **9** IV 280.] Antimicrobial preservative.

Calcium butyrate *[5743-36-2]* **$C_8H_{14}O_4Ca$, M 214.3, d $^{30}_4$ 1.271.** Recrystallise the butyrate from water (5ml/g) by partial evaporation in a desiccator and dry it in a vacuum to constant weight. [Pathak & Bhide *J Indian Chem Soc* **30** 47, 48 *1953*.] Its ***dissociation constant*** at 25° is 0.29 [Colman-Porter & Monk *J Chem Soc* 4363 *1952*, DOI: 10.1039/JR9520004363; *Beilstein* **2** IV 785].

Calcium carbamate *[543-88-4]* [H_2NCO_2] **$(H_2NCO_2)_2$ Ca, M 160.1.** Recrystallise calcium carbamate from aqueous ethanol. [*Beilstein* **4** H 75, **4** I 336, **4** II 557, **4** III 149, **4** IV 234.]

Calcium formate *[544-17-2]* **$[HCO_2]_2$ Ca, M 130.1, m 300°(dec on heating), d ^{25} 2.009g/cm^3.** Recrystallise white food additive from water (5ml/g) by partial evaporation in a desiccator. The solubility of this white solid in H_2O in g/100ml is 16.1 (0°), 16.6 (20°), and 18.4 (100°); and is insoluble in EtOH. [*Beilstein* **2** IV 16.]

Calcium D-gluconate monohydrate *[299-28-5, 18016-24-5, 66905-23-5 (H_2O)]* **$C_{12}H_{22}O_{14}Ca.\ H_2O$, M 430.4(anhydr), m dec on heating, $[\alpha]^{20}_{546}$ +11.0, $[\alpha]^{20}_D$ +9.0 (c 1.2, H_2O).** Calcium gluconate is soluble in H_2O (3.5g in 100g at 25°). Dissolve it in H_2O, filter and precipitate it by adding MeOH. Filter off the solid and dry it in a vacuum at 85°. *Alternatively*, dissolve it in H_2O, filter (from insoluble inorganic Ca) and evaporate it to dryness under vacuum at 85°. [March et al. *J Am Pharm Assoc* **41** 366 *1952*, DOI: 10.1002/jps.3030410709; *Beilstein* **3** IV 1255.] Used as a Ca supplement, protects against osteoarthritis.

Calcium D-heptagluconate dihydrate *[17140-60-2]* **$C_{14}H_{26}O_{16}Ca.\ 2H_2O$, M 526.4 ($2H_2O$), $[\alpha]^{20}_{546}$ +5.2, $[\alpha]^{20}_D$ +4.4 (c 5, H_2O).** Purify it in the same way as for calcium D-gluconate. [*Beilstein* **3** III 1112.]

Calcium ionophore I {ETH 1001, [(-)-4*R*,5*R*)-4,5-dimethyl-1,8-dioxo-3,6-dioxaoctamethylene]bis(12-methylaminododecanoate)} *[58801-34-6]* **$C_{38}H_{72}N_2O_8$, M 685.0.** This is a neutral Ca ***selectophore***. It can be purified by thick layer (2mm) chromatography (Kieselgel F_{245}) and eluted with $Me_2CO/CHCl_3$ (2:1). [Ammann et al. *Helv Chim Acta* **56** 1780 *1973*, DOI: 10.1002/hlca.19730560538; Simon & Carafoli *Methods Enzymol* **56** 439 *1979*, DOI: 10.1016/0076-6879(79)56043-1.]

Calcium ionophore II (ETH 129, *N,N,N',N'*-tetracyclohexyl-3-oxapentanediamide, *N,N,N',N'*-tetra(cyclohexyl)diglycolic acid diamide) *[74267-27-9]* **$C_{28}H_{48}N_2O_3$, M 460.7, m 153-154°.** Recrystallise it from Me_2CO. It forms 1:2 and 1:3 metal/ligand complexes with Mg^{2+} and Ca^{2+} ions, respectively, and induces

selectivity in membranes for Ca^{2+} over Mg^{2+} by a factor of *ca* 10^4. [Pretsch et al. *Helv Chim Acta* **63** 191 *1980*, DOI: 10.1002/hlca.19800630117; Simon & Carafoli *Methods Enzymol* **56** 439 *1977*, DOI: 10.1016/0076-6879(79)56043-1.]

Calcium ionophore III [A23187 calcimycin antibiotic] *[52665-69-7]* **$C_{29}H_{37}N_3O_6$, M 523.6, m 181-182°, $[\alpha]_D^{25}$-56.0 (c 1, $CHCl_3$).** It recrystallises from Me_2CO as colourless needles. Protect it from light and moisture, store in a refrigerator. It is soluble in Me_2SO (50mg/ml by heating or sonication), EtOH, EtOAc, MeOH and $CHCl_3$ (20mg/ml) and can be stored for 3 months without loss of activity. Aqueous solutions can be made by dissolving in Me_2SO, and diluting with H_2O. If stored at 2-8°, in a dessicated state and protected from light, it is stable for ~5years. The Mg and Ca salts are soluble in organic solvents and cross biological membranes. It has a pKa of 6.9 in 90% Me_2SO. The Ca complex crystallises from 50% EtOH as colourless prisms. It is ***highly* TOXIC**. [Pressman *Ann Rev Biochem* **45** 501 *1976*, DOI: 10.1146/ annurev.bi.45.070176.002441; Chaney et al. *J Am Chem Soc* **96** 1932 *1974*, DOI: 10.1021/ja00813a047; Suzuki et al. *Anal Chem* **61** 382 *1989*, DOI: 10.1021/ac00179a018; Simon & Carafoli *Methods Enzymol* **56** 439 *1977*, DOI: 10.1016/0076-6879(79)56043-1; for a new role see Verma et al. *Cell Calcium* **50** 510 *2011*, DOI: 10.1016/j.ceca.2011.08.007.]

Calcium isobutyrate *[533-90-4]* **$C_8H_{14}O_4Ca$, M 248.2, 214.3.** Crystallise it from water (3ml/g) by partial evaporation in a desiccator. It forms a ***pentahydrate*** at low temperatures, but the crystals filtered from a saturated solution at 80° are the ***monohydrate***; the transition temperature is 62.5°. [Lumsden *J Chem Soc* **81** 350 *1902*, DOI: 10.1039/CT9028100350.] It has a ***dissociation constant*** of 0.31 [Colman-Porter & Monk *J Chem Soc* 4363 *1952*, DOI: 10.1039/JR9520004363]. Calcium lactate ($5H_2O$) *[814-80-2, 15743-47-5]* **$C_6H_{10}O_6Ca$, M 308.3($5H_2O$), m 120°($5H_2O$), 240°(anhydr), d ^{25} 1.494g/cm^3, n$_D^{25}$ 1.470.** Crystallise calcium lactate from warm water (10ml/g; solubility at 30° is 7.9g/100ml) by cooling to 0°. It is very soluble in EtOH. [*Beilstein* **3** IV 636.] The *S*(+)-***calcium lactate* (calcium 2-hydroxypropionate)** *[41372-22-9]* has **$[\alpha]_D^{20}$ -4.2 (c 5, H_2O).** Used as anti-acid, in foods, e.g. baking powder, added to sugar-free foods to prevent tooth decay, and prolongs fresh-cut fruit to shelf life.

Calcium propionate *[4075-81-4]* **$C_6H_{10}O_4Ca$, M 186.2, m dec on heating.** Crystallise this antifungal salt from water (solubility in g/100ml is 49 at 0° and 55.8 at 100°) by partial evaporation in a desiccator. It is slightly soluble in MeOH and EtOH, but insoluble in Me_2CO and hydrocarbon solvents. [*Beilstein* **2** H 238, **2** II 218, **2** III 516, **2** IV 702.] It is used as a food additive.

Calcium salicylate ($2H_2O$) *[824-35-1, 59788-56-6]* **$C_{14}H_{14}O_8Ca$, M 314.0(anhydr), pK$_1^{20}$ 3.08, pK$_2^{20}$ 13.43 (for acid).** Recrystallise calcium salicylate from water (3ml/g) between 90° and 0°. [*Beilstein* **10** H 60, **10** II 33, **10** III 94, **10** IV 128.] Used in overbased greases [Patent US7407920 B2, applied US 10/911,132 aug 5, 2008.]

Carbonate ionophore I [ETH 6010] (heptyl 4-trifluoroacetylbenzoate) *[129476-47-7]* **$C_{16}H_{19}F_3O_3$, M 316.3, b 170°/0.02mm, d$_4^{20}$ 0.909.** Purify the ionophore by flash chromatography (2g of reagent with 30g of Silica Gel 60) and elute with EtOAc/hexane (1:19). The fractions that absorb light at 260nm are pooled, evaporated and dried at room temperature (10.3 Torr). The oily residue is distilled in a bubble-tube apparatus (170°/0.02 Torr). Its IR ($CHCl_3$) has peaks at 1720, 1280, 940cm^{-1}, and its solubility in tetrahydrofuran is 50mg/0.5ml. It is a lipophilic ***neutral ionophore selective*** for carbonate as well as being an optical humidity sensor. [Behringer et al. *Anal Chim Acta* **233** 41 *1990,* DOI: 10.1016/S0003-2670(00)83459-5.]

Cerium (III) acetate (cerium triacetate) *[537-00-8, 206996-60-3 (xH_2O)]* **$C_6H_9O_6Ce$, M 317.3(anhydr), pK$_1^{25}$ 8.1 (9.29), pK$_2^{25}$ 16.3, pK$_3^{25}$ 26.0 (for Ce^{3+}).** Recrystallise it twice from anhydrous acetic acid, then pump dry under a vacuum at 100° for 8 hours. [*Beilstein* **2** I 50, **2** II 119, **2** III 196, **2** IV 115.]

Cesium oleate *[31642-12-3]* **$C_6H_9O_6Cs$, M 414.4.** Recrystallise cesium oleate from EtOAc, dry it in an oven at 40° and store it over P_2O_5. It forms stable emulsions [Finkle et al. *J Am Chem Soc* **45** 2780 *1923,* DOI: 10.1021/ja01665a002.] [*Beilstein* **2** II 437, **2** III 1405.]

Cesium perfluoro-octanoate (cesium pentadecafluorooctanoate, CsPFO) *[17125-60-9]* **($C_8F_{15}O_2)_3Cs$, M 546.0.** Recrystallise it from a butanol/petroleum ether mixture, dry it in an oven at 40° and store it over P_2O_5 under vacuum. It is prepared by neutralising an aqueous solution of pentadecafluorooctanoic acid {PFO [335-67-1], $C_8HF_{15}O$, M 414.1, m 40-50°, b 189-192°/atm, solubility in H_2O ~9.5g/100ml at ~25°} with $Cs_2(CO_3)_3$ {[54451-25-1] M 460.3(anhydr)}, evaporating to dryness in an oven at 100°, then recrystallising twice from *n*-BuOH. [For preparation and phase diagram by ^{133}Cs NMR see Boden et al. *J Phys Chem* **97(29)** 7678 *1993*, DOI: 10.1021/j100131a043.] [*Beilstein* **2** IV 994.] It is a water surfactant.

Chloro-tri-isopropoxy titanium (IV) *[20717-86-6]* **$C_9H_{21}ClO_3Ti$, M 260.6, m 45-50°, b 61-65°/0.1mm, d^{25} 1.091g/ml.** When distilled under vacuum, the distillate sets slowly to a solid on standing. Stock reagents are made by dissolving the warm liquid in pentane, toluene, Et_2O, THF, CH_2Cl_2, and can be stored in a pure state or in solution under dry N_2 for several months. The reagent is **HIGHLY FLAMMABLE** (wear protective clothing), and is ***hygroscopic*** being readily hydrolysed by H_2O. Also commercially available in hexanes (1M, d^{25} 1.091g/ml), and use syringes techniques and closed systems under N_2. [Reetz et al. *Chem Ber* **118** 1421 *1985*, DOI: 10.1002/cber.19851180412; Fieser **14** 87.] This reagent increases the region- and stereo- control in aldol reactions [Kanemasa et al. *Tetrahedron Lett* **34** 677 *1993*, DOI: 10.1016/S0040-4039(00)61650-7].

Chromium (0) hexacarbonyl *[13007-92-6]* **$Cr(CO)_6$, M 220.1, m 130°(dec), >150°(dec), b 210°/atm(dec), d_4^{20} 1.77.** Wash the complex with cold EtOH, then Et_2O, and allow it to dry in air. *Alternatively*, recrystallise it from dry Et_2O. This is best accomplished by placing the hexacarbonyl in a Soxhlet extractor and extracting exhaustively with dry Et_2O. Pure $Cr(CO)_6$ is filtered off and dried in air. Completely colourless refracting crystals are obtained by sublimation at 40-50°/<0.5mm in an apparatus where the collecting finger is cooled by Dry-ice and in which there is a wide short bore between the hot and cold sections to prevent clogging by the crystals. Loss of product in the crystallisation and sublimation is slight. It is important not to overdo the drying as the solid is appreciably volatile and **TOXIC** [vapour pressure is 0.04(8°), 1.0(48°) and 66.5(100°) mm]. Also, do not allow the Et_2O solutions to stand too long as a brown deposit is formed which is sensitive to light, and to avoid the possibility of violent decomposition. It sinters at 90°, decomposes at 130°, and **EXPLODES** at 210°. It is also soluble in $CHCl_3$, CH_2Cl_2 and THF. [Owen et al. *Inorg Synth* **3** 156 *1950*, DOI: 10.1002/9780470132340.ch42; Podall et al. *J Am Chem Soc* **83** 2057 *1961*, DOI: 10.1021/ja01470a008.] Useful precursor which mediates [5+5] cycloaddition reactions to provide phenanthrenes [Menon et al. *Tetrahedron* **63** 8788 *2007*, DOI: 10.1016/ j.tet.2007.06.032]. **POISONOUS**, **possible carcinogen.**

Chromocene [bis(cyclopentadienyl) chromium II) *[1271-24-5]* **$C_{10}H_{10}Cr$, M 182.2, m 168-170°, 173°, d^{25} 1.43g/cm^3.** Chromocene forms dark red (scarlet) ***pyrophoric*** crystals on sublimation at 50°/0.1mm followed by resublimation at 75-90°/0.1mm. Although it is stable at least to 300°, it is readily oxidised in air, and effervesces slowly in H_2O to give cyclopentadiene. All operations should be carried out in a dry box. It decomposes in CCl_4 or CS_2, and for IR even grinding with nujol, KBr or KI causes some decomposition. [Wilkinson *J Am Chem Soc* **76** 209 *1954*, DOI: 10.1021/ja01630a053; Wilkinson et al. *J Inorg Nucl Chem* **3** 104 *1956*, DOI: 10.1016/0022-1902(56)80073-0; *Beilstein* **16** IV 1774, for some reactions see Beneš et al. *J Organomet Chem* **290** 147 *1985*, DOI: 10.1016/0022-328X(85)87428-3.]

Chromoionophore I [ETH 5294] [9-diethylamino-5-octadecanoyl-imino-5-*H*-benzo[a]-phenoxazine] *[125829-24-5]* **$C_{38}H_{53}N_3O_2$, M 583.9, m 91-93°, b ~680°/atm, d^{25} 1.1g/ml, n_D^{20} 1.57.** Purify it by flash chromatography (Silica Gel) and elute with EtOAc. The coloured fractions are pooled, evaporated and recrystallised from EtOAc. It is fluorescent with λ_{ex} 614nm; λ_{em} 663 (protonated). It is a ***lipophilic fluorescent chromoionophore*** and is a selectophore for K^+ and Ca^{2+} ions. [Morf et al. *Anal Chem* **62** 738 *1990*, DOI: 10.1021/ac00206a018; Lapresta-Fernandez & Capitan-Vallvey *Anal Chim Acta* **706)** 328 *2011*, DOI: 10.1016/j.aca.2011.08.042.]

Cobalt (II) *meso*-5.10,15,20-tetraphenylporphine complex (Co TTP) *[14172-90-8]* **$C_{44}H_{28}N_4Co$, M 671.7, m >300°.** It yields brown crystals from Et_2O or $CHCl_3$/MeOH (cf. *iron chloride complex)*. It crystallises on extraction (Soxhlet) with $*C_6H_6$. It is soluble in most organic solvents except MeOH and petroleum ether. It has λ_{max} at 409nm and 524nm. [UV, IR: Rothemund & Menotti *J Am Chem Soc* **70** 1808 *1948*, DOI: 10.1021/ja01185a047; Thomas & Martell *J Am Chem Soc* **81** 5111 *1959*, DOI: 10.1021/ja01528a024; *Beilstein*

26 III 1960.] Used in a new synthetic approach for substituted dihydrooxepines [Sengül & Balci *JCS Perkin Trans 1* 2071 *1997*, DOI: 10.1039/A701105I.]

Cobaltic (III) acetylacetonate [Co(acac)$_3$] *[21679-46-9]* **($C_5H_7O_2)_3Co, M 356.3, m 211°, 210-213°, 211.5°,** Recrystallise it from *C_6H_6/petroleum ether and dry it in a vacuum. [Charles & Pawlikowski *J Phys* Chem **62** 440 *1938*, DOI: 10.1021/j150562a017; *Beilstein* **1** H 783.] Used for the preparation of a new family of monoporphyrinates [Spyroulias et al. *JCS Chem Commun* 783 *1997*, DOI: 10.1039/A608013H].

Cobaltous acetate tetrahydrate *[6147-53-1(4H_2O), 71-48-7 (anhydr)]* **($C_2H_3O_2)_2Co. 4H_2O, M 249.1, 177.0(anhydr), m 140°(4H_2O), d ^{25} 1.705g/ml(4H_2O), n $^{20}_D$ 1.452(4H_2O), pK$_1^{25}$ 9.85 (for Co^{2+}).** Several recrystallisations from 50% aqueous acetic acid give the ***tetrahydrate*** (intense red crystals). It is converted to the ***anhydrous*** salt (pink crystals) by drying at 80°/1mm for 60 hours. It is soluble in EtOH, dilute acids, $PhCO_2Et$. [*Beilstein* **2** IV 120, Fieser **4** 99, **16** 95.]

Cobaltous acetylacetonate *[14024-48-7, 123334-29-2 (xH_2O)]* **($C_5H_7O_2)_2Co, M 257.2, m 165-170°, 172°.** Recrystallise it from Me_2CO or MeOH and dry it in a vacuum. [*Beilstein* **1** H 783; Fieser **16** 26, **17** 87.]

12-Crown-4 (lithium ionophore V, 1,4,7,10-tetraoxacyclododecane) *[294-93-9]* **$C_8H_{16}O_4$, M 176.2, m 16°, 17°, b 61-70°/0.5mm, d ^{25} 1.089g/cm^3, n $^{20}_D$ 1.463.** The distilled crude ionophore has to be recrystallised from pentane at -20° to remove acyclic material. It is then dried over P_2O_5. It complexes Li^+. [Anet et al. *Acta Chem Scand* **27** 3395 *1973*, DOI: 10.3891/acta.chem.scand.27-3395; *Beilstein* **19/11** V 334; Fieser **6** 133, **9** 126.]

Cupric acetate *[142-71-2 (anhydrous), 6046-93-1 (H$_2$O), 66923-66-8 (xH_2O)]* **($C_2H_3O_2)_2Cu, M 181.6(anhydr), m 115°(hydrate), b 240°/atm(dec), d ^{25} 1.882g/cm^3 (H_2O), n $^{20}_D$ 1.450(H_2O). pK$_1^{25}$ 8.0, pK$_2^{25}$ 13.1 (for Cu^{2+}).** Recrystallise the blue $Cu(OAc)_2$ twice from warm dilute acetic acid solutions (5ml/g) by cooling. Its solubility (g/100ml) in H_2O is 7.2 at ~10° and 20 at ~90°; and is soluble in EtOH, but slightly in Et_2O and glycerol. [Richardson 'Copper Compounds' in *Ullmann's Encyclopedia of Industrial Chemistry 2005*, Wiley-VCH, Weinheim, DOI: 10.1002/14356007.a07_567; *Beilstein* **2** IV 94, 111; for applications see Fieser **1** 159, **2** 84, **3** 65, **4** 105, **6** 138, **10** 103, **12** 140, **13** 85, **15** 99.]

Cupric benzoate *[533-01-7]* **$C_{14}H_{10}O_4Cu, M 305.8, b 249.3°/760mm, d ^{25} 1.197g/cm^3.** Recrystallise the blue solid from hot water. Dry it at ~90° for 3 hours. Its solubility in EtOH/*C_6H_6 (90%) at 25° is 0.1%. [Crawford & Stewart *J Chem Soc* 288 *1953*, DOI: 10.1039/JR9530000288; *Beilstein* **9** I 60, **9** III 376, **9** IV 280.]

Cupric lactate monohydrate *[814-81-3]* **$C_6H_{10}O_6Cu. H_2O, M 259.7.** The ***monohydrate*** crystallises from hot H_2O (3ml/g) on cooling. [*Beilstein* **3** II 203, **3** III 465, **3** IV 636.]

Cupric oleate *[1120-44-1]* **$C_{36}H_{66}O_6Cu, M 626.5.** Crystallise cupric oleate from diethyl ether. Slightly soluble in EtOH and insoluble in H_2O. [*Beilstein* **2** H 465, **2** I 196, **2** I202, **2** II 436, **2** III 1404, **2** IV 1646.] Also sold as a green-blue liquid fungicide for fruits and vegetables; and used as a dispersant, lubricant antioxidant and polyamide stabiliser.

Cupric phthalocyanine (phthalocyanine blue, Pigment Blue 15) *[147-14-8]* **$C_{32}H_{16}N_8Cu, M 576.1, m 600°(dec), CI 74160 ICI.** Precipitate it twice from concentrated H_2SO_4 by slow dilution with water. It has also been purified by two or three sublimations at 580° in an argon flow at 300-400Pa. Its solubility in H_2O is 0.1g/100ml at 20°, and has it λ_{max} at 678nm in H_2O. [*Beilstein* **26** III/IV 4256.]

(1,5-Cyclootadiene)(1,3,5-cyclooctatetraene)ruthenium [Ru(COD)(COT)] *[127382-91-6]* **$C_{16}H_{22}Ru, M 315.4, m 88-94°, 92-94°.** It can been prepared directly under argon and pressure equalisation, by adding freshly distilled cycloocta-1,5-diene (12.5ml, COD, see [*111-78-4*, *1552-12-1*]) in MeOH (5ml) to Zn dust (6g) in a flask which is placed in an ultrasound bath (Branson, Bransonic Model B220) thermostated at 70°. A solution of $RuCl_3$. 3H_2O (530mg) in MeOH (12ml) is slowly added during 20 minutes to the refluxing COD mixture under N_2 flow and ultrasound. After addition is complete the mixture is sonicated for a further 2 hours under

reflux at 70°. The solids are filtered off and the filtrate is evaporated with a vacuum line. The residual brown oil is extracted with the minimum volumes of hexane (3 x, total ~70ml), placed on an Al_2O_3 (Merck 1079, or Brockman Activity II-III) column under N_2 and eluted with hexane. The yellow band is collected, the volatiles are removed *in vacuo* to give orange crystals (590mg, 93%). Analytically pure ***Ru(COD)(COT)*** [$C_{16}H_{22}Ru$] is obtained as yellow crystals upon recrystallisation (70-90% recovery) from hexane at ~ -78°/~6 hours preferably under N_2 or argon. [Itoh et al. *J Organomet Chem* **272** 179 *1984*, DOI: 10.1016/0022-328X(84)80465-9; Pertici et al. *JCS Dalton Trans* 1961 *1980*, DOI: 10.1039/DT9800001961.] The ^{1}H NMR (60MHz, *C_6D_6, TMS) has τ at 4.78 (dd, 2H), 5.22 (m, 2H), 6.21 (m, 2H), 7.08 (m, 4H), 7.78 (m, 8H), 8.36 (m, 2H) and 9.10 (m, 2H); compare with the ^{1}H NMR (60MHz, *C_6D_6, TMS) of Ru(COD)$_2$ (see below) which has τ at 4.42 (t, 2H), 6.15 (dd, 4H), 6.45 (m, 4H), and 7.49—8.95 (m, 12H).

Alternatively, thermal isomerisation of **Ru(COD)$_2$** (75mg, see [63395-36-8]) in $CDCl_3$ (0.5ml) in an NMR tube filled with argon occurs when the sealed tube is heated at 70° for 12 minutes as observed by the spectrum. Evaporation of the solution and purification as above gave yellow-orange crystals of Ru(COD)(COT) in >85% yield with no deuterium incorporation as observed by NMR. Isomerisation in *C_6D_6 is very slow at 70° giving a mixture of three isomers after 5 hours [Itoh et al. *J Organomet Chem* **272** 179 *1984*, DOI: 10.1016/0022-328X(84)80465-9; see also Petrici et al. *JCS Dalton Trans* 1961 *1980*, DOI: 10.1039/DT9800001961]. A synthesis *via* a Grignard reduction of $[RuCl_2(COD)]_n$ has also been described [Pelzer et al. *Chem Mater* **16** 4937 *2004*, DOI: 10.1021/cm049086b]. For its catalytic activity see Chapter 5, Catalysts-Part 1 [Mistudo et al. *J Am Chem Soc* **121** 1839 *1999*, DOI: 10.1021/ja9835741]. It is a key precursor for the preparation of stabilised Ru nanoparticles [Pan et al. *J Am Chem Soc* **123** 7584 *2001*, DOI: 10.1021/ja003961m; cf. Chapter 7].

Cyclopentadienyl iron(II) dicarbonyl dimer [di(cyclopentadienyl)tetracarbonyl-diiron), ($C_5H_5Fe)_2(CO)_4$] *[38117-54-3]* **$C_{14}H_{10}O_4Fe_2$, M 353.9, m 194° (dec) (sealed tube).** This key precursor to a variety of cyclopentadienyl-carbonyl complexes is prepared from $Fe(CO)_5$ (10ml, *[13463-40-6]*, **CARE**, poisonous, work in an efficient fume cupboard) by refluxing with an excess of dicyclopentadiene (10ml, cyclopentadiene dimer see 77-73-6) for *ca* 40 hours under a N_2 or argon atmosphere in the absence of light, removing the solvent, adding $CHCl_3$ (50ml), and removing any $Fe_2(CO)_9$ and insoluble material by centrifugation. The decanted supernatant is cooled in a Dry-ice/Me_2CO bath, the crystals are collected by centrifugation and recrystallised from $CHCl_3$ to give a ~30% yield (based on CO) of analytically pure dark reddish-purple crystals of ***($C_5H_5Fe)_2(CO)_4$*, m 194° (dec)** (sealed tube). The solid is stable to air and light, but solutions deteriorate under these conditions. It forms ferrocene (in 75% yield based on C_5H_5) when heated at 210°. It is readily soluble in EtOH, $CHCl_3$, pyridine, less soluble in CCl_4 and CS_2, and sparingly soluble in light petroleum giving red solutions in each case. It is insoluble in H_2O and is unaffected by it. The ***measured molecular weight*** by isothermal distillation is ***368***. The IR has strong bands at λ_{max} at 4.95μ, 5.1 μ and 5.6 μ (in CCl_4) and 12.1 μ (CS_2). In the presence of O_2 a solution of the complex in EtOH/$CHCl_3$/concHCl/3hours provides red crystals of ***$C_5H_5Fe(CO)_2Cl$*** (from $CHCl_3$/petroleum ether 85:15, decomposing > 87°). This chloride is not ionic but gives the orange cation ***$C_5H_5Fe(CO)_2^+$*** with $AgNO_3/HNO_3$, and yellow crystals of ***$C_5H_5Fe(CO)_2CN$*** (from $CHCl_3$, decomposing > 120°) by reaction with NaCN/MeOH/24 hours in 46% yield. [Piper, Cotton and Wilkinson *J Inorg Nucl Chem* **1** 165 *1955*, DOI: 10.1016/0022-1902(55)80053-X; *Beilstein* **16** IV 1826.] When ***($C_5H_5Fe)_2(CO)_4$*** is treated with NaHg it provides the ***anion $C_5H_5Fe(CO)_2^-$*** that can be alkylated with MeI to furnish ***$C_5H_5Fe(CO)_2Me$*** and related alkyl derivatives. [Aktogu et al. *J Organomet Chem* **262** 49 *1984*, DOI: 10.1016/S0022-328X(00)99122-8; R.B. King *Organometallic Synthesis Vol 1*, p 45, Academic Press, NY, *1965*.] [*Beilstein* **16** IV 1826; for further applications see Fieser **8** 41.]

2,4-Cyclopentadien-1-yl lithium (lithium cyclopentadienide, CpLi) *[16733-97-4]* **C_5H_5Li, M 72.0.** CpLi is a white air and moisture sensitive solid which should be stored under N_2 preferably at low temperature. Like CpNa *[4984-82-1]* and CpK, it is handled in a dry box or Schlenk equipment in an inert atmosphere (compare with CpTl below). To avoid excessive manipulation, the reagents are sometimes prepared *in situ* in the reactions without being isolated. The solid is prepared in Schlenk equipment under a N_2 atmosphere by adding dropwise redistilled cyclopentadiene (2.34ml, 28.5mmol) to a solution of EtLi (28.5mmol) in *benzene (50ml) and stirred magnetically until precipitation of a voluminous white solid is complete. This is filtered, or centrifuged, off under N_2, washed with dry Et_2O and dried *in vacuo*. It is sparingly soluble in Et_2O but is soluble in THF. [Wagner & Ebel *Tetrahedron* **26** 5155 *1970*, DOI: 10.1016/S0040-4020(01)93167-9.] For the

preparation of a standard solution (use drybox, or Schlenk equipment under N_2) cyclopentadiene (~10.0mmol) in dry THF (7ml) is refluxed with excess of lithium metal (see Ford *J Am Chem Soc* **92** 2857 *1970*, DOI: 10.1021/ja00712a042) for 4 hours, filtered through a sintered glass funnel and diluted to a total volume of 10ml with THF which provides a 1.00M solution for further use. [Ford *J Organomet Chem* **32** 27 *1971*, DOI: 10.1016/S0022-328X(00)80156-4.] Its UV in THF has no maxima above 210nm, and its IR has ν_{max} (solid in Nujol) at 3048 (m), 2906 (w), 1742 (m), 1629 (m), 1548 (w), 1513 (w), 1426 (m), 1364 (sw), 1304 (w), 1258 (w), 1166 (w), 1110 (w), 1003 (s), 935 (sw), 887 (sw) and 746 (ss) cm^{-1}; the ^1H NMR [100MHz, shift relative to β-CH_2 of THF (1.767ppm of 2% TMS in THF) at 27°] has a peak at δ 5.59 (at 1.0M) or 5.70 (at 0.01M) [Ford *J Organomet Chem* **32** 27 *1971*, DOI: 10.1016/S0022-328X(00)80156-4; the ^{13}C NMR (22.6MHz, $MeOCH_2CH_2OMe/*C_6D_6$ 3:1, under N_2 at 30°, TMS) has a multiplet with δ centered at 103.59 (m, $^1J_{^{13}C\text{-}H}$ 159.4 and 6.9Hz). [Fischer et al. *J Organomet Chem* **116** 65 *1976*, DOI: 10.1016/S0022-328X(00)87196-X.]

Cyclopentadienyl thallium [(η^5-2,4-cyclopentadien-1-yl)thallium, thallium(I) cyclopentadienide, CpTl) *[34822-90-7]* **C_5H_5Tl, M 269.5, blackens at ~60° in air and at ~230° in a sealed capillary, but does not melt below 270°.** CpTl is purified by repeated sublimation through a glass plug at ~80°/0.005mm, 75°/0.1mm or 100-110°/10mm to give pale yellow acicular (small pointed needles) crystals. It is moderately stable in air but darkens superficially after several months. As it is somewhat light sensitive, it should be stored in dark brown screw cap containers, and thus keeps for prolonged periods of time. It reacts with some solvents, e.g. $CHCl_3$ and CCl_4 (forming TlCl), and CS_2 forming black and red materials), or is very poorly soluble, e.g. in THF, Et_2O and $*C_6H_6$. However, it is soluble enough in the latter solvents, even at low temperatures (e.g. -20°), to react almost completely to give high yields of products. ***It is a more convenient reagent for cyclopentadienylation than CpNa, CpK or CpLi because it is less basic, can be prepared in aqueous medium, can be prepared on a large scale, and is stable in air at room temperature for long periods.*** The cyclopentadiene ring of CpTl has IR in accord with C_{5v} symmetry, exhibiting one C—H stretching band at ν_{max} 3101 cm^{-1} in the gas phase at 150° to 249° which compares with ferrocene (3109 cm^{-1}), nickelocene (3107 cm^{-1}), di-cyclopentadienylmanganese (3101 cm^{-1}), di-cyclopentadienyl-magnesium(II) (3095 cm^{-1}), and benzene (3099 cm^{-1}), and is supported by theoretical considerations. The five membered ring is flat and ionic with the positive charge delocalised within it, and the Tl bears the counter negative charge and is centered on top of it. [Cotton & Reynolds *J Am Chem Soc* **80** 269 *1958*, DOI: 10.1021/ja01535a004; Roberts et al. *J Mol Spectr* **35** 476 *1970*, DOI: 10.1016/0022-2852(70)90188-8; Fritz *Chem Ber* **92** 780 *1959*, DOI: 10.1002/cber.19590920405.]
CpTl is conveniently prepared by dissolving or suspending a thallium(I) salt [TlCl 3.6g, TlBr 5.26g, TlI does not react, TlSCN 3.94g, $TlNO_3$ 4.00g or Tl(I) acetylacetonate 4.55g] in a solution of KOH (10g) in H_2O (100ml) in a Waring Blender (900ml jar capacity), adding cyclopentadiene (2.0ml, freshly distilled *[542-92-7]*) and stirring for 30 seconds. Longer stirring gives a fine suspension that is difficult to collect. The white product is filtered off, washed with EtOH (2 x 10ml), dried in a desiccator over anhydrous $CaSO_4$ to give CpTl in 91%, 93%, 0%, 99%, 97% and 87% yields respectively which is usually used without purification. The preparation can be scaled up to give ~50g of CpTl, and the preferred salt is TlBr. If desired, further purification can be performed by high vacuum sublimation as described above. [Hunt & Doyle *Inorg Nucl Chem Lett* **2** 283 *1966*, DOI: 10.1016/0020-1650(66)80043-0; Cotton & Reynolds *J Am Chem Soc* **80** 269 *1958*, DOI: 10.1021/ja01535a004; Corey et al. *J Am Chem Soc* **93** 1489 *1971*, DOI: 10.1021/ja00735a031.] **Note *that all thallium compounds are POISONOUS and due precautions have to be exercised.***
CpTl is a source of the C_5H_5 ligand, and reactions are performed under N_2 with highly purified solvents. The following are a few of the many reported reactions of CpTl. It has been used to prepare ferrocene, cobaltocene, nickelocene, also complexes such as Cp_2TiCl_2 with $TiCl_4$ in $*C_6H_6$, or of $Cp(MeOCp_2)Pd(II)$ from $[CpPd(OMe)Cl]_2$ with CpTl in $*C_6H_6$ [Hunt & Doyle *Inorg Nucl Chem Lett* **2** 283 *1966*, DOI: 10.1016/0020-1650(66)80043-0.], as well as compounds like the 1-methoxymethylcyclopenta-2,4-diene key intermediate for the synthesis of prostaglandins [Corey et al. *J Am Chem Soc* **93** 1489 *1971*, DOI: 10.1021/ja00735a031]; it reacts with $[CpMo(NO)I_2]_2$ in THF to give $Cp_2Mo(NO)I$ where the iodine can be replaced [King *Inorg Chem* **7** 90 *1968*, DOI: 10.1021/ic50059a018]; CpTl reacted with electrophilic olefins, e.g. tetracyanoethylene, in MeCN or THF to form compounds of the type $Tl^+[Cp(CN)C(CN)_2]^-$ [Freeman & Sneddon *Inorg Chem* **19** 1125 *1980*, DOI: 10.1021/ic50207a005], and the reaction of CpTl (10-80% molar excess) with 7-chloronorbornadiene in dry diglyme at 150°/3-4 hours gave, after filtration of Tl salts, the hydrocarbon ***hexahydro-3,4,7-methenocyclopenta[a]pentalene*** in 8-12% yield from a one-step synthesis (a hydrocarbon which would have required several synthetic steps to prepare) [Battiste & Timberlake *J Org Chem* **42** 176 *1977*, DOI: 10.1021/

jo00421a043]. [Meister *Angew Chem* **69** 533 *1957* DOI: 10.1002/ange.19570691606; *Beilstein* **16** IV 1690, Fieser **8** 138.]

6,6-Dibenzyl-14-crown-4 (lithium ionophore VI, 6,6-dibenzyl-1,4,8,11-tetra-oxa-cyclo-tetradecane) *[106868-21-7]* **$C_{24}H_{32}O_4$, M 384.5, m 102-103°**. Dissolve it in $CHCl_3$, wash this with saturated aqueous NaCl, dry ($MgSO_4$), evaporate and purify it by chromatography on silica gel and gradient elution with *C_6H_6/MeOH followed by preparative reverse phase HPLC on an octadecyl silanised silica (ODS) column and eluting with MeOH. It can be recrystallised from MeOH (IR has ν_{max} at 1120 cm^{-1}, C-O-C in KBr). Its solubility in H_2O is 50mg/ml at ~25°. [Kimura et al. *Anal Chem* **59** 2331 1987, DOI: 10.1021/ac00146a004; see also Maruyama et al. *JCS Perkin Trans 1* 2069 *1986*, DOI: 10.1039/P19860002069; and Tsukube et al. *JCS Perkin Trans 1* 1033 *1986*, DOI: 10.1039/P19860001033.] It complexes selectively with, and is a neutral carrier for, Li^+ ions; used for making ion selective electrodes with good selectivity over K^+ and Na^+ ions.

Di-*n*-butyltin (IV) oxide *[818-08-6]* **$C_8H_{18}OSn$, M 248.9, m >300° (starts dec at ~210°), d ^{25} 1.6g/cm^3.** The oxide is prepared by hydrolysis of di-*n*-butyltin dichloride with KOH. Hence wash it with a little aqueous M KOH, then H_2O and dry at ~80°/10mm until the IR is free from OH bands. [Cummins *Aust J Chem* **18** 98 *1965*, DOI: 10.1071/CH9650098; *Beilstein* **4** I 588; Fieser **12** 160, **13** 95, **15** 116, **16** 112; Cervantes et al. 'Organotin catalysts in Organosilicon Chemistry' *Appl Organometal Chem* **26** 157 *2012*, DOI: 10.1002/aoc.2832.]

Dicarbonyl(cyclopentadienyl)Co (I) *[12078-25-0]* **$C_7H_5O_2Co$, M 180.1, m -22°, b 7537-38.5°/2mm, 75°/22mm, b 139-140°(dec)/710mm, d ^{25} 1.35g/cm^3.** Best distilled in an atmosphere of CO in a vacuum. The red brown liquid decomposes slightly on distillation even in a vacuum to liberate some CO. Operations should be performed in an efficient fume cupboard. It is soluble in organic solvents and stable in air but decomposes slowly in sunlight and rapidly under UV. [Piper et al. *J Inorg Nucl Chem* **1** 165 *1955*, DOI: 10.1016/0022-1902(55)80053-X; King & Stone *Inorg Synth* **7** 99 *1963*, DOI: 10.1002/9780470132388.ch31; *Beilstein* **16** IV 1827; for applications see Fieser **5** 172, **6** 153, **7** 84, **12** 160, **13** 96, **14** 116, **16** 112, **17** 102.] It catalyses the cyclotrimerisation of alkynes [Cammak et al. *J Org Chem* **61** 4798 *1996*, DOI: 10.1021/ jo960143x], and promotes [2+2+2]-cyclisation of allenediynes to tricyclic steroid skeletons [Petit et al. *Tetrahedron* **62** 10582 *2006*, DOI: 10.1016/j.tet.2006.05.091]. **TOXIC.**

Dichloro(2,2':6', 2"-terpyridine)platinum(II) dihydrate *[151120-25-1]* **$C_{15}H_{11}Cl_2N_3Pt.\ 2H_2O$, M 535.3, decomposes at 240-260°.** The aqueous filtrate from the reaction between terpyridyl (2.3g) and potassium platinochloride (4.0g) in H_2O at 90° for 6 hours, is evaporated, cooled, and treated with HCl whereby the red chloride separates as the ***dihydrate***, whereas the black ***trihydrate*** slowly crystallises from a cold aqueous solution and is air-dried. It is converted to the ***dihydrate*** in a desiccator over H_2SO_4, by washing with EtOH, heating in H_2O (slowly), or by precipitating from a warm aqueous solution with hydrochloric acid. This salt is not decomposed by boiling HCl, and is insoluble in most organic solvents. It ***intercalates*** with helical and double stranded DNA [Lippard *Acc Chem Res* **11** 211 *1987*, DOI: 10.1021/ar50125a006]. [Morgan & Burstall *J Chem Soc* 1498 *1934*, DOI: 10.1039/JR9340001498; *Beilstein* **26** IV 260.]

Diethyl aluminium chloride *[96-10-6]* **$C_4H_{10}ClAl$, M 120.6, m -75.5°, -50°, b 106.5-108°/24.5mm, 125-126°/50mm, d ^{25} 0.961g/ml.** Distil it from excess dry NaCl (to remove ethyl aluminium dichloride) in a 50-cm column containing a heated nichrome spiral. **HIGHLY FLAMMABLE AND TOXIC.** [*Beilstein* **4** IV 4403; for applications see Fieser **4** 144, **15** 2, **16** 1, **17** 204.]

***N, N'*-Diheptyl-*N,N'*-5,5-tetramethyl-3,7-dioxanonanediamide [lithium ionophore I (ETH 149)]** *[58821-96-8]* **$C_{25}H_{50}N_2O_4$, M 442.7.** Purify it by chromatography on Kieselgel using $CHCl_3$ as eluent (IR has ν_{max} at 1640cm^{-1}). [Kirsch et al. *Helv Chim Acta* **60** 2326 *1977*, DOI: 10.1002/hlca.19770600723; Simon & Carafoli *Methods Enzymol* **56** 439 *1977*, DOI: 10.1016/0076-6879(79)56043-1.]

Diphenylmercury (II) *[587-85-9]* **$C_{12}H_{10}Hg$, M 354.8, m 121-124°, 125.5-126°, 128-129°, b 204°/atm, d ^{25} 2.32g/ml.** Sublime Ph_2Hg, then crystallise it from nitromethane or ethanol. If phenylmercuric halides are present, they can be converted to phenylmercuric hydroxide which, being much more soluble, remain in the

alcohol or *benzene used for crystallisation. Thus, crude material (10g) is dissolved in warm ethanol (*ca* 150ml) and shaken with moist Ag_2O (*ca* 10g) for 30 minutes, then heated under reflux for 30 minutes and filtered hot. Concentrating the filtrate by evaporation gives diphenylmercury, which is then recrystallised from *benzene [Blair et al. *J Chem Soc* 3174 *1959*, DOI: 10.1039/JR9590003174]. [Calvery *Org Synth* Coll Vol **1** 228 *1941*, DOI: 10.15227/orgsyn.009.0054; *Beilstein* **16** IV 1702.] **POISONOUS.**

Disodium calcium ethylenediaminetetraacetate *[662-33-9, 39208-14-5, 23411-34-9 ($2H_2O$)]* **$C_{10}H_{12}N_2O_8CaNa_2$, M 374.3, (see pKs for EDTA in entry below).** Dissolve it in a small amount of water, filter it and precipitate it with excess EtOH. Dry it at 80°. [*Beilstein* **4** IV 2451.] It is a useful buffer.
Disodium dihydrogen ethylenediaminetetraacetic acid* ($2H_2O$)** *[6381-92-6]* **$C_{10}H_{14}N_2O_8Na_2$. $2H_2O$, M 372.2, m 248°(dec), pK_1^{25} 0.26 pK_2^{25} 0.96, pK_3^{25} 2.60, pK_4^{25} 2.67, pK_5^{25} 6.16, pK_6^{25} 10.26 (see EDTA).** Analytical reagent grade material can be used as primary standard after drying at 80°. Commercial grade material can be purified by crystallisation from water or by preparing a 10% aqueous solution at room temperature, then adding ethanol slowly until a slight permanent precipitate is formed, filtering, and adding an equal volume of ethanol. The precipitate is filtered off onto a sintered-glass funnel, is washed with acetone, followed by diethyl ether, and dried in air overnight to give the ***dihydrate. Drying at 80° for at least 24 hours converts it to the *anhydrous* form. [*Beilstein* **4** IV 2451.] It is a useful buffer.
Disodium magnesium ethylenediaminetetraacetate *[14402-88-1]* **$C_{10}H_{12}N_2O_8Na_2Mg$. xH_2O, M 358.5, pK_1^{25} 0.26 pK_2^{25} 0.96, pK_3^{25} 2.60, pK_4^{25} 2.67, pK_5^{25} 6.16, pK_6^{25} 10.26 (see EDTA).** Dissolve it in a small amount of water, filter and precipitate it with an excess of MeOH. Dry it at 80°. [*Beilstein* **4** IV 2450.] It is a useful buffer.

Disodium succinate *[150-90-3]* **$C_4H_4O_4Na_2$, M 162.1, m 120°.** Crystallise it twice from water (1.2ml/g, its solubility in HO is 30g/100ml at 25°) and dry it at 125°. It has been freed from other metal ions by passage of a 0.1M solution through a column of Dowex resin A-1 (Na form). It is ***hygroscopic***. [*Beilstein* **2** H 606, **2** IV 1908.]

Di-*p*-tolylmercury *[50696-65-6, 537-64-4]* **$C_{14}H_{14}Hg$, M 382.8, m 244-246°.** Crystallise it from xylene. [Whitmore et al. *Org Synth* Coll Vol **1** 231 *1941*, DOI: 10.1002/0471264180.os003.18; *Beilstein* **16** H 947, **16** I 667, **16** III 1329, **16** IV 1705.]

Di-*p*-tolyl phenylphosphonate *[94548-75-1]* **$C_{20}H_{19}O_3P$, M 388.3, n_D^{25} 1.5758.** Purify as described under diisooctyl phenylphosphonate.

Eosin B (Eosine bluish, Eosin Scarlet, Acid Red 91, 4',5'-dibromo-2',7'-dinitrofluorescein disodium salt) *[548-24-3]* **$C_{20}H_6Br_2N_2O_9Na_2$, M 624.1, λ_{max} 395nm and 514nm, CI 45400.** Free it from inorganic halides by repeated crystallisation from butan-1-ol. [See as below.] [*Beilstein* **19/6** V 469.]
Eosin Y (as di-Na salt) (2',4',5',7'-tetrabromofluorescein di-Na salt) *[17372-87-1]* **$C_{20}H_6Br_4O_5Na_2$, M 691.9, λ_{max} 518nm.** Dissolve it in water and precipitate it by adding dilute HCl. The precipitate is washed with water, crystallised from ethanol, then dissolved in the calculated amount of dilute NaOH solution and evaporated to dryness on a water-bath. The purified disodium salt is then recrystallised twice from ethanol [Parker & Hatchard *Trans Faraday Soc* **57** 1894 *1961*, DOI: 10.1039/TF9615701894]. [*Beilstein* **19** III/IV 2917.]

Ethylmercuric chloride *[107-27-7]* **C_2H_5ClHg, M 265.1, m 192.5°, 193-194°.** Mercuric chloride can be removed by suspending ethylmercuric chloride in hot distilled water, filtering with suction onto a sintered-glass crucible and drying it. Then crystallise it from ethanol and sublime it under reduced pressure. It can also be crystallised from water. [Marvel et al. *J Am Chem Soc* **47** 3009 *1925*, DOI: 10.1021/ja01689a026.]
Ethylmercuric iodide *[2440-42-8]* **C_2H_5IHg, M 356.6, m 182°, 186°.** Crystallise it once from water (50ml/g). [See previous entry, Marvel et al. *J Am Chem Soc* **4** 3009 *1925*, DOI: 10.1021/ja01689a026.] **POISONOUS.**

Ethylzinc (zinc diethyl) *[557-20-0]* **$C_4H_{10}Zn$, M 123.5, m -28°, -33.8°, b 116.8°/761mm, d^{25} 1.205/ml, n_D^{20} 1.498.** The presence of EtI in the liquid can be detected by its absorption spectrum. This can be removed by 2 or 3 passages over a Zn/Cu couple at ~150°. Any hydrocarbon impurities are removed by distillation at ~760mm in an inert atmosphere as it is flammable. It is moisture sensitive, hydrolyses to give ethane so store it in sealed

ampoules under N_2 or argon. It is commercially available also as a ~15% solution in toluene (d_4^{20} 0.915) or ~ 1M *n*-hexane (d_4^{20} 0.726). Solutions should be stored under dry N_2 or argon, and if they contain some precipitate, the solutions should be filtered through a sintered frit under inert gas pressure. *Alternatively*, siphon carefully the required volume of supernatant. [Noller *Org Synth* Coll Vol **2** 184 *1943*, DOI: 10.15227/orgsyn.012.0086; Bamford et al. *J Chem Soc* 468 *1946*, DOI: 10.1039/JR9460000468; *Beilstein* **4** III 1999, **4** IV 4423; for applications see Fieser **1** 253, **2** 134, **3** 257, **4** 153, **5** 219, **6** 194, **11** 182, **17** 115.]

Ethynyl tri-*n*-butylstannane *[994-89-8]* **$C_{14}H_{28}Sn$, M 315.1, b 76°/0.2mm, 130-135°/0.7mm, 200°/2mm, d ^{25} 1.089g/ml, n_D^{20} 1.4770.** Purify the stannane by dissolving the reagent (*ca* 50g) in heptane (250ml), washing it with H_2O (100ml), drying ($MgSO_4$), evaporating and distilling in a vacuum. It has IR with ν_{max} at 3280 (≡ C–H), 2950, 2850, 2005 (C≡C), 1455, 1065 and 865cm^{-1}. [Bottaro et al. *J Org Chem* **46** 5221 *1981*, DOI: 10.1021/jo00338a035; Stille & Simpson *J Am Chem Soc* **109** 2138 *1987*, DOI: 10.1021/ja00241a035; for interaction with di-n-butylstannane see Nesmeyanov & Borisov *Bull Acad Sci USSR, Div Chem Sci* **16** 227 *1967*, DOI: 10.1007/BF00907149 (translated in *January, 1967*).]

Europium (III) acetate dihydrate *[62667-64-5]* **$C_6H_9O_6Eu.\ 2H_2O$, M 329.1(anhydr), 383.1, pK_1^{25} 8.31 (for aquo Eu^{3+}).** Recrystallise it several times from water [Ganapathy et al. *J Am Chem Soc* **108** 3159 *1986*, DOI: 10.1021/ja00272a001]. [*Beilstein* **2** II 119.] See lanthanide shift reagents in 'Aliphatic Compounds', Chapter 3

Ferrocene *[102-54-5]* **$C_{10}H_{10}Fe$, M 186.0, m 173-174°, b 249°/atm, λ_{max} 358nm.** Purify ferrocene by crystallisation from pentane or cyclohexane (also *C_6H_6 or MeOH can be used). It is moderately soluble in Et_2O and sublimes readily above 100°. Crystallisation from EtOH gave material **m 172.5-173°**. [Wilkinson *Org Synth* Coll Vol **4** 473 *1963*, DOI: 10.15227/orgsyn.036.0031; Miller et al. *J Chem Soc* 632 *1952*, DOI: 10.1039/JR9520000632.] It has also been crystallised from methanol and sublimed *in vacuo*. [Saltiel et al. *J Am Chem Soc* **109** 1209 *1987*, DOI: 10.1021/ja00238a034; *Beilstein* **16** IV 1783.]

Ferrocene carboxaldehyde *[12093-10-6]* **$C_{11}H_{10}OFe$, M 214.1, m 117-120°, 118-120°, 121°, 124.5°.** The aldehyde forms red crystals from heptane/CH_2Cl_2, EtOH or petroleum ether and sublimes at 70°/1mm. The ***cyanohydrin*** has **m 104°** (from *C_6H_6/EtOH). The ***semicarbazone*** has **m 217-219°(dec)** after recrystallisation from aqueous EtOH. The ***oxime*** provides two isomers from petroleum ether *viz* **m 96-99°** and **m 155°**. The ***O-acetyloxime*** has **m 80-81°** after recrystallisation from hexane [Lindsay & Hauser *J Org Chem* **22** 355 *1957*, DOI: 10.1021/jo01355a001]. The ***2,4-dinitrophenylhydrazone*** has **m 248°(dec)**. [*Beilstein* 16 IV 1798, Graham et al. *J Am Chem Soc* **79** 3416 *1957*, DOI: 10.1021/ja01570a027; Broadhead et al. *J Chem Soc* 650 *1958*, DOI: 10.1039/JR9580000650.] ***Chiral*** ferrocene aziridinylmethanols were prepared for selective azomethine ylide cycloaddition reactions [Dogan et al. *Org Lett* **8** 4687 *2006*, DOI: 10.1021/ ol061521f].

Ferrocene carboxylic acid *[1271-42-7]* **$C_{11}H_{10}O_2Fe$, M 230.1, m 210°(dec), 225-230°(dec), pK^{20} 4.4 (H_2O), 6.29 (68% aqueous MeOH).** The acid crystallises as yellow crystals from petroleum ether (**m 225-230°dec**), $CHCl_3$ (**m 208.5°dec**), toluene/petroleum ether (**m 195-205°dec**), or aqueous ethanol. [Matsue et al. *J Am Chem Soc* **107** 3411 *1985*, DOI: 10.1021/ja00298a003.] The ***acid chloride*** **m 49°** crystallises from pentane, and has UV with λ_{max} at 458nm [Lau & Hart *J Org Chem* **24** 280 *1959*, DOI: 10.1021/jo01084a647]. The ***methyl ester*** crystallises from aqueous MeOH with **m 70-71°**. The ***anhydride*** has **m 143-145°** when recrystallised from petroleum ether [Acton & Silverstein *J Org Chem* **24** 1487 *1959*, DOI: 10.1021/jo01092a024]. The ***amide*** has **m 168-170°** when crystallised from $CHCl_3$/Et_2O or **m 167-169°** when crystallised from *C_6H_6/MeOH. [Reeves *Org Synth* **56** 28 *1977*, DOI: 10.15227/orgsyn.056.0028; Arimoto & Haven *J Am Chem Soc* **77** 6295 *1955*, DOI: 10.1021/ja01628a068; Benkeser et al. *J Am Chem Soc* **76** 4025 *1954*, DOI: 10.1021/ja01644a047.] [Hall et al. *J Am Chem Soc* **90** 4972 *1968*, DOI: 10.1021/ja01020a034; *Beilstein* **16** IV 1807.] Esterification of alcohols and phenols with this acid gave esters used for GCMS analysis [Wasinski & Andersson *J Chromatogr A* **1157** 376 *2007*, DOI: 10.1016/ j.chroma.2007.04.060].

Ferrocene-1,1'-dicarboxylic acid *[1293-87-4]* **$C_{12}H_{10}O_4Fe$, M 274.1, m >250°(dec), >300°, pK_1^{25} 3.9, pK_2^{25} 5.3.** The dicarboxylic acid crystallises in orange-yellow crystals from AcOH and sublimes above 230°. The ***monomethyl ester*** has **m 147-149°** [Nesmeyanov & Reutov *Dokl Acad Nauk USSS* **115** 518 *1957*, *Chem Abstr*

26 469 *1960*]. The ***dimethyl ester*** has **m 114-115°** [Woodward et al. *J Am Chem Soc* **74**, 3458 *1953*, DOI: 10.1021/ja01133a543]. The ***diacid chloride*** has **m 92-93°** when recrystallised from petroleum ether. [Nesmeyanov & Reutov *Dokl Acad Nauk SSSR* **120** 1267 *1958*, Kazitsyna et al. *Dokl Acad Nauk SSSR* **127** 333 *1959*, *Beilstein* **16** IV 1811.]

Ferrocene-1,1,-dimethanol *[1291-48-1]* **$C_{12}H_{14}O_2Fe$, M 246.1, m 107-108°.** The diol is obtained from the diacid by $LiAlH_4$ reduction and recrystallised from Et_2O/petroleum ether. [Rinehart et al. *J Am Chem Soc* **82** 4111 *1960*, DOI: 10.1021/ja01500a074; *Beilstein* **16** IV 1795.]

1-(Ferrocenyl)ethanol (α-methylferrocenemethanol) *[1277-49-2]* **$C_{12}H_{14}OFe$, M 230.1, m 73-75°, 76-77°, 76-79°.** This versatile reagent is obtained by reduction of acetylferrocene (22.8g, see [1271-55-2]) in dry Et_2O (500ml) with $LiAlH_4$ (1.9g) solution in anhydrous Et_2O and refluxing for 2 hours. Excess of hydride is destroyed with EtOAc, the mixture is treated with a solution of NH_4Cl (28g) in H_2O, stirred for 0.5 hours at 0°, filtered, the organic layer is washed twice with H_2O, dried ($MgSO_4$), and evaporated to dryness. The residue (20.5g, 89%) is recrystallised from Et_2O/petroleum ether to give the ***carbinol*** as orange rods. It is free from a C=O band but has a strong broad OH band in the IR spectrum. The ***acetyl derivative*** (Ac_2O/pyridine/0°/15 hours), after sublimation at 60°/0.2mm, has **m 67-68°** and an IR band at 5.78μ (s, C=O), but no band in the OH region. [Arimoto & Haven *J Am Chem Soc* **77** 6295, DOI: 10.1021/ja01628a068; *Beilstein* **16** IV 1975.] Ligand in $Ti(NEt_2)_4$-catalysed intramolecular hydroamination of terminal alkynes (Markownikov *vs* anti-Markownikov addition) [Tillack et al. *Eur J Org Chem* 5001 *2005*, DOI: 10.1002/ejoc.200500423].

Germanium tetraethoxide *[14165-55-0]* **$C_8H_{20}O_4Ge$, M 252.8, m -72°, b 54.5°/5mm, 71-72°/11mm, 188-190°/722mm, d^{25} 1.1288g/ml, n_D^{20} 1.407.** Distil $Ge(OEt)_4$ through a 10cm Vigreux column under reduced pressure. *Alternatively*, distil it through a Fenske glass helices column fitted with a total condensation variable take-off stillhead. Fractionate it under reduced pressure using a reflux ratio of 10:1. [Johnson & Fritz *J Am Chem Soc* **75** 718 *1953*, DOI: 10.1021/ja01099a061; Bradley et al. *J Chem Soc* 4916 *1956*, DOI: 10.1039/JR9560004916; *Beilstein* **1** IV 1308.] It is readily hydrolysed so use strictly anhydrous conditions.

Hexabutyldistannane **{hexabutylditin, bis[(tributyl)tin}** *[813-19-4]* **$C_{24}H_{54}Sn_2$, M 580.4, b 160-162°/0.3mm, 198°/10mm, d^{25} 1.1520g/cm^3, n_D^{20} 1.5120.** Purify bis[(tributyl)tin] by distilling it in a vacuum and store it in the dark. *Alternatively*, purify by reverse-phase flash chromatography using a C-18 column. ^{119}Sn NMR recommended δ -83ppm, $^1J(^{119}Sn—^{119}Sn)$ 2748Hz [Mitchell e-EUROS *Encyclopedia of Reagents for Organic Synthesis* 15 April *2001*, DOI: 10.1002/047084289X.rh002]. [Shirai et al. *Yakugaku Zasshi* **90** 59 *1970*, *Chem Abstr* **72** 90593 *1970*, *Beilstein* **4** I 590; for applications see Fieser **14** 173, **16** 174.] This reagent was used in the radioiodination of styrylpyridines [Qu et al. *J Med Chem* **50** 2157 *2007*, DOI: 10.1021/jm070025+], and to stannylate aryl halides for **Stille coupling** [Bourderioux & Routier *Tetrahedron* **63** 9465 *2007*, DOI: 10.1016/ j.tet.2007.06.118]. **TOXIC substance.**

Hexamethylditin {hexamethyldistannane, bis[(trimethyl)tin]} *[661-69-8]* **$C_6H_{18}Sn_2$, M 327.6, m 23-24 °, 23.5°, b 85-88°/45mm, 182°/756mm, d^{25} 1.58g/ml.** Wash bis[(trimethyl)tin] with H_2O and extract with $*C_6H_6$, dry by filtering through powdered Na_2SO_4, remove $*C_6H_6$ on a rotary evaporator and fractionally distil the oily residue under vacuum (**b 85-88°/45mm**). ***It boils at ca 182° at atmospheric pressure, but it cannot be distilled in air because the hot vapours 'flash' in the condenser***. [Kraus & Sessions *J Am Chem Soc* **47** 2361 *1925*, DOI: 10.1021/ja01686a015; Morris & Selwood *J Am Chem Soc* **63** 2509 *1941*, DOI: 10.1021/ja01854a056; Pedley et al. *Trans Faraday Soc* **53** 1612 *1957*, DOI: 10.1039/TF9575301612; *Beilstein* **4** IV 4346; for applications see Fieser **6** 273, **13** 142, **17** 143.] Aryl tin compounds were prepared with this reagent for microwave-assisted **Stille cross-coupling** with halogenated pyridines [Dehlinger et al. *Tetrahedron Lett* **47** 8973 *2006*, DOI: 10.1016/j.tetlet.2006.10.015], and for copper-promoted *O*-arylation of phenols [Vakalopoulos et al. *Tetrahedron Lett* **47** 8607 *2006*, DOI: 10.1016/j.tetlet.2006.09.095].

Hexarhodium(0) hexadecacarbonyl *[28407-51-4]* **$Rh_6(CO)_{16}$, M 1065.6, m 220° (dec, in air), 235°, d_4^{20}**

2.87. It slowly loses CO when heated in air, but may be regenerated by heating at 80-200° in the presence of CO at 200 atmospheres pressure for 15 hours, preferably in the presence of Cu. It forms ***black crystals*** which are insoluble in hexane. It has bands at 2073, 2026 and 1800 cm^{-1} in the IR. [Hieber & Lagally *Z Anorg Allgem Chem* **251** 96 *1963*, DOI: 10.1002/zaac.19432510110; Corey et al. *J Am Chem Soc* **85** 1202 1963, DOI: 10.1021/ja00891a040; DOI: 10.1021/ja00891a040; James et al. *Inorg Synth* **16** 49 *1976*, DOI:10.1002/9780470132470.ch15; Doyle et al. *Tetrahedron Lett* **22** 1783 *1981*, DOI: 10.1016/S0040-4039(01)90438-1]. Useful catalyst. **POISONOUS**.

Iron(II) acetylacetonate [iron(II) bis(2,4-pentanedionato-κO2,κO4), $Fe(2^+)(acac)_2$] *[14024-17-0]* **$C_{10}H_{14}O_4Fe$, M 254.1, m 175°(dec).** The preparation and handling of this complex should be done in a dry box or Schlenk equipment under dry pre-purified N_2; and solvents should be de-gassed prior to use. $Fe(acac)_2$ is prepared by adding $FeCl_2.4H_2O$ (25g) in degassed H_2O (50ml) containing a small amount of sodium dithionite to reduce any Fe(III) impurities, to a degassed aqueous solution (300ml) containing piperidine (27.3ml) and redistilled acetylacetone (28.1ml, *[123-54-6]*). After 15 minutes the resulting precipitate is filtered off and washed with degassed H_2O, EtOH then Et_2O and the yellow-brown powder [presumed to be $Fe(acac)_2.2H_2O$ Emmert & Jarczynski *Chem Ber* **64** 1072 *1931*, DOI: 10.1002/cber.19310640521] is transferred into a sublimation apparatus with a large cold finger and pumped dry at 10^{-3} mm for 6 hours; and the hydrated complex is then heated at 90°/10^{-3}mm for at least 12 hours to dehydrate it and the orange-brown solid is sublimed twice at 165-175°/10^{-3}mm. The small orange-brown crystals that sublime at first become darker as the crystals grow, giving finally larger black clusters which are analytically pure anhydrous solid. ***Note*** that the complex is very sensitive to O_2 in air, darkens in colour upon oxidation, and great care should be exercised to avoid oxidation when using it. It maybe ***pyrophoric*** when dry. Its ***molecular weight*** (cryoscopic and ebullioscopic) in $*C_6H_6$ increases as the concentration increases reaching a maximum for a hexamer, and the data are supported by the UV absorption spectra. [Buckingham et al. *Aust J Chem* **20** 281 *1967*, DOI: 10.1071/CH9670281; Dwyer & Sargeson *Pr J Soc NSWales* **90**, 141, 142 *1956*; for the formation constant see Izatt et al. *J Phys Chem* **59** 80 *1955*, DOI: 10.1021/j150523a022; [Murray Jr e-EUROS *Encyclopedia of Reagents for Organic Synthesis* 15 October *2010*, DOI: 10.1002/047084289X.rn01225]. *Beilstein* **1** III 3122, **1** IV 3675.] *Note*: **iron(1+) bis(2,4-pentanedionato-κO2,κO4)** has [*20149-10-4*], see Chapter 5, Catalysts-Part 1 for $Fe(III)(acac)_3$, *[14024-18-1]*.

Iron(II) bis(1,1,1,5,5,5-hexafluoropentan-2,4-dionate) [iron(II) bis(1,1,1,5,5,5-hexafluoro-2,4-pentanedionato-κO2,κO4), $Fe(2^+)(facac)_2$, $Fe(hfacac)_2$] *[28736-68-7]* **$C_{10}H_2F_{12}O_4Fe$, M 470.1, mp 40°.** The preparation and handling of this complex [cf. $Fe(acac)_2$, *14024-17-0*] should be carried out in a dry box or Schlenk equipment under dry pre-purified N_2, and solvents should be de-gassed prior to use. $Fe(hfacac)_2$ is prepared by adding $FeSO_4.7H_2O$ (11.8g) in H_2O (50ml) slowly to a mixture of redistilled hexafluoroacetylacetone (12.2ml, see *[1522-22-1]*) and piperidine (8.5ml), whereby a dark violet precipitate separates immediately. This solid is filtered off, washed with a large volume of H_2O (1000 ml), placed in a sublimation apparatus and evacuated at 10^{-3}mm at ~25° for hours. The temperature is slowly raised to 40° and kept at 45-50° and 10^{-3}mm for 3 days, and the dark violet crystals that formed on the cold finger are collected, and if necessary are ground to a fine powder and re-sublimed to give analytically ***pure $Fe(hfacac)_2$*** (IR is free of bands at 3300-3500 cm^{-3}, i.e. absence of H_2O). It requires a much longer period of evacuation than $Fe(acac)_2$ for dehydration. The strong electron withdrawing effects of the CF_3 groups make this complex relatively more stable to aerial oxidation than $Fe(acac)_2$. It can be recrystallised from very dry $*C_6H_6$ without alteration, where its molecular weight (cryoscopic and ebullioscopic) increases with increase in concentration up to a value of 1.7 (compare with 6 for $Fe(acac)_2$ above). [Buckingham et al. *Aust J Chem* **20** 281 *1967*, DOI: 10.1071/CH9670281; for crystal structure see Dickman *Acta Cryst* C **56(1)** 58 *2000*, DOI: 10.1107/S0108270199013487.]

Iron(II) dicyanobis(2.2'-dipyridine) trihydrate [$Fe(bpy)_2(CN)_2$. $3H_2O$] *[15603-10-8]* **$C_{22}H_{16}N_6Fe$. $3H_2O$, M 474.3, dec. on heating.** The iron complex is prepared from 2,2'-dipyridine (4.7g, 30mmol) and ferrous ammonium sulfate hexahydrate (3.9g, 10mmol) in H_2O (400ml) which are heated to just below boiling, and a freshly prepared solution of KCN (10g) in H_2O (20ml) is added all at once to it, stirred, and the hot mixture is allowed to cool to room temperature. The complex separates as very dark violet (almost black) fine crystals rapidly, but is allowed to stand for 1 hour. The solid is collected and washed liberally with H_2O. Unused bipyridine is recovered from the filtrate by extraction with Et_2O. The iron complex can be purified by dissolving

it in concentrated H_2SO_4 (25ml) and slowly diluting it with H_2O (800ml, CARE as it will warm up) with stirring. The crystalline solid is collected washed free from H_2SO_4 with small volumes of H_2O, sucked dry, rinsed with Me_2CO and dried *in vacuo* to give analytically ***pure trihydrated complex*** (3.5g, 75%). It is soluble in H_2O to give a pale red solution, in EtOH to give a deep red-violet liquid, and in $CHCl_3$ to give a deep blue colour; but is only very slightly soluble in basic solution. Large amounts can be dissolved in concentrated H_2SO_4 to give the yellow di-protonated species which on gradual dilution with H_2O the solution changes its hue to orange then to red and finally to the dark violet colour of the original crystals. It is a diamagnetic Fe(II) complex which is readily oxidised to the corresponding Fe(III) complex and can be titrated with Ce(IV) sulfate in H_2SO_4. On titration with $HClO_4$ in anhydrous AcOH (**Care** due to possible **explosion**; Schilt *J Am Chem Soc* **82** 5779 *1960*, DOI: 10.1021/ja01507a004), the first equivalence point leads to a mono-protonated orange species, and at the second equivalence point (not quite as sharp as the first) it provides the yellow di-protonated species. The electronic (Schilt *J Am Chem Soc* **82** 3000 *1960*, DOI: 10.1021/ja01497a007; Schilt *J Am Chem Soc* **82** 5779 *1960*, DOI: 10.1021/ja01507a004; Madeja & König *J Inorg Nucl Chem* **25** 377 *1963*, DOI: 10.1016/0022-1902(63)80188-8; and vibrational spectra (Schilt *Inorg Chem* **3** 1323 *1964*, DOI: 10.1021/ic50019a029*)* have been reported, and the ***cis-configuration*** has been deduced from IR (Hamer & Orgel *Nature* **190** 439 *1961*, DOI: 10.1038/190439a0; Schilt *Inorg Chem* **3** 1323 *1964*, DOI: 10.1021/ic50019a029) and stereochemical (Madeja *Chem Zvesti* **19** 186 *1965*) considerations. [Schilt et al. *Inorg Synth* **12** 247 *1970*, DOI: 10.1002/9780470132432.ch43.]

Iron enneacarbonyl (di-iron nonacarbonyl) *[15321-51-4]* **$Fe_2(CO)_9$, M 363.9, m 100°(dec) d ^{25} 2.08g/cm^3.** Wash the orange crystals with EtOH and Et_2O, then dry it in air. It sublimes at 35° in a high vacuum. It forms dark yellow plates which are stable for several days when kept in small amounts. Large amounts, especially when placed in a desiccator, spontaneously ***ignite*** in a period of one day. It decomposes in moist air. It is insoluble in hydrocarbon solvents but forms complexes with several organic compounds. [Sheline & Pitzer *J Am Chem Soc* **72** 1107 *1950*, DOI: 10.1021/ja01159a012; Speyer & Wolf *Chem Ber* **60** 1424 *1927*, DOI: 10.1002/cber.19270600626; for applications see Fieser **1** 259, **2** 139, **3** 101, **4** 157, **5** 221, **6** 195, **7** 110, **8** 498, **13** 320, **15** 334, **16** 351.] **TOXIC**.

Iron(III) ethoxide [$Fe(OEt)_3$] *[5058-42-4]* **$C_6H_{15}O_3Fe$, M 191.0, m 120°, volatilies at 155°/0.1mm in a molecular still, b 72.6°/760mm, d ^{25} 0.87g/cm^3.** The ethoxide is prepared by adding excess of ammonia to a solution of anhydrous $FeCl_3$ (15g) in $*C_6H_6$ (170ml) and EtOH (76ml), which results in an exothermic reaction at the end of which the mixture is evaporated to dryness *in vacuo*. The residue is extracted with $*C_6H_6$ (150ml), the NH_4Cl is filtered off, the filtrate is evaporated to dryness *in vacuo* to leave a viscous brown rsesidue. This is dissolved in hot EtOH (30ml) and brown crystals of analytically ***pure ferric ethoxide*** (4.2g) deposit slowly. It is ***trimeric*** in $*C_6H_6$ solution (molecular weight by ebullioscopy) and is used for preparing other useful ferric trialkoxides by alcohol exchange in benzene solution, e.g. with *n*-PrOH, *n*-BuOH, *iso*-BuOH or *n*-amyl alcohol, *via* the azeotropic removal of EtOH. It is soluble in anhydrous hexane and alcohols, and is commercially available as a 1M solution in EtOH. [Bradley et al. *J Chem Soc* 126 *1958*, DOI: 10.1039/JR9580000126; see also synthesis revisited Seisenbaeva et al. *Inorg Chim Acta* **358(12)** 3506 *2005*, DOI: 10.1016/j.ica.2005.03.048; for synthesis, magnetic and electronic spectra see Adams et al. *Aust J Chem* **19** 363 *1966*, DOI: 10.1071/CH9660363; *Beilstein* **1** IV 1243.]

Iron pentacarbonyl (pentacarbonyl iron) *[13463-40-6]* **$Fe(CO)_5$, M 195.9, m -20°, b 102.8°/749mm, 103°/760mm, n_D^{20} 1.5196, d ^{25} 1.490g/cm^3.** It is a pale yellow viscous liquid that is **PYROPHORIC** and readily absorbed by the skin. **HIGHLY TOXIC (protect from light and air)**. It should be purified in a vacuum line by distilling and collecting in a trap at -96° (toluene-Dry-ice slush). It has been distilled at atmospheric pressure (use a very efficient fume cupboard). At 180°/atmospheric pressure it decomposes to give Fe and CO. In UV light in petroleum ether it forms $Fe_2(CO)_9$ (see previous entry). [Hagen et al. *Inorg Chem* **17** 1369 *1978*, DOI: 10.1021/ic50183a055; Ewens et al. *Trans Faraday Soc* **35** 681 *1939*, DOI: 10.1039/TF9393500681; for applications see Fieser **1** 519, **2** 229, **3** 167, **4** 268, **5** 357, **6** 304, **10** 221, **13** 152, **17** 270.]

Iron(III) *meso*-5,10,15,20-tetraphenylporphine chloride complex [5,10,15,20-tetraphenyl-21*H*, 23*H*-porphine iron(III) chloride] *[16456-81-8]* **$C_{44}H_{28}ClN_4Fe$, M 704.0, λ_{max} 418nm.** Purify the complex by extraction from a thimble (Soxhlet) with $CHCl_3$. Concentrate the extract to *ca* 10ml and add *ca* 80ml of hot

MeOH. Dark blue crystals separate on cooling. It can be recrystallised several times from $CHCl_3$/MeOH. Avoid prolonged heating. It is quite soluble in organic solvents but insoluble in petroleum ether. [Rothemund & Menotti *J Am Chem Soc* **70** 1808 *1948,* DOI: 10.1021/ja01185a047; UV: Dorough et al. *J Am Chem Soc* **73** 4315 *1951*, DOI: 10.1021/ja01153a085; *Beilstein* **26** III 1960.] [As catalyst for silylation of OH groups see Firouzabadi et al. *Synth Commun* **27** 2709 1997*,* DOI: 10.1080/00397919708004140.]

Lanthanide shift reagents See in 'Aliphatic Compounds', Chapter 3, europium (III) acetate above and $Eu(tmc)_3$ and $Eu(tfc)_3$ below.

Lead II acetate (sugar of lead) *[301-04-2 (anhydrous), 6080-56-4 (3H$_2$O)]* **$C_4H_6O_4Pb.\ 3H_2O$, M 325.3(anhydr), m 75° ($3H_2O$) 280°(anhydr), d^{20} 3.25g/cm^3(anhydr), d^{20} 2.55g/cm^3($3H_2O$), d^{20} 1.69g/cm^3($10H_2O$), n$_D^{25}$ 1.567($3H_2O$), pK$_1^{25}$ 7.1 (for Pb^{2+}), pK$_2^{25}$ 10.1 ($HPbO_2^-$), pK$_3^{25}$ 10.8 (PbO_2^{2-}).** Crystallise $Pb(OAc)_2$ twice from anhydrous acetic acid and dry it under vacuum for 24 hours at 100°. The solubility of anhydrous salt in H_2O (g/100ml) is 19.8 (0°), 44.31 (20°), 69.5 (30°) and 218.3 (50°); and in MeOH it is 102.75 (66.1°) for ***anhydrous salt***, and for the ***trihydrate*** it is 74.75 (15°) and 214.95 (66.1°); and in glycerol it is 20 (15°) for the anhydrous salt and 143 (20°) for the trihydrate. [*Beilstein* **2** IV 118; Fieser **1** 532, **2** 233, **4** 276.] **POISONOUS.**

Lead (bis-cyclopentadienyl) (plumbocene, Cp_2Pb) *[1294-74-2]* **$C_{10}H_{10}Pb$, M 337.4, sublimes at 150°/10^{-7}mm.** Purify it by vacuum sublimation. Handle and store it under N_2. It was prepared by reaction of sodium cyclopentadienide with a Pb salt, e.g. $Pb(NO_3)_2$ (in DMF) or PbI_2 (in THF) [Fischer & Grubert *Z Anorg Allgem Chem* **286(5-6)** 237 *1956*, DOI: 10.1002/zaac.19562860507; Izod et al. *Organometallics* **27** 4386 *2008*, DOI: 10.1021/om800598b]. With the PbI_2 (in THF) method the plumbocene was less ***pyrophoric*** on sublimation. [Dave, et al. *J Chem Soc* 3684 *1959*, DOI: 10.1039/JR9590003684; *Beilstein* **16** IV 1614.] [For photoelectron spectrum of Cp_2Pb see Cradock & Duncan *JCS Faraday Trans 2* 194 *1978*, DOI: 10.1039/ F29787400194].

Lead tetraacetate *[546-67-6]* **$C_8H_{12}O_8Pb$, M 443.2, m 175°, 175-180°, d^{20} 2.228g/cm^3.** Colourless prisms or needles purified by dissolving in hot glacial acetic acid containing a little acetic anhydride, treated with decolorising charcoal, collected on a hot water funnel or preheated Büchner funnel with minimum contact with moist air, and dried in a vacuum desiccator over KOH pellets. Store it in a well-stoppered vessel as it is decomposed readily by moisture to form brown PbO_2. It attacks skin, is soluble in hot AcOH, *C_6H_6, $CHCl_3$, tetrachloroethane, decomposes by alcohols, and is used as a ***powerful oxidising agent***. [Bailar et al. *Inorg Synth* **I** 47 *1939*, DOI: 10.1002/9780470132326.ch17; Baudler in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 767 *1963*, *Beilstein* **2** IV 118; Fieser **1** 537, **2** 234, **3** 168, **4** 278, **5** 365, **6** 313, **8** 269, **9** 265, **10** 228, **12** 270, **13** 155, **14** 188, **16** 193.] The tetraacetate induces the addition of CF_2I_2 to alkenes and alkynes at 60° [Li & Chen *Synthesis* 1481 *1997*, DOI: 10.1055/s-1997-1378]. **TOXIC.**

Lithium benzoate *[553-54-8]* **$C_7H_5O_2Li$, M 128.1, m >300°, 370°, 375-441°(decomposition), d^{25} 1.19g/cm^3,** Crystallise the salt from EtOH (13ml/g) by partial evaporation. Its solubility in H_2O (wt %) is 25.68 (-11°), 26.76 (-5°), 27.03 (0°), 27.22 (5.7°), 29.54 (22°), and 29.87 (25°); and the presence of benzoic acid increases its solubility in H_2O. [*Beilstein* **9** I 107, **9** IV 279.]

Lithium diisopropylamide (LDA) *[4111-54-0]* **$C_6H_{14}NLi$, M 107.1, b 82-84°/atm, 84°/atm, d^{22} 0.722 g/cm^3, flash point -6°.** $LiN(iso\text{-}Pr)_2$ is purified by refluxing over Na wire or NaH for 30 minutes and then distilled into a receiver under N_2. Because of the low boiling point of the amide, a dispersion of NaH in mineral oil can also be used directly in this purification without prior removal of the oil. It is **HIGHLY FLAMMABLE,** and is decomposed by air and moisture. Solutions of LDA are also commercially available in hexanes (10 wt % suspension), in mineral oil (30 wt% suspension), and in THF/heptane/ethylbenzene (1.8—2M solution, d^{25} 0.836—0.812g/cm^3), [Wittig & Hesse *Org Synth* **50** 66 *1970*, DOI: 10.15227/orgsyn.050.0066; *Beilstein* **4** H 154, **4** I 369, **4** II 630, **4** III 274, **4** IV 510; for applications see Fieser **1** 611, **2** 249, **3** 184, **4** 298, **5** 400, **6** 334, **7** 204, **8** 292, **9** 280, **10** 241, **11** 296, **12** 277, **13** 163, **15** 188, **16** 196, **17** 165.]

Lithium formate monohydrate *[6108-23-2 (H_2O), 556-63-8 (anhydrous)]* **$HCO_2Li.\ H_2O$, M 70.0, m 94°, d$_4^{20}$**

1.46. Crystallise HCO_2Li from hot water (0.5ml/g) by chilling. [*Beilstein* **2** III 22, **2** IV 13.]

Lithium methylate (lithium methoxide) *[865-34-9]* **CH_3OLi, M 38.0.** The most probable impurity is LiOH due to hydrolysis by moisture. It is important to keep the sample dry. It can be dried by keeping in a vacuum at 60-80° under dry N_2 using an oil pump for a few hours. Store it under N_2 in the cold. It should not have bands above 3000cm^{-1}, and its IR (KBr) should have ν_{max} at 1078, 2790, 2840 and 2930cm^{-1}. 1M and 2.2M solutions in MeOH are also commercially available. [*J Org Chem* **21** 156 *1956*, DOI: 10.1021/jo01108a002; *Beilstein* **1** IV 1220, 1241.]

Lithium pentamethylcyclopentadienide (LiCp', 1,2,3,4,5-pentamethyl-2,4-pentadiene-1-yllithium) *[51905-34-1]* **$C_{10}H_{15}Li$, M 142.2, m >230°.** In the necessary Schlenk equipment under argon or dry N_2 an equimolar amount of 4M *n*-BuLi in hexane is added dropwise to a stirred solution of equimolar pentamethylcyclopentadiene (Cp') in dry THF (30ml per g of Cp') at 0° which gives a pulpy pale yellow suspension. Magnetic stirring is continued for 2 hours while the temperature is allowed to rise to ~25°; and this can be used directly for coordinating a Cp' ligand to metals. If LiCp' is to be isolated, then the solvent to be used is petroleum ether (~15ml per g of Cp'), addition of the *n*-BuLi solution is done within a few minutes without cooling as the reaction is slower than in THF, and stirring is continued for 24 hours. The solvent is removed *in vacuo*, or the colourless to pale grey solid (>90% yield) is filtered off, washed with petroleum ether under N_2 and dried *in vacuo*. [Kohl et al. in *Organometallic Synthesis* (R. Bruce King and J.J. Eisch) **vol 3** 381, Elsevier Amsterdam *1986*]. LiCp' is air and moisture sensitive, and should be stored and weighed in an inert atmosphere. [King & Bisnette *J Organomet Chem* **8** 287 *1967*, DOI: 10.1016/S0022-328X(00)91042-8.] This reagent has been prepared also *in situ* from Cp' with MeLi/THF at 0° [White et al. *Synth Commun* **3** 425 *1973*, DOI: 10.1080/00397917308065936], with *n*-BuLi in dimethoxyethane [Manriquez & Bercaw *J Am Chem Soc* **96** 6229 *1974*, DOI: 10.1021/ja00826a071], or as a slurry of LiCp' in Et_2O at ~25° [Beachley et al. *Organometallics* **4** 1675 *1985*, DOI: 10.1021/om00128a033]. The metal-Cp' bond in LiCp' has a more covalent nature than that in KCp' and NaCp' which are more ionic [Jutzi et al. *Chem Ber* **118** 1959 *1985*, DOI: 10.1002/cber.19851180520].

Lithium picrate (lithium 2,4,6-trinitrophenolate) *[18390-55-1]* **$C_6H_2N_3O_7Li$, M 235.0.** Recrystallise the picrate three times from EtOH and dry it under vacuum at 45° for 48 hours [D'Aprano & Sesta *J Phys Chem* **91** 2415 *1987*, DOI: 10.1021/j100293a042]. [*Beilstein* **6** H 276, **6** II 263, **6** III 880, **6** IV 1390.] The necessary precautions should be taken in case of **EXPLOSION**.

Lithium salicylate *[552-38-5]* **$C_7H_5O_3Li$, M 144.1, m >350°.** Recrystallise the salicylate from EtOH (2ml/g) by partial evaporation. [*Beilstein* **10** H 59, **10** II 32, **10** III 93, **10** IV 126.]

Magnesium acetate *[142-72-3 (anhydrous), 16674-78-5 ($4H_2O$)]* **$C_4H_6O_4Mg$, M 142.4, m 80°($4H_2O$), d ^{25} 1.45g/cm^3.** Crystallise it from anhydrous acetic acid, then dry it under vacuum for 24 hours at 100°. [Nencollas *J Chem Soc* 744 *1956*, *Beilstein* **2** IV 113.]

Magnesium benzoate trihydrate *[553-70-8]* **$C_{14}H_{10}O_4Mg.\ 3H_2O$, M 320.6($3H_2O$), m ~200°.** Crystallise it from water (6ml/g) between 100° and 0°. [*Beilstein* **9** III 376, **9** IV 280.]

Magnesium ethylate (magnesium ethoxide) *[2414-98-4]* **$C_4H_{10}O_2Mg$, M 114.4.** Dissolve *ca* 1g of solid in 12.8ml of absolute EtOH and 20ml of dry xylene, and reflux in a dry atmosphere (use $CaCl_2$ in a drying tube at the top of the condenser). Add 10ml of absolute EtOH and cool. Filter the solid under dry N_2 and dry it in a vacuum. *Alternatively*, dissolve it in absolute EtOH and pass it through molecular sieves (40 mesh) under N_2, evaporate under N_2, and store it in a tightly stoppered container. [Smith & Wiley *J Am Chem Soc* **68** 887 *1946*, DOI: 10.1021/ja01209a056; *Beilstein* **1** III 1283.]

Magnesium D-gluconate *[3632-91-5, 59625-89-7 (xH_2O)]* **$C_{12}H_{22}O_{14}Mg$, M 414.6(anhydr), $[\alpha]_{546}^{20}$ +13.5, $[\alpha]_D^{20}$ +11.3 (c 1, H_2O).** Crystallise it from dilute EtOH to give *ca* ***trihydrate***, and then dry it at 98° in high vacuum. It is insoluble in EtOH, and the solubility in H_2O is 16% at 25°. [Prescott et al. *Ind Eng Chem* **45** 338

1953, DOI: 10.1021/ie50518a030; *Beilstein* **3** IV 1256.]

Magnesium ionophore I (ETH 1117), (*N,N*'-diheptyl-*N,N*'-dimethyl-1,4-butanediamide) *[75513-72-3]* **$C_{20}H_{40}N_2O_2$, M 340.6.** Purify it by flash chromatography (at 40 kPa) on silica and eluting with EtOH/hexane (4:1). Its IR ($CHCl_3$) has ν_{max} at 1630 cm^{-1}. [Erne et al. *Helv Chim Acta* **63** 2271 *1980*, DOI: 10.1002/hlca.19800630816.] It is a good Mg^{2+} ***selectophore*** compared with Na^+, K^+ and Ca^{2+} [Lanter et al. *Anal Chem* **52** 2400 *1980*, DOI: 10.1021/ac50064a037].
Magnesium ionophore II **(ETH 5214), [*N,N*''-octamethylene-bis(*N*'-heptyl-*N*"-methyl methylmalonamide)]** *[119110-37-1]* **$C_{32}H_{62}N_4O_4$, M 566.9.** The reagent (*ca* 700mg) can be purified by flash chromatography on Silica Gel 60 (30g) and eluting with CH_2Cl_2/Me_2CO (4:1). [Hu et al. *Anal Chem* **61** 574 *1989*, DOI: 10.1021/ac00181a015.]

Magnesium lactate *[18917-37-1]* **$C_6H_{10}O_6Mg$, M 202.5.** Recrystallise the salt from water (6ml/g) between 100° to 0°. [*Beilstein* **3** IV 636.] A food and beverages additive, and Mg supplement. ***Magnesium succinate*** *[556-32-1]* **$C_4H_4O_4Mg$, M 140.4** crystallises from water (0.5ml/g) between 100° and 0°. [*Beilstein* **2** IV 1912.] Used as a Mg supplement.

Magon [3-hydroxy-4-(hydroxyphenylazo)-2-naphthoyl-2,4-dimethylanilide, Xylidyl Blue II] *[523-67-1]* **$C_{25}H_{21}N_3O_4$, M 411.5, m 246-247°**. Suspend it in H_2O and add aqueous NaOH until it dissolves, filter and acidify with dilute HCl. Collect the red dye, dissolve it in hot EtOH (solubility is 100mg/L at *ca* 25°) concentrate to a small volume and allow to cool. The solubility of the Na salt in H_2O is 0.4mg/ml. The reagent is dried at 100° and is stable at ~25° indefinitely; and ethanolic solutions are stable for at least 2 months. [Mann & Yoe *Anal Chim Acta* **16** 155 *1957*, DOI: 10.1016/S0003-2670(00)89905-5; Mann & Yoe *Anal Chem* **28** 202 *1956*, DOI: 10.1021/ac60110a016.]

Manganese (II) acetylacetone *[14024-58-9]* **$C_{10}H_{14}O_4Mn$, M 253.2, m 248-250°(dec), ~250°, 261°(dec).** Purify it by stirring 16g of reagent for a few minutes with 100ml absolute EtOH and filter by suction as rapidly as possible through coarse filter paper. Sufficient EtOH is added to the filtrate, to make up for the loss of EtOH and to redissolve any solid that separates. Water (15ml) is added to the filtrate, and the solution is evaporated with a stream of N_2 until reduced to half its volume. Cool for a few minutes and filter off the yellow crystals, dry them under a stream of N_2, then in a vacuum at room temperature for 6-8 hours. These conditions are important for obtaining the ***dihydrate***. A vacuum to several mm of Hg or much lower pressure for several days produces the ***anhydrous complex***. The degree of hydration can be established by determining the loss in weight of 100g of sample after heating for 4 hours at 100° and <20mmHg. The theoretical loss in weight for $2H_2O$ is 12.5%. The material sublimes at 200°/2mm. It is soluble in heptane, MeOH, EtOH or $*C_6H_6$ at 30°. [Charles et al. *Inorg Synth* **6** 164 *1960*, DOI: 10.1002/9780470132371.ch51; Fernelius & Bryant *Inorg Synth* **5** 105 *1957*, DOI: 10.1002/9780470132364.ch29; *Beilstein* **3** II 3122, **1** IV 3674.]

Manganese (0) decacarbonyl *[10170-69-1]* **$Mn_2(CO)_{10}$, M 390.0, m 151-152°, 154-155°(sealed tube) , d^{25} 1.75g/cm^3.** Golden yellow crystals which in the absence of CO begin to decompose at 110°, and on further heating yield a metallic mirror. In the presence of 3000psi of CO it does not decompose on heating to 250°. It is soluble in common organic solvents, insoluble in H_2O, not very stable in air, to heat or UV light. It dissolves in a lot of $*C_6H_6$ and can be crystallised from it. It distils with steam at 92-100°. It can be purified by sublimation under reduced pressure (<0.5mm) at room temperature to give well-formed golden yellow crystals. If the sample is orange coloured, this sublimation leads to a mixture of golden-yellow and dark red crystals of the carbonyl and carbonyl iodide, respectively, which can be separated by hand picking under a microscope. Separation followed by resublimation provides the pure compounds. **POISONOUS.** [Brimm et al. *J Am Chem Soc* ***76*** 3831 *1954*, DOI: 10.1021/ja01643a071; Closson et al. *J Am Chem Soc* **80** 6167 *1958*, DOI: 10.1021/ja01556a005; Podall et al. *J Am Chem Soc* **82** 1325 *1960*, DOI: 10.1021/ja01491a013.]

Manganous acetate tetrahydrate *[6156-78-1 ($4H_2O$), 638-38-0 (anhydrous)]* **$C_4H_6O_4Mn$. $4H_2O$, M 245.1($4H_2O$), m 80°($4H_2O$), 210°(anhydr), d^{25} 1.74g/cm^3(anhydr), d^{25} 1.59g/cm^3($4H_2O$), pK^{25} 10.59 (for Mn^{2+} hydrolysis).** Crystallise it from water acidified with acetic acid. It is also soluble in MeOH EtOH and AcOH. [*Beilstein* **2** IV 120.]

Manganous lactate trihydrate *[6505-50-6 (3H_2O), 51877-53-3 (xH_2O)]* **$C_6H_{10}O_6Mn.\ 3H_2O$, M 287.1(3H_2O).** Recrystallise the lactate from water. [IR: Ranade & Biswas *J Indian Chem Soc* **44** 314 1967; for X-ray structure of the ***trihydrate*** see Kemmitt et al. *Aust J Chem* **54(1)** 37 *2001*, DOI: 10.1071/ CH01012; *Beilstein* **3** IV 637.]

Mercuric(II) acetate [$Hg(OAc)_2$] *[1600-27-7]* **M 318.7, m 178-180°, 179-182°, pK_1^{25} 2.47, pK_2^{25} 3.49 (for Hg^{2+} hydrolysis).** It is prepared from HgO and acetic acid. Recrystallise it from glacial acetic acid. Its solubility in H_2O is 1g/2.5ml at ~20° and 1g/ml at 100°, and it is soluble in EtOH. The solid is light sensitive and is hydrolysed slowly in H_2O to yield a yellow oxide. Store it in a tightly stoppered bottle away from light. It is a reagent for ***mercuration of alkenes*** (and aromatic compounds, cf. mercury trifluoroacetate below) [Larock *Tetrahedron* **38** 1713 *1982*, DOI: 10.1016/0040-4020(82)80245-7]; ***de-mercuration*** being achieved with $NaBH_4$. Mercuric acetate in 10% aqueous AcOH (reflux for ~20 hours) has been used to dehydrogenate cyclic secondary amines, e.g. 2-methyl, 2,5-dimethyl and 2,4,4-trimethyl (but not 2,2-dimethyl or 2,2,3-trimethyl) pyrrolidines to the respective Δ^1pyrrolines; the reaction being followed by the precipitation of mercurous acetate [Bonnett et al. *J Chem Soc* 2087 *1959*, DOI: 10.1039/JR9590002087]. [Wagenknecht & Juza in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **II** p 1120-1121 *1965*, *Beilstein* **2** IV 114; for applications see Fieser **1** 644, **2** 264, **3** 194, **4** 319, **5** 424, **6** 358, **10** 252, **15** 198, **17** 176.] **POISONOUS.**

Mercury(II) bis(cyclopentadienyl) ($HgCp_2$, mercurocene) *[18263-08-6, 12083-67-9]* **$C_{10}H_{10}Hg$, M 330.8 starts to dec at ~60° but melts at 83-85°.** $HgCp_2$ has been prepared by metathesis between TlCp [*34822-90-7*, see above] and $HgCl_2$ at -40° in THF [see Cradock & Duncan, below]. The pale yellow crystals are purified by low-temperature (-78°) recrystallisation from Et_2O. Store it at low temperature in the dark as it decomposes slowly at room temperature even in the dark. It reacts with $FeCl_2$ in tetrahydrofuran to give ferrocene quantitatively. It is soluble in Et_2O, *C_6H_6, $CHCl_3$, CCl_4, and most organic solvents. [Campbell & Fyfe *J Am Chem Soc* **94** 8387 *1972*, DOI: 10.1021/ja00779a017; Wilkinson & Piper *J Inorg Nucl Chem* **2** 32 *1956*, DOI: 10.1016/0022-1902(56)80101-2; Piper & Wilkinson *J Inorg Nucl Chem* **3** 104 *1956*, DOI: 10.1016/0022-1902(56)80073-0; *Beilstein* **16** IV 1702.] [For photoelectron spectrum of Cp_2Hg see Cradock & Duncan *JCS Faraday Trans 2* 194 *1978*, DOI: 10.1039/F29787400194]. **POISONOUS.**

Mercury dibromofluorescein disodium salt {mercurochrome, merobromin, [2',7'-dibromo-4'-(hydroxy-mercurio)-fluorescein di-Na salt] *[129-16-8]* **$C_{20}H_8Br_2Na_2O_6Hg$, M 750.6, 804.8(3H_2O), m>300°**. The green Na salt is dissolved in the minimum volume of H_2O, or the free acid suspended in H_2O and dilute NaOH is added to cause it to dissolve, filter and acidify it with dilute HCl. Collect the precipitate, wash it with H_2O by centrifugation and dry it in a vacuum. The ***di Na salt*** can be purified by dissolving it in the minimum volume of H_2O and is precipitated by adding EtOH, filter, wash it with EtOH or Me_2CO and dry it in a vacuum. Its solubility in 95% EtOH is 2% and in MeOH it is 16%. [White *J Am Chem Soc* 42 2355 *1920*, DOI: 10.1021/ja01456a031.] Useful disinfectant.

Mercury Orange [1-(4-chloromercuriophenylazo)-2-naphthol] *[3076-91-3]* **$C_{16}H_{11}ClN_2OHg$, M 483.3, m 291.5-293°(corr) with bleaching.** Wash the dark red powder several times with boiling 50% EtOH and recrystallise it from 1-butanol (0.9g/l of boiling alcohol). The fine needles are insoluble in H_2O but slightly soluble in cold alcohols, $CHCl_3$ and soluble in aqueous alkalis. [Chaikin *J Am Chem Soc* **70** 3522 *1948*, DOI: 10.1021/ja01190a600.]

Mercury(II) trifluoroacetate *[13257-51-7]* **$C_2F_3O_2Ag$, M 426.6, m 171-173°.** It is prepared from HgO and trifluoroacetic acid and is recrystallised from trifluoroacetic anhydride/trifluoroacetic acid. It is a useful reagent for mercuration of aromatic compounds [Lau & Kochi *J Am Chem Soc* **108** 6720 *1986*, DOI: 10.1021/ja00281a043]. It is soluble in THF, DME, and dioxane but insoluble in hexane. Store it in a tightly stoppered bottle away from light. [cf. Aylett in *Comprehensive Inorganic Chemistry (Bailar et al. eds)* **Vol 3** p187 *1973*, Kočovský & Luxenburger *e-EROS Encyclopedia of Reagents for Organic Synthesis* 14 March *2008*, DOI: 10.1002/047084289X.rm046.pub2; *Beilstein* **2** IV 458; for applications see Fieser **1** 659, **3** 195, **4** 325, **5** 429, **6** 360, **9** 294, **13** 175, **16** 377.] It is very **TOXIC**, can be absorbed through the skin and is ***hygroscopic***.

Methylmercuric chloride *[115-09-3]* **CH_3ClHg, M 251.1, m 167°, 170°.** Recrystallise it from absolute EtOH

(20ml/g). Its UV has λ_{max} at 206nm (ε 1.37). [See EtHgCl above; Breitinger & Kress. *J Organomet Chem* **256** 217 *1983*, DOI: 10.1016/S0022-328X(00)99198-8; Slotta et al. *J Prakt Chem* **120** 249 *1929*, Waugh et al. *J Phys Chem* **59** 395 *1955*, DOI: 10.1021/j150527a004; *Beilstein* **16** IV 1729.]

Molybdenum hexacarbonyl *[13939-06-5]* **$Mo(CO)_6$, M 264.0, ~150° dec without melting, b 156°/atm, d^{25} 1.96g/cm^3.** Sublime it in a vacuum before use [Connor et al. *JCS Dalton Trans* 511 *1986*, DOI: 10.1039/DT9860000511]. Useful catalyst, alone or with other ligands, for alkyne metathesis [Marradi *Synlett* (spotlight 119) 1195 *2005*, DOI: 10.1055/s-2005-865206.] **TOXIC**.

Monoperoxyphthalic acid magnesium hexahydrate salt (MMPP) *[84665-66-7, 78948-87-5]* **$C_{16}H_{10}O_{10}Mg.6H_2O$, M 494.7, m ~93°(dec).** MMPP is a ***safer reagent*** than *m*-chloroperbenzoic acid for oxidation reactions because it is not as explosive and has advantages of solubility. It is soluble in H_2O, low-molecular-weight alcohols, *i*-PrOH and DMF. The product of reaction, Mg phthalate, is soluble in H_2O. It has been used in aqueous phase to oxidise compounds in e.g. $CHCl_3$ and using a phase transfer catalyst, e.g. methyltrioctylammonium chloride [Brougham et al. *Synthesis* 1015 *1987*, DOI: 10.1055/s-1987-28153]. The 749xidizing activity can be checked (as for perbenzoic acid in Silbert et al. *Org Synth* Coll Vol **5** 904 *1973*, DOI: 10.15227/orgsyn.044.0081], and if found to be low it would be best to prepare afresh from phthalic anhydride (1mol), H_2O_2 (1mol) and MgO at 20-25° to give MMPP. [Hignett, European Pat Appl 27 693 *1981*, *Chem Abstr* **95** 168810 *1981*, *Beilstein* **9** IV 3260.]

Neopentoxy lithium *[3710-27-8]* **$C_5H_{11}Oli$, M 94.1.** Recrystallise the alkoxide from hexane [Kress & Osborn *J Am Chem Soc* **109** 3953 *1987*, DOI: 10.1021/ja00247a020]. [*Beilstein* **1** H 406, **1** I 201, **1** II 435. **1** III 1448, **1** IV 1690, *for neopentyl alcohol and Al and Fe neopentoxides*.]

New Methylene Blue N (2,8-dimethyl-3,7-bis(ethylamino)phenothazinium chloride 0.5 $ZnCl_2$) *[6586-05-6]* **$C_{18}H_{22}ClN_3S.0.5ZnCl_2$, M 416.1, m >200°(dec), λ_{max} 591nm and 630nm, pK_1 3.54, pK_2 4.82.** Crystallise the dye from *benzene/MeOH (3:1). [*Beilstein* **27** IV 5163.]

Nickel (II) acetate ($4H_2O$) *[6018-89-9]* **$C_4H_6O_4Ni.4H_2O$, M 248.9, d^{25} 1.798g/ml, pK_1^{25} 8.94 (from Ni^{2+} hydrolysis).** The acetate crystallises from aqueous AcOH as the green ***tetrahydrate salt***. It is soluble in 6 parts of H_2O. It forms ***lower hydrates*** and should be kept in a well-sealed container. [Hardt & Pohlmann *Z Anorg Allgem Chem* **343** 92 *1966,* DOI: 10.1002/zaac.19663430112; *Beilstein* **2** IV 120.] Polynuclear-nickel polyoxotungstate duster compounds prepared from nickel acetate are ideal for the design of nuclear magnets [Clemente-Juan et al. *Inorg Chem* **38** 55 *1999*, DOI: 10.1021/ic9807902].

Nickelocene [bis-(cyclopentadienyl)nickel II] *[1271-28-9]* **$C_{10}H_{10}Ni$, M 188.9, m 173-174°(under N_2).** Dissolve it in Et_2O, filter and evaporate in a vacuum. Purify it rapidly by recrystallisation from petroleum ether using a solid CO_2/Me_2CO bath. It has **m 171-173°**(in an evacuated tube). Also purify by vacuum sublimation. [Wilkinson et al. *J Am Chem Soc* **76** 1970 *1954*, DOI: 10.1021/ja01636a080; *Beilstein* **16** IV 1831.]

Nickel (II) phthalocyanine *[14055-02-8]* **$C_{32}H_{16}N_8Ni$, M 571.3, m >300°, λ_{max} 670nm.** Wash it well with H_2O and boiling EtOH and sublime it at high vacuum in a slow stream of CO_2. A special apparatus is used (see reference), with the phthallocyanine being heated to red heat. The ***sublimate*** is in the form of needles with an extremely bright ***red lustre***. The powder is ***dull greenish blue*** in colour. [Barrett et al. *J Chem Soc* 1719 *1936,* DOI: 10.1039/JR9360001719; *Beilstein* **26** III/IV 4255.]

Nickel 5,10,15,20-tetraphenylporphyrin (NiTPP) *[14172-92-0]* **$C_{44}H_{28}N_8Ni$, M 671.4, λ_{max} 414(525)nm.** Purify it by chromatography on neutral (Grade I) alumina, followed by recrystallisation from CH_2Cl_2/MeOH [Yamashita et al. *J Phys Chem* **91** 3055 *1987*, DOI: 10.1021/j100295a082]. [*Beilstein* **26** III/IV 1960.]

Phenylmercuric acetate (PMA, PhHgOAc) *[62-38-4]* **$C_8H_8O_2Hg$, M 336.7, m 148-151°, 149°, 151.8-152.8°.** This acetate forms small colourless lustrous prisms from EtOH. Its solubility in H_2O is 0.17%, but it is

more soluble in EtOH, Me_2CO and $*C_6H_6$. [Maynard *J Am Chem Soc* **46** 1510 *1925*, DOI: 10.1021/ja01671a024; Coleman et al. *J Am Chem Soc* **59** 2703 *1937*, DOI: 10.1021/ja01291a067; Grave et al. *J Am Pharm Assoc* **25** 752 *1936*, DOI: 10.1002/jps.3080250906; *Beilstein* **16** IV 1720; Fieser **6** 458.] Used as a preservative in paints, and as a disinfectant. See PhHgOH below.

Phenylmercuric hydroxide (PhHgOH)*[100-57-2]* **C_6H_6OHg, M 294.7, m 195-203°, pK^{25} 10 (~4.5).** Crystallise it from dilute aqueous NaOH. [Waugh et al. *J Phys Chem* **59** 395 *1955* DOI: 10.1021/j150527a004; *Beilstein* **16** IV 1721.] ***Phenylmercuric nitrate* (PhHgNO$_3$)** *[8003-05-2]* **$C_6H_5NO_3Hg.C_6H_6OHg$, M 634.4, m 175-185°, 178-188°.** When recrystallised from water or aqueous EtOH, it has **m 191-191.5°**, and from 95% EtOH it has **m 186.5°** [Challenger & Rothstein *J Chem Soc 1258* 1934, DOI: 10.1039/JR9340001258]. When recrystallised from $*C_6H_6$ or $CHCl_3$, it has **m 131-131.5°** [Morton et al. *J Am Chem Soc* **69** 908 *1947*, DOI: 10.1021/ja01196a051.] [*Beilstein* **16** III 1348, **16** IV 1721.]

Phthalocyanine *[574-93-6]* **$C_{32}H_{18}N_8$, M 514.6, m >300°(dec).** Purify phthalocyanine by sublimation (two to three times) in an argon flow at 300-400Pa; and similarly for the Cu(II), Ni(II), Pb(II), VO(II) and Zn(II) phthalocyanine complexes. It is suitable as a laser dye with λ_{max} 670nm. [*Beilstein* **26** III/IV 4255.]

Platinum (II) acetate (diacetatoplatinum) *[3375-31-3, 38928-89-1]* **$C_4H_6O_4Pt$, M 313.2 (monomer), m 245°(dec).** Purify the purple crystals by dissolving them in $CHCl_3$, filtering, mixing with half its volume of glacial acetic acid and set aside to evaporate at room temperature. The resulting large, ***almost black***, crystals are collected, washed with H_2O and dried in air. It dissolves in $CHCl_3$, $*C_6H_6$ and toluene to give ***purple solutions***. Its molecular weights (ebullioscopically) in $CHCl_3$, $*C_6H_6$ and chlorobenzene are 950 (±2), 937 and 888, respectively, indicate that it is ***trimeric in solution***. [Stephenson et al. *J Chem Soc* 3632 *1965*, DOI: 10.1039/JR9650003632.]

Platinum (II) acetylacetonate *[15170-57-7]* **$C_{10}H_{14}O_4Pt$, M 393.3, m 249-252°.** It crystallises from $*C_6H_6$ as yellow crystals and is dried in air or in a vacuum desiccator. It is soluble in $CHCl_3$, and Me_2CO, but insoluble in H_2O. [Werner *Chem Ber* **34** 2584 *1901*, DOI: 10.1002/cber.190103402206; Fernelius & Bryant *Inorg Synth* **5** 105 *1957*, DOI: 10.1002/9780470132364.ch29; *Beilstein* **1** H 783, **1** IV 3678.]

Potassium antimonyltartrate trihydrate *[28300-74-5 ($3H_2O$), 331753-56-1 (xH_2O)]* **$C_8H_4O_{12}K_2Sb_2$, M 613.8(anhydr), m >300°(dec), d^{25} 2.6g/ml, $[\alpha]_D^{20}$ +141 (c 2, H_2O).** Crystallise *'**tartar emetic**'* from water between 100°(3ml/g) and 0°(12ml/g). Insol in EtOH. Dry it at 100°. [Chinoporos & Papathanasopolos *J Phys Chem* **65** 1643 *1961*, DOI: 10.1021/j100905a512; *Beilstein* **3** IV 1227.] It is an expectorant and a parasitide.

Potassium benzoate *[582-25-2]* **$C_7H_5O_2K$, M 160.2, m >300°(dec), d^{25} 1.5g/cm^3.** Crystallise it from water (1ml/g) between 100° and 0°. Its solubility in H_2O (g/100ml) is 69.87 (17.5°), 73.83 (25°), 79 (33.3°), 88.33 (20°), and it is soluble in EtOH, slightly soluble in MeOH and insoluble in Et_2O. [*Beilstein* **9** III 375, **9** IV 279; Fieser **1** 49.] ***Potassium 4-aminobenzoate*** *[138-84-1]* **$C_{17}H_6NO_2K$, M 175.2.** Crystallise the aminobenzoate from EtOH. [*Beilstein* **14** II 246, **14** IV 1128.]

Potassium *tert*-butoxide *[865-47-4]* **C_4H_9OK, M 112.2.** It sublimes at 220°/1mm. The last traces of *tert*-BuOH are removed by heating at 150-160°/2mm for 1 hour. It is best prepared afresh as likely impurities are *tert*-BuOH, KOH and K_2CO_3 depending on its exposure to air. Its solubility at 25-26° in hexane, toluene, Et_2O, and THF is 0.27%, 2.27%, 4.34% and 25.0%, respectively. Solutions in *tert*-BuOH (1M, d^{25} 0.82g/ml) and in THF (1M, d^{25} 0.902g/ml) are commercially available. [Feuer et.al. *J Am Chem Soc* **78** 4364, DOI: 10.1021/ja01598a045; Doering & Urban *J Am Chem Soc* **78** 5938 *1956*, DOI: 10.1021/ja01603a060; *Beilstein* **1** IV 1612.]

Potassium citrate tribasic monohydrate (tripotassium citrate monohydrate) *[6100-05-6]* **$C_6H_5O_7K_3.H_2O$, M 324.4, m 275°(dec).** Its solubility in H_2O is 154g/100ml and it loses H_2O at 180°. [*Beilstein* **3** III 1091.]

Potassium dihydrogen citrate *[866-83-1]* **$C_6H_7O_7K$, M 230.2.** It crystallises from H_2O with a solubility of 11.5% at 100°. Dry it at 80°, or in a vacuum desiccator over Sicapent. [*Beilstein* **3** I 209, **3** III 336, **3** IV 402.]

Potassium hydrogen D-glucarate (D-tetrahydroxyadipic acid mono K salt, D-glucosaccharic acid mono K salt) *[18404-47-2]* **$C_6H_9O_8K$, M 286.3, 248.2, m 188°(dec), $[\alpha]_D^{20}$ +4.95 (c 1.2, H_2O), pK_1^{25} 5.0 (free acid).** Crystallise it from water. [Wolfrom & Neely *J Am Chem Soc* **75** 2778 *1953*, DOI: 10.1021/ja01107a519; *Beilstein* **3** H 579, **3** II 378, **3** III 1119, **3** IV 1291.]

Potassium hydrogen malate *[4675-64-3]* **$C_4H_5O_5K$, M 172.2.** A saturated aqueous solution at 60° is decolorised with activated charcoal, and filtered. The filtrate is cooled in a water-ice bath, and the salt is precipitated by adding EtOH. After five recrystallisations from ethanol-water mixtures, it is dried overnight at 130° in air. Assaying by titration found that after the first crystallisation it was 99.69% pure, and after the third recrystallisation it was ***99.99% pure***; and was used for dissociation constants measurements after the fifth recrystallisation. [For the resolution of the dissociation constants of *dl*-malic acid from 0° to 50° see Eden & Bates *J Res Nat Bur Stand* **62** 161 *1959*, http://dx.doi.org/10.6028/jres.062.028]. [*Beilstein* **3** III 915, **3** IV 1123.]

Potassium hydrogen oxalate (H_2O) *[127-95-7]* **C_2HO_4K, M 137.1, m ~300°(dec), d^{25} 2.0g/cm³.** Crystallise the white acid oxalate from boiling H_2O [solubility in w/v% is 2.5 (~25°) and 16.7 (boiling)], filtering and cooling to 25°. The crystals, after washing three or four times with water, are allowed to dry in air. [*Beilstein* **2** III 1552.] It is an ink stain remover, a mordant in dyeing and used for scouring metal. [see K tetaoxalate below.]

Potassium hydrogen phthalate (KHP) *[877-24-7]* **$C_8H_5O_4K$, M 204.2, m 295°, d^{25} 1.636g/cm³, pK^{25} 5.4.** Crystallise it first from a dilute aqueous solution of K_2CO_3, then H_2O (3ml/g) between 100° and 0°. Before being used as a standard in volumetric analysis, analytical grade potassium hydrogen phthalate should be dried at 120° for 2 hours, then allowed to cool in a desiccator. [*Beilstein* **9** IV 3169.] Buffering agent for pH electrode calibration at *ca* pH 4.

Potassium hydrogen *d*-tartrate *[868-14-4]* **$C_4H_5O_6K$, M 188.2, d^{25} 1.954g/ml, n_D^{25} 1.511, $[\alpha]_D^{20}$ +10 (c 2, 10% HCl), $[\alpha]_{546}^{20}$ +37.5 (c 10, M NaOH).** It crystallises from water (17ml/g) between 100° and 0°. Dry it at 110°. [*Beilstein* **3** IV 1222.] It is a product of fermentation of grape juice, and can precipitate in bottles of wine. In cooking it is known as ***'cream of tartar'***.

Potassium laurate (potassium dodecanoate) *[10124-65-9]* **$C_{12}H_{23}O_2K$, M 338.4.** Recrystallise potassium laurate three times from EtOH [Neto & Helene *J Phys Chem* **91** 1466 *1987*, DOI: 10.1021/j100290a037]. [*Beilstein* **2** H 360, **2** I 156, **2** II 318, **2** III 880, **2** IV 186.] It is a detergent. See purification of sodium dodecanoate below.

Potassium nonafluorobutane sulfonate *[29420-49-3]* **$C_4F_9O_3SK$, M 338.2, m >300°.** Wash it with H_2O and dry it *in vacuo*. When the K salt is distilled with 100% H_2SO_4, it gives the ***free acid*** which can be distilled (**b** 105°/22mm, 210-212°/760mm) and then converted back into the pure K salt by careful neutralisation with aqueous KOH. [Gramstad & Haszeldine *J Chem Soc* 2640 *1957*, DOI: 10.1039/JR9570002640; *Beilstein* **2** IV 818.]

Potassium oleate *[143-18-0]* **$C_{18}H_{33}O_2K$, M 320.6.** Recrystallise potassium oleate from EtOH (1g/ml). It can appear as a white-yellow waxy solid or a clear amber liquid with a soapy odour, and dissolves in H_2O slowly. [*Beilstein* **2** H 465, **2** I 196, **2** I 202, **2** II 436, **2** III 1404, **2** IV 1646.]

Potassium oxalate monohydrate *[6487-48-5]* **$C_2O_4K_2.H_2O$, M 184.2, m 160°(hydrate, dec), 365°(anhydr), d_4^{20} 2.13.** Recrystallise the oxalate from hot water. Its solubility in H_2O is 36.4g/100ml at 20°. It forms various K + oxalic acid salts [e.g. potassium hydrogen oxalate $KH(C_2O_4)$—see above, and $KH_3(C_2O_4)_2$ which is, surprisingly, called potassium tetraoxalate—see below]. [*Beilstein* **2** I 224, **2** II, 485, **2** III 1552, **2** IV 1823.]

Potassium pentamethylcyclopentadienide (KCp', 1,2,3,4,5-pentamethyl-2,4-pentadiene-1-ylpotassium) *[94348-92-2]* **$C_{10}O_{15}K$, M 174.3, m >230°.** In an efficient fume cupboard, liquid NH_3 (1.3L) is condensed into a flask containing freshly cut K metal (11.7g, 300mg-atoms) under an argon or N_2 atmosphere, stirred at -78°, and a small crystal of $Fe(NO_3)_3.9H_2O$ is added to the blue coloured solution. The mixture is made to warm to room temperature allowing refluxing until the blue solution turns into a light grey suspension. Cp' (40.9g,

300mmol) is added *via* a syringe, the mixture is stirred at reflux (MeOH condenser cooled at -78°) for 4 hours, and the NH_3 is allowed to evaporate using a stream of N_2. The residue is dried *in vacuo* and stored in a N_2 atmosphere as it is air and moisture sensitive, and unlike other Cp'Ms it can be spontaneously flammable in air. It is more soluble in THF than Cp'Li but less soluble than Cp'Na. It is a Cp' ligand source for complexing with a large number of metals and non-metal halides. [Kohl et al. in *Organometallic Synthesis* (R. Bruce King and J.J. Eisch eds) **vol 3** 381, Elsevier Amsterdam *1986*, DOI: 10.1080/00945718708059453].

Potassium phthalimide (phthalimide K salt) *[1074-82-4]* **$C_8H_4NO_2K$, M 185.2, m >300°**. The solid may contain phthalimide and K_2CO_3 from hydrolysis. If too much hydrolysis has occurred (this can be checked by extraction with cold Me_2CO in which the salt is insoluble, evaporate the Me_2CO and weigh the residue), it would be better to prepare it afresh. If little hydrolysis has occurred, then recrystallise it from a large volume of EtOH, and wash the solid with a little Me_2CO and dry it in a continuous vacuum to constant weight. [Salzerg & Supniewski *Org Synth* Coll Vol **1** 119 *1941*, DOI: 10.15227/orgsyn.007.0008; Raman & IR: Hase *J Mol Struct* **48** 33 *1978*, DOI: 10.1016/0022-2860(78)87220-2; Dykman *Chem Ind (London)* 40 *1972*, IR, NMR: Assef et al. *Bull Soc Chim Fr* II 167 *1979*, *Beilstein* **21/10** V 270.] This salt is useful for transforming allyl- and alkyl halides into phthalimido protected primary amines which react with hydrazine to provide the respective primary amine and insoluble phthalazin-2,4-dione [Lu et al. *J Am Chem Soc* **129** 7768 *2007*, DOI: 10.1021/ja072844p].

Potassium picrate *[573-83-1]* **$C_6H_2N_3O_7K$, M 267.2, m 250°, (detonates at 331°, before boiling), d^{25} 1.852g/cm³.** Recrystallise it from water or 95% EtOH, and dry it at room temperature in vacuum. It is soluble in 200 parts of cold water and 4 parts of boiling water. Store wet. [*Beilstein* **3** III 880, **3** IV 1390.] **THE DRY SOLID EXPLODES WHEN STRUCK OR HEATED.**

Potassium propionate *[327-62-8]* **$C_3H_5O_2K$, M 112.2, m >300°, 410°.** Recrystallise $C_2H_5CO_2K$ from water (30ml/g) or 95% EtOH. [*Beilstein* **2** II 217, **2** III 516, **2** IV 701.]

Potassium sodium tartrate tetrahydrate *[6381-59-5 ($4H_2O$), 304-59-6 (R,R)]* **$C_4H_4O_6KNa.4H_2O$, M 282.3, m 75°(hydrate), b 220°/atm (becoming anhydrous at ~130°), d^{25} 1.79g/cm³.** Recrystallise the tartrate from distilled water (1.5ml/g) by cooling to 0°. Solubility in H_2O is 26g/100ml (0°) and 66g/100ml (26°). [*Beilstein* **3** IV 1223.] ***Potassium d-tartrate monohydrate*** *[921-53-9]* **$C_4H_4O_6KNa.H_2O$, M 235.3, m loses H_2O at 150°, d_4^{20} 1.98.** Recrystallise it from pure water (solubility: 0.4ml/g at 100°, 0.7ml/g at 14°). [*Beilstein* **3** IV 1223.]

Potassium tetraoxalate dihydrate [oxalic acid hemipotassium salt] *[6100-20-5 ($2H_2O$), 127-96-8]* **$C_4H_{10}O_{10}K$, M 254.2, b 365.1°/760mm, d^{25} 1.84g/cm³.** Crystallise it from water below 50° (solubility is ~0.1M at 20°, and 8.3g at 100°). Dry it <60°/760mm. [See potassium acid oxalate above, *Beilstein* **2** IV 1823.]

Potassium trifluoroacetate *[2923-16-2]* **$C_2F_3O_2K$, M 152.1, m 140-142°, d^{25} 1.49g/ml, pK^{25} 0.52 (for CF_3CO_2H)**. To purify it, dissolve the salt in trifluoroacetic acid with *ca* 2% of trifluoroacetic anhydride (**CARE**), filter it and evaporate it carefully to dryness (avoid over heating), and finally dry it in a vacuum at 100°. It can be recrystallised from trifluoroacetic acid (solubility in the acid is *ca* 50.1%). [Simons & Lorentzen *J Am Chem Soc* **74** 4746 *1952*, DOI: 10.1021/ja01139a006; Hara & Cady *J Am Chem Soc* **76** 4285 *1954*, DOI: 10.1021/ja01646a009; Watt & Muga *J Inorg Nucl Chem* **9** 166 *1959*, DOI: 10.1016/0022-1902(59)80077-4; Beilstein **2** IV 458, Fieser **11** 557.]

Pyridinium chlorochromate (PCC) *[26299-14-9]* **$C_5H_6ClNO_3Cr$, M 215.6, m 205°(dec), 205-208°(dec).** Dry it in a vacuum for 1 hour. It is not hygroscopic and can be stored for extended periods at room temperature without change. If the purity is very suspect, it can be readily prepared. It is soluble in CH_2Cl_2, Et_2O, Me_2CO, MeCN, THF and $*C_6H_6$. [Corey & Scuggs *Tetrahedron Lett* 2647 *1975*, DOI: 10.1016/S0040-4039(00)75204-X; Piancatelli et al. *Synthesis* 245 *1982*, DOI: 10.1055/s-1982-29766.] [Applications see Fieser **6** 498, **7** 308, **8** 425, **9** 397, **10** 334, **11** 450, **12** 417, **13** 262, **14** 269, **15** 267.] It is a stable versatile oxidising agent [Piancatelli et al. *Synthesis* 245 *1982*, DOI: 10.1055/s-1982-29766], used for mild and selective oxidation of alcohols [Kasmai et al. *J Org Chem* **60** 2267 *1995*, DOI: 10.1021/jo00112a059], and the oxidation of an allylic methylene group in a synthesis of α,β-unsaturated lactones from D-glucose [Srikanth et al. *Tetrahedron* **62** 11165 *2006*, DOI: 10.1016/j.tet.2006.09.016]. (Possible **CARCINOGEN**.) § Available commercially on a polymer support.

Pyridinium dichromate *[20039-37-6]* **$C_{10}H_{10}N_2^{2+}.Cr_2O_7^{2-}$, M 376.2, m 145-148°, 152-153°.** Dissolve it in the minimum volume of H_2O and add 5 volumes of cold Me_2CO and cool to -20°. After 3 hours the orange crystals are collected, washed with a little cold Me_2CO and dried in a vacuum. It is soluble in dimethylformamide (0.9g/ml at 25°), and in H_2O, and has a characteristic IR with ν_{max} at 930, 875, 765, 730 and 730 cm^{-1}. [Corey & Schmidt *Tetrahedron Lett* 399 *1979*, DOI: 10.1016/S0040-4039(01)93515-4; Coats & Corrigan *Chem Ind (London)* 1594 *1969*.] (Possible **CARCINOGEN**.)
§ Available commercially on silica gel and on a polymer support.

Pyronin B [di-(3,6-bis(diethylamino)xanthylium chloride) diFeCl_5 complex] *[2150-48-3]* **$C_{42}H_{54}Cl_8N_4O_2Fe_2$, M 1042.2, m 176-178° (diFe complex), CI 45010, λ_{max} 553nm, pK^{25} 7.7.** Recrystallise it from EtOH. It forms an Fe stain. It is a biological stain used in the ***methyl green-pyronin method*** for differential coloration of nucleic acids. [For 'Analysis and testing of biological stains' see Penney et al. *Biotechnic and Histochemistry* **1** 1 *2002*, PMID 12564600; *Beilstein* **18/10** V 182.]

Quinolinium chlorochromate *[108703-35-1]* **$C_9H_7N.HCrO_3Cl$, M 265.6, m 127-130°.** It is a yellow-brown solid which is stable in air for long periods. If it has deteriorated or been kept for too long, it is best to prepare it freshly. Add freshly distilled quinoline (13ml) to a mixture of chromic acid (CrO_3) (10g) and ~ 5M HCl (11ml of conc HCl and 10ml of H_2O) at 0°. A yellow-brown solid separates, it is filtered off on a sintered glass funnel, dried for 1 hour in a vacuum, and can be stored for extended periods without serious loss in activity. It is a good oxidant for primary alcohols in CH_2Cl_2. [Singh et al. *Chem Ind (London)* 751 *1986*, method of Corey & Suggs *Tetrahedron Lett* 2647 *1975*, DOI: 10.1016/S0040-4039(00)75204-X; for structure and solvent dependent kinetic study of the oxidation of substituted benzaldehydes see Jeyanthi & Elango *Int J Chem Kinet* **35** 154 *2003*, DOI: 10.1002/kin.10112; *Beilstein* **20/7** V 276.]

Resorufin (7-hydroxy-3H-phenoxazine-3-one Na salt) *[635-78-9]* **$C_{12}H_7NO_3$, M 213.2, m >300°, λ_{max} 573nm. pK_1^{30} 6.93, pK_2^{30} 9.26, pK_3^{30} 10.0.** Wash Resorufin with water and recrystallise it several times from EtOH. **Resazurin** {the *N*-10-oxide of resorufin, {*[550-82-3, 62758-13-8 (Na salt)]* **$C_{12}H_7NO_4$, M 229.2**} is a blue dye (above pH 6.5) that is weakly fluorescent but can be reversibly reduced to the pink coloured (below pH 3.8) and ***highly red fluorescent resorufin***. It has been used as an oxidation-reduction indicator in cell viability assays. [González-Pinzón et al. *J Geophys Res* **117** (G3) G00N06, Bibcode:2012JGRG.117.0N06G *2012*, DOI: 10.1029/2012JG001965; *Beilstein* **27** III/IV 2263; see detail in 'Physiologically Active Compounds', Chapter 6]

Rhodium (I) carbonyl chloride (di-μ-chloro-tetracarbonyl dirhodium I) *[14532-22-9]* **$[Rh(CO)_2Cl]_2$, M 388.8, d^{25} 2.708g/cm^3, m 121°, 124-125°.** This catalyst is soluble in most organic solvents, but not petroleum ethers, and forms orange-red crystals from hexane. It sublimes at 80°/0.1mm to a red solid. It decomposes on exposure to air when in organic solvents but the solid is stable in dry air. It is moisture sensitive and should be stored in ampoules under N_2 or argon. It catalyses ring-opening silylformylation of olefins. [McCleverty & Wilkinson *Inorg Synth* **8** 211 *1966*, DOI: 10.1002/9780470132463; Dahl et al. *J Am Chem Soc* **83** 1761 *1961*, DOI: 10.1021/ja01468a049; Cramer et al. *Inorg Synth* **15** 14 *1974*, DOI: 10.1002/9780470132463.ch4; Fukumoto et al. *J Org Chem* **58** 4187 *1993*, DOI: 10.1021/jo00068a004; Colton et al. *Aust J Chem* **23** 1351 *1970*, DOI: 10.1071/CH9701351.]

Rhodizonic acid sodium salt (5,6-dihydroxycyclohex-5-ene-1,2,3,4-tetraone di-Na salt) *[523-21-7]* **$C_6O_6Na_2$, M 214.0, m >300°, pK_1^{25} 4.378 (±0.009), pK_2^{25} 4.652 (±0.014), pK_1^{30} 4.1 (4.25), pK_2^{30} 4.5 (4.72).** The ***free acid*** is obtained by acidifiying and extracting with Et_2O, drying ($MgSO_4$), filtering, evaporating and distilling in a vacuum (**b 155-160°/14mm**). The ***free acid*** solidifies on cooling, and the colourless crystals can be recrystallised from tetrahydrofuran/petroleum ether or $*C_6H_6$. It forms a ***dihydrate*** **m 130-140°, 131-132°**, *[118-76-3]* **$C_6H_2O_6.2H_2O$.** The ***pure di Na salt*** is formed by dissolving the acid in 2 equivalents of NaOH and evaporating in a vacuum. It forms violet crystals which give an orange solution in H_2O that is unstable for extended periods even at 0°, and should be prepared freshly before use. Salts of rhodizonic acid **cannot** be purified by recrystallisation without great loss due to conversion to crotonate, so that the original material must be ***prepared anew*** if pure salt is required. It can be washed with NaOAc solution, then EtOH, to

remove excess NaOAc, dried under vacuum and stored in the dark. Rhodizonates have various shades of red, from yellow to purple with respective colours of their solutions depending on the pH, and transmitting reflected light with a greenish lustre. [UV and tautomerism: Schwarzenbach & Suter *Helv Chim Acta* **24** 617 *1941*, DOI: 10.1002/hlca.19410240183; Polarography: Preisler & Berger *J Am Chem Soc* **64** 67 *1942*, DOI: 10.1021/ja01253a016; Souchay & Taibouet *J Chim Phys* **49** C108 *1952*, *Beilstein* **8** H 535, **8** II 572, **8** III 4214, **8** IV 3609.]

Ruthenium (III) acetylacetonate *[14284-93-6]* **$(C_5H_7O_2)_3Ru$, M 398.4, m 240°(dec).** Purify the complex by recrystallisation from *benzene. [Wilkinson *J Am Chem Soc* **74** 6146 *1952*, DOI: 10.1021/ja01143a538; *Beilstein* **1** IV 3677.] $Ru(acac)_3$ complex catalyses the reduction of dimethyl oxalate to ethylene glycol under mild hydrogenation conditions [Teunissen & Elsevier *JCS Chem Commun* 667 *1997*, DOI: 10.1039/A700862G].

Ruthenocene [bis-(π-cyclopentadienyl)ruthenium] *[1287-13-4]* **$C_{10}H_{10}Ru$, M 231.2, m 195.5°, 199-210°.** If it has to be prepared *ab initio*, then in a flask (500ml), under continuous flushing with N_2, and stirring, dry 1,2-dimethoxyethane (300ml) is added followed by Na (7.2g, 0.312 g.atom) cut in small pieces then cyclopentadiene (31.0ml, 0.376 mole; see *[542-92-7]*, prepared from the dimer, cf. Wilkinson *Org Synth* Coll Vol **4** 473 *1963*, DOI: 10.15227/orgsyn.036.0031] is added dropwise. After H_2 evolution stops, the mixture is kept just below boiling for 1-2 hours until all the Na has dissolved. If some metal remains undissolved, cool, and add a few milliliters of cyclopentadiene, and heat again until complete dissolution of the metal occurs. To this solution of sodium pentadienide [see also *4989-82-1*], under N_2 and stirring, is added a mixture of $RuCl_3$ (14.6g, 0.07 mole) and Ru metal (2.4g, 0.024 g.atom), and heated just below reflux for 80 hours. The solvent is removed under reduced pressure, the flask is filled with N_2, the solid residue is transferred (use a dry-box) to a sublimator, and sublimed at 0.1mm and 130° (bath temperature). It is advantageous to use a Dry-ice sublimation finger. The sublimate is dissolved in $*C_6H_6$, passed through a column of activated Al_2O_3 (2.5 x 30cm), and evaporated to give pure ***non-pyrophoric*** **ruthenocene** (12.2-15.1g, 56-69%), m 199-200°. The residue from sublimation is, however, ***pyrophoric***, but this residue can be destroyed by adding H_2O under N_2. It can be further sublimed in high vacuum at 120°. It forms yellow crystals which can be recrystallised from CCl_4 as transparent plates. [Bublitz et al. *Org Synth* Coll Vol **5** 1001 *1973*, DOI: 10.15227/orgsyn.041.0096; Wilkinson *J Am Chem Soc* **74** 6146 *1952*, DOI: 10.1021/ja01143a538; *Beilstein* **16** IV 1833.] It is generally less reactive than ferrocene towards electrophiles.
Two other alternative syntheses have been adopted using Schlenk techiques in an atmosphere of N_2 or argon, with dry and de-oxygenated solvents. In the ***first***, [Sn-*n*-$Bu_3(C_5H_5)$] (32.0g, 90mmol, prepared from Sn-*n*-Bu_3Cl, 1461-22-9, and LiC_5H_5 as per Davison & Rakita *Inorg Chem* **9** 289 *1970*, DOI: 10.1021/ic50084a022) is added to a suspension of $[RuCl_2(COD)_n]$ (8.4g, 30mmol, see [50982-12-2]) in EtOH (150ml), and the mixture is stirred and refluxed for 48 hours whereby the Ru polymer dissolved. The hot solution is filtered in air, and on cooling the ***pale yellow ruthenocene*** that crystallises out is filtered off, washed thoroughly with cold EtOH (2 x 20ml) then Et_2O (2 x 20ml), and recrystallised to analytical purity (5.2g, 75%) from hot EtOH or Me_2CO. Its ^1H NMR (500MHz, $CDCl_3$) has δ at 4.55 (s, C_5H_5), and its ^{13}C NMR (125MHz, $CDCl_3$) has δ at 20.1 (s, C_5H_5) (any *n*-butyl signals from impurities would be at their usual shifts). In the ***second***, $[RuCl_2(COD)_n]$ (1.4g, 50mmol) and cyclopentadienyl thallium (2.7g, 10mmol, see [34822-90-7]) in dimethoxyethane (~50ml) are refluxed for 1 hour, filtered hot (in air), the solvent is removed *in vacuo*, the residue is extracted with Et_2O (4 x 20ml), filtered, evaporated, and the residue is recrystallised and/or sublimed, as above, to give pure *ruthenocene* (0.9g, 78%). [Albers et al. *Organometallics* **5** 2321 *1986,* DOI: 10.1021/om00142a025.] The Raman spectrum of the melt has ν_{max} at 160w, 325s(p), 396m, 590vw, 815m(p), 830w, 1060m, 1098s(p), 1195vw 1360w, 1410m cm^{-1} (p is with polarized light) [Aleksanyan et al. *J Organomet Chem* **124** 293 *1977*, DOI: 10.1016/S0022-328X(00)92593-2].

Silver acetate *[563-63-3]* **$C_4H_3O_2Ag$, M 166.9, pK^{25} >11.1 (for aquo Ag^+ hydrolysis).** Shake AgOAc with acetic acid for three days, and the process is repeated with fresh acid. The solid is then dried in a vacuum oven at 40° for 48 hours. It has also been recrystallised from water containing a trace of acetic acid, and dried in air. Store it in the dark. [*Beilstein* **2** IV 112; Fieser **1** 1002, **2** 362, **6** 511, **8** 440.] Effective cycloaddition reactions of isocyanoacetates with a variety of olefins are catalysed by silver acetate [Grigg et al. *Tetrahedron* **55** 2025 *1999*, DOI: 10.1016/S0040-4020(98)01216-2], which is also used in a novel preparation of highly reflect-

ive and conductive silvered polymer films [Southward et al. *Chem Mater* **11** 501 *1999*, DOI: 10.1021/cm981014v].

Silver lactate *[128-00-7]* **$C_3H_5O_3Ag$, M 196.9, m ~ 100°, 120-122°.** Recrystallise it from H_2O by adding EtOH. The solid is collected, washed with EtOH, then Et_2O, and dried at 80° to give the ***dihydrate***. It is a white powder soluble in 15 parts of H_2O but only slightly soluble in EtOH. Store it in the dark. [Engelhardt & Maddrell *Justus Liebigs Ann Chem* **63** 83 *1847*, DOI: 10.1002/jlac.18470630104; Karrer et al. *Helv Chim Acta* **2** 242 *1919*, DOI: 10.1002/hlca.19190020126; *Beilstein* **3** III 464.] It is used as a binder in compresses and is an antiseptic.

Silver tetrafluoroborate *[14104-20-2]* **$AgBF_4$, M 194.7, m 70-73°, dec >200° (to form a silver mirror).** The anhydrous salt has been freshly prepared under dry N_2, by suspending AgF (34g, 268mmol) in dry $MeNO_2$ (30.5ml) while BF_3 is passed through with stirring. The temperature rises to 60°, and is maintained by occasional dipping into an ice bath. After about 30 minutes most of the AgF dissolves and ~280mmoles of BF_3 will have dissolved. Excess BF_3 is removed by bubbling dry N_2 for 1 hour through the murky solution which is then filtered (through a sintered glass frit, under N_2), and the $MeNO_2$ is distilled off at 70°/5mm into a liquid N_2 trap. The off-white solid is ground in a mortar under dry *n*-pentane in a glove box flushed with dry N_2, and the solvent is evaporated under N_2 at ~25°. The residual salt (237mmole, 88.5%) is pumped dry at 70° and stored under *n*-pentane. [Olah & Quin *J Inorg Nucl Chem* **14** 295 *1960*, DOI: 10.1016/0022-1902(60)80279-5.] The synthesis has been carried out in $*C_6H_6$ with which it forms a ***1:2 complex*** [Heyns & Paulsen *Angew Chem* **72** 349 *1960*, DOI: 10.1002/ange.19600721009], although a ***1:1 complex*** [Meerwein et al. *Arch Pharm* **291** 541 *1958*, DOI: 10.1002/ardp.19582911103] and ***2:3 complexes*** [Sharp & Sharpe *J Chem Soc* 1855 *1956*, DOI: 10.1039/JR9560001855] were reported. $AgBF_4$ is very soluble in H_2O, Et_2O, toluene, $MeNO_3$, moderately soluble in $*C_6H_6$, cyclohexene but insoluble in pentane and cyclohexane. The solubility in unsaturated hydrocarbons is attributed to π-bond complexing. A solution obtained by dissolving Ag_2O (1.0g) in 45% fluoroboric acid (7.2g) has been used for the synthesis of ***Nezukone*** (4-isopropyltropone) [Birch & Keeton *J Chem Soc (C)* 109 *1968*, DOI: 10.1039/J39680000109]. The salt is used for making tetrafluoroborate salts of complexes and other salts (see examples in this chapter) by displacing chloride from precious metal complexes, e.g. ***$Ru(Me_2SO_4)Cl_2$*** with excess $AgBF_4$ under N_2 in refluxing EtOH (*ca* 1 hour) and repeatedly recrystallising from H_2O/EtOH to give a 60% yield of ***$[Ru(Me_2SO_4)(H_2O)_2]\ BF_4$***, which is used for the oxidation of alcohols by persulfate [Bressan et al. *J Mol Catal* **79** 85 *1993*, DOI: 10.1016/0304-5102(93)85093-9]. It provides a silver-ion template for improved macrolactamisation of linear dipeptides, e.g. to form cyclohexadepsipeptides [Yanjie et al. *Synlett* 1901 *2007*, DOI: 10.1055/s-2007-984510]. [For applications see Fieser **1** 1015, **2** 365, **3** 250, **4** 428, **5** 587, **6** 519, **8** 443, **9** 414, **11** 471, **12** 434, **13** 273.]

Silver trifluoroacetate *[2966-50-9]* **$C_2F_3O_2Ag$, M 220.9, m 251-255°, 251-260°(dec).** Extract the salt (Soxhlet) with Et_2O. The extract is filtered and evaporated to dryness, then the powdered residue is completely dried in a vacuum desiccator over silica gel. Its solubility in Et_2O is 33.5g in 750ml. It can be recrystallised from $*C_6H_6$ (solubility is: 1.9g in 30ml of $*C_6H_6$, and 33.5g will dissolve in 750ml of anhydrous Et_2O). [Traynham & Dehn *J Org Chem* **23** 1545 *1958*, DOI: 10.1021/jo01104a039; Haszeldine *J Chem Soc* 584 *1951*, DOI: 10.1039/JR9510000584.] Store it in the dark. It is also soluble in trifluoroacetic acid (15.2% at 30°), toluene, *o*-xylene and dioxane [Hara & Cady *J Am Chem Soc* **76** 4285 *1954*, DOI: 10.1021/ja01646a009]. [*Beilstein* **2** IV 461; For applications see Fieser **1** 1018, **7** 323, **8** 444, **10** 355, **11** 557, **12** 529, **16** 301, **17** 313.]

Sodium acetate (anhydrous) *[127-09-3, 6131-90-4 ($3H_2O$)]* **$C_4H_3O_2Na$, M 82.0, m 58°($3H_2O$), >300°(dec), 324°(anhydr), b 881.4°/atm (anhydr), 122°/atm ($3H_2O$, dec), d^{20} 1.528g/cm³(anhydr), d^{20} 1.45g/cm³($3H_2O$), n_D^{25} 1.464.** Crystallise it from acetic acid and keep it under vacuum for 10 hours at 120°. *Alternatively*, it crystallises from aqueous EtOH as the ***trihydrate***. This material can be converted to ***anhydrous*** salt by heating slowly in a porcelain, nickel or iron dish, so that the salt liquefies. Steam is evolved and the mass again solidifies. Heating is now increased so that the salt melts again. (***Note***: if it is heated too strongly, the salt can char; avoid this.) After several minutes, the salt is allowed to solidify and is cooled to a convenient temperature (in a desiccator) before being powdered and bottled. The water content should now be less than 0.02%. It is a white ***deliquescent*** powder. The solubility (g/100ml) in H_2O is 119 (0°), 123.3 (20°), 137.2 (60°) and 162.9 (100°) for the ***anhydrous salt***, and 32.9 (-10°), 36.2 (0°), 46.4 (20°) and 82 (50°) for the ***trihydrate***; in

MeOH it is 16 (15°) and 16.55 (67.7°) for ***anhydrous salt***; in EtOH it is 5.3 (25°) for the ***trihydrate***; and in Me_2CO it is 0.05 (15°). [*Beilstein* **2** II 113, **2** III 184, **2** IV 109; Fieser **1** 1024, **5** 591.]

Sodium acetylacetonate [Na(acac), 2,4-pentanedione ion (1-) sodium (1:1)] *[15435-71-9]* **$C_5H_7O_2Na$, M 122.1, m 217-219° and is quite stable to heating below 191°, d_4^{20} 1.213.** It is prepared by two different procedures. In the ***first***, 2,4-pentanedione (100g, 1.0 mole) in H_2O or EtOH is slowly added to NaOH (40g. 1.0 mole) in the minimum amount of H_2O while keeping the temperature below 70°. On cooling Na(acac) (98g, 80%) crystallises out. Note that addition of solid NaOH resulted in a product containing NaOH. Recrystallisation from aqueous EtOH, Me_2CO or EtOAc gives pearly plates of the ***dihydrate*** (most probably a coordinated compound) that is soluble EtOAc but not in toluene. It gives off H_2O on heating, and the ***anhydrous*** form (salt form ?) is no longer soluble in EtOAc. In the ***second*** procedure, 2,4-pentanedione (50g, 0.5 mole) is added to Na metal (11.5g, 0.5 mole) in toluene (100ml) while the temperature is maintained at 100° to keep the metal in the molten state (**CARE**, as the experiment may be dangerous; N_2 should be flushing through the apparatus until the metal has dissolved). Na(acac) (101g, 83%) separates during the reaction. **Note** that using lower temperatures provide Na(acac) contaminated with Na. The product can be recrystallised from EtOH (see above) or by dissolving in EtOH and adding $*C_6H_6$. Its solubility in *n*-hexane, cyclohexane, or $*C_6H_6$ is less than 0.01% at 70°. However, although quite insoluble in $*C_6H_6$ or toluene, a suspension of Na(acac) will dissolve in these solvents on warming if excess of 2,4-pentanedione, or other related dicarbonyl compounds, e.g. benzoylacetone or ethyl acetoacetate, are added. ***Note*** that on heating the anhydrous or hydrated material decomposition and charring occurs if the sample in a soft glass tube is used. However, if the tube is placed in a bath at ~212° and the temperature is raised slowly, a sharp and ***reproducible melting point*** (**217-219°**) can be obtained with very little decomposition. [Hatch & Sutherland *J Org Chem* **13** 249 *1948*, DOI: 10.1021/jo01160a012; Sidgwick & Brewer *J Chem Soc* **127** 2379 *1925*, DOI: 10.1039/CT9252702379.] The ratios of mole of decomposition product/mole of 'salt' after 50 hours when heated under N_2 at 27° and 191° are both 0.07, i.e. it is reasonably stable at high temperatures. [Charles & Pawlikowski *J Phys Chem* **62** 440 *1958*, DOI: 10.1021/j150562a017.]
Its UV (EtOH) has λ_{max} at 277 (ε 800 x 10^3) nm [Hatch & Sutherland *J Org Chem* **13** 249 *1948*, DOI: 10.1021/jo01160a012]; and its electrical molecular conductivities (dilution) are: 5.794 (8), 8.254 (16), 11.187 (32), 14.426 (64), 18.116 (128), 21.82 (256), 25.636 (512), 29.927 (1024), and do not approach complete dissociation when nearing maximum dilution as hydrolysis may well be occurring [White *J Chem Soc* 1413 *1928,* DOI: 10.1039/JR9280001413]. Like K(acac) and Cs(acac), Na(acac) is unstable in aqueous solution or in moist conditions and is decomposed by hot H_2O into Me_2CO and the alkali acetate [Morgan & Moss *J Chem Soc* **105** 189 *1914*, DOI: 10.1039/CT9140500189]. Store it in a dry atmosphere. [Marchi *Inorg Synth* **2** 10 *1946*, DOI: 10.1002/9780470132333.ch4; Fernelius & Bryant *Inorg Synth* **5** 105 *1957*, DOI: 10.1002/9780470132364.ch29.]

Sodium acetylide *[1066-26-8]* **C_2HNa, M 48.0.** It disproportionates at *ca* 180° to sodium carbide. It sometimes contains diluents, e.g. xylene, butyl ether or dioxane that can be removed by filtration followed by a vacuum at 65-60°/5mm. *Alternatively*, the acetylide is purged with HC≡CH at 100-125° to remove diluent. NaC_2H adsorbs 2.2x, 2.0x and 1.6x its wt of xylene, butyl ether and dioxane, respectively. Powdered NaC_2H is yellow or yellow-grey in colour and is relatively stable. It can be heated to *ca* 300° in the absence of air. Although no explosion or evolution of gas occurs, it turns brown due to disproportionation. At 170-190° in air it ignites slowly and burns smoothly. At 215-235° in air it 'flash-ignites' and burns quickly. It can be dropped into a ***slight excess*** of H_2O without flashing or burning, but vigorous evolution of HC≡CH (**HIGHLY FLAMMABLE IN AIR**) occurs. A sample had been stored in the absence of air for one year without deterioration. Due to the high flammability of HC≡CH, the salt should be stored dry and should be treated with care. After long storage, NaC≡CH can be redissolved in liquid NH_3 and used for the same purposes as the fresh material. However, it may be slightly turbid due to the presence of moisture. [Rutledge *J Org Chem* **22** 649 *1957*, DOI: 10.1021/jo01357a016; Greene *J Am Chem Soc* **77** 5013 *1955*, DOI: 10.1021/ja01624a019; Greenlee et al. *Inorg Synth* **2** 75 *1946*, DOI: 10.1002/9780470132333.ch21; Campbell & Campbell *Org Synth* **30** 15 *1950*, DOI: 10.15227/orgsyn.0300015; *Beilstein* **1** H 238; Fieser **1** 1027.] It is available commercially under N_2 in Sure/Seal bottles as an 18 wt% solution in xylene/mineral oil. See 'Aliphatic Compounds', Chapter 3, for its preparation.

Sodium alginate (Algin) *[9005-38-3]* **$(C_6H_8O_6)_n$ Na_m, M 48,000-186000**. This is the Na salt of ***alginic acid*** {see [9005-32-7] in Carbohydrates Chapter 7}. Free Algin from heavy metal impurities by treatment with ion-exchange resins (Na^+-form), or with a dilute solution of the sodium salt of EDTA. *Alternatively*, dissolve it in 0.1M NaCl, centrifuge and fractionally precipitate it by gradual addition of EtOH or 4M NaCl. The resulting gels are centrifuged off, washed with aqueous EtOH or acetone, and dried under vacuum. [Büchner et al. *J Chem Soc* 3974 *1961*, DOI: 10.1039/JR9610003974.]

Sodium 4-aminobenzoate *[555-06-6]* **$C_7H_6NO_2Na$, M 159.1.** Recrystallise it from water. [Hermann *Helv Chim Acta* **9** 785 *1926*, DOI: 10.1002/hlca.192600901103; *Beilstein* **14** II 247.]
Sodium 4-aminosalicylate dihydrate *[6018-19-5]* **$C_7H_6NO_3Na.\ 2H_2O$, M 175.1, m 250°.** Recrystallise it from water at room temperature (2ml/g) by adding acetone and cooling. [*Beilstein* **14** III 1436, **14** IV 1969.]
Sodium antimonyl tartrate **(Stibnal, sodium tartar emetic)***[34521-09-0]* **$C_8H_4O_{12}Na_2Sb_2$, M 581.6, *alternatively*, $C_4H_4O_7NaSb$, M 308.8.** It crystallises from water. [*Beilstein* **3** III 1014, **3** IV 1227.]
Sodium barbitone (sodium 5,5-diethylbarbiturate) *[144-02-5]* **$C_8H_{11}N_2O_3Na$, M 206.2, pK_1^{25} 3.99, pK_2^{25} 12.5 (barbituric acid).** Crystallise it from water (3ml/g) by adding an equal volume of EtOH and cooling to 5°. Dry it under vacuum over P_2O_5. It is a useful buffer. [*Beilstein* **24** III/IV 1904.]
Sodium benzoate *[532-32-1]* **$C_7H_5O_2Na$, M 144.1, m>300°, 410°, d^{25} 1.497g/cm³.** Crystallise the white powder from EtOH (12ml/g). Its solubility (g/100ml) in H_2O is 62.69 (0°), 62.87 (30°) and 71.11 (100°); in MeOH it is 8.22 (15°) and 7.55 (67.2°); in EtOH it is 2.3 (25°) and 8.3 (78°); and in 1,4-dioxane it is 0.082 (25°). It is soluble in liquid NH_3 and pyridine. [*Beilstein* **9** IV 27; Fieser **1** 1044, **2** 377.] It is used as a food additive and preservative.

Sodium *tert*-butoxide *[865-48-5]* **$(CH_3)_3CONa$, M 96.1.** It sublimes at 180°/1mm. Its solubility in *tert*-BuOH is 0.208M at 30.2° and 0.382M at 60°, and it is quite soluble in tetrahydrofuran (32g/100g). It should not be used if it has a brown colour. [Feuer et al. *J Am Chem Soc* **78** 4364 *1956*, DOI: 10.1021/ja01598a045; Hurdet al. *Inorg Synth* **1** 87 1939, DOI: 10.1002/9780470132326.ch30; IR: Seubold *J Org Chem* **21** 156 *1956*, DOI: 10.1021/jo01108a002; *Beilstein* **1** IV 1609.] It is a strong non-nucleophilic base.

Sodium butyrate *[156-54-7]* **$C_4H_7O_2Na$, M 110.1, m 250-253°.** Prepare it by neutralising the acid with Na_2CO_3, and recrystallising it from EtOH. [*Beilstein* **2** IV 779.] It is physiologically active: decreases Ca^{2+} release from intracellular stores, inhibits histone deacylase and induces apoptosis in several cell lines.

Sodium carboxymethylcellulose *[9004-32-4]*. Dialyse it for 48 hours against distilled water and freeze-dry if a solid is required. It is commercially available in Av. M_w from **~90,000 (m 274° dec) to ~700,000 (m 270° dec).**

Sodium decanoate (sodium caproate) *[1002-62-6]* **$C_{10}H_{19}O_2Na$, M 194.2.** Neutralise sodium hydroxide by adding a slight excess of free decanoic acid and recovering the excess acid by Et_2O extraction. The salt is recrystallised from the aqueous solution by adding pure acetone and repeating the steps several times, then drying the salt in an oven at *ca* 110° [Chaudhury & Awuwallia *Trans Faraday Soc* **77** 3119 *1981*, DOI: 10.1039/F19817703119]. [*Beilstein* **2** IV 1041.]

Sodium deoxycholate monohydrat *[302-95-4, 145224-92-6]* **$C_{24}H_{39}O_4Na.\ H_2O$, M 432.6, $[\alpha]_D^{20}$ +48 (c 1, EtOH), +44 (c 1, H_2O).** Recrystallise it from EtOH and dry it in an oven at 100°. The solution is freed from soluble components by repeated extraction with acid-washed charcoal. [*Beilstein* **10** IV 1608.] It is a useful protein solubilising agent

Sodium diethyloxaloacetate *[63277-17-8, 40876-98-0]* **$C_8H_{11}O_5Na$, M 210.2, m 188-190°.** Extract it several times with boiling Et_2O (until the solvent remains colourless), and then the residue is dried in air. [*Beilstein* **3** H 789.]

Sodium diformylamide *[18197-26-7]* **$(CHO)_2NNa$, M 95.0**. Grind the amide under dry tetrahydrofuran (fumehood), filter and wash it with this solvent, then dry it *in vacuo*. It is soluble in EtOH and H_2O but insoluble in Et_2O and petroleum ether. [IR and preparation: Rakshit *J Chem Soc* **103** 1557 *1913*, DOI: 10.1039/CT9130301557; Yinglin & Hongwen *Synthesis* 122 *1990*, DOI: 10.1055/s-1990-26805; Allenstein &

Beyl *Chem Ber* **100** 3551 *1967*, DOI: 10.1002/cber.19671001110; Allenstein et al. *Chem Ber* **102** 4089 *1969*, DOI: 10.1002/cber.19691021216; *Beilstein* **2** II 22.]

Sodium *p*-**dimethylaminoazobenzene**-*o*'-**carboxylate (Methyl Red Na salt)** *[845-10-3]* **$C_{15}H_{14}N_3O_2Na$, M 291.2.** It can be precipitated from aqueous solution as the ***free acid*** which is recrystallised from 95% EtOH, then reconverted to the sodium salt. In H_2O it is pink at pH 4.2 and yellow at pH 6.2 and has UV with λ_{max} at 437nm. ***Methyl Red Hydrochloride*** *[63451-28-5]* has **M 305.8**, **m 175°(dec)** and UV with λ_{max} at 493nm. [*Beilstein* **16** H 329, **16** II 164.]

Sodium *p*-**dimethylaminoazobenzene-***p*'**-carboxylate** *[845-46-5]* **$C_{15}H_{14}N_3O_2Na$, M 291.3.** It has been precipitated from aqueous solution as the free acid which was recrystallised from 95% EtOH, then reconverted to the sodium salt. [*Beilstein* **16** H 329.]

Sodium dodecanoate (sodium laurate) *[629-25-4]* **$C_{12}H_{23}O_2Na$, M 222.3 m 244-246°. pK^{20} 5.3 (COOH).** Neutralise it by adding a slight excess of dodecanoic acid and removing it by ether extraction. The salt is recrystallised from the aqueous solution by adding pure Me_2CO and repeating the process (see sodium decanoate). It has also been recrystallised from MeOH. It is a detergent. [*Beilstein* **2** IV 1085.]

Sodium ethoxide *[141-52-6]* **C_2H_5ONa, M 68.1.** It is a ***hygroscopic*** powder which should be stored under N_2 in a cool place. A likely impurity is EtOH which can be removed by warming at 60-80° under high vacuum. It is hydrolysed by H_2O to yield NaOH and EtOH. Other impurities, if kept in air for long periods are NaOH and Na_2CO_3. In this case the powder cannot be used if these impurities affect the reactivity, and a fresh sample would be acquired. It is prepared by adding Na to absolute EtOH under N_2 and evaporated *in vacuo*, or used *in situ*. [IR: Seubold *J Org Chem* **21** 156 *1956*, DOI: 10.1021/jo01108a002]. [*Beilstein* **1** IV 1289; Fieser **1** 1065, **3** 265, **4** 451, **6** 540.] Commercially available as a 21wt% solution in EtOH (**d^{25} 0.868g/ml^3**, **n_D^{20} 1.385).**

Sodium ethylmercurithiosalicylate (Thimerosal) *[54-64-8]* **$(C_2H_5HgS)C_6H_4CO_2Na$, M 404.8, m ~230°.** Recrystallise this antibacterial from EtOH/Et_2O. It is also used as an antifungal preservative. **HIGHLY TOXIC.** [Trikojus *Nature* **158** 472 *1946*, DOI: 10.1038/158472a0; *Beilstein* **10** III 213, **10** IV 272.]

Sodium fluoroacetate (FCH_2CO_2Na) *[62-74-8]* **$C_2H_2FO_2Na$, M 100.0, m 200-205°(dec).** It is a free-flowing white **HIGHLY POISONOUS** powder which is purified by dissolving it in *ca* 4 parts of H_2O, and the pH is checked. If it is alkaline, add a few drops of FCH_2CO_2H to make the solution just acidic. Evaporate (fumehood) on a steam bath until crystals start to separate, cool and filter the solid off. More solid can be obtained by adding EtOH to the filtrate. Dry it at 100° *in vacuo*. The ***p-nitrobenzyl ester*** crystallises from EtOH with **m 76°**. The ***free acid*** interferes with the citric acid cycle. [Saunders & Stacey *J Chem Soc* 1773 *1948*, DOI: 10.1039/JR9480001773; *Beilstein* **2** IV 446.] **VERY TOXIC**, lethal oral human dose is 2—10mg/Kg.

Sodium formate (anhydrous) *[141-53-7]* **CHO_2Na, M 68.0, m 253°, 259-262°, d^{25} 1.92g/cm**. A saturated aqueous solution at 90° (0.8ml water/g) is filtered and allowed to cool slowly. (The final temperature should be above 30° to prevent formation of the hydrate.) After two such crystallisations, the crystals are dried in an oven at 130°, then under high vacuum. [Westrum et al. *J Phys Chem* **64** 1553 *1960*, DOI: 10.1021/j100839a052; Roecker & Meyer *J Am Chem Soc* **108** 4066 *1986*, DOI: 10.1021/ja00274a035.] The salt has also been recrystallised twice from 1mM DTPA (diethylenetriaminepentaacetic acid, which was recrystallised 4x from MilliQ water and dried in a vacuum), then twice from water [Bielski & Thomas *J Am Chem Soc* **109** 7761 *1987*, DOI: 10.1021/ja00259a026]. [*Beilstein* **2** IV 3, Fieser **8** 458]

Sodium D-gluconate *[527-07-1]* **$C_6H_{11}O_7Na$, M 218.1, m 200-205°dec, $[\alpha]_{546}^{20}$ +14, $[\alpha]_D^{20}$ +12 (c 20, H_2O).** Crystallise it from a small volume of H_2O (solubility is 59g/100ml at 25°), or dissolve it in H_2O and add EtOH since it is sparingly soluble in EtOH. It is insoluble in Et_2O. It forms a Cu complex in alkaline solution and a complex with Fe in neutral solution. [Sawyer & Bagger *J Am Chem Soc* **81** 5302 *1959*, DOI: 10.1021/ja01529a014; *Beilstein* **3** I 188, **3** IV 255.]

Sodium glycochenodeoxycholate *[640-79-9, 16564-43-5]* **$C_{26}H_{42}NO_5Na$, M 471.6, m 245-250°, $[\alpha]_D^{23}$ +41.2**

(c 1, H_2O). Dissolve it in EtOH, filter it and concentrate it to crystallisation, and recrystallise from a little EtOH. It also recrystallises from EtOH/Et_2O. [*Beilstein* **10** IV 1611.] [For behaviour with sodium glycoursodeoxycholate in binary mixed micelles of bile salt and non-ionic surfactant see Takamura et al. *Colloids and Surfaces B*: *Biointerfaces* **7**(5) 239 *1996*, DOI: 10.1016/0927-7765(96)01304-5.]

Sodium glycocholate (*N*-cholylglycine sodium salt hydrate) *[863-57-0]* **$C_{26}H_{42}NO_6Na.xH_2O$, M 487.6(anhydr), m 210-215°, 230-240°, micellar avg wt 1000, CMC 7mM (20-25°), $[\alpha]_D^{23}$ +29.2 (c 1, H_2O).** Dissolve this bile salt in EtOH, filter it and concentrated to crystallisation, and recrystallise from a little EtOH. It also crystallises from 95% EtOH/Et_2O. [*Beilstein* **3** IV 573, **10** IV 2077.]

Sodium glycolate dihydrate (sodium hydroxyacetate) *[2836-32-0]* **$C_2H_3O_3Na.$ $2H_2O$, M 98.0(anhydr), m 210-218°, pK^{25} 3.83 (for acid).** Precipitate it from aqueous solution by adding EtOH and dry it in air. Also recrystallise it from H_2O, where its solubility is 38% at 0° and 61% at100°. [*Beilstein* **3** III 370, **3** IV 573.]

***Sodium hydrogen diglycollate* (2,2'-oxydiacetic acid monosodium salt)** *[50795-24-9]* **$C_4H_5O_5Na$, M 156.1, pK_1^{20} 2.70, pK_2^{20} 4.22 (for acid).** Crystallise it from hot water (7.5ml/g) by cooling to 0° with constant stirring. The crystals are filtered off on to a sintered-glass funnel and dried at 110° overnight. Its solubility in water is 2.6% (at 0°) and 20% (at 90°). [*Beilstein* **3** III 377, **3** IV 577.] [For use as a reference buffer see Keyworth & Hahn *Talanta* **1** 41 *1958*, DOI: 10.1016/0039-9140(58)80006-5.]

Sodium hydrogen oxalate monohydrate *[1186-49-8]* **$C_2HO_4Na.$ H_2O, M 130.0, m 100°(loses H_2O), b 200°(dec).** Crystallise it from hot water (5ml/g) by cooling. Its solubility in H_2O is 1.7% at 15.5° and 21.3% at boiling. [Souchay & Lenfsen *Justus Liebigs Ann Chem* **99** 31 *1856*, DOI: 10.1002/jlac.18560990104; for twin structure by X-ray crystallography see Komunjer & Lefaucheux *Crystal Res Tech* **30**(4) 463 *1995*, DOI: 10.1002/crat.2170300407; *Beilstein* **2** H 513, **2** I 223, IV 1817.]

Sodium hydrogen succinate *[2922-54-5]* **$C_4H_5O_4Na$, M 140.0.** Crystallise it from hot water and dry it at 110°. Its solubility in H_2O is 17% at 0°, 40% at 25° and 86% at 75°. [Marshall & Bain *J Chem Soc* **97 [I]** 1074 *1910*, DOI: 10.1039/CT9109701074; *Beilstein* **2** H 606, **2** I 262, **2** III 16557, **2** IV 1911.]

Sodium hydrogen *d*-tartrate *[526-94-3]* **$C_4H_5O_6Na$, M 172.1, m 100°(loses H_2O), m 253°dec, $[\alpha]_{546}$ +26 (c 1, H_2O) and $[\alpha]_D^{20}$ +24 (c 1, H_2O).** It crystallises from warm water (10ml/g) by cooling to 0°. [*Beilstein* **3** IV 1219.]

Sodium 2-hydroxy-4-methoxybenzophenone-5-sulfonate *[6628-37-1]* **$C_{14}H_{11}O_6SNa$, M 330.3.** Crystallise it from MeOH and dry it under vacuum.

Sodium p-hydroxyphenylazobenzene-p'-sulfonate *[2623-36-1]* **$C_{12}H_{13}N_2O_6SNa.$ $2H_2O$, M 336.3.** Recrystallise it from 95% EtOH.

Sodium ionophore I (ETH 227) (*N*,*N*',*N*"-triheptyl-*N*,*N*',*N*"-trimethyl-4,4',4"-propylidyne-tris(3-oxabutyramide) *[61183-76-4]* **$C_{36}H_{71}N_3O_6$, M 642.0.** It is purified (*ca* 200mg) by TLC on Kieselgel F_{254} with $CHCl_3$/Me_2CO (1:1) as solvent, followed by HPLC (50mg) with an octadecyltrimethylsilane modified column (Mercksorb SI 100, 10μm) [IR, NMR, MS: Güggi et al. *Helv Chim Acta* **59** 2417 *1976*, DOI: 10.1002/hlca.19760590716]. [See Simon & Carafoli *Methods Enzymol* **56** 439 *1977*, DOI: 10.1016/0076-6879(79)56043-1.]

***Sodium ionophore V* (ETH 4120) [2,2'(4-octadecanoyloxymethyl-1,2-phenylenedioxy) *N*,*N*,*N*',*N*'-tetracyclohexyldiacetamide** *[129880-73-5]* **$C_{53}H_{88}N_2O_6$, M 849.3.** Purify it (*ca* 1.5g) by flash chromatography (120g of silica gel 60) with hexane/EtOAc (7:3) and recrystallisation from hexane/EtOAc [Prepn and properties: Géhrig et al. *Anal Chim Acta* **233** 295 *1990*, DOI: 10.1016/S0003-2670(00)83491-1].

***Sodium ionophore VI* {bis[(12-crown-4)methyl]dodecyl methyl malonate}** *[80403-59-4]* **$C_{34}H_{62}O_{12}$, M 662.9.** Purify it by gel permeation or column chromatography. [Preparation and NMR data: Shono et al. *J Electroanal Chem* **132** 99 *1982*, DOI: 10.1016/0022-0728(82)85009-2; Cram & Cram *Science* **183** 803 *1974*, DOI: 10.1126/science.183.4127.803.]

Sodium *RS*-mandelate *[114-21-6]* **$C_8H_7O_3Na$, M 174.1, b 321.8°/760mm, pK^{25} 3.41 (for the acid).** It crystallises from 95% EtOH and is dried in a vacuum. [Ross & Morrison *J Chem Soc* 1016 *1933*, DOI: 10.1039/

JR9330001016; Banks & Davies *J Chem Soc* 73 *1938*, DOI: 10.1039/JR9380000073; *Beilstein* **10** III 450.]

Sodium 2-mercaptoethanesulfonate (MESNA) *[19767-45-4]* **$C_2H_5NaO_3S_2$, M 164.2, pK_1^{20} <0, pK_2^{20} 9.53 (SH).** Recrstallise it from H_2O and has **m > 250°**. Alternatively, purify it by passing a 2M solution through Amberlite IRA-120 (H^+ form), evaporate the eluate *in vacuo*. The viscous oily residue is then carefully neutralised with aqueous NaOH and evaporated *in vacuo*. Recrystallise the salt residue from H_2O. [Schramm et al. *J Am Chem Soc* **77** 6231 *1955*, DOI: 10.1021/ja01628a052; *Beilstein* **4** IV 85.] It is a detoxifying agent.

Sodium methoxide *[124-41-4]* **CH_3ONa, M 54.0.** It behaves like sodium ethoxide. It is ***hygroscopic*** and hydrolyses in moist air to NaOH and MeOH. Should be kept and used under N_2. If erratic results are obtained, it should be freshly prepared thus: Clean Na (37g) cut in 1-3g pieces is added in small portions to stirred MeOH (800ml) in a 2L three-necked flask under a condenser with a drying tube. After all the Na has dissolved, the MeOH is distilled off *in vacuo*, and the residual NaOMe is dried at 150° *in vacuo* and kept under dry N_2 until required [Burness *Org Synth* **39** 49 *1959*, DOI: 10.15227/orgsyn.039.0049]. [*Beilstein* **1** IV 1220; for applications see Fieser **1** 1091, **2** 385, **3** 259, **4** 457, **5** 617, **6** 545, **8** 463, **9** 430, **11** 489.]

Sodium monensin *[22373-78-0]* **$C_{36}H_{61}O_{11}Na$, M 692.8.** Crystallise this polyether antibiotic from EtOH/H_2O [Cox et al. *J Am Chem Soc* **107** 4297 *1985*, DOI: 10.1021/ja00300a037]. It is a Na^+ ionophore, blocks glycoprotein secretion, and could induce catecholamine secretion from chromaffin cells. It is used in potentiometric and spectroscopic studies of alkali metal on complexes.
Sodium oleate **(sodium *cis*-9-octadecenoate)** *[143-19-1]* **$C_{18}H_{33}O_2Na$, M 304.3,** has **m 205°, 233-235°**, and is recrystallised from EtOH, and dried at 100°. [*Beilstein* **2** IV 1645.] It is a soap and is an anti-foaming agent. It also activates protein kinase C in hepatocytes. ***Sodium oxalate*** *[62-76-0]* **C_2O_4Na, M 134.0,** has **m 250-270°(dec), d_4^{20} 2.34**, and crystallises from hot water (16ml/g). For volumetric analysis, analytical sodium oxalate should be dried at 120°/2 hours then cool in a desiccator. [*Beilstein* **2** IV 1819.] ***Sodium palmitate*** *[408-35-5]* **$C_{16}H_{31}O_2Na$, M 278.4,** has **m 283-290°, 285-201°** and crystallises from EtOH. [*Beilstein* **2** IV 1157.]

Sodium pentamethylcyclopentadienide (NaCp', 1,2,3,4,5-pentamethyl-2,4-pentadiene-1-ylsodium) *[40585-51-1]* **$C_{10}H_{15}Na$, M 158.2, m >230°, d^{25} 0.905g/cm^3.** It is prepared, handled and stored as for KCp' but is not as flammable. It is a Cp' ligand source for complexing with a large number of metals and non-metal halides. [Kohl et al. in *Organometallic Synthesis* (R. Bruce King and J.J. Eisch eds) ***Vol 3*** 381, Elsevier Amsterdam *1986*]. A 0.5M solution in THF is commercially available.

Sodium phenoxide *[139-02-6, 156150-40-2 ($3H_2O$)]* **$C_6H_5ONa.\ 3H_2O$, M 170.1, m 61-64°.** The ground powder is washed with Et_2O, then heated at 60°/1mm for 12 to 24 hours to remove any free phenol and solvent. [Kornblum & Lurie *J Am Chem Soc* **81** 2705 *1959*, DOI: 10.1021/ja01520a030; *Beilstein* **6** I 718.]
Sodium phenylacetate *[114-70-5]* **$C_8H_7O_2Na$, M 158.1.** Its aqueous solution is evaporated to crystallisation on a steam bath; the crystals are washed with absolute EtOH and dried under vacuum at 80°. [*Beilstein* **9** IV 1614.]
Sodium o-phenylphenolate tetrahydrate *[132-27-4]* **$C_{12}H_9ONa.\ 4H_2O$, M 264.3.** Crystallise the salt from acetone and dry it under vacuum at room temperature. This salt is a preservative, mould inhibitor and a fungicide [*Beilstein* **16** IV 4600.]

Sodium phenylpyruvate *[114-76-1]* **$C_9H_7O_3Na$, M 186.1, m >300°.** The salt should have no OH broad bands in the IR at ~3000cm^{-1}. If so then dry the solid thoroughly in a vacuum over P_2O_5. Otherwise wash the salt well with Et_2O till free of acid and dry it *in vacuo*. *Alternatively*, add a slight excess of the ***free acid*** (see *[156-06-9]*) in EtOH to ethanolic NaOH, evaporate to dryness and extract excess acid from the salt with dry Et_2O. [*Beilstein* **10** I 325.]

Sodium phytate monohydrate [*myo*-inositolhexakis(H_2PO_4) Na salt] *[14306-25-3]* **$C_6H_{18}O_{24}P_6Na_x.\ xH_2O$, M 857.9.** Crystallise sodium phytate from hot water. [*Beilstein* **6** IV 7927.]

Sodium polyacrylate (NaPAA) *[9003-04-7]* **$[C_3H_3O_2Na]_n$.** Commercial polyacrylamide is first neutralized with an aqueous solution of NaOH, and the polymer is precipitated with acetone. The precipitate is redissolved in a small amount of water and freeze-dried. The polymer is then repeatedly washed with EtOH and water to

remove traces of low-molecular-weight material, and finally dried in vacuum at 60° [Vink *JCS Faraday Trans 1* **75** 1207 *1979*, DOI: 10.1039/F19797501207]. It has also been dialysed overnight against distilled water, then freeze-dried. It is commercially available as a 35 wt% solution in H_2O of polymer with M_w ~8,000 (d^{25} 1.32g/cm^3, n_D^{20} 1.428), and a 45 wt% solution in H_2O of polymer with M_w ~15,000 (d^{25} 1.25g/cm^3, n_D^{20} 1.405).

Sodium poly(α-L-glutamate) (PLGNa) [$C_5H_6NO_3Na]_n$, M 1.1x10^5. After saponification of poly(γ-methyl-α-L-glutamate), PLGNa is obtained by washing it with acetone, drying it in a vacuum, dissolving it in water and precipitating it with isopropanol at 5°. Impurities and low-molecular-weight fractions are removed by electrodialysis of the aqueous solution for 50 hours, followed by ultrafiltration through a Diafilter G 10 T impermeable to polymers of molecular weights greater than 10^4. The polymer is recovered by freeze-drying and stored in a desiccator until used. The molecular weight was determined by viscosity measurements. [Mori et al. *JCS Faraday Trans 1 2583 1978*, DOI: 10.1039/F19787402583.]

Sodium propionate *[137-40-6]* **$C_3H_5O_2Na$, M 96.1, m 285-286°, 287-289°**. Recrystallise it from H_2O (solubility 10%) and dry by heating at 100° for 4 hours. The solubility of the anhydrous salt in MeOH is 13% at 15° and 13.77% at 68°. It is insoluble in *C_6H_6 and Me_2CO. [Henstock *J Chem Soc* 1340 *1934*, DOI: 10.1039/JR9340001340; *Beilstein* **2** IV 701.]

Sodium stearate *[822-16-2]* **$C_{18}H_{35}O_2Na$, M 306.6, m 245-255°, d ^{25} 1.02g/cm^3.** It is better to prepare it by adding a slight excess of octadecanoic acid to ethanolic NaOH, evaporating and extracting the residue with dry Et_2O to remove free acid. It is a very common soap. [*Beilstein* **2** III 1003.]

Sodium R-(+)-tartrate dihydrate *[6106-24-7]* **$C_4H_4O_6Na_2.2H_2O$, M 230.1, m 120°(loses H_2O), d_4^{20} 1.82, $[\alpha]_D^{20}$ +26 (c 1, H_2O).** It crystallises from warm dilute aqueous NaOH on cooling. [*Beilstein* **3** H 524.]

Sodium trifluoroacetate *[2923-18-4]* **$C_2F_3O_2Na$, M 136.0, m 205-207°(dec), 206-210°(dec), pK^{25} 0.52 (for $CF_3CO_2^-$).** A possible contaminant is NaCl. The solid is treated with CF_3CO_2H and evaporated twice. Its solubility in CF_3CO_2H is 13.1% at 29.8°. The residue is crystallised from dilute EtOH, and the solid is dried in vacuum at 100°. [Hara & Cady *J Am Chem Soc* **76** 4285 *1954*, DOI: 10.1021/ja01646a009.] It can be precipitated from EtOH by adding dioxane, then recrystallising several times from hot absolute EtOH. Dry it at 120-130°/1mm. [*Beilstein* **2** IV 461; Fieser **11** 557.]

Stannous bis-cyclopentadienyl (stannocene, $SnCp_2$) *[1294-75-3, 26078-96-6]* **$C_{10}H_{10}Sn$, M 248.9.** $SnCp_2$ was prepared from sodium cylopentadienide [*4894-81-2*, see Chapter 5, Catalysis Part 1] and anhydrous $SnCl_2$ in THF [general procedure: Wilkinson *Org Synth* **36** 31 *1956*, DOI: 10.15227/orgsyn.036.0031; Wilkinson et al. *J Inorg Nuclear Chem* **2** 95 *1956*, DOI: 10.1016/0022-1902(56)80004-3]. Purify it by vacuum sublimation. ***It is sensitive to moisture in solvents.*** Handle and store it under dry N_2. The related thallium and indium compounds are similarly purified. [For preparation and properties, IR, UV & NMR see Dave, Evans and Wilinson *J Chem Soc* 3684 *1959*, DOI: 10.1039/ JR9590003684; for photoelectron spectra see Cradock & Duncan *JCS Faraday Trans 2* 194 *1978*, DOI: 10.1039/F29787400194].

Strontium acetate *[543-94-2]* **$(C_2H_3O_2)_2Sr$, M 205.7, d^{25} 2.1g/ml, pK^{25} 13.0 (for aquo Sr^{2+} hydrolysis).** Crystallise it from AcOH, then dry it under vacuum for 24 hours at 100°. [*Beilstein* **2** II 91.]

Strontium lactate trihydrate *[29870-99-3]* **$(C_3H_5O_3)_2Sr.3H_2O$, M 319.8($3H_2O$), m 120°(loses $3H_2O$).** It crystallises from aqueous EtOH. Its solubility in H_2O is 33g/100ml at ~25° and 200g/100ml at 100°, and is slightly soluble in EtOH. [*Beilstein* **3** IV 633.]

Strontium oxalate monohydrate *[814-95-9]* **$C_2O_4Sr.H_2O$, M 193.6(H_2O), m 150°.** It crystallises from hot water on cooling. The solubility at ~25° in H_2O is 1g/20L, and in 3.5% AcOH and 25% AcOH it is 1g/1.9L and 1g/1.1L respectively. **IRRITANT**. [*Beilstein* **2** H 515, **2** IV 1826.]

Strontium salicylate *[526-26-1]* **$(C_7H_6O_3)_2Sr$, M 361.8, b 336.3°/atm.** It crystallises from hot water (4ml/g) or EtOH. [*Beilstein* **10** IV 125.]

Strontium tartrate *[868-19-9]* **$C_4H_6O_6Sr$, M 237.7.** It crystallises from hot water. Crystals of a ***pentahydrate*** can be grown from silica gel impregnated with L-tartaric acid and using $Sr(NO_3)_2$. The SEM, XRD and FTIR of the crystals have been measured. The ***pentahydrate*** is thermally stable up to 105° but decomposes on further heating liberating H_2O at various stages and finally reduced to strontium oxide [Firdous et al. *Cryst Res Technol* **43(10)** 1015 *2008*, DOI: 10.1002/crat.200800115]. [*Beilstein* **3** IV 1219.]

Tantalium pentaethoxide *[6074-84-6]* **$(C_2H_5O)_5Ta$, M 406.3, m 21°, b 147°/0.2mm, 155°/0.01mm, 202°/10mm, d ^{25} 1.566g/ml, n $_D^{20}$ 1.487, pK_1^{25} 9.6, pK_2^{25} 13.0 (for tantalic acid).** Purify it by distillation under reduced pressure. It aggregates in *C_6H_6, EtOH, MeCN, pyridine and diisopropyl ether. Store it in a dry atmosphere. [Bradley et al. *J Chem Soc* 726 *1955*, DOI: 10.1039/JR9550000726; Bradley et al. *J Chem Soc* 5 *1956*, DOI: 10.1039/JR9560000005; *Beilstein* **1** IV 1312.]

Tetraallyltin (tetraallylstannane) *[7393-43-3]* **$(C_3H_5)_4Sn$, M 283.0, b 52°/0.2mm, 69-70°/15mm, d ^{25} 1.179/ml, n $_D^{20}$ 1.539.** Possible contaminants are allyl chloride and allyltin chloride. Check the ^{1}H NMR and IR [Fishwick & Wallbridge *J Organomet Chem* **25** 69 *1970*, DOI: 10.1016/S0022-328X(00)86206-3], and if impure, dissolve it in Et_2O and shake it with a 5% aqueous solution of NaF which precipitates allyltin fluoride. Separate the Et_2O layer, dry ($MgSO_4$), and distil it at ~0.2mm. It decomposes slightly on repeated distillation. [O'Brien et al. *Inorg Synth* **13** 73 *1972*, DOI: 10.1002/9780470132449.ch14; Fishwick & Wallbridge *J Chem Soc (A)* 57 *1971*, DOI: 10.1039/J19710000057; *Beilstein* **4** III 1922.]

Tetrabutylammonium borohydride *[33725-74-5]* **$(C_4H_9)_4.NBH_4$, M 257.3, m 124-128°, 128-129°.** Purify it by recrystallisation from EtOAc followed by careful drying under vacuum at 50-60°. Samples purified in this way showed no signs of loss of ***active* H** after storage at room temperature for more than 1 year. Nevertheless samples should be stored at *ca* 6° in tightly stoppered bottles if kept for long periods. It is soluble in CH_2Cl_2. [Raber & Guida *J Org Chem* **41** 690 *1976*, DOI: 10.1021/jo00866a022; Brändström et al. *Tetrahedron Lett* 3173 *1972*, DOI: 10.1016/S0040-4039(01)93995-4.]

Tetrabutyl orthotitanate monomer (titanium IV tetra-*n*-butoxide) *[5593-70-4]* **$(C_4H_9O)_4Ti$, M 340.4, b 142°/0.1mm, 134-136°/0.5mm, 160°/0.8mm, 174°/6mm, 189°/13mm, d ^{20} 1.00/ml, d $_4^{35}$ 0.993, n $_D^{20}$ 1.491.** Dissolve it in *C_6H_6, filter if solid is present, evaporate and vacuum fractionate through a Widmer 24inch column. The ester hydrolyses when exposed to air to give hydrated ortho-titanic acid. The titanium content can be determined thus: weigh a sample (*ca* 0.25g) into a weighed crucible and cover it with 10ml of H_2O and a few drops of concentrated HNO_3. Heat (hot plate) carefully till most of the H_2O has evaporated. Cool and add more H_2O (10ml) and concentrated HNO_3 (2ml), and evaporate carefully (no spillage) to dryness and ignite the residue at 600-650°/1 hour. Weigh the residual TiO_2. [Bradley et al. *J Chem Soc* 2773 *1952*, DOI: 10.1039/JR9520002773; Speer *J Org Chem* **14** 655 *1949*, DOI: 10.1021/jo01156a019; *Beilstein* 1 II 398, **1** III 1515, **1** IV 1415, Fieser **15** 316.] It was used to prepare nanosised titania in the anatase form *via* controlled hydrolysis of titanium alkoxide [Chen et al. *J Mater Sci* **31** 3497 *1996*, DOI: 10.1007/BF00360754], and for preparing nanocrystalline TiO_2 powders at room temperature [Wang et al. *Mater Lett* **43** 87 *2000*, DOI: 10.1016/S0167-577X(99)00236-0].

Tetrabutyl tin (tin tetrabutyl) *[1461-25-2]* **$(C_4H_9)_4Sn$, M 347.2, m -97°, b 94.5-96°/0.28mm, 145°/11mm, 245-247°/atm, d ^{25} 1.0559/ml, n $_D^{20}$ 1.473.** Dissolve it in Et_2O, dry it over $MgSO_4$, filter, evaporate and distil it under reduced pressure. Although it does not crystallise easily, once the melt has crystallised, then it will recrystallise more easily. It is soluble in Et_2O, Me_2CO, EtOAc and EtOH, but insoluble in MeOH and H_2O, and shows no apparent reaction with H_2O. [Johnson & Fritz *J Org Chem* **19** 74 *1954*, DOI: 10.1021/jo01366a014; Staveley et al. *J Chem Soc* 1992 *1954*, DOI: 10.1039/JR9540001992; Van der Kerk & Luijten *Org Synth* Coll Vol **4** 881 *1963*, DOI: 10.15227/orgsyn.036.0086; *Beilstein* **4** III 1920, **4** IV 4312.]

Tetraethyl lead *[78-00-2]* **$(C_2H_5)_4Pb$, M 323.5, m -136°, b 84-85°/15mm, 200°/atm 227.7°/atm, dec), d ^{25} 1.653/ml, n $_D^{20}$ 1.519.** Its more volatile contaminants can be removed by exposure to a low pressure (by continuous pumping) for 1 hour at 0°. Purify it by stirring with an equal volume of H_2SO_4 (d 1.40), keeping the temperature below 30°, repeating this process until the acid layer is colourless. It is then washed with dilute Na_2CO_3 and distilled water, dried with $CaCl_2$ and fractionally distilled at low pressure under H_2 or N_2 [Calingaert *Chem Rev* **2** 43 *1926*, DOI: 10.1021/cr60005a002]. It prevents 'knocking' in petrol combustion engines. [Milde & Beatty *Adv Chem Res* **23** 306-318 *1959*, DOI: 10.1021/ba-1959-0023.ch029 *Beilstein* **4** H 639.] A 50 wt% solution in xylene (b 147°/atm, d ^{25} 1.108/ml, n $_D^{20}$ 1.502) is available commercially. **VERY POISONOUS.**

Tetraisopropyl orthotitanate (titanium IV tetraisopropoxide) *[546-68-9]* **(i-$C_3H_7O)_4Ti$, M 284.3, m 18.5°,**

18-20°, b 80°/2mm, 78°/12mm, 228-229°/755mm, d ^{20} 0.96/ml, n $_D^{20}$ 1.464. Dissolve it in dry *C_6H_6 , filter if a solid separates, evaporate and fractionate. It is hydrolysed by H_2O to give solid $Ti_2O(iso\text{-}OPr)_2$ **m *ca* 48°**. [Bradley et al. *J Chem Soc* 2027, *1952*, DOI: 10.1039/JR9520002027; Bradley et al. *J Chem Soc* 469 *1957*, DOI: 10.1039/JR9570000469; *Beilstein* **1** II 328, **1** IV 1469S; for applications see Fieser **6** 11, **10** 404, **11** 374, **12** 19, **12** 504, **13** 13, **13** 311, **14** 247, **14** 311, **15** 322, **16** 399, **17** 347.] This propoxide was used for ***trans-esterifications*** with various alcohols under neutral conditions [Imwinkelried et al. *Org Synth* **65** 230 *1987*, DOI: 10.15227/orgsyn.065.0230], in the ***Sharpless asymmetric epoxidation*** of allylic alcohols [Katsuki & Martin *Org React* **48** 1 *1996*, DOI: 10.1002/0471264180.or048.01], was applied in the formation of ***a heterosupramolecule*** consisting of a TiO_2 nanocrystalline-viologen electron acceptor complex whose light–induced electron transfer was demonstrated [Cusak et al. *Chem Mater* **9** 1765 *1997*, DOI: 10.1021/cm9605173], and was used for ***making porous titanosilicates***, potential ion-exchange materials, for the selective removal and safe storage of radioactive ^{137}Cs and ^{90}Sr nuclear wastes [Behrens et al. *Chem Mater* **8** 1236 *1996*, DOI: 10.1021/cm950534c].

Tetrakis(diethylamino) titanium [(titanium IV tetrakis(diethylamide)] *[4419-47-0]* **$[(C_2H_5)_2N]_4Ti$, M 336.4, b 85-90°/0.1mm, 112°/0.1mm, d ^{25} 0.931/ml, n $_D^{20}$ 1.536.** Dissolve it in *C_6H_6, filter if a solid separates, evaporate under reduced pressure and distil it. It is an orange liquid which reacts violently with alcohols. [Bradley et al. *J Chem Soc* 3857 *1960*, DOI: 10.1039/JR9600003857; *Beilstein* **4** IV 313.]

Tetramethyloxorhenium [$(CH_3)_4ReO$] *[53022-70-1]* **$(CH_3)_4ORe$, M 262.4, m ~45° (no dec <150°).** It is best prepared by adding a 1M solution of MeLi in Et_2O (80ml, 80mmol) slowly to a stirred suspension of $ReOCl_3(PPh_3)_2$ (8.32g, 10mmol, cf. [17442-18-1]) in Et_2O (120ml) at -78°, and the mixture is allowed to warm slowly to ~25° to form a dark brown solution which is stirred further for 0.5 hours. The excess of MeLi is destroyed by dropwise addition, at -78°, of H_2O (~10ml), and allowed to warm to ~25°, and then cooled again, to -30°; and H_2O_2 (2.5g, 30% diluted in 20ml of H_2O) is added slowly dropwise with vigorous stirring. The colour of the solution changes to red rapidly and stirring is continued for 0.5 hours after the temperature has risen to ~25°. This mixture is then cooled to -78°, the Et_2O layer is filtered free from ice, dried first with $CaCl_2$ at ~25° then with molecular sieves, cooled again to -78°, filtered, and the solvent is carefully evaporated at -50°. The red-purple (carmine) crystalline residue is sublimed onto a probe at -78°, in a 1mm vacuum, to give Me_4ReO (1.26g, ~48%; but can be as high as 70% by very careful removal of solvent). Lower yields are obtained if due care is not taken during the removal of solvent *in vacuo*. The low melting solid is extremely volatile subliming readily even at -35°/10^{-3}mm; it co-distils at low temperatures with Et_2O or petroleum ether, and always occurs during removal of solvents (see earlier), hence the temperature has to be kept as low as possible, and a cold probe should be included in the system to avoid losses. In an ***alternative method*** $ReOCl_4$ (3mmol) is reacted with MeLi (12mmol) in Et_2O at -78° to give a 20% yield of Me_4ReO, although this low yield may well be due to evaporative losses.

Me_4ReO is thermally stable and can be stored indefinitely *in vacuo*. It is very soluble in petroleum ethers, Et_2O, CS_2, CCl_4, but these solutions slowly decompose with time even in the absence of air. However, solutions in THF and aromatic hydrocarbons are more stable. It is surprisingly unreactive at ~25° in Et_2O, H_2O, mineral acids, alcohols, H_2, CO, CO_2, SO_2, HCl gas, butadiene, tertiary phosphines, amines, tetramethylthiuram disulfide and 1,1-diphenyl-2-picrylhydrazyl. It is however, highly reactive with air and oxygen producing instantly white fumes and crystals of $MeReO_3$ (methyltrioxorhenium, **MTO**, the carrier catalyst, see *[70197-13-6]*). In *C_6H_6 solution with air, it slowly oxidises to form yellow-orange products (cf. yellow cis-Me_3ReO_3 [56090-01-8]). In the mass spectrum, ions of Re isotopes are identified (^{185}Re 37%, ^{187}Re 63%) with the natural isotopic abundance. The solid state IR (at ~ -250° co-condensed with argon) has ν_{max} at 2974s(CH str), 1231s(CH def), 1018s(Re=O str), 1004sh,br, 746m(Me rock), 552m and 529s(ReC str) cm^{-1}, and IR (de-oxygenated CS_2) has ν_{max} at 2980s, 1370m, 1002s, 749w, 520m cm^{-1}. [Mertis et al. *JCS Chem Commun* 93a *1974*, DOI: 10.1039/C3974000093A; Mertis, Williamson and Wilkinson *JCS Dalton Trans* 607 *1975*, DOI: 10.1039/DT9750000607; Mertis & Wilkinson *JCS Dalton Trans* 1488 *1976*, DOI: 10.1039/DT9760001488; Beattie & Jones *Inorg Chem* **18** 2318 *1979*, DOI: 10.1021/ic50198a056.]

Tetramethyltin (tetramethylstannane, tin tetramethyl) *[594-27-4]* **$(CH_3)_4Sn$, M 178.8, m -55°, b 76.6°/748mm, 74-75°/atm, 78°/atm, d ^{25} 1.291g/ml, n $_D^{20}$ 1.441.** Organotin compounds are **HIGHLY TOXIC,** and all due precautions should be taken when handling them. Me_4Sn is an ethereal smelling liquid that is highly

flammable with a flash point of less than 20°, and should be stored at low temperatures. An improved preparation of Me_4Sn has been achieved by carrying out the reaction in the higher boiling di-*n*-butyl ether, and preparing the Grignard reagent *in situ*. Under strictly anhydrous conditions, to Mg turnings (50g, 2.06g.atoms) in dry *n*-Bu_2O (600ml, containing a few crystals of I_2) is added dropwise a solution of MeI (225g, 1.59moles, freshly distilled) in *n*-Bu_2O (600ml) with gentle stirring. After the initial reaction has started, the MeI solution is added at such a rate as to keep the solution refluxing gently, requiring *ca* 3 hours. Cool the solution to ~25° and add to it, dropwise, anhydrous $SnCl_4$ (75g, 0.29 moles) while sustaining gentle reflux (*ca* 2-2,5 hours). The mixture is then refluxed steadily (85-95°) for 1 hour, and set aside at ~25° for several hours. The reflux condenser is replaced by a Claisen head and the mixture is distilled; whereby Me_4Sn and *n*-Bu_2O distil together at ~85-95°/atm. It dissolves stopcock silicone greases. The Me_4Sn is purified by fractionation through a Todd column (35-40 plates) to give ***pure stannane*** with **b 76.6°/748mm** in 91% yield. [Edgell & Ward *J Am Chem Soc* **76** 1169 *1954*, DOI: 10.1021/ja01633a073.] Its IR (liquid film) has ν_{max} at 2920 (vs) and 3000 (vs) C-H str, 1443 (s) and 1198 (s) CH_3 deformation, 770 (vs) CH_3 rocking, **528 (s) C-Sn** str cm^{-1}, and from Raman spectrum 160 (vs) and 145 (vs) cm^{-1} for **C-Sn-C** bending [Taimsalu & Wood *Trans Farad Soc* **59** 1754 *1963*, DOI: 10.1039/TF9635901754; Edgell & Ward *J Am Chem Soc* **77** 6486 *1955*, DOI: 10.1021/ja01629a014]. The ^{119}Sn NMR (15.5 MHz, at 28°C, 12mm tube not spinning, neat $SnCl_4$ as external standard) has δ at -147.8 ($J_{H\text{-}^{119}Sn}$ = 54.0Hz from 60MHz proton spectrum) [Lassigne & Wells *Can J Chem* **55** 927 *1977*, DOI: 10.1139/v77-130; for ^1H and ^{13}C NMR spectra see Singh *J Organomet Chem* **99** 251 *1975*, DOI: 10.1016/S0022-328X(00)88454-5.] [*Beilstein* **4** H 631, **4** I 583, **4** II 1010, **4** III 1917, **4** IV 4307.]

Tetraphenyltin *[595-90-4]* **($C_6H_5)_4Sn$, M 427.1, m 224-225°, 224-227°, 226°, b >420°.** $SnPh_4$ forms yellow crystals from $CHCl_3$, petroleum ether (b 77-120°), xylene or *benzene/cyclohexane, and is dried at 75°/20mm. [Gilman & Rosenberg *J Am Chem Soc* **74** 531 *1952*, DOI: 10.1021/ja01122a074; *Beilstein* **16** IV 1592.]

Tetra-*n*-propylammonium perruthenate (TPAP, tetrapropyl tetraoxoruthenate) *[114615-82-6]* **($C_3H_7)_4NRuO_4$, M 351.4, m 160°(dec).** It is a dark green solid that is stable at ~25° for long periods without much deterioration, and is best kept in a refrigerator. It is a ***mild oxidant***, and should ***not*** be heated directly as it may explode. It can be used stoichiometrically or catalytically with a ***co-oxidant*** [Ley et al. *Aldrichimica Acta* **23** 13 *1990*, *Synthesis* 639 *1994*, DOI: 10.1055/s-1994-25538]. Small amounts decompose in a flame at ~155° in air. It can be washed with aqueous *n*-propanol, then H_2O and dried over KOH in a vacuum. It is soluble in CH_2Cl_2 and MeCN. Generally, at ambient temperatures in these solvents it is most useful, when in conjunction with ***N-methylmorpholine N-oxide*** (**NMO**), for the oxidation of primary and secondary alcohols, including allylic and benzylic alcohols, lactol oxidation, heteroatom oxidation, and some cleavage reactions. [Dengel et al. *Transition Met Chem* **10** 98 *1985*, DOI: 10.1007/BF00618458; Griffith et al. *JCS Chem Commun* 1625 *1987*, DOI: 10.1039/C39870001625; for a review see Ley et al. *Synthesis* 639 *1994*, DOI: 10.1055/s-1994-25538; and for its catalytic activity see chapter 5 in 'Catalysts'.] The **TPAP/NMO** system has been used to oxidise *N, N'*-dihydroxyimidazolines to the respective nitronyl-nitroxides free radicals in CH_2Cl_2 (~25°, 1-12hrs) in 44-90% yields [Gorini et al. *Synlett* 948 *2006*, DOI: 10.1055/s-002-4768]. In conjunction with NMO, Swern oxidation or Dess-Martin periodinane conditions, it promotes the oxidation of hydroxyl-substituted tri-*n*-butylammonium trifluoroarylborates without cleavage of the C—B bond [Molander & Petrillo *J Am Chem Soc* **128** 9634 *2006*, DOI: 10.1021/ja062974i]. [For applications see Fieser **14** 302, **16** 325.]
§ Polymer supported reagent is available commercially.

Thallium (I) acetate (TlOAc) *[563-68-8]* **CH_3CO_2Tl, M 263.4, m 131°.** Thallous (I) acetate crystallises from EtOH (needles) or Me_2CO. The salt forms white deliquescent crystals (specific gravity 3.68) which are soluble in H_2O and EtOH. Store it in sealed containers. It forms TlOAc.AcOH crystals which melt at 64°. [*Beilstein* **2** H 115, **2** II 119, **2** III 195.] **POISONOUS — HANDLE CAREFULLY WITH GLOVES, and work in a well-ventilated fume hood.**

Thallium (III) triacetate [$Tl(OAc)_3$] *[2570-63-0]* **($C_2H_3O_2)_3Tl$, M 381.5, m 182°(dec.).** The salt is prepared by stirring thallic oxide (50g) in AcOH (300ml) at 65° until all the brown-black solid has dissolved (~24 hours), then filter and cool to obtain the salt as white crystals which are collected by decantation and dried over P_2O_5 *in vacuo* as they turn brown in air. A second crop can be obtained by concentrating the filtrate (total yield 73g, 99%). On a large scale (457g) of the brown trioxide was treated with AcOH (2L) containing Ac_2O (110ml) by

stirring at 80-90°, the walls of the flask were washed down with a further volume of AcOH (500ml). Heating (90-100°) and stirring was continued for 2 hours (all the brown oxide had dissolved), the hot solution was filtered using a sintered glass funnel, cooled to ~20°, and collected onto a glass frit. The solid was dissolved in the minimum volume of AcOH (~800ml) at 80-90°, filtered through a glass frit and allowed to cool first to ~20° then to ~15°, and collected by filtration. The $Tl(OAc)_3$ was dried by spreading it in a large dish in a desiccator over KOH pellets overnight to give ~97% pure salt (467g, 61% yield). It promotes the quantitative photochemical decarboxylation of a variety of aliphatic acids to yield a high proportion of the corresponding alkanes with some alkenes, dialkyls and other minor products at wavelength 3500Å; whereas at wavelength 2537Å the alkyldimers are formed in high yields. [Kochi & Bethea *J Org Chem* **33** 75 *1968*, DOI: 10.1021/jo01265a015.] [For use in the oxidation of olefins see Moriarty & Gopal *Tetrahedron Lett* 347 *1972*, DOI: 10.1016/S0040-4039(01)84321-5]. [*Beilstein* **2** H 115, **2** III 195.] **POISONOUS — HANDLE CAREFULLY WITH GLOVES, and work in a well-ventilated fume hood.**

Thallium (III) trifluoroacetate [$Tl(tfl)_3$, $Tl(OCOCF)_3$] *[23586-53-0]* **($(C_2F_3O_2)_3Tl$, M 543.4, m dec slowly >100°, 213° (dec.).** This ***thallation reagent*** is prepared in 90-100% yield by heating a suspension of thallium(III) oxide in TFA containing 10-20% of H_2O until clear. This colourless solution can be used directly in thallation reactions or a granular solid salt can be isolated by evaporation *in vacuo*, and then used in inert solvents such as MeCN. The salt does not have a sharp melting point and decomposes slowly >100°. It is ***water sensitive*** but can be stored at ~25° in a stoppered container away from light without appreciable decompostion for long periods. A solution of the salt in TFA, however, can tolerate up to ~20% of H_2O to give a 0.8M solution before serious hydrolysis of the salt occurs. It thallated aromatic rings (e.g. PhCl, PhF, toluene, xylene, *o*-benzoic acid) in TFA to produce the corresponding $ArylTl(tfl)_2$ at low temperatures which can be isolated in 70-100% yields, or reacted further (e.g. with KI) to displace the $Tl(tfl)_2$ group and form the respective iodides. [McKillop et al. *J Am Chem Soc* **93** 4841 *1971*, DOI: 10.1021/ja00748a029; Taylor et al. *Org Synth* Coll Vol **6** 709 *1988*, DOI: 10.15227/orgsyn.055.0070; *Beilstein* **2** II 186; Fieser **3** 286, **4** 498, **5** 658, **6** 579, **7** 365, **8** 478, **13** 295.] Useful oxidant for the synthesis of S-substituted cysteine peptides, and proteins containing disulfide bonds [Yajima et al. *Tetrahedron* **44** 805 *1988*, DOI: 10.1016/S0040-4020(01)86118-4]. **POISONOUS — HANDLE CAREFULLY WITH GLOVES, and work in a well-ventilated fume hood.**

Thallous (I) ethoxide (TlOEt) *[20398-06-5]* **C_2H_5OTl, M 249.4, d^{25} 3.522g/ml, n_D^{20} 1.676.** The alkoxide is prepared by refluxing dry EtOH in a modified Soxhlet extractor whereby the hot alcohol leaches thallium shot or turnings (see below) placed in the vapours of refluxing alcohol while oxygen flows through the apparatus which is protected from moisture with a soda lime drying tube at the top of the condenser. The apparatus devised by Fieser and Fieser can be used. Thallium shot (m 303°) is made by holding a clean piece if metal with tongs and heated with a blow torch allowing the molten metal to drip in ~2L of cold H_2O. *Alternatively*, thallium turnings made with a pencil sharpener from thallium rods can be used. A Soxhlet flask (500ml) containing dry EtOH (300ml) is placed under Tl shot (100ml, dried by pressing with filter paper) in the crucible above, and the EtOH is refluxed while a rapid stream of dry O_2 is made to flow just beneath the metal. The volume of boiling EtOH in the flask is maintained at ~300ml by further addition of dry EtOH. When all the metal has been converted to TlOEt (12-16 hours), and all the oily alkoxide has run into the flask which will form a separate heavy oily liquid layer (note that TlOEt had d = 3.522), boiling is stopped and the volume of the alkoxide solution is adjusted to 300ml which would give a saturated solution containing 9g of TiOEt/100ml. Store away from moisture. *Alternatively*, the oily layer can be sucked out with a vacuum into a container, but great care should be taken to avoid contact with moisture. Thallium in the ethoxide solution can be determined as TlOH by cooling it in an ice bath without separating the excess of EtOH (to avoid partial conversion of TlOH to black Tl_2OH), and adding an equal volume of boiled and re-cooled H_2O (i.e. free from O_2) and evaporating *in vacuo* to give yellow crystalline TlOH. [See Fieser **2** 407, **4** 501, **5** 656, **6** 577, **7** 362, **10** 395; Dönges in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 877-878 *1963*, Freudenberg & Uthemann *Chem Ber* **52** 1508 *1919*, DOI: 10.1002/cber.19190520813.] **POISONOUS— use gloves, work in a good fume hood.**

Tin (II) acetate (stannous acetate) *[638-39-1]* **($(CH_3CO_2)_2Sn$, M 236.8, m 180-182°, 182.55-183°, b 239-241°/atm(some dec under N_2), d^{25} 2.31g/ml.** It is prepared by dissolving blue-black SnO_2 (25g) in refluxing 50%v/v AcOH (200ml), evaporating *in vacuo* (over KOH) and subliming the white residue *in vacuo* at 150-155° (~96% yield of white orthorhombic crystals). *Alternatively*, finely divided Sn is refluxed in glacial AcOH for

80-90 hours [not less as $Sn(OAc)_2$ 2AcOH is formed] and isolated as before. It hydrolyses slowly in H_2O to give blue Black SnO_2, Me_2CO, CO_2 and H_2; and can be stored for long periods under N_2, and is soluble in EtOH (2.9%), Me_2CO (1.4%) and 2N AcOH (33%). It is a useful ***reducing (and acetylating) agent***. [Donaldson et al. *J Chem Soc* 5942 *1964*, DOI: 10.1039/JR9640005942.]

Titanium (IV) methoxide *[992-92-7]* **$(CH_3O)_4Ti$, M 172.0, m 200-210°, b 243°/52mm.** It is extremely sensitive to moisture. Dissolve it in H_2O-free $*C_6H_6$, filter, evaporate and distil it *in vacuo* under N_2. It is **FLAMMABLE** and **TOXIC**. [for $Ti(OEt)_4$ see: Bradley et al. *J Chem Soc* 721 *1955*, DOI: 10.1039/JR9550000721; Bradley et al. *Metal Alkoxides* Academic Press *1978,* ISBN 0121242501.] [*Beilstein* **1** II 274.] This ethoxide was used for preparing polyoxotitanates [Clegg et al. *JCS Dalton Trans* 681 *1996*, DOI: 10.1039/DT9960000681].

Titanocene dichloride *[1271-19-8]* **$C_{10}H_{10}Cl_2Ti$, M 248.9, m 260-280°(dec), 289.2°, 298-291°, d^{25} 1.6g/ml.** It forms bright red crystals from toluene or xylene/$CHCl_3$ (1:1) and sublimes at 190°/2mm. It is moderately soluble in EtOH and insoluble in Et_2O, $*C_6H_6$, CS_2, CCl_4, petroleum ether and H_2O. The crystalline ***dipicrate*** explodes on melting at **139-140°**. [Wilkinson et al. *J Am Chem Soc* **75** 1011 *1953*, DOI: 10.1021/ja01100a527; IR: Wilkinson & Birmingham *J Am Chem Soc* **76** 4281 *1954*, DOI: 10.1021/ja01646a008; NMR and X-ray: Glivicky & McCowan *Can J Chem* **51** 2609 *1973*, DOI: 10.1139/v73-394; *Beilstein* **16** IV 1769; for aplications see Fieser **6** 48, **10** 130, **12** 168, **13** 102, **14** 120, **16** 116.] This titanocene catalyses a one-pot synthesis of α-methylene-γ-butyrolactones from benzaldehydes and bromomethylacrylates [Paira et al. *Tetrahedron Lett* **48** 3205 *2007*, DOI: 10.1016/j.tetlet.2007.03.036].

Tri-*n*-butyl tin chloride (TBTC) *[1461-22-9]* **$(C_4H_9)_3SnCl$, M 325.5, b 98-100°/0.4mm, 140-152°/10mm, 172°/25mm, d^{25} 1.21g/ml, n_D^{20} 1.492.** Fractionate it in an inert atmosphere and seal it in small aliquots in glass ampoules. It is sensitive to moisture. [Jones et al. *J Chem Soc* 1446 *1947*, DOI: 10.1039/JR9470001446; *Beilstein* **4** III 1926, **4** IV 4330; for applications see Fieser **6** 604, **7** 378, **13** 315.]

Tributyl tin hydride *[688-73-3]* **$(C_4H_9)_3SnH$, M 291.1, b 76°/0.7mm, 81°/0.9mm, d^{25} 1.082g/ml, n_D^{20} 1.473.** Dissolve it in Et_2O, add quinol (500mg for 300ml, to stabilise it), dry over Na_2SO_4, filter, evaporate and distil it under dry N_2. It is a clear liquid if dry and decomposes very slowly. In the presence of H_2O, traces of tributyl tin hydroxide are formed in a few days. Store it in sealed glass ampoules in small aliquots. It is estimated by reaction with aqueous NaOH when H_2 is liberated. **CARE**: stored samples may be under pressure due to liberated H_2. [Ono et al. *Tetrahedron* **41** 4013 *1985*, DOI: 10.1016/S0040-4020(01)97180-7; Neuman *Synthesis* 665 *1987*, DOI: 10.1055/s-1987-28044; Curran *Synthesis* 417 *1988*, DOI: 10.1055/s-1988-27600; *Beilstein* **4** IV 4312; for applications see Fieser **1** 1192, **2** 424, **3** 294, **4** 518, **5** 685, **6** 604, **7** 379, **8** 497, **9** 476, **10** 411, **11** 545, **12** 516, **13** 316, **14** 312, **15** 325, **16** 343, **17** 351.] This hydride is a ***radical reagent*** for reductive cleavage [Neumann *Synthesis* 665 *1987*, DOI: 10.1055/s-1987-28044], radical dehalogenation and intramolecular radical cyclisation [Curran *Synthesis* 417 *1988*, DOI: 10.1055/s-1988-27600], radical prompted intramolecular cyclisation [Singh & Batra *Tetrahedron Lett* **47** 7043 *2006*, DOI: 10.1016/j.tetlet.2006.07.106], and is a tin fragment used in a synthesis of ***(+)-panepophenanthrin*** [Comméiras et al. *Tetrahedron* **62** 9892 *2006*, DOI:10.1016/j.tet.2006.08.010].

Triethyltin hydroxide *[994-32-1]* **$(C_2H_5)_3SnOH$, M 222.9, m 49-50°, b 153-155°/20mm.** Treat it with HCl, followed by KOH, and filter it to remove diethyltin oxide [Prince *J Chem Soc* 1783 *1959*, DOI: 10.1039/JR9590001783]. [*Beilstein* **4** H 633, **4** I 585, **4** II 1012, **4** III 1924, **4** IV 4325.]

Triiron dodecacarbonyl *[17685-52-8]* **$Fe_3(CO)_{12}$, M 503.7, m 165°(dec).** The dark black-green solid usually contains 10% by weight of MeOH as stabiliser. This can be removed by keeping it in a vacuum at 0.5mm for at least 5 hours. It can be sublimed slowly at high vacuum and is soluble in organic solvents. [Landesberg et al. *J Org Chem* **37** 930 *1972*, DOI: 10.1021/jo00972a002; Case & Whiting *J Chem Soc* 4632 *1960*, DOI: 10.1039/JR9600004632; King et al. *Inorg Synth* **7** 193 *1963*; DOI: 10.1002/9780470132388.ch52; McFarlane et al. *Inorg Synth* **8** 181 *1966*, DOI:10.1002/9780470132395.ch47] **TOXIC as it is a source of carbon monoxide.**

Trimethyloxonium tetrafluoroborate *[420-37-1]* **$(CH_3)_3O.BF_4$, M 147.9, m 141-143°(sinters, open capil-**

lary), 179.6-180.0°(dec), 210-220°(dec). The salt must be a white crystalline solid **m ~ 179.6-180.0°** (**dec**, sealed tube). Under a N_2 atmosphere (e.g. Dry Box), wash it twice with CH_2Cl_2, then twice with Na-dried Et_2O, and dry by passing dry N_2 over the salt until free from Et_2O [Curphey *Org Synth* Coll Vol **6** 1019 *1988*, DOI: 10.15227/orgsyn.051.0142]. The oxonium salt, purified in this way, can be handled in air for short periods. The sample kept in a desiccator (Drierite) for 1 month at -20° had an unaltered melting point, and samples stored in this way for >1 year are satisfactory for alkylations. ^1H NMR in liquid SO_2 in a sealed tube had a single peak at δ 4.54 (impurities have δ at 3.39). [Meerwein *Org Synth* Coll Vol **5** 1096 *1973*, DOI: 10.15227/orgsyn.046.0120.] If the sample looks good, dry it in a vacuum desiccator for 2 hours (25°/1mm) and store it under N_2 at -20°. The melting point depends on heating rate. [*Beilstein* **1** IV 1248; for applications see Fieser **1** 1232, **2** 438, **3** 314, **4** 541, **13** 327.]

Cis*-Trimethylrhenium dioxide [*cis*-trimethyldioxorhenium(VII), *cis*-$(CH_3)_3ReO_2$]** *[56090-01-8]* **$(CH_3)_3ReO_2$, M 263.3, m 10-11°.** This yellow dioxide is best prepared, in ~60% yield, from Me_4ReO (preceding oxide [53022-7-1], e.g. 0.5g) in Et_2O (e.g. 40ml) at -78° by exposing the solution to nitric oxide when the red colour disappears while allowing to warm to ~25° with stirring. After 1 hour (without isolating the nitroso intermediate), the Et_2O is removed at -40° *in vacuo* and the yellow crystalline residue is ***sublimed at 10^{-3}mm onto a probe at -78° to give ***cis-$(CH_3)_3ReO_2$***, which can be recrystallised from petroleum ether solution on cooling to -78°, or distilled *in vacuo*. It is reasonably stable at room temperature, and like the starting material it fumes in air forming needles of **MTO**, the carrier catalyst (see above). Store it under N_2 or argon in a sealed ampoule. Its IR spectrum is consistent with the trigonal bipyramidal structure, where bands due to methyl vibrations are present together with two strong bands at ν_{max} 992 and 951 cm^{-1} attributable to ***cis-ReO_2***. This structure is also consistent with the ^1H NMR in CS_2 or deuteriotoluene which has two sharp resonances at δ 2.07 and 2.50 in the ratio 1:2 in which the higher field band is assumed to be from the axial methyl group. The lines do not broaden on cooling to -78° or heating to 85° in toluene solution which is consistent with a rigid molecule. The MS is as predicted from the two isotopes of Re (see above). [Mertis & Wilkinson *JCS Dalton Trans* 1488 *1976*, DOI: 10.1039/DT9760001488; Beattie & Jones *Inorg Chem* **18** 2318 *1979*, DOI: 10.1021/ic50198a056.]

Trimethyltin chloride (chlorotrimethylstannane) *[1066-45-1]* **$(CH_3)_3SnCl$, M 199.3, m 37.5-39.5°, 42°, b 45-47°/10mm, 152°/760mm, 154-156°/atm.** Me_3SnCl forms colourless needles that have **HIGHLY TOXIC** vapours and is best purified by distillation at atmospheric pressure or in a vacuum. It has been prepared by dropwise addition of a solution of Et_2O saturated with dry HCl (20ml) to freshly distilled ***(dimethylamino)-trimethylstannane*** (2.21g, **b 126°/atm**, d^{25} 1.274, n_D^{20} 1.463 *[993-50-0]*) in dry Et_2O (10ml). $Me_2NH.HCl$ precipitated out, was filtered, the solvent was evaporated at <20°/15mm, and the residue was distilled at 760mm providing the colourless crystalline solid ***Me_3SnCl*** (1.80g, 89.7%). It sublimes slowly at ~25°/20mm. [Jones & Lappert *J Organomet Chem* **3** 295 *1965*, DOI: 10.1016/S0022-328X(00)84649-5; for ^1H and ^{13}C NMR see Singh *J Organomet Chem* **99** 251 *1975*, DOI: 10.1016/S0022-328X(00)88454-5.] It is also available commercially as 1.0M solutions in hexanes or THF. Like the reaction of Me_2N-$SnMe_3$, the ***Me_3SnCl*** reacts with H_2O on heating to give ***Me_3SnOH*** (almost quantitatively, *[56-24-6]*) as white crystals **m 118°**, which sublime at their melting points. It has IR (Nujol mull) with ν_{max} at 3620 (m), 2985 (m), 2915 (m), 1405 (w), 1195 (m), 920 (s), 765 (s), **540** (s) **Sn-C** str, 370 (s) and 316 (w) cm^{-1}; it exists as a ***dimer $[Me_3SnOH]_2$*** in the solid state (IR mull) and in $*C_6H_6$, CCl_4 and in $CHCl_3$ solutions (ebullioscopy) [Okawara & Yasuda *J Organomet Chem* **1** 356 *1964*, DOI: 10.1016/S0022-328X(00)80063-7].

Triphenylantimony III (triphenylstibine) *[603-36-1]* **$(C_6H_5)_3Sb$, M 353.1, m 52-54°, b 377°/atm, d^{25} 1.53g/cm^3.** Recrystallise Ph_3Sb from acetonitrile [Hayes et al. *J Am Chem Soc* **107** 1346 *1985*, DOI: 10.1021/ja00291a039; Hiers *Org Synth* Coll Vol **1** 550 *1941*, DOI: 10.15227/orgsyn.007.0080]. [*Beilstein* **16** H 891, **16** IV 1198.]

Triphenylbismuth (bismuth triphenyl) *[603-33-8]* **$(C_6H_5)_3Bi$, M 440.3, m 75-76°, 77-78°, 78.5°, b 124°/7mm, $d_4^{98.5}$ 1.6427(melt).** Dissolve Ph_3Bi in EtOH, precipitate it with H_2O, extract with Et_2O, dry and evaporate till the residue crystallises. It has been recrystallised from EtOH and Et_2O/EtOH and is a stable compound. [Forward et al. *J Chem Soc* suppl p121 *1949*, DOI: 10.1039/JR949000S121; Pfeiffer et al. *Chem Ber* **37** 4620 *1904*, DOI: 10.1002/cber.19040370468; Gilman & Yablunky *J Am Chem Soc* **62** 665 *1940*, DOI: 10.1021/ja01860a068; UV: Jaffé *J Chem Phys* **22** 1430 *1954*, DOI: org/10.1063/1.1740411; *Beilstein* **4** III

1841.] Controlled hydrolysis of Ph_3Bi in supercritical CO_2 using a high-pressure cold wall reactor provided conformal bismuth oxide films [O'Neil & Watkins *Chem Mater* **19** 5460 *2007*, DOI: 10.1021/cm070288s].

Triphenyltin chloride (Fentin, chlorotriphenylstannane, triphenylchlorostannane) *[639-58-7]* **$(C_6H_5)_3SnCl$, M 385.5, m 103-106°(dec), 108°(dec), b 240°/13.5mm.** Purify it by distillation, followed by recrystallisation from MeOH by adding petroleum ether (b 30-60°), **m 105-106°** [Kozeschow et al. *Chem Ber* **67** 1348 *1934*, DOI: 10.1002/cber.19340670810], or by crystallisation from Et_2O, or 5 parts of EtOH and a small volume of petroleum ether. [Krause *Chem Ber* **51** 912 *1918*, DOI: 10.1002/cber.191805101112.] It ***sublimes*** in a vacuum. [*Beilstein* **16** H 914, **16** I 540, **16** II 625, **16** III 1240, **16** IV 1606; Fieser **10** 451.] **VERY TOXIC.**

Triphenyltin hydroxide *[76-87-9]* **$(C_6H_5)_3SnOH$, M 367.0, m 122-123.5°, 124-126°.** West, Baney and Powell [*J Am Chem Soc* **82** 6269 *1960*, DOI: 10.1021/ja01509a018] purified a sample which was grossly contaminated with tetraphenyltin and diphenyltin oxide by dissolving it in EtOH, most of the impurities remaining behind as an insoluble residue. Evaporation of the EtOH extract gave the crude hydroxide which was converted to ***triphenyltin chloride*** (above) by grinding in a mortar under 12M HCl, then evaporating the acidic solution. The residual ***chloride***, after crystallisation from EtOH, had **m** 104-105°. It was dissolved in Et_2O and converted to the hydroxide by stirring with excess aqueous ammonia. The ether layer was separated, dried, and evaporated to give triphenyltin hydroxide which, after crystallisation from EtOH (or MeCN) and drying under vacuum, was in the form of white crystals (**m 119-120°**), which retained some cloudiness in the melt above 120°. The hydroxide retains water (0.1-0.5 moles of water per mole) tenaciously. [Glidewell & Liles *Acta Cryst* (B) **34** 129 *1978*, DOI: 10.1107/S0567740878002435; *Beilstein* **16** I 540, **16** II 625, **16** III 1240, **16** IV 1606.]

Tris(2,2'-bipyridine)ruthenium(II) dichloride ($6H_2O$) *[14323-06-9 (anhydrous), 50525-27-4 ($6H_2O$)]* **$C_{30}H_{24}Cl_2N_6Ru.6H_2O$, M 748.6, m >300°.** Recrystallise the red solid from water, then from MeOH [Ikezawa et al. *J Am Chem Soc* **108** 1589 *1986*, DOI: 10.1021/ja00267a032]. Soluble in Me_2CO. [For synthesis see Broomhead & Young *Inorg Synth* **28** 338 *1990*, DOI: 10.1002/9780470132593.ch86.]

Tris(η^5-2,4-cyclopentadien-1-yl)samarium III [$SmCp_3$] *[1298-55-1]* **$C_{15}H_{15}Sm$, M 345.6, m 365°.** $SmCp_3$ was prepared by stirring $SmCl_3$ with cyclopentadienyl sodium [see 4989-82-1] in THF, the solvent is removed and the residue is heated at 200-250° in a high vacuum. Crystalline $SmCp_3$ is stable up to 400° and sublimes at 220°/10^{-4}mm (also 145°/10^{-3}mm) to give orange or yellow-orange crystals that are soluble in THF and are hydrolysed in H_2O. The IR is similar to that of $SmCp_2$. [Wilkinson & Birmingham *J Am Chem Soc* **76** 6210 *1954*, DOI: 10.1021/ja01652a114; Birmingham & Wilkinson *J Am Chem Soc* **78** 42 *1956*, DOI: 10.1021/ja01582a009; Watt & Gillow *J Am Chem Soc* **91** 775 *1969*, DOI: 10.1021/ja01031a061.] It is used in the selective reduction of specific double bonds, i.e. has regioselectivity [Qian et al. *J Organomet Chem* **344** 175 *1988*, DOI: 10.1016/0022-328X(88)80477-7]. The ***acetonitrile $SmCp_3$ complex*** *[100439-84-7]* M 386.7 forms bright yellow crystals soluble in MeCN, the ***cyclohexylisocyanide $SmCp_3$ complex*** *[37299-04-0]* is soluble in $*C_6H_6$ and has **m 148°**, and the ***pyridine $SmCp_3$ complex*** *[114269-11-3]* **M 424.7** is obtained as a yellow crystalline solid by dissolving it in pyridine and evaporating to dryness and is soluble in pyridine and MeCN. [Deacon et al. *Aust J Chem* **40** 895 *1987*, DOI: 10.1071/CH9870895.]

Tris(d,d-dicampholylmethanato) europium (III) [$Eu(dcm)_3$] *[52351-64-1]* **$C_{63}H_{105}EuO_6$, M 1110.5, m 220-227.5°, 229-232°, $[\alpha]_D^{25}$ +28.6 (c 5.4, CCl_4, and varies markedly with concentration).** Dissolve it in pentane, filter it from any insoluble material, evaporate to dryness and dry the residue (white powder) at 100°/0.1mm for 36 hours. Its IR has ν_{max} at 1540cm^{-1}. [McCreary et al. *J Am Chem Soc* **96** 1038 *1974*, DOI: 10.1021/ja00811a016.] Useful ***chiral shift reagent*** for determining enantiomeric ratios by NMR spectroscopy, and gives the highest chemical shift difference compared to other shift reagents.

Tris-[(3-trifluoromethylhydroxymethylene)-d-camphorato] europium (III) **[$Eu(tfc)_3$]** *[34830-11-0]* **$C_{36}H_{42}EuF_9O_6$, M 893.6, m 195-299° (dec), ~220°, $[\alpha]_D^{24}$ +152 (c 2, CCl_4, and varies markedly with concentration).** Purify it by extraction with pentane, filter and the filtrate is evaporated and the residual bright yellow amorphous powder is dried at 100°/0.1mm for 36 hours. A sample purified by fractional molecular distillation at 180-200°/0.004mm gave a liquid which solidified and softened at ~130°, melted at ~180° and was analytically pure. Its IR (CCl_4) has ν_{max} at ν_{max} 1630-1680 cm^{-1} and the ^1H NMR (CCl_4) has δ at -1.3 to 0.5 (br), -0.08 (s), 0.41 (s), 1.6-2.3 and 3.39 (s). [McCreary et al. *J Am Chem Soc* **96** 1038 *1974*, DOI: 10.1021/

ja00811a016; Goering et al. *J Am Chem Soc* **93** 5913 *1971*, DOI: 10.1021/ja00751a065.] Optically active NMR shift reagent. Used with Ag(fod) for enantiomeric resolution of *sec*-butylisothiouronium chloride [Wenzel & Zala *Anal Chem* **59** 562 *1987*, DOI: 10.1021/ac00131a006].

Trisodium citrate dihydrate *[68-04-2 (Anhydrous), 6132-04-3 (2H_2O), 6858 (5H_2O)]* **$C_6H_5O_7Na_3$. 2H_2O, M 294.1(2H_2O), m 150°(loses H_2O) and dec >300°.** Crystallise the salt from warm water by cooling to 0°. Solubility in H_2O is 92g/100ml at 25°. [*Beilstein* **3** III 1100, **3** IV 1274.] Useful antacid, and effective in removing scale from boilers and radiators.

Tungsten hexacarbonyl *[14040-11-0]* **W$(CO)_6$, M 351.9, m 150°, d ^{25} 2.65g/cm^3.** Sublime it *in vacuo* before use [Connor et al. *JCS Dalton Trans* 511 *1986*, DOI: 10.1039/DT9860000511]. Catalyst in the photochemical cyclisation of silyloxytrienes *via* either a 6-endo pathway or a ***Cope rearrangement*** [Miura et al. *J Organomet Chem* **692** 562 *2007*, DOI: 10.1016/j.jorganchem.2006.08.037], a precursor to a ***Fischer carbine complex*** which reduces Pd(II) to nanoparticulate Pd(0) that is catalytically active in Hiyama cross-coupling [Srimani et al. *Org Lett* **9** 3639 *2007*, DOI: 10.1021/ol7015143]. **TOXIC due to possible release of carbon monoxide.**

Vanadium (III) acetylacetonate (vanadyl tris[2,4-pentadienato-O,O'], V[AcAc]$_3$) *[13476-99-8]* **($C_5H_7O_2)_3$V, M 348.3, m 181-184°, 185-190°, pK $_1^{25}$ 2.92, pK $_2^{25}$ 3.5(for aquo V^{3+} hydrolysis).** It crystallises from acetylacetone in brown plates. It can be distilled in small quantities without decomposition. It is soluble in $CHCl_3$ and *C_6H_6, and evaporation of a $CHCl_3$ solution yields brown crystals which are washed with cold EtOH and dried in vacuum or at 100° in a CO_2 atmosphere. Under moist conditions it readily oxidises [V$(AcAc)_3$ to V$(AcAc)_2$O]. [Fernelius & Bryant *Inorg Synth* **5** 105 *1957*, DOI: 10.1002/9780470132364.ch29; McKaveney & Freiser *Anal Chem* **30** 526 *1958*, DOI: 10.1021/ac60136a023; *Beilstein* **1** IV 3672.]
Vanadyl (IV) acetylacetonate **(vanadyloxa bis[2,4-pentadienato-O,O'], VO[AcAc]$_2$)** *[3153-26-2]* **($C_5H_7O_2)_2$VO, M 265.2, m 235°(dec), 256-259°, 258°, d ^{25} 1.50g/cm^3.** It provides blue-green crystals from acetone. It is soluble in $CHCl_3$, CH_2Cl_2, MeOH, EtOH and *C_6H_6. [cf. Fernelius & Bryant *Inorg Synth* **5** 105 *1957*, DOI: 10.1002/9780470132364.ch29; Rowe & Jones *Inorg Synth* **5** 113 *1957*, DOI: 10.1002/9780470132364.ch30; *Beilstein* **1** IV 3672; for applications see Fieser **2** 256, **3** 331, **11** 47.]

Vinylferrocene (ferrocenylethene) *[1271-51-8]* **$C_{12}H_{12}$Fe, M 212.1, m 51-52.5°, 51-53°, b 80-85°/0.2mm.** Dissolve vinylferrocene in Et_2O, wash it with H_2O and brine, dry (Na_2SO_4), and evaporate to a small volume. Purify it through an Al_2O_3 (Spence grade H) column by eluting the yellow band with petroleum ether (b 40-60°). The low melting orange crystals can be sublimed. The ***tetracyanoethylene adduct*** *[49716-63-4]* crystallises from *C_6H_6/pentane and has **m 137-139°(dec)**. [Horspool & Sutherland *Can J Chem* **46** 3453 *1968*, DOI: 10.1139/v68-574; Berger et al. *J Org Chem* **39** 377 *1974*, DOI: 10.1021/jo00918a012; Rausch & Siegel *J Organomet Chem* **11** 317 *1968*, DOI: 10.1016/0022-328X(68)80054-3; *Beilstein* **16** III 1787.] Useful for the preparation of 2-aminoethylferrocenes and lithium amides [Joly et al. *Tetrahedron* **63** 761 *2007*, DOI: 10.1016/j.tet.2006.10.078].

Vinyltributylstannane (vinyltributyltin) *[7486-35-3]* **($C_5H_7O_2)_2$VO, M 317.1, b 104-106°/3.5mm, d ^{25} 1.085g/ml, n $_D^{20}$ 1.478.** Fractionate the stannane under reduced pressure and taking the middle fraction to remove impurities such as (n-Bu)$_3$SnCl. [Seyferth & Stone *J Am Chem Soc* **79** 515 *1957*, DOI: 10.1021/ja01560a003; *Beilstein* **16** III 1279, **4** IV 4315] Useful vinyl nucleophile for bromoacetylenes [Yoshida et al. *Org Lett* **6** 1979 *2004*, DOI: 10.1021/ol049438k] and bromoaromatics [Occhiato et al. *J Med Chem* **47** 3546 *2004*, DOI: 10.1021/jm031131o].

Zinc acetate dihydrate *[5970-45-6]* **($CH_3CO_2)_2$Zn. 2H_2O, M 219.5, m 100°(loses 2H_2O), 237°, d $_4^{20}$ 1.74, pK^{25} 8.96 (for hydrolysis of Zn^{2+} to $ZnOH^+$).** It crystallises (in poor yield) from hot water or, better, from EtOH. [*Beilstein* **2** III 193, **2** IV 114.]

Zinc acetonylacetate [Zn(acac)$_2$] *[14024-63-6, 108503-47-5 (xH_2O)]* **($C_5H_7O_2)_2$Zn. xH_2O, M 263.6(anhydr), m 135-138°, 138°, 138°.** The zinc complex crystallises from hot 95% EtOH. [Fernelius &

Bryant *Inorg Synth* **5** 105 *1957*, DOI: 10.1002/9780470132364.ch29; Wakita et al. *J Organometal Chem* **301** C17 *1986*, DOI: 10.1016/0022-328X(86)80017-1; *Beilstein* **2** IV 144.]

Zinc caprylate (zinc n-octanoate) *[557-09-5]* **$C_{16}H_{30}O_4Zn$, M 351.8, m 135-136°, 136°, 142°.** It crystallises from boiling EtOH in plates, but is sparingly soluble in boiling H_2O. Originally precipitated by addition of an aqueous solution of zinc sulfate to an ammoniacal solution of caprylic acid. Store dry as it as it hydrolyses in moist air liberating caprylic acid. It has fungicidal activity. [Van Renesse *Justus Liebigs Ann Chem* **171** 380 *1874*, DOI: 10.1002/jlac.18741710224; *Beilstein* **2** H 284.]

Zinc formate dihydrate *[557-41-5, 5970-62-7]* **$(CHO_2)_2Zn.\ 2H_2O$, M 191.4($2H_2O$), m 140°(loses H_2O), d ^{20} 2.21g/cm^3.** It crystallises from hot water (solubility is 5.2g/100ml at 20°). [*Beilstein* **2** H 16, **2** I 14, **2** II 21, **2** III 25, **2** IV 17.]

Zinc RS-lactate trihydrate *[554-05-2, 16039-53-5 ($2H_2O$), 51120-75-3 (*DL- *$3H_2O$), 312619-27-5 (*L- *H_2O)]* **$C_6H_{12}O_7Zn$, M 297.5, m 272-274° (L- H_2O).** It crystallises from water (6ml/g). [*Beilstein* **3** I 107, **3** II 204, **3** III 464, **3** IV 637.]

Zincon (*o*-[1-(2-hydroxy-5-sulfo)-3-phenyl-5-formazono]-benzoic acid) *[135-52-4]* **$C_{20}H_{16}N_4O_6S$, M 440.4.** Main impurities are inorganic salts which can be removed by treatment with dilute acetic acid. Organic contaminants are removed by refluxing with ether. It can be recrystallised from dilute H_2SO_4 and it complexes with Zn ions (see below). [Fichter & Schiess *Chem Ber* **33** 747 *1900*, DOI: 10.1002/cber.190003301131; *Beilstein* **16** IV 421.]

Zincon disodium salt (*o*-[1-(2-hydroxy-5-sulfo)-3-phenyl-5-formazono]-benzoic acid di-Na salt) *[135-52-4, 56484-13-0]* **$C_{20}H_{15}N_4O_6SNa$, M 462.4, m ~250-260° (dec), λ_{max} 523nm, 490nm.** Zincon solution is prepared by dissolving 0.13g of the powder in aqueous N NaOH (2ml diluted to 100ml with H_2O). This gives a deep red colour which is stable for one week. It is a good reagent for zinc ions but also forms stable complexes with Cu ions as well in colorimetry. Used in chelate titration for Ca, Cd, Hg, Pb as well as Zn ions. [UV-VIS: Rush & Yoe *Anal Chem* **26** 1345 *1954*, DOI: 10.1021/ac60092a024; Hunter & Roberts *J Chem Soc* 820 *1941*, DOI: 10.1039/JR9410000820; Platte & Marcy *Anal Chem* **31** 1226 *1959*, DOI: 10.1021/ac60151a048;] The ***free acid*** (see above) has been recrystallised from dilute H_2SO_4. [Fichter & Scheiss *Chem Ber* **33** 747 *1900*, DOI: 10.1002/cber.190003301131; *Beilstein* **16** IV 421.]

Zinc phthalocyanine *[14320-04-8]* **$C_{32}H_{16}N_8Zn$, M 577.9, λ_{max} 701nm.** Sublime it in oxygen-free N_2. [For solvent effects on photochemical and fluorescence properties of zinc phthalocyanines see Ogunsipe et al. *J Mol Struct* **650(1)** 131 *2003*, DOI: 10.1016/S0022-2860(03)00155-8]. [*Beilstein* **26** III/IV 4257.]

Zinc 5,10,15,20-tetraphenylporphyrin *[14074-80-7]* **$C_{44}H_{28}N_4Zn$, M 678.1, λ_{max} 418nm and 556nm.** Purify the porphyrin by chromatography on neutral (Grade I) alumina, followed by recrystallisation from CH_2Cl_2/MeOH [Yamashita et al. *J Phys Chem* **91** 3055 *1987*, DOI: 10.1021/j100295a082]. [*Beilstein* **26** IV 1959.]

Zirconium (IV) acetonylacetonate *[17501-44-9]* **$(C_5H_7O_2)_4Zr$, M 487.7, m 190-193° (sealed capillary) 194.5-195°. 192-195°.** The zirconium complex crystallises from hot 95% EtOH (**m** 190-191°) or petroleum ether and sublimes *in vacuo* at 140° with slight decomposition. The ***decahydrate*** effloresces in air and dehydrates in a 0.1mm vacuum. Its solubility in 1L at 20° is 30g in CS_2, 47g in CCl_4, 44g in ethylene dibromide, 56g in acetonylacetone and 200g in $*C_6H_6$. [Young, Arch et al. *Inorg Synth* **2** 121 *1964*, DOI: 10.1002/9780470132333.ch35; *Beilstein* **1** H 782, **1** II 835, **1** III 3121, **1** IV 3672; see Fieser **13** 351]

Zirconium (IV) propoxide *[23519-77-9]* **$(C_3H_7O)_4Zr$, M 327.6, b 198°/0.03mm, 208°/0.1mm, d ^{25} 1.044g/ml, n $^{20}_D$ 1.451.** Although it was reported that it could not be crystallised or sublimed even at 150°/10^{-4}mm [Bradley & Wardlaw *J Chem Soc* 280 *1951*, DOI: 10.1039/JR9510000280], the propoxide, when properly prepared, has been purifed by distillation in a high vacuum [Bradley et al. *J Chem Soc* 2025 *1953*, DOI: 10.1039/JR9530002025]. [*Beilstein* **1** IV 1420; for applications see Fieser **11** 605, **13** 352.] This propoxide is the common precursor for the preparation of Zirconia (ZrO_2) [Sui et al. *Langmuir* **22(9)** 4390 *2006*, DOI: 10.1021/la053513y; Heine et al. *Combustion and Flame* **144(4)** 809820 *2006*, DOI: 10.1016/j.combustflame.2005.09.012].

CHAPTER 5

CATALYSTS

INTRODUCTION

Catalysts, and the process of catalysis, are almost as old as the chemical and physical sciences. Over the centuries a large number of metals and their derivatives, and a large variety of organic compounds, have been found to catalyse reactions successfully. The importance of catalysis in the sciences can be judged by the number of Nobel Prizes that have been awarded over the years for discoveries in this field of research. During the past two or so decades much research emphasis has concentrated on combining metals with organic ligands, by complexation, in order to achieve greater metal solubility in a variety of solvents, not only for more efficient catalysis but also, by using chiral ligands, to achieve high, if not almost complete, regioselectivity and/or stereoselectivity. This is evidenced by the award of the 2001, 2005 and 2010 Nobel Prizes for Chemistry respectively for *Catalytic Asymmetric Synthesis* (to W. S. Knowles, R. Nyori and K. B. Sharpless), for *Catalytic Olefin Metathesis* (to Y. Chauvin, R. H. Grubbs and R. R. Schrock) and for *Catalytic Cross-Coupling Reactions* (to R. Heck, E-I Negishi and A. Suzuki). In addition to the many recently published reviews and monographs on various aspects of catalysis, several new journals have appeared, e.g. *ChemCatChem* (from 2009) and *Advanced Synthesis & Catalysis* (from 2001), and others that can be found on the internet. Original research papers, and reviews, on 'cutting edge' discoveries in chemical and enzyme catalysis can be published particularly in these periodicals, allowing proximity and cross communication between these fields of work.

Commercial suppliers of chemicals have availed themselves of this surge in new catalysts, and are now providing a large variety of recently discovered catalysts to the scientific community. The present chapter addresses a selection of these commercially available catalysts. Generally they can be used as supplied. However, some samples may have partially deteriorated, or have short shelf lives; so knowledge about their purification, or assessment of purity, is essential. Purification details are provided for these, and in many cases published details of their preparations have also been included. Knowledge of the preparations provides information about probable impurities, and may dictate the best purification procedures. Since several catalysts (and some ligands) have high and/or *not* well defined melting points, some spectroscopic data, and optical properties if they are chiral, have been included.

This chapter is divided into two sections. The first section includes heterogeneous and homogeneous catalysts. The second section contains ligands and reagents used for the preparation of these catalysts and of these ligands, as well as a section on phase transfer catalysts, and a section containing a small number of chiral auxiliaries. There are some substances mentioned in this chapter, but not included here, whose purification procedures are described in Chapters 3, 4 and 6. Their purification procedures are **not** repeated here. However, they can be located *via* their Chemical Abstracts Registry Numbers (CASRN), also used for cross referencing, and their place in the book can be found from the CASRN Index which provides their respective page entries. **Abbreviations** of titles of periodicals are defined as in the Chemical Abstracts Service Source Index (CASSI), but without punctuation. Fieser & Fieser's *Reagents for Organic Synthesis* references will be shortened to Fieser throughout.

It should be pointed out that great care must be taken to ascertain that the catalyst is indeed the metal or reagent used, and not traces of unsuspected contaminating metal. This point has been clearly made in the article by J.M. Crow *entitled 'When is a catalyst not a catalyst' (Chemistry World* ***8*** 46 *2011). He draws attention to the papers of* Buchwald & Bolm *Angew Chem Int Ed* **48** 5586 *2009*, DOI: 10.1002/anie.200902237; Larsson et al. *Angew Chem Int Ed* **48** 5691 *2009*, DOI: 10.1002/anie.200902236; Leadbeater & Marco *Angew Chem Int Ed* **42** 1407 *2003*, DOI: 10.1002/anie.200390362; Arvela et al. *J Org Chem* **70** 161 *2005*, DOI: 10.1021/jo048531j; *and the measurement of trace impurities at the ppb (parts per billion) and/or ppt (parts per trillion) levels in* Gonda, Tolnai and Novák *Chem Eur J* **16** 11822 *2010,* DOI: 10.1002/chem.201001880; *and the possibility of co-catalysis*.

Purification of Laboratory Chemicals.

CATALYSTS—PART 1

HETEROGENEOUS METAL CATALYSTS

Copper Chromite (Lazier catalyst, copper chromium oxide) *[12053-18-8]* **$2CuO.Cr_2O_3$, M 311.1.** It is also known as **Adkins catalyst** (with very slight difference in preparation). The catalyst is prepared by adding $Cu(NO_3)_2.3\ H_2O$ (109g) to a warm solution of $Ba(NO_3)_2$ (13g) in H_2O (140ml) at 70° and stirring until clear. Ammonium chromate solution, made by dissolving ammonium dichromate (63g) in H_2O (300ml) and adding concentrated aqueous ammonia (75ml, sp.gr. 0.90), is stirred in a thin stream into the solution of the above nitrates, stirred for 5 minutes further and the red-brown precipitate of copper barium ammonium chromate is filtered off, washed with H_2O, drained well and dried at 110°. The salt is placed in a suitable container and heated in a muffle furnace at 350-450° for 1 hour. ***Note*** that a spontaneous exothermic reaction occurs on heating with evolution of gas. The ignited blue-black residue (~80g), composed of copper and barium chromates and CuO, is pulverised thoroughly, suspended in aqueous 10% AcOH (600ml), stirred for 10 minutes, allowed to settle during 15 minutes, the supernatant is decanted, and the process is repeated. Filter off the solid, dry it at 110° and grind it in a mortar to give the catalyst (~70g) as a fine black powder. It is not affected by air or moisture and no special storing precautions are necessary. Other than the use of $Na_2Cr_2O_7$ (Adkin) instead of $(NH_4)_2Cr_2O_7$ (Lazier), there seems to be very little difference in the preparation procedure or the activity of the catalyst [see Fieser **2** 82]. Note that the inclusion of barium is for protection against sulfate which is a catalyst poison, and stabilises it against reduction. If a ***barium free*** catalyst is required, then it is omitted in the preparation and the amount of $Cu(NO_3)_2.3\ H_2O$ should be increased to 121g without altering the preparation procedure. [Lazier & Arnold *Org Synth* Coll Vol **2** 142 *1943*, DOI: 10.15227/orgsyn.019.0031; Adkins et al. *J Am Chem Soc* **72** 2626 *1950*, DOI: 10.1021/ja01162a079]. It is an effective catalyst for the reduction of aldehydes, ketones and esters to the corresponding alcohols, aliphatic but not aromatic double bonds, the reduction of amides to amines, and for the decarboxylation of carboxylic acids [see Fieser **1** 186]. These reactions however may have to be carried out in stainless steel bombs or autoclaves as several reactions require high temperatures (100-260°) and pressures (up to 5000psi).

Nickel *[7440-02-0]* **Ni, M 58.7, m 1455°, b 2730°, d^{25} 8.90.** The catalytic use of the metal can be divided into (a) the Raney nickel type and (b) the non-Raney nickel type.

***Raney Nickel type*:** This catalyst was introduced by the Raney Catalyst Division of Grace & Co and is made from a Ni-Al alloy (~1:1, e.g. by fusion at 1200-1500°). The catalyst is prepared by treating the alloy with alkali, which dissolves the Al, and the alkali is washed off as thoroughly as possible. The method was developed by Adkins and coworkers at the University of Wisconsin (USA) and the catalyst was designated as **W**-1 to **W**-6 (chronological, not activity, order) [Billica & Atkins *Org Synth* Coll Vol **3** 176 *1955*, DOI: 10.15227/orgsyn.029.0024; and for comparison of Ws see Adkins & Krsek *J Am Chem Soc* **70** 412 *1948*, DOI: 10.1021/ja01181a501]. The catalyst has been used very extensively for reduction reactions, as well as for replacing sulfur by hydrogen in compounds; and there is a large volume of literature on this subject [see Fieser **1** 440, 723, **2** 289, 293, **4** 267, **5** 263, 381, 570, 736, **6** 502, **7** 321, **8** 433, **9** 405, **10** 339, **11** 457, **12** 175, 218, 338, 422, **13** 265, **14** 270, **16** 278, **17** 296]. The reactions normally require stirring or shaking at ambient temperatures, and pressures of H_2 not greater than 100psi. A variety of equipment for this purpose is available commercially. The catalyst is essentially prepared by adding the Ni-Al alloy (150g) in small portions to aqueous sodium hydroxide (190g in 750ml of H_2O) with stirring in an ice bath at 10° at such a rate that the temperature is kept below 25°, *ca* 2 hours. *n*-Octanol may be added to prevent excessive foaming. This reaction should be carried out in an efficient fume cupboard as H_2 is liberated during the reaction (with the possibility of igniting), and it is preferable to use magnetic stirring to avoid sparking from an electric motor. When addition of the alloy is complete, allow the temperature of the mixture to rise to ~25°, and then heat it gradually (avoiding frothing over) on a boiling water bath until evolution of H_2 is complete (8-12 hours). Add distilled H_2O to restore the original volume, stir, allow the Ni to settle down, then decant the supernatant liquid. Transfer the Ni to a graduated cylinder with H_2O, allow it to settle, decant the supernatant liquid, add aqueous NaOH (25g, in 250ml H_2O), shake the mixture thoroughly, allow the Ni to settle again and decant off the supernatant alkaline liquid. Wash the Ni with H_2O (~750ml each time) by shaking, allow it to settle and decant the supernatant H_2O. Repeat

the process until the washings are neutral to litmus and then a further 10 times. This may require 30 to 40 washings. Repeat the washing process three times with 95% EtOH, then again three times with absolute EtOH. Store the Ni catalyst in bottles which are filled with absolute EtOH to the brim and stopper them. Keep them in a cold store room. Yield of Raney Ni is usually ~75g. The metal should be kept moist, or under liquid, at all times because the dry solid is highly **pyrophoric**. The more active the catalyst, the more readily it ignites. For this reason it is best to spoon the catalyst out from the settled material. When prepared as above it contains ~0.6g of Ni per ml of settled solid, and a level tablespoonful contains ~3g of Ni. [Mozingo *Org Synth* Coll Vol **3** 181 *1955*, DOI: 10.15227/orgsyn.021.0015]. The activity of Raney Ni deteriorates slowly with time, but if prepared properly and stored as above it should be quite active for about 6 months. Its activity can be enhanced immensely by addition of a very small amount of triethylamine and platinic chloride [Levering & Lieber *J Am Chem Soc* **71** 1515 *1949*, DOI: 10.1021/ja01172a528]. It has been used both as a ***catalytic oxidation catalyst*** (with an appropriate donor), as well as a ***reduction catalyst*** [Kleiderer & Kornfeld *J Org Chem* **13** 455 *1948*, DOI: 10.1021/jo01161a022].

Non-Raney Nickel type*:** This includes a catalyst of the composition Ni/Al_2O_3 formed by treating Ni-Al alloy with H_2O at 70° [Tyman *Chem Ind (London)* 404 *1964*], and the commercially available Ni on silica (with 60 wt% loading on Kieselguhr) and Ni on silica/alumina (with~65 wt% loading). All ***Ni coordination compounds which have catalytic activity can come under this heading.

Palladium *[7440-05-3]* **Pd, M 106.4, m 1555°, b 3167°/atm, d_4^{20} 0.951, electrical resistivity at 0° is μΩ-cm.** Pd is a silver-white metal which also occurs as a black powder or in a compressible spongy form. It is reactive towards HNO_3, H_2SO_4, HCl and $HClO_3$, particularly in the presence of air or oxygen; and forms dihalides with halogen at high temperatures. It has the capacity of adsorbing and absorbing large volumes of H_2. It is extremely useful in chemical reactions as displayed in a limited way in this chapter. Apart from its extensive value in metal coordination chemistry it has out-classed many related metals in the field of catalysis. As well as its use in catalysis as the free metal in precipitated form, pellet or granular form, it has found extensive use in catalysis when diluted with C *[7440-44-0]*, $BaSO_4$, $CaSO_4$, $SrSO_4$, Kieselguhr, and Al_2O_3 (see below). The following catalyst preparations have been used for many decades:

Palladium on charcoal (5% Pd)— A clear solution of $PdCl_2$ (8.2g, 46mmol) in concentrated HCl (20ml, 240mmol) and H_2O (50ml), obtained by heating on a steam bath for 2 hours or until complete dissolution, is added with stirring to a suspension of charcoal (93g, HNO_3—washed)† in H_2O (1.2L) at 80° followed by 37% formaldehyde solution (80ml, 100mmol). The solution is made slightly alkaline to litmus (pH ~8.0) by careful addition of aqueous 30% sodium hydroxide with stirring which is continued further for 5 minutes longer. The catalyst is filtered off and washed with H_2O (10 x 250ml), drained well then dried at 25°, first in air then over KOH or $CaCl_2$ in a desiccator. The dry catalyst (93-98g), which is in a reduced state is stored in a tightly closed vessel. [*Do not dry at high temperatures as ignition may occur*.]

† *Darco G-60, Norit or other carbons can be used and should be heated on a steam bath with 10% aqueous HNO_3 for 2-3 hours, washed free from acid (check pH of washings), and dried at 100-110° before use* (see chapter on Aliphatic Compounds).

A comparison of the rates of hydrogenation with 5% Pd/C, 5% Pt/C, 5% Rh/C and 5% Ru/C catalysts towards reduction of C=C, C=O, C-OH and benzene rings in various solvents at 25° and initial H_2 pressure of 1 atmosphere were made by Breitner, Roginski & Rylander [*J Org Chem* **24** 1855 *1959*, DOI: 10.1021/jo01094a004.]

Note that palladised charcoal has also been used for ***dehydrogenation***, e.g. tetralin is converted to naphthalene by boiling for 4 hours in the presence of Pd/C in a slow stream of CO_2, and α-tetralone is dehydrogenated to naphthalene by boiling (1 hour, with internal temperature of 235°) in the presence of Pd/C and a slow stream of CO_2 in 75% yield.

Palladium on charcoal (10% Pd)— A clear solution of $PdCl_2$ (8.3g) in concentrated HCl (5.5ml) and H_2O (40ml), prepared as above, is poured into a solution of $NaOAc.3H_2O$ (135g) in H_2O (500ml) in a hydrogenation bottle, and charcoal (45g, HNO_3—washed, see above†) is added and the mixture is hydrogenated until absorption ceases (1-2 hours). The catalyst is collected on a filter funnel, washed with H_2O (5 x 400ml), drained well, dried in air and then in a desiccator over KOH or $CaCl_2$; store the reduced catalyst (48-50g) as above.

Palladium chloride on charcoal (5% Pd)— A clear solution of $PdCl_2$ (8.2g, 46mmol) in concentrated HCl (20ml, 240mmol) and H_2O (50ml), obtained by heating on a steam bath for 2 hours or until complete dissolution, is diluted with H_2O (140ml) and poured over charcoal (92g, HNO_3—washed, see above†) in a 20cm

evaporating dish, thoroughly mixed and dried, firstly on a steam bath and then in an oven at 100° with occasional stirring until the catalyst (98-100g) is completely dry and is then stored in a stoppered bottle until required. When required, the desired aliquot of catalyst is transferred to a hydrogenation bottle (or flask) and reduced in the solvent used for hydrogenation by shaking with H_2 in the hydrogenation apparatus. When absorption of H_2 is complete, the catalyst is filtered off, washed with fresh solvent to remove HCl, returned to the hydrogenation bottle (which should have been rinsed with the same fresh solvent), the material for reduction is added and hydrogenation is carried out in the usual way.

Palladium on barium sulfate (5% Pd)— To a rapidly stirred hot (80°) solution of reagent grade $Ba(OH)_2\ 8H_2O$ (126.2g, 400mmol) in H_2O (1.2L), 6N H_2SO_4 (120ml, 360mol) is added all at once then more 6N H_2SO_4 is added to the $BaSO_4$ suspension that is formed in order to be just acidic to litmus (pH ~5). A clear solution of $PdCl_2$ (8.2g, 46mmol) in concentrated HCl (20ml, 240mmol) and H_2O (50ml), obtained by heating on a steam bath for 2 hours or until complete dissolution, is subsequently added to the hot (80°) stirred $BaSO_4$ suspension# followed by 37% formaldehyde solution (8ml, 100mmol). The suspension is made alkaline to litmus (pH ~8.0) by careful addition of aqueous 30% sodium hydroxide with stirring, which is continued further for 5 minutes longer, and allowed to settle. The clear colourless supernatant liquid is decanted off, replaced by H_2O, resuspended, and washed ten times by decantation. The catalyst is collected on a 90mm medium porosity sintered glass funnel, drained until the filter cake begins to crack, washed again with H_2O (95 x 250ml), drained as completely as possible and placed in an oven at 80° until a dry catalyst (93-98g) is obtained. Store it as above. [This catalyst is particularly useful for ***Rosenmund catalytic reductions*** of acid chlorides (RCOCl) to aldehydes (RCHO), cf. Hershberg & Cason *Org Synth* Coll Vol **3** 626 *1955*, DOI: 10.15227orgsyn.023.0063.]

#An equivalent weight of precipitated $BaCO_3$ (93g) may be used instead for $BaSO_4$; but the volume of concentrated HCl in preparing the $PdCl_2$ solution should be reduced to 8.2ml (to avoid decomposition of the carbonate) to give ***5% Pd on calcium carbonate*** catalyst. [Mozingo *Org Synth* Coll Vol **3** 685 *1955*, DOI: 10.15227/orgsyn.026.0077.]

Note that at the completion of hydrogenations with these catalysts, the used catalysts that are filtered off should be kept moist with solvent or H_2O as they may be ***pyrophoric*** when dry. Also, with the catalysts that have been prepared using the formaldehyde (HCHO) procedure, the spent catalysts from reduction reactions in which MeOH is used as solvent are particularly flammable, possible because MeOH/HCHO form an ***oxidation-reduction couple*** since there is no guarantee that the catalyst is completely free from HCHO.

Other commonly used supports for Pd include **$CaCO_3$** [Busch & Stöve *Chem Ber* **49** 1063 *1916*, DOI: 10.1002/cber.191604901114], **$SrCO_3$** [Martin & Robinson *J Chem Soc* 491 *1943*, DOI: 10.1039/JR9430000491], **Al_2O_3** [Alan C. Johnson US pat 2,366,409, *Chem Abstr* **39** 2001 *1945*], **Kieselguhr** [Rosenmud & Langer *Chem Ber* **56** 2262 *1923*, DOI: 10.1002/cber.19230561012; Sabalitschka & Moses *Chem Ber* **60** 786 *1927*, DOI: 10.1002/cber.19270600333], **silica-gel** [Fester & Brude *Chem Ber* **56** 2245 *1923*, DOI: 10.1002/cber.19230561007], **asbestos** [Zelinsky & Borisoff *Chem Ber* **57** 150 *1924*, DOI: 10.1002/cber.19240570126; Zelinsky & Turowa-Pollak *Chem Ber* **58** 1292, 1298 *1925*, DOI: 10.1002/cber.19250580717, DOI: 10.1002/cber.19250580718] and **polyvinyl alcohol** [Kavanagh & Nord *J Am Chem Soc* **66** 2126 *1944*, DOI: 10.1021/ja01240a506].

Platinum *[7440-06-4]* **Pt, M 195.1, m 1772°, b 3827°, d^{20} 21.45.** Platinum, when used directly or on a carbon, alumina or silica support, or *via* its oxide, is generally an excellent catalyst for the reduction of compounds. Hydrogenations using Pt catalysts are usually carried out at ambient temperatures, and atmospheric pressure of H_2, and the reaction can be followed by using a manometer and noting the absorption of gas. They may require, as in the reduction of aromatic rings to alicyclic rings, somewhat elevated pressures (a few to several atmospheres) and temperatures. Specialised equipment is used in such cases (see Ni catalysts above).

***Platinum Black*:** It is obtained by reducing a solution of chloroplatinic acid *[16941-12-1]* with alkaline formaldehyde and shaking vigorously to coagulate the colloidal metal formed [Feulgen *Chem Ber* **54** 360 *1921*, DOI: 10.1002/cber.19210540225]. In addition to its use as a catalyst, it destroys H_2O_2 in liquids or solvents by shaking them with the metal until liberation of O_2 ceases [Cope & Ciganek *Org Syn* Coll Vol **4** 612 *1963*, DOI: 10.15227/orgsyn.039.0040].

***Platinum Sponge*:** Ammonium hexachloroplatinate is precipitated when recovered Pt residues are dissolved in *aqua regia* (see below), evaporated to dryness then dissolved in the minimum volume of H_2O and treated with saturated ammonium chloride. The $(NH_4)_2PtCl_6$ is filtered off and dried at 100°. Ignition of this salt gives Pt *sponge*. [Wickers *J Am Chem Soc* **43** 1268 *1921*, DOI: 10.1021/ja01439a008.]

Brown & Brown Catalyst: This is usually prepared *in situ* by adding a solution of $NaBH_4$ in EtOH stabilised

with NaOH to a suspension of charcoal (see palladium catalysts above) in a solution of chloroplatinic acid in EtOH (or aqueous EtOH) to form the supported catalyst. Excess HCl is added, followed by the substrate for reduction, then $NaBH_4$ in EtOH stabilised with NaOH is added dropwise at such a rate as to maintain atmospheric pressure of H_2. Here the supported catalyst and H_2 are generated *in situ* resulting in more effective reductions. [Brown et al. *J Org Chem* **28** 214 *1963*, DOI: 10.1021/jo01036a501.]

Platinum on support: The catalyst is prepared from a cooled solution of the metal (5.0g, or $PtCl_4$ or H_2PtCl_6) in H_2O (50ml) and concentrated HCl (5ml) and support [11g, acid washed charcoal (see Pd above), neutral alumina, silica or asbestos (Gooch asbestos, termolyte not chrysolite, boil with concentrated HNO_3, filter, wash free from acid with H_2O and dry at 100º)] in a freezing mixture and treat with formalin (50ml, 40% formaldehyde). The mixture is then stirred while aqueous KOH (50g in 50ml of H_2O) solution is added slowly and keeping the temperature below 5º. The temperature is then allowed to rise to 60º in 15 minutes. The catalyst is washed thoroughly with H_2O by decantation, finally with dilute AcOH, collected onto a suction filter and washed with H_2O until free from chloride ions and alkali, and drained well. Dry the solid at 100º and store it in a desiccator. This method gives a catalyst containing *ca* 30-40% of metal, but the amount can be adjusted by varying the ratio of metal to support. [Brown & Brown *J Am Chem Soc* **84** 2827, 2829 *1962*, DOI: 10.1021/ja00873a037, DOI: 10.1021/ja00873a039.]

A comparison of the rates of hydrogenation with 5% Pd/C, 5% Pt/C, 5% Rh/C and 5% Ru/C catalysts towards reduction of C=C, C=O, C-OH and benzene rings in various solvents at 25º and initial H_2 pressure of 1 atmosphere were made by Breitner, Roginski & Rylander [*J Org Chem* **24** 1855 *1959*, DOI: 10.1021/jo01094a004].

Platinum (IV) oxide (Adams catalyst) *[1H_2O 12137-21-2; xH_2O 52785-06-5]* **PtO_2, M 227.1, M 245.1 (1 H_2O), m >450º.** Adams catalyst can be prepared in three ways.

Firstly*,** from ammonium hexachloroplatinate (IV) *[16919-58-7]* [3.0g, $(NH_4)_2PtCl_6$] and KNO_3 (30g, Analytical Grade; $NaNO_3$ yields slightly less active catalyst) which are thoroughly mixed in a porcelain dish (fume cupboard, use a head shield for protection***) and heated gently at first until the rapid evolution of gas subsides, then strongly until the temperature reaches 300º (15 minutes, no splattering). The liquid mass is heated further at 500-530º for 30 minutes and allowed to cool. Add H_2O (50ml) to the residue, stir and allow the brown platinum oxide (PtO_2. H_2O) to settle. Wash it once or twice with H_2O by decantation, collect it on a filter, wash it free from nitrates (stop washing if the solid starts to become ***colloidal#***; traces of $NaNO_3$ do not affect catalytic activity) and dry the oxide in a desiccator. Store it in small aliquots. **#** If ***colloidal Pt*** filters through, it can be checked by testing a small volume of the filtrate for Pt by acidifying it with HCl, adding a few drops of stannous chloride when a yellow or brown colour results depending on the amount of Pt present. The yellow colour is soluble in Et_2O rendering the ***test more sensitive***. If Pt is present in the filtrate then heat the filtrate with excess formalin and aqueous NaOH, cool, and the platinum black which separates is filtered off and worked up with other Pt residues. The weight of PtO_2 obtained is about equal to half the weight of $(NH_4)_2PtCl_6$.

Secondly, purest possible chloroplatinic acid [3.5g, H_2PtCl_6] in H_2O (10ml) is mixed with KNO_3 (35g, Analytical Grade; $NaNO_3$ yields slightly less active catalyst) in a porcelain dish, evaporate gently to dryness and heat at 350-370º for 10 minutes (use a strong heat source, ***fume cupboard, use a head shield for protection***) when brown oxides of nitrogen evolve and brown PtO_2 separates. Stir more vigorously if frothing occurs and direct an additional burner at the top of the mixture. [Take care not to allow the top of the mixture to solidify, e.g. by removing the burner that is underneath, otherwise frothing over occurs]. The temperature is raised to 400º in the following 15 minutes, after which liberation of fumes decreases considerably, and the temperature is raised further to 500-550º (*ca* 2 minutes); at this stage evolution of brown gases practically ceases but there is still a gentle evolution of gas. Maintain at this temperture (with burner at full heat) for 30 minutes by which time fusion is complete. Allow the container to cool slowly to ~20-25º, add H_2O (50ml) and isolate the catalyst as above.

Thirdly*,** Pt metal and or Pt metal residues are dissolved in *aqua regia* [prepared by adding slowly concentrated HNO_3 (1 volume) to concentrated hydrochloric acid (3 volumes) in a glass container in an efficient fume cupboard and head protection***] using gentle heat if necessary, evaporate several times almost to dryness with concentrated HCl, dissolve the final residue in a small volume of H_2O and precipitate the metal as $(NH_4)_2PtCl_6$ with saturated aqueous NH_4Cl. Filter off the precipitate, dry it at 100º and continue as in the first procedure (see above). [Adams et al. *Org Synth* Coll Vol **1** 463, 466 *1941*, DOI: 10.15227/orgsyn.008.0092; Bruce *J Am Chem Soc* **58** 687 *1936*, DOI: 10.1021/ja01295a501.]

Reactions catalysed by Adams catalyst can be carried out in alcoholic solution which is sometimes enhanced by

the presence of HCl; a variety of other organic solvents have been used which include EtOAc, EtOAc+15% AcOH, EtOAc+8%EtOH, and glacial AcOH; and neat CF_3CO_2H is a particularly good solvent for the reduction of C=N in heterocyclic compounds.

PtO_2 on silisic acid has been prepared in much the same way as above (***fume cupboard and head protection***) from chloroplatinic acid (7g) in H_2O (25ml) and silicic acid (20g, 200 mesh) in a borosilicate beaker (100ml) which are stirred into a smooth paste and heated on a burner until desiccated. Heat to ~360º and add powdered $NaNO_3$ (70g) in portions while stirring and mixing vigorously with a glass rod (evolution of brown fumes occurs at each addition with frothing) and heat until gas evolution ceases. Add further molten $NaNO_3$ (20g) to the beaker with heating while scratching its sides. Cool, and transfer to a 2L beaker containing H_2O (1.5L), stir for 2 hours, allow to settle, decant the supernatant and collect on a medium porosity sintered glass funnel. Wash the solid well with H_2O, then with 95% EtOH (2 x) and Et_2O, dry it in air for 1 hour then in a vacuum desiccator (P_2O_5). The dry powder is then pulverised in a mortar and sieved (200 mesh) until all the solid has passed through (use a Camel's-hair brush to help the solid through) to give the catalyst as a light brown powder (21.0g) containing ~0.14g of Pt per gram of solid. Store it in screw caped vials. It can be exposed to light and air without loss of activity. It gives very reproducible hydrogenation results and has been used analytically for the estimation of reducible groups [Vandenheuvel *Anal Chem* **28** 362 *1956*, DOI: 10.1021/ac60111a019]; and for the hydrogenation of methyl esters in EtOH without causing trans-esterification [Ackman & Burgher *J Lipid Res* **5** 130 *1964*, PMID: 14173321].

Other applications*:** Prior to the development of catalysts in which Pt is coordinated to a plethora of ligands in order to achieve particular specificities (e.g. Pt with phosphine ligands below), some specificites were obtained by manipulating the metal. Examples include a ***platinum-tin chloride catalyst made from ***H_2PtCl_6 and $SnCl_2$*** for specific reduction of olefins [Cramer et al. *J Am Chem Soc* **85** 1691 *1963*, DOI: 10.1021/ja00894a035], ***PtO_2/Pt black+$FeCl_2$/Zn(OAc)$_2$*** for reduction of unsaturated aldehydes to unsaturated alcohols, e.g. cinnamaldehyde to cinnamyl alcohol [Tulley & Adams *J Am Chem Soc* **47** 3061 *1925*, DOI: 10.1021/ja01689a036], and ***PtS_2/C*** which is less active than the oxide but is insensitive to poisons (e.g. sulfur compounds) and will reduce a nitro group without affecting halogen substituents, e.g. chloronitrobenzenes to chloroanilines [Dovell & Greenfield *J Am Chem Soc* **87** 2767 *1965*, DOI: 10.1021/ja01090a050].

Rhenium metal used in preparing the following catalysts has *[7440-15-5]* Re, M 186.2, m 3180º, b 5596º, d^{20} 21.02.

Rhenium(II) oxide **($ReO.2H_2O$)** *[12143-03-2]* **$ReO.2H_2O$, M 238.2.** This catalyst is prepared in a fume cupboard by the reduction of ammonium perrhenate with either Na/liqNH_3, Li/liqNH_3, or Li/EtNH_2 which give consistently $ReO.2H_2O$. In dried apparatus used typically for Na/liqNH_3 reduction, liquid NH_3 or EtNH_2 (50-75ml) and NH_4ReO_4 (1-2g, weighed) are stirred in a dry atmosphere until the salt dissolves; then Na or Li (15-30g) are added in chunks as rapidly as possible. The colourless solution becomes typically blue-black and is stirred until the colour disappears (15 minutes to 2 hours). The NH_3 or EtNH_2 are allowed to evaporate while the total volume is kept constant by addition of EtOH. The residue is transferred to a fritted glass thimble in a Soxhlet apparatus and extracted with dilute HCl (~2N) for 24 hours (the pot acquiring a brown colour), then with EtOH for an equal time. When the brown acid extract, that decolorises aqueous $KMnO_4$, is basified with aqueous NH_4OH black $ReO.2H_2O$ precipitates, and the supernatant now does not decolorise aqueous $KMnO_4$. The solid is collected, washed with cold EtOH, and dried at 100º *in vacuo* over P_2O_5 (conditions under which it is stable and does not dehydrate) to provide the hydrated oxide (75-85%) as a very finely divided black powder. ***Note*** that any solid left in the thimble has the same composition as this oxide. It is stored as a suspension in EtOH which tends to settle rather readily, or as a suspension in distilled H_2O which requires more than 24 hours to settle out completely. Aliquots of suspensions (with or without evaporating to dryness) are used as the heterogeneous catalyst. The amount of rhenium can be determined as described by Broadbent and Selin [*J Org Chem* 28 2343 *1963*, DOI: 10.1021/jo01044a045].

$ReO.2H_2O$ catalyses the hydrogenation of a wide variety of organic substrates in high yields with unusual selectivity, being particularly efficient for carboxylic acids. Hydrogenations are carried out in a rocking Parr reactor under pressures of ~200 atmospheres and temperatures varying from ~20º to ~200º, and reduction times from 0.5 to ~10 hours. The catalyst prepared by the Li/liqNH_3 method is only marginally better than by the other methods. [Broadbent & Seegmiller *J Org Chem* **28** 2347 *1963*, DOI: 10.1021/jo01044a047.]

Rhenium(III) oxide **(Re_2O_3)** *[12060-05-8]* **Re_2O_3, M 420.5.** Re_2O_3 is prepared from a mixture of ammonium

perrhenate (2.04g, 160mmol, NH_4ReO_4), a solution of 8*N* NH_4Ac (20ml, 160mmol) and glacial AcOH (2ml, 35mmol) in H_2O (100ml) in an ice-water bath to which is added dropwise, with vigorous stirring, an ice-cold solution of $NaBH_4$ (3.4g, 90mmol) in H_2O (100ml) over a 1 hour period. After half of the $NaBH_4$ solution is added, a further amount of AcOH (2ml, 35mmol) is added in one lot. Stirring is continued for 15 minutes and the solution is centrifuged at full speed in an ultracentrifuge, the supernatant is decanted off, the oxide is washed twice by suspension in H_2O and finally re-suspended in H_2O, and stored as such before use. The fine solid remains in suspension for 12-24 hours. Analysis indicated that reduction was ~85% complete giving a yield of 70-90% (~1.35g). The activity is checked by its ability to effect hydrogenation of styrene at room temperature in 6-10 hours. It catalyses a range of substrates including aliphatic olefins, maleic acid, benzene, nitrobenzene, bromonitrobenzene, naphthalene, pyridine, ketones and nitriles mostly in yields approaching 100% with (e.g. H_2O or EtOH), and without solvents. Typically the substrate (0.2mol, with or without solvent) and catalyst (0.2g of Re) in a 420ml rocking Parr bomb under hydrogen pressures up to 3000psi (204 atmospheres) are heated (40-50° increments) until the pressure starts to drop. Reductions occur in the temperature range of 25-250°. [Broadbent & Johnson *J Org Chem* **27** 4400 *1962*, DOI: 10.1021/jo01059a065.]

Rhenium(IV) oxide *[12036-09-8]* **ReO_2. $2.5H_2O$, M 218.2.** A vigorously stirred mixture of a solution of ammonium perrhenate (1.2g) in H_2O (150ml) and an excess of granular zinc (5-10g, previously treated with a little dilute acid, to remove any surface oxide, and washed thoroughly to clean the surface) is treated dropwise over a period of several hours with 3N H_2SO_4 (64ml) at such a rate that black finely divided rhenium oxide is suspended into the solution (which is periodically decanted from the zinc); then the oxide is centrifuged off, the supernatant is returned to the reaction flask and addition of acid is resumed. The acid should not be added rapidly as the finely divided rhenium oxide coats the zinc and slows (or prevents) further reaction, and does not produce a Zn-free product. At the end of the reaction all the rhenium oxide residues from centrifugation are combined and washed with H_2O by decantation until the washings are free from sulfate. Conversion from perrhenate to rhenium (IV) oxide is >60%, and nearer 100% if an excess of Zn is maintained in the reaction by further addition of the metal. ReO_2. $2.5H_2O$ analyses as a hydrate, is very stable, resists dehydration at 95° *in vacuo* over P_2O_5, and loses H_2O only very slowly at 250°; however when the hydrated oxide is heated at 250° in $*C_6H_6$ under hydrogenation conditions anhydrous ReO_2 can be isolated from the experiment. It exists in two crystallographic forms: ***the α-form*** is obtained when synthesised below 300° (Re + $2ReO_3$ = $3ReO_2$), and is irreversibly transformed into the ***orthorhombic β-form*** which is obtained when synthesised above 300° [Rogers et al. *Inorg Synth* **13** 135, 142-145 *1972*, DOI: 10.1002/9780470132449.ch27; Rogers et al. *Inorg Synth* **30** 96 *1995*, DOI: 10.1002/9780470132616.ch20].

ReO_2. $2.5H_2O$ has catalytic activity for the hydrogenation of a variety of organic substrates, and although generally less active than Nickel or palladium catalysts (i.e. requires higher temperatures and/or pressures), it is however much more effective than these for the reduction of the carboxylic acid function. It has a potentially valuable selectivity, and very few other elements exhibit this characteristic to such a degree. [Broadbent & Selin [*J Org Chem* **28** 2343 *1963*, DOI: 10.1021/jo01044a045.]

Rhenium(VI) oxide **(ReO_3)** *[1314-28-9]* **ReO_3, M 234.2, b 750°, d^{20} 6.9-7.4.** ReO_3 is prepared from the heptoxide (1.0g, see below) by adding it directly to *p*-dioxane (10-25ml) or tetrahydrofuran and warming gently to produce a colourless to dark green solution, and the excess solvent is removed *in vacuo* to give a sticky, tarry, black complex. The complex decomposes when carefully heated to *ca* 145° to give gaseous products and a pure, red, crystalline residue of ReO_3 (84-95%yield). This is finely ground and stored dry in a screw-cap vial. It forms non-hygroscopic, red/maroon-coloured crystals (with a green lustre) which are air stable below 100°, and disproportionates in a vacuum to rhenium(IV) and rhenium(VII) oxides at 400°. It is inert to H_2O, dilute alkali, and is thus more convenient to handle and store than the hygroscopic heptoxide which also has high catalytic activity. Analysis showed it to have the formula of the anhydrous oxide ReO_3. It is oxidised by HNO_3 to $HReO_4$. It has catalytic activity when used as such or when prepared *in situ* by using Re_2O_7 and allowing it to be reduced to ReO_3 during the hydrogenation process. This oxide, when used directly or prepared *in situ*, is the most effective hydrogenation catalyst of all the Re catalysts. It is very efficient in reducing carboxylic and carboxamide groups without reducing the aromatic ring, with the latter producing amines. Benzoic acid, ethyl benzoate, benzaldehyde, and *m*-nitrobenzaldehyde are reduced to the respective carbinols without hydrogenolysis to the toluenes as in most catalytic hydrogenations. Like the preceding rhenium oxide catalysts hydrogenations are carried out in shaking Parr-Bomb reactors under pressures of *ca* 200 atmospheres and temperatures ranging from ~100° to ~200° depending on when the substrates begin to absorb H_2 at a reasonable rate. [Broadbent & Bartley *J Org Chem* **28** 2345 *1963*, DOI: 10.1021/jo01044a046; Nechamkin et al. *Inorg*

Synth **3** 186 *1950*, DOI: 10.1002/9780470132340.ch49.] It is also obtained in quantitative yield from Re_2O_7 (purified by sublimation) in a CO atmosphere by heating at 175° until the oxide is blue, the temperature is raised slowly to 225°, then increased to 280° after the colour of the oxide has turned to red [Melaven et al. *Inorg Synth* **3** 188 *1950*, DOI: 10.1002/9780470132340.ch50].

Rhenium(VII) oxide **(rhenium heptoxide)** *[1314-68-7]* **Re_2O_7, M 484.4, m 300.3°, b 360.3°, d^{20} 6.103.** Dirhenium heptoxide is prepared by heating the metal or its lower oxides in a stream of oxygen or air at 400° to 425°. It forms canary-yellow crystals which are as deliquescent as P_2O_5, and sublimes at 250°/760mm and melts at 297° in a sealed tube [Ogawa *Bull Chem Soc Jpn* **7** 265 *1932*, DOI: 10.1246/bcsj.7.265]. Great care should be taken to avoid moisture during handling and storage. It is very soluble in H_2O to form perrhenic acid $HReO_4$. It is also soluble in most organic solvents such as ethers, esters, alcohols, dioxane and pyridine. [Melaven et al. *Inorg Synth* **3** 188 *1950*, DOI: 10.1002/9780470132340.ch50.]

Reduction of Re_2O_7 during hydrogenation reactions generates ***rhenium 'blacks'*** which mainly consist of ReO_3 and is among the best catalyst for reducing a variety of carboxylic acids to alcohols (at ~160°/*ca* 200 atmospheres/few hours) in very good yields. The alcohols are occasionally accompanied with esters; unreduced acids rarely survive, amides are reduced to the respective amines and the usual functional groups that are reduced by Ni and Pt catalysts are also reduced with this rhenium catalyst. [Broadbent et al. *J Org Chem* **24** 1847 *1959*, DOI: 10.1021/jo01094a003.]

It is a precursor for organorhenium oxides which catalyse olefin oxidation, metathesis and other transformations. It is a ***Lewis-acid metal oxide*** which forms adducts of the formula $Re_2O_7.n$L with a variety of O, N and S ligands such as 1,2-dimethoxyethane, 4,4'-di-*tert*-butyl-2,2'-bipyridine, and 1,4,7-trithiacyclononane respectively [Herrmann et al. *Inorg Chem* **34** 4701 *1995*, DOI: 10.1021/ic00123a001].

Rhenium(VII) sulfide **(rhenium heptasulfide)** *[12038-67-4]* **Re_2S_7, M 596.9.** The heptasulfide is obtained by bubbling H_2S through a 3% solution of potassium perrhenate in 5-6 N HCl maintained at the boiling point until precipitation is complete. The suspension is allowed to stand overnight, then it is filtered through a sintered glass funnel, the solid is washed with 1:4 aqueous HCl, H_2O, dried for several days in a desiccator over $CaCl_2$, powdered in a mortar and stored in a common screw capped vial. The catalyst is not adversely affected by occasional exposure to air, is prepared with high catalytic reproducibility, is insoluble in concentrated non-oxidising acids, is stable under all the conditions of hydrogenation used (1000-3600psi/25° to 335°/0.5 to 3 hours), and is not reduced to form H_2S. It is remarkably ***resistant to 'poisoning'***. It catalyses the reduction of a variety of organic substrates in high yields including sulfides, with desulfurisation [e.g. diphenylsulfide to benzene (94%), and thiophenol to a mixture of benzene (60%) and cyclohexane (40%)]; and without desulfurisation [e.g. allyl phenyl sulfide to propyl phenyl sulfide (100%), and of thiophene to thiophane (70%)]. [Broadbent et al. *J Am Chem Soc* **76** 1519 *1954*, DOI: 10.1021/ja01635a016.] When the heptasulfide is heated for 16 hours at 350-400° in a tube furnace under a stream of CO_2 to blow out sulfur vapours, and cooled in a desiccator, it gives ***rhenium disulfide*** *[12038-63-0]*. The catalytic activity of ReS_2 parallels that of Re_2S_7 but to a lesser extent, and is more active than related molybdenum or cobalt catalysts. [Broadbent et al. *J Am Chem Soc* **76** 1519 *1954*. DOI: 10.1021/ja01635a016.]

Rhodium metal used in preparing the following catalysts has [*[7440-16-6]* Rh, M 102.9, m 1966°, b 3727°, d^{20} 12.41].

Rhodium on alumina **(5% Rh loading). $Rh—Al_2O_3$** has been used as a general catalyst for the complete reduction of the aromatic ring in phenols, e.g. gallic acid to *cis*-3,4,5-trihydroxycyclohexane carboxylic acid [Burgstahler & Bithos *Org Synth* **42** 62 *1962*, DOI: 10.15227/orgsyn.042.0062] requiring high pressures (2200psi) and temperatures (~100°) for 8-12 hours [see also Smith & Stump *J Am Chem Soc* **83** 2739 *1961*, DOI: 10.1021/ja01473a032; Kaye & Matthews *J Org Chem* **28** 325 *1963*, DOI: 10.1021/jo01037a012], the hydrogenation of 1-naphthol to *cis*-1-hydroxydecalin [6psi, 25°, 12 hours; Meyers et al. *J Org Chem* **29** 3427 *1964*, DOI: 10.1021/jo01034a520], resorcinol gives cyclohexane-1,3-dione [50psi, 25°, 16-18 hours; Sircar & Meyers *J Org Chem* **30** 3206 *1965*, DOI: 10.1021/jo01020a506], D-mandelic acid gives pure D-hexahydromandelic acid but L-mandelic acid gives (±)-hexahydromandelic acid [3-4 atmospheres, 25°, 1.5 hours, AcOH is mandatory; Stocker *J Org Chem* **27** 2288 *1962*, DOI: 10.1021/jo01053a077], reduction of vinylic and allylic double bonds [500psi, 100°, 15 minutes; Ham & Coker *J Org Chem* 29 194 *1964*, DOI:10.1021/ jo01024a045], reduction of oximes or aliphatic nitriles to primary amines [1-2 atmospheres, ~25°, 1-2 hours; Freifelder et al. *J Org Chem* **27** 2209 *1962*, DOI: 10.1021/jo01053a504; Freifelder *J Am Chem Soc*

82 2386 *1960*, DOI: 10.1021/ja01494a067], hydrogenolysis of ketals to the corresponding dialkyl ethers [Howard & Brown *J Org Chem* **26** 1026 *1961*, DOI: 10.1021/jo01063a010], hydrogenation of heterocyclic compounds e.g. 1,2,3,4-tetrahydroisoquinoline-3-carboxylic acid to *cis*-decahydroisoquinoline-3-carboxylic acid [40psi, ~25°, 3 hours; Rapala et al. *J Am Chem Soc* **79** 3770 *1957*, DOI: 10.1021/ja01571a042], nicotinic acid to hexahydronicotinic (nipecotinic) acid without decarboxylation [2 atmospheres, ~25°, 4 hours; Freifelder *J Org Chem* **27** 4046 *1962*, DOI: 10.1021/jo01058a501; Freifelder *J Org Chem* **28** 602, 1135 *1963*], complete hydrogenation of quinoxaline [Broadbent at al. *J Am Chem Soc* **82** 189 *1960*, DOI: 10.1021/ja01486a043], reduction of the 4,5-double bond of pyrimidine nucleosides and nucleotides [Cohn & Doherty *J Am Chem Soc* **78** 2863 *1956*, DOI: 10.1021/ja01593a063], dehydrogenation e.g. hydrogen transfer from hexahydrohexahelicene to benzene in order to provide hexahelicene and cyclohexane in 73% yield [Newman & Lednicer *J Am Chem Soc* **78** 4765 *1956*, DOI: 10.1021/ja01599a060; cf. also Anderson & Anderson *J Org Chem* **22** 1197 *1957*, DOI: 10.1021/jo01361a018], and hydrogenation of anilines to cyclohexylamine with little hydrogenolysis [Freifelder et al. *J Org Chem* **30** 2485 *1965*, DOI: 10.1021/jo01018a524].

Rhodium on carbon* (5% and 10% loading), Rh/C.** A 10%-Rh, 0.1%Pd on carbon catalyst has been prepared from a mixture of $RhCl_3.3H_2O$ (5.26g), $PdCl_2$ (0.34g) and carbon (18g, e.g. Darco G-60, or any acid washed charcoal can be used) in H_2O (200ml) is rapidly stirred and heated to 80°. Lithium hydroxide hydrate (2.7g) dissolved in H_2O (10ml) is added in one lot and heating is stopped but the mixture is stirred overnight, filtered, and washed with 0.5% v/v aqueous AcOH (100ml) then dried *in vacuo* at 65° to give 20.6-21g of catalyst. One gram of this catalyst will absorb 0.0022-0.0028 mole of H_2 in aqueous suspension. It has been used, for example, in the reduction of *p*-aminobenzoic acid to a mixture of *cis*- and *trans*- 4-aminocyclohexanecarboxylic acid [at 50psi/~25°/~24 hours] which was converted to 2-azabicyclo[2.2.2]octan-3-one (3-isoquinuclidone) in 81-84% yield. ***The point was made that when fresh catalyst is added to the reaction vessel, it should be moistened with the solvent; and that hydrogen should be removed by evacuation at the end of the reduction in order to avoid having a hydrogen-air atmosphere that could be explosive. [Pearlman *Org Synth* Coll Vol **5** 670 *1973*, DOI: 10.15227/orgsyn.049.0075; Pearlman *Tetrahedron Lett* **8** 1663 *1967*, DOI: 10.1016/S0040-4039(00)70335-2.] It is a useful catalyst (even without the trace of Pd) for the reduction of nitriles to primary amines, and the hydrogenation of aromatic and pyridine rings, aldehydes and sugars. It is superior to Rh-Al_2O_3 for reduction of the pyridine ring and larger amounts of catalyst have to be added to overcome the poisoning effect of the piperidine products [Freifelder et al. *J Org Chem* **27** 284 *1962*, DOI: 10.1021/jo01048a505]. It is useful for the stepwise reduction of 3-*H*-pyrrolizine to 3,4-dihydropyrrolizine, and then to the fully reduced pyrrolizidine [Schweizer & Light *J Am Chem Soc* **86** 2963 *1964*, DOI: 10.1021/ja01068a059]; and in boiling norbornadiene complete conversion to a mixture of dimers and trimers occurs [Mrowca & Katz *J Am Chem Soc* **88** 4012 *1966,* DOI: 10.1021/ja00969a021]. A comparison of the rates of hydrogenation with 5% Pd/C, 5%Pt/C, 5% Rh/C and 5% Ru/C catalysts towards reduction of C=C, C=O, C-OH and benzene rings in various solvents at 25° and initial H_2 pressure of 1 atmosphere were made by Breitner, Roginski & Rylander [*J Org Chem* **24** 1855 *1959*, DOI: 10.1021/jo01094a004.]

Ruthenium metal used in preparing the following catalysts has *[7440-18-8]* Ru, M 101.1, m 2310°, b 3900°, d^{20} 12.5].

***Ruthenium-aluminium oxide/hydroxide catalyst* (~2.5wt% Ru loading).** The preparation of this catalyst is described in Chapter 7 because it consists of Ru(0) nanoparticles encapsulated in an aluminium oxy-hydroxide matrix and is superior as a catalyst to the commercially available material. It is a recyclable catalyst for the efficient oxidant-free alcohol dehydrogenation (compare with $RuCl_3.3H_2O$ or xH_2O above) of a wide range of alcohols including benzylic alcohols, secondary long chain fatty alcohols, secondary allylic alcohols, 3-pyridylmethanol, 2-thiophenylmethanol and 4-methylthiobenzyl alcohol in dry toluene to the respective carbonyl compounds under argon at dehydrogenation temperatures of 80° to 110°, using 3-6 mol% of Ru, in yields of >90%. It is 5 times superior to the commercial Ru/Al_2O_2 catalyst and is re-usable, after washing with Me_2CO and drying in air, at least 10 times without loss of activity. [Kim et al. *Org Lett* **8** 2543 *2006*, DOI: 10.1021/ol060750z.]

***Ruthenium on alumina* (5% Ru/Al_2O_3 reduced loading).** Ru/Al_2O_3 can be freshly prepared by treating alumina powder with a ruthenium compound, e.g. $RuCl_3.xH_2O$ in H_2O, $Ru(acac)_3$ or $Ru_3(CO)_{12}$ in *benzene (to give a solid that is ~5wt% in Ru), followed by evaporating the solvent and reducing the solid in a stream of H_2 at 500°. This catalyst will oxidise dibenzothiophene or dibenzothiophene oxide (Ru molar ratio 11:1) in $*C_6H_6$

to dibenzothiophene sulfone at 100° in air (70 atmospheres) for 12 hours in 97% yield. ***Slow poisoning*** of Ru occurs during the oxidation. The activity of the catalyst depends on the preparation, but is much more active than the following catalysts in the sequence $Ru_3(CO)_{12}$ > $Ru(acac)_3$ > $RuCl_3.xH_2O$. Ru/C or Ru/SiO_2, and the commercially available Ru/Al_2O_3 are less active than the above preparation. Pt/Al_2O_3 or Ir/Al_2O_3 gives only a trace of the sulfone, and Pd/Al_2O_3, Rh/Al_2O_3, Os/Al_2O_3 or Cu/Al_2O_3 are totally inactive. It should be noted that with this catalyst oxidation of *n*-Bu_2S (0.2M in $*C_6H_6$; in the ratio of Ru/sulfide 21:1) provides 44 and 9% molar yields of *n*-Bu_2SO and *n*-Bu_2SO_2 respectively, with full recovery of unreacted *n*-Bu_2S. [Ledlie & Howell *Tetrahedron Lett* **17** 785 *1976*, DOI:10.1016/S0040-4039(00)77951-2.]

***Ruthenium on carbon* (5% Ru/C loading).** A comparison of the rates of hydrogenation with 5% Pd/C, 5%Pt/C, 5% Rh/C and 5% Ru/C catalysts towards reduction of C=C, C=O, C-OH and benzene rings in various solvents at 25° and initial H_2 pressure of 1 atmosphere were made by Breitner, Roginski & Rylander [*J Org Chem* **24** 1855 *1959*, DOI: 10.1021/jo01094a004.] Ru/C is a superior catalyst than Pd/C and Pd/C for the hydrogenation of ketones in basic and neutral media and in some cases (e.g. tetramethylcyclobutan-1,3-dione at 1000-1500psi of H_2/125°/1 hour) >90% yields of diols were obtained [Hasek et al. *J Org Chem* **27** 700 *1961*, DOI: 10.1021/jo01062a013], C=C (with some selectivity), and acetylenes were reduced to alkanes [Berkowitz & Rylander *J Org Chem* **24** 708 *1959*, DOI: 10.1021/jo01087a610], nitrobenzene was reduced to hydrazobenzene in alcoholic KOH in 80% yield without over-reduction to aniline [Peitra & Res *Ann Chim (Rome)* **48** 299 *1958*], and 10% Ru/C was better than other catalysts for reducing phenolic rings in polycyclic compounds [Walton et al. *J Am Chem Soc* **78** 4760 *1956*, DOI: 10.1021/ja01599a059].

Ruthenium(IV) oxide *[12036-10-1]* **RuO_2, M 133.1, d^{25} 6.97.** The dioxide is prepared by heating Ru metal in a silica boat in a silica combustion tube placed horizontally in a furnace, and a slow stream of dry oxygen is allowed to flow over it while it is being heated at 1000° for 24 hours. During heating a little of the oxide volatilises and small crystals may condense on the walls at the downstream end of the tube. A 90-95% yield of polycrystalline RuO_2 remains in the boat. It forms tetragonal dark blue crystals which are insoluble in organic solvents, H_2O and acids but soluble in fused alkali. [Schäfer & Heitland *Z Anorg Allgem Chem* **304** 249 *1960*, DOI: 10.1002/zaac.19603040502; Schäfer et al. *Z Anorg Allgem Chem* **319** 327 *1963*, DOI: 10.1002/zaac.19633190514; Rogers et al. *Inorg Synth* **13** 135 *1972*, DOI: 10.1002/9780470132449.ch27; **30** 96 *1995*, DOI: 10.1002/9780470132616.ch20.] It is a good catalyst, no doubt by being converted into the metal *in situ* which promotes catalysis. It has been used for the reduction of aromatic rings to cyclohexane rings [e.g. at 1350psi/147°/16 hours, or 70psi/90°/1 hour; Freifelder & Stone *J Am Chem Soc* **80** 5270 *1958*, DOI: 10.1021/ja01552a063; Freifelder & Stone *J Org Chem* **26** 3805 *1961*, DOI: 10.1021/jo01068a043; Freifelder & Stone *J Org Chem* **27** 3568 *1962*, DOI: 10.1021/jo01057a041; Johnson et al. *J Am Chem Soc* **84** 2181 *1962*, DOI: 10.1021/ja00870a033], and phenolic compounds to the respective cyclohexanols [Rapala & Farkas *J Org Chem* **23** 1404 *1958*, DOI: 10.1021/jo01103a628; Counsell *Tetrahedron* **15** 202 *1961*, DOI: 10.1016/0040-4020(61)80027-6; Ireland & Schiess *J Org Chem* **28** 6 *1963*, DOI: 10.1021/jo01036a002]; but with some enones only the double bond was reduced without affecting the carbonyl function [Rapala & Farkas *J Am Chem Soc* **80** 1008 *1958*, DOI: 10.1021/ja01537a074].

HOMOGENEOUS METAL CATALYSTS

Allylpalladium(II) chloride dimer [di-μ-chloro-η^3-allylpalladium(II)] *[12012-95-2]* **[$Pd(\eta^3\text{-}C_3H_5)Cl]_2$, M 365.9, m 155-156°(dec.), ~160°(dec.).** It is prepared from allyl chloride, $PdCl_2$, and NaCl in the presence of carbon monoxide and is extracted into $CHCl_3$, washed with H_2O, dried ($CaCl_2$), filtered and evaporated to dryness to give the complex as yellow crystals (use a very efficient fume cupboard). These can be used as such, but by recrystallisation from a mixture of CH_2Cl_2 and hexane analytically pure catalyst can be obtained (**m 155-156° dec.**). It also crystallises from benzene and is soluble in MeOH, Et_2O, Me_2CO and $CHCl_3$. The ^1H NMR ($CDCl_3$) has two doublets at δ_H 3.03 (anti CH_2, J = 12.0Hz) and 4.10 (syn CH_2, J = 7.1Hz), and a triplet at δ_H 5.48 (CH) 2:2:1. [Tatsuno et al. *Inorg Synth* **28** 342 *1990*, DOI: 10.1002/9780470132616.ch20; Shaw *Proc Chem Soc* 247 *1960*, ***notes*** *start on p 233*, DOI: 10.1039/PS9600000233; Hüttel et al. *Chem Ber* **94** 766 *1961*, DOI: 10.1002/cber.19610940329; Dent et al. *J Chem Soc* 1585 *1964*, DOI: 10.1039/JR9640001585.]

It is a labile Pd complex, but is very useful for preparing a variety of stable catalytic Pd(0) complexes with a wide selection of ligands to perform stereoselective reactions. A particularly useful ligand is *cis,cis,cis*-1,2,3,4-tetrakis(diphenylphosphinomethyl)cyclopentane [Tedicyp] [Laurenti et al. *J Org Chem* **66** 1633 *2001*, DOI: 10.1021/jo001146j]. The catalyst with this ligand is typically prepared under argon, in a Schlenk type system,

by dissolving $[Pd(\eta^3\text{-}C_3H_5)Cl]_2$ (4.2mg, 11.6μmol) and Tedicyp (20mg, 23.2μmol, see *[333380-86-2]* in Part 2) in dry tetrahydrofuran (10ml) and stirring for 10 minutes before use. It gives a solution of 2.32μmol/ml of catalyst, which has ^{31}P NMR (162MHz, $CDCl_3$) with δ at 25 (vbrs, *width* 80Hz), 19.4 (vbrs, *width* 110Hz). It is very efficient in catalysing allylic substitutions with high turnover numbers (up to 9,800,000) and frequencies (up to 190,000 h^{-1}).
$[Pd(\eta^3\text{-}C_3H_5)Cl]_2$ is used for cross-coupling reactions [Wallow & Novak *J Org Chem* **59** 5034 *1994*, DOI: 10.1021/jo00096a056], the Heck reactions with olefins [Fall et al. *Synthesis* 1683 *2007*, DOI: 10.1055/s-2007-966063] and enol ethers [Battace et al. *Eur J Org Chem* 3122 *2007*, DOI: 10.1002/ejoc.200700152], and the formation of ethyl cyclopropane carboxylates with ethyl diazoacetate and olefins [Armstrong *J Org Chem* **31** 618 *1966*, DOI: 10.1021/jo01340a522] to name a few.

Bis(acetonitrile)dichloropalladium(II) *[14592-56-4]* **$Pd(II)Cl_2(MeCN)_2$, M 259.4, dec > 200°.** It is prepared by mixing anhydrous $PdCl_2$ (1mol) and MeCN (2mols) until clear and precipitating the complex with petroleum ether. *Alternatively*, MeCN (3ml) is added to a solution of K_2PdCl_4 (2g) in H_2O (40ml) and stirred at ~25° until separation of yellow prisms is complete (could take up to 8 days). Filter these off, wash them with H_2O, EtOH, Et_2O, and dry them *in vacuo*. Further purification, if necessary, can be achieved by dissolving it in anhydrous solvents (which are not likely to displace the ligands) such as MeOH, toluene, THF, precipitating it with light petroleum, and drying the solid *in vacuo*. It is also soluble in $*C_6H_6$ to the extent of 100mg/4.0ml. In addition to its use as a source of metal for palladium complexes and catalysts such as $PdCl_2$(*R*)-BINAP *[115826-95-4]* (see Ozawa et al. *Organometallics* **12** 4188 *1993*, DOI: 10.1021/om00034a064), it also catalyses Overman rearrangements (aza-Claisen rearrangement, Overman & Garpenter *Org React* **66** 1 *2005*, DOI: 10.1002/0471264180.or066.01; see below). A particularly interesting example of the rearrangement being the high diastereoselectivity which is directed by a δ-methoxymethylether group in δ-substituted allylic trichloroacetamidates, where the ether oxygen atoms coordinate with Pd to direct the orientation of the reaction [Jamieson & Sutherland *Tetrahedron* **63** 2123 *2007,* DOI: 10.1016/j.tet.2006.12.067]. The IR spectrum shows, from the RCN and M-X vibrations, that the MeCN groups have a *trans*-planar configuration, unlike related Pt complexes which have the *cis*-configuration. For IR see reference (Nujol) has ν_{max} at 1417m, 1358m, ~1160wbr, 1030m, 970wbr cm^{-1} [Walton *Spectrochim Acta* **21** 1795 *1965*, DOI: 10.1016/0371-1951(65)80091-1].

Bis(benzonitrile)dichloropalladium(II) *[14220-64-5]* **$Pd(II)Cl_2(PhCN)_2$, M 383.6, m 131°.** It is prepared and purified in the same manner as the $Pd(II)Cl_2(MeCN)_2$ complex above. *Alternatively*, anhydrous $PdCl_2$ (2g) suspended in benzonitrile (50ml) is stirred at 100°. Most of the $PdCl_2$ dissolves after 20 minutes to give a red solution which is filtered while hot, and the hot filtrate is poured slowly into petroleum ether (b 40-60°). The light yellow complex that crystallises out is collected, washed with petroleum ether and dried *in vacuo* (4.0g, 93%). It can be purified further by dissolving it in the minimum volume of $*C_6H_6$, and the hot red solution is filtered and diluted with petroleum ether to allow the complex to crystallise out. [Doyle et al. *Inorg Synth* **6** 216 *1960*, DOI: 10.1002/9780470132371.ch69; Kharasch et al. *J Am Chem Soc* **60** 882 *1938*, DOI: 10.1021/ja01271a035.] $Pd(II)Cl_2(PhCN)_2$ is an effective catalyst for the regiospecific cycloaddition cross-coupling reactions of aziridines with carbodiimides to form imidazolidin-2-imines in 40-94% yields [Baeg & Alper *J Org Chem* **57** 157 *1992*, DOI: 10.1021/jo00027a030]. In the presence of a ***Buchwald ligand*** (e.g. 2-di-*t*-butyl-2'4'6'-tri-*i*-propylbiphenyl) in CH_2Cl_2, it catalyses the stereoselective formation of α-*O*-glycosides from protected glycalimidates with a variety of phenols or protected glycosides in high yields at room temperature [Schuff, Mercer and Nguyen *Org Lett* **9** 3173 *2007*, DOI: 10.1021/ol071268z]. Also, in the presence of Xantphos {4,5-bis(diphenylphospheno)-9,9-dimethylxanthene, see *[161265-03-8]*}, it promotes Stille-type cross coupling reactions between alkynyl-$SnBu_3$ and α-halo esters or amides under neutral conditions in THF to provide 3-alkynoates or alkynoamides in high yields without homocoupling of the alkynyltin reagents [Shi et al. *Chem Commun* 2342 *2007*, DOI: 10.1039/B703221H]. The IR spectrum shows, from the RCN and M-X vibrations, that the PhCN groups have a *trans*-planar configuration, unlike related Pt complexes which have the *cis*-configuration. The IR (Nujol) has ν_{max} at 3096w, 3057w, 3033w, 3002vwm 2287s, 1480m-w, 1440s, 760s, 678s cm^{-1} [Walton *Spectrochim Acta* **21** 1795 *1965*, DOI: 10.1016/0371-1951(65)80091-1].

Bis(cyclopentadienyl)cobalt(II) (cobaltocene, Cp_5Co) *[1277-43-6]* **$C_5H_5CoC_5H_5$, M 189.1, m 173-174° (under N_2), 176-180°(dec).** Cp_2Co is prepared by adding anhydrous $CoCl_2$ (0.5 mol, prepared by dehydrating the salt at 200° in a vacuum) to a cold solution of 1 mol of sodium cyclopentadienide *[4984-82-1]* in THF (see

below), stirring for 2 hours, removing the solvent and subliming the product directly from the mixture at 150-200°/10^{-4} mm in 75-80% yields; or by using $CoBr_2$ and refluxing for 3 hours. *Alternatively*, (method of Wilkinson et al. *J Inorg Nucl Chem* **2** 95 *1956*, DOI: 10.1016/0022-1902(56)80004-3), cyclopentadiene (42ml, 0.5mol) and Et_2NH (~100ml, 1mol) are added slowly to $CoBr_2$ (0.25mol) with cooling, and then stirring at ~25° for 6-8 hours; the solvent is removed *in vacuo* and the residue is extracted with petroleum ether, filtered, and the solvent is evaporated to give dark violet monoclinic crystals m 171-173°.
When anhydrous ***cobalticenium chloride*** (5g, prepared from sodiocyclopentadienide and anhydrous $CoCl_2$ in THF as above but stirring at the boiling point for 2 hours, evaporating the solvent and adding 1:1 hydrochloric acid) in dry 1,2-dimethoxyethane (150ml) is treated with excess of $NaBH_4$ (5g, or LAH) in small portions while stirring (H_2 is evolved), then warm to 60°, or add H_2O (2ml), the mixture becomes deep wine-red in colour. After 1 hour the solution is filtered, the solid is washed with Et_2O and the filtrate is evaporated to a few mls *in vacuo*, diluted with petroleum ether (b ~40-60°), concentrated again and applied on to an alumina column (20 x 2cm). The first red band that elutes with petroleum ether is evaporated, and the residue is sublimed *in vacuo* onto a cold finger at -70° to give wine-red crystals of ***π-cyclopentadienyl(cyclopentadiene)cobalt*** **[*π*-$C_5H_5CoC_5H_6$]** (yield 80%) with **m 98-99°**, has **M 193** (ebulioscopic in $*C_6H_6$), and a UV with λ_{max} nm(ε) at 263.8 (1.78 x 10^5), 327 (9.27 x 10^3), and 395 (5.27 x 10^3). It has a ***camphorous odour*** and should be kept under argon as it is stable in air for only a few minutes, but for a few hours in degassed solutions of organic solvents. [Green et al. *J Chem Soc* 3753 *1959*, DOI: 10.1039/JR9590003753.]
Sodium cyclopentadienide *[4984-82-1]* **C_5H_5, C_5H_5Na, M 88.1**, is prepared under N_2 by slowly adding cyclopentadiene (37ml) to a cooled suspension of sodium (10g) in THF (150ml) when H_2 evolves rapidly and a solution of sodium cyclopentadienide is formed. The colour of the soluton depends on the purity of the solvent and the amount of air in the system. Clear pale orange or red solutions are obtained with good conditions, but dark red to purple colours are obtained in the presence of traces of air without, however, seriously decreasing the yields of the complexes formed. [Wilkinson et al. *J Inorg Nucl Chem* **2** 95 *1956*, DOI: 10.1016/0022-1902(56)80004-3; Reynolds & Wilkinson *J Inorg Nuclear Chem* **9** 86 *1959*, DOI: 10.1016/0022-1902(59)80015-4; *Beilstein* **16** IV 1698.] It is available commercially as a 2.0M solution in THF as sodium cyclopentadienylide. The dry solid is ***pyrophoric***.
Cp_2Co catalyses the condensation of acetylene and mono-substituted acetylenes (but not di-substituted acetylenes) with nitriles at 150° to give 30-70% yields of substituted pyridines [Wakatsuki & Yamazaki *Synthesis* 26 *1976*, DOI: 10.1055/s-1976-23943]. This synthesis has been applied successfully in a 2+2+2 cycloaddition reaction between di(trimethylsilyl)propargyl ether and acetonitrile to prepare a pyridine intermediate which was used to obtain pyridoxine (vitamin B_6) [Geiger et al. *Helv Chim Acta* **67** 1274 *1984*, DOI: 10.1002/ hlca.19840670513].

The above are general procedures and they have been used for preparing **Bis(cyclopentadienyl)chromium (II) [Cp_2Cr]** *[1271-24-5]* **$C_5H_5CrC_5H_5$, M 182.2, m 168-170°** [Wilkinson et al. *J Inorg Nucl Chem* **2** 95 *1956*, DOI: 10.1016/0022-1902(56)80004-3; *Beilstein* **16** IV 1774], **Bis(cyclopentadienyl)magnesium(II) [Cp_2Mg]** *[1284-72-6]* **$C_5H_5MgC_5H_5$, M 154.5, m 176-178°, 180°(dec)** [Wilkinson et al. *J Inorg Nucl Chem* **2**95 *1956*, DOI: 10.1016/0022-1902(56)80004-3; Barber *J Inorg Nucl Chem* **4** 373 *1957*, DOI: 10.1016/0022-1902(57)80026-8; *Beilstein* **16** IV 1695], *and* **Bis(cyclopentadienyl)vanadium(II) [Cp_2V]** *[1277-47-0]* **$C_5H_5VC_5H_5$, M 181.1, m 165-167°** [Wilkinson et al. *J Inorg Nucl Chem* **2** 95 *1956* DOI: 10.1016/0022-1902(56)80004-3; *Beilstein* **16** IV 1771].

Bis(dibenzylideneacetone)palladium(0) [$Pd(dba)_2$] *[32005-36-0]* **$C_{34}H_{28}O_2Pd$, M 575.3.** The precise nature of this complex is not clear, but a product with reproducible stoichiometry [$C_{34}H_{28}O_2Pd$] is prepared first by stirring $PdCl_2$ (8.87g, 50mmol) and NaCl (2.92g, 50mmol) in MeOH (250ml) at 25° for 16 hours, filtering through a cotton wool plug, diluting the filtrate to ~1.5L with MeOH, and heating to 60° to form $Na_2[PdCl_6]$. Dibenzylideneacetone (36.5g, 150mmol, see *[538-58-9]*, cf. 'Organic Compounds' in Chapter 3) is then added to this warm solution stirred solution of $Na_2[PdCl_6]$, and stirring for a further 15 minutes and anhydrous NaOAc (75g) is added. The reaction begins immediately, heating is stopped but stirring is continued until the reaction cools to room temperature. The dark brown precipitate that is formed is washed with MeOH (2 x 25ml), H_2O (5 x 50ml), Me_2CO (5 x 15ml) and dried in air to constant weight (923g, 80% yield) [Rettig et al. *Inorg Synth* **17** 134 *1977*, DOI: 10.1002/9780470132487.ch37]. See the related complexes of **$Pd(dm\text{-}dba)_2$** below for their structures in $CDCl_3$ solution. Catalysis with these complexes occurs at room temperature in the

presence the ligand DIPHOS [dpe, 1,2-bis-[diphenylphospheno]ethane (see *[1663-45-2]* in 'Metal-Organic Compounds' in Chapter 4) which is more efficient than with the less stable $Pd(PPh_3)_4$. It is used for the synthesis of allylic substituted cyclopentadienes [Fiaud & Malleron *Tetrahedron Lett* **21** 4437 *1980*, DOI: 10.1016/S0040-4039(00)92193-2] and is a homogeneous catalyst [Fiaud & Malleron *Tetrahedron Lett* **22** 1399 *1981*, DOI: 10.1016/S0040-4039(01)90332-6; Black *Aldrichimica Acta* **15** 13 *1982*] which catalyses the alkylation of a variety of nucleophiles under mild conditions [Ferroud et al. *Tetrahedron Lett* **25** 4379 *1984*, DOI: 10.1016/S0040-4039(01)81443-X.] Together with cyclic thiourea ligands such as *1N,3N*-bis(1,4-di-*tert*-butylphen-2-yl)imidazoline-2-thione, it catalyses efficient aerobic oxidations of alcohols to aldehydes and ketones in toluene in yields >95% [Yang et al. *Synlett* 3057 *2006*, DOI: 10.1055/s-2006-951501.]

Bis(3,5,3',5'-dimethoxybenzylideneacetone)palladium(0) {bis[1,3-bis(3',5'-methoxybenzylidene)acetone palladium(0), [Pd(dm-dba)$_2$]} *[811862-77-8]* **$C_{42}H_{44}O_{10}Pd$, M 815.2, m 170-178º.** This Pd catalyst with the dimethoxy-dba ligand is prepared and purified as for $Pd(dba)_2$ above but using 1,5-bis(3',5'-dimethoxyphenyl)penta-1*E*,4*E*-diene-3-one (dm-dba, *[39777-58-7]*),* instead of dba. *Alternatively*, Fairland's method can be used, whereby NaCl (3.3g, 56mmol) is added to $PdCl_2$ (5g, 28mmol) in MeOH (140ml) and stirred under argon at 25º for 24 hours, filtered and evaporated *in vacuo* to half its volume. To this solution at 60º is added dm-dba (20.6g, 88mmol), stirred at 60º for 15 minutes, anhydrous NaOAc (42.3g) is added and allowed to cool to 25º. The mixture is stirred at 25º for 2 hours as the dark red precipitate of the complex separates. The solid is collected, washed with MeOH (2 x 100ml), H_2O (2 x 100ml) then Me_2CO (2 x 20ml), partially dried by suction, placed in a Schlenk flask and stirred under a flow of N_2 overnight to give the complex as a maroon/purple microcrystalline solid (11g 68%). It was found to have higher activity than those of the complex with the unsubstituted ligand [i.e. $Pd(dba)_2$] in Suzuki-Miyaura cross-coupling reactions of organic halides with arylboronic acids. ***Note*** that a solution of the complex, as in the case of $Pd(dba)_2$ above, in $CDCl_3$, was found to contain one dm-dba ligand coordinated to Pd and one free in solution. Addition of two equivalents of Ph_3P to the complex in THF and $(CD_3)_2CO$ resulted in the formation of the η^2-(dm-dba)$Pd^{(0)}(Ph_3P)_2$ complex as shown by the presence of two phosphorous doublets in the ^{31}P NMR spectrum. [Fairlamb et al. *Org Lett* **6** 4435 *2004*, DOI: 10.1021/ol048413i; cf. *Handbook of Organopalladium for Organic Synthesis* Negishi ed. Wiley, Hoboken NJ *2002*, ISBN 0-471-31506-0.] For **Pd_2(*p,p'*-dimethoxy-dba)$_3$** see **Pd_2(dba)$_3$($CDCl_3$)** below.

Bis(di-*tert*-butyl(4-dimethylaminophenyl)phosphine)dichloropalladium(II) [(A-^{ta}Phos)$_2PdCl_2$] *[887919-35-9]* **$C_{32}H_{56}Cl_2N_2P_2Pd$, M 708.1.** The catalyst is prepared by mixing one equivalent of di-*tert*-butylphosphine, 1 equivalent of 4-dimethylaminophenyl bromide and 1 mol% of Pd_2dba_3 at 90º for 12 hours. The mixture is cooled to 25º, filtered through a short silica gel plug, the plug is rinsed with toluene and the combined filtrate is evaporated under vacuum. The residue is dissolved in tetrahydrofuran and 0.35 equivalents of solid $PdCl_2$(COD) are added followed by stirring at 25º for 12 hours. The product is filtered off, and the yellow solid collected is washed with pentane and dried *in vacuo* to give ~85% yield of (A-^{ta}Phos)$_2PdCl_2$ which provides the correct microanalysis for C and H. It has ^1H NMR (CD_2Cl_2) with δ at 7.5 (s br, 4 H, ArH), 6.42 (d, J = 8.3Hz, 4H, ArH), 2.75 (s, 12H, NMe_2), 1.38 (t, J_{PH} = 6.6Hz, 36H, *tert*-Bu); and ^{31}P NMR ($CDCl_3$) with δ at 52.1.
Similarly ***bis[di-*tert*-butyl(p-trifluoromethylphenyl]phosphine)dichloropalladium(II)*** can be prepared which has ^1H NMR ($CDCl_3$) with δ at 8.0 (s br, 4 H, ArH), 7.59 (d, J = 7.9Hz, 4H, ArH), 1.62 (t, J_{PH} = 7.0Hz, 36H, *tert*-Bu); ^{31}P NMR ($CDCl_3$) with δ at 55.7; and ^{19}F NMR ($CDCl_3$) with δ at -63.4. Also ***bis[di-*tert*-butyl[phenyl]phosphine)dichloro-palladium (II)*** was prepared in the same way and has ^1H NMR ($CDCl_3$) with δ at 7.9-7.8 (m, 4 H, ArH), 7.36-7.30 (m, 6H, ArH), 1.56 (t, J_{PH} = 6.9Hz, 36H, *tert*-Bu); ^{31}P NMR ($CDCl_3$) with δ at 54.4. These are ***air-stable active catalysts*** for Suzuki-Miyaura cross-coupling with aryl halides including 5- and 6-membered heteroaryl halides in the presence of bases such as K_2CO_3, Na_2CO_3, KOAc, K_3PO_4 with high turn over numbers (TON) of 100 to 100,000 [Guram et al. *Org Lett* **8** 1787 *2006*, DOI: 10.1021/ol060268g].

2-[Bis(2,4-di-*tert*-butylphenoxy)phosphinooxy]-3,5-di(*tert*-butyl)phenyl-palladium(II) chloride dimer {Bedford's Catalyst, 2[bis(2,4-di-*tert*-butylphenoxy)phosphino-κP-oxy)-3,5-di-*tert*-butylphenyl-κC]di-μ-chloro-dipalladium} *[217189-40-7]* **$C_{84}H_{124}Cl_2O_6P_2Pd_2$, M 1575.6.** The thoroughly characterised Bedford catalyst, an *ortho*-metallated dimer, is prepared in 96% yield from the bulky tris(2,4-di-*tert*-butylphenyl)phosphite and $PdCl_2$. The catalyst is remarkably stable to moisture and air, showing no signs of deterioration after several weeks, can be kept in air for at least 6 months and is not decomposed on heating at 130º in toluene for 24 hours. It is very efficient for coupling aryl halides with either arylboronic acids (***Suzuki***

reaction) or aryltin compounds (***Stille reaction***) in solvents such as toluene or tetrahydrofuran to form biaryls with very high turn over numbers (TONs up to 1,000,000 moles of product/mol of Pd) at even very low Pd catalyst concentrations, and in moderate to high yields [Albisson et al. *JCS Chem Commun* 2095 *1998*, DOI: 10.1039/A806041J]. ***Bedford's catalyst*** also proved to be extremely active in the arylation (with e.g. aryl bromides) of alkenes (e.g. acrylate, styrene) with turn over numbers of up to 5,750,000 (mole product/mol Pd), and turn over frequencies of 300,000 (mol product/mol Pd/hour) [Albisson et al. *Tetrahedron Lett* **39** 9793 *1998*, DOI: 10.1016/S0040-4039(98)02175-3].

***R,R*-(+) *and S,S*-(-) *N,N'*-Bis(3,5-di-*tert*-butylsalicylidene)-1,2-*trans*-cyclohexanediamine Manganese(III) Chloride [Jacobsen's catalyst,**) *[R,R-138124-32-0, S,S-135620-04-1]* **$C_{36}H_{52}ClN_2O_2Mn$, M 635.2, m 330-332°, 324-326°, $[\alpha]_D^{20}$ ±580 (c 0.01, EtOH).** This complex is commonly referred to as the Mn(salen) catalyst. If this enantioselective catalyst for the epoxidation of olefins requires purification, the brown powder (*ca* 6g) is dissolved in CH_2Cl_2 (100ml), extracted with H_2O (2 x 100ml), the organic phase is dried (Na_2SO_4), filtered, evaporated to dryness and the solid residue is dried in a vacuum desiccator over $CaSO_4$. [Jacobsen et al. *J Am Chem Soc* **113** 7063 *1991*, DOI: 10.1021/ja00018a068]. For large scale preparation see Larrow et al. *J Org Chem* **59** 1939 *1994*, DOI: 10.1021/jo00086a062; and Deng & Jacobsen *J Org Chem* **57** 4320 *1992*, DOI: 10.1021/jo00041a054. For epoxidation of indenes see Hughes et al. *J Org Chem* **62** 2222 *1997*, DOI: 10.1021/jo961735i; and for the epoxidation of isoflavones see Adam et al. *Tetrahedron: Asymmetry* **9** 1121 *1998*, DOI: 10.1016/S0957-4166(98)00102-5; Jacobsen et al. *Tetrahedron* **50** 4323 *1994*, DOI: 10.1016/S0040-4020(01)89369-8; Jacobsen's Asymmetric Catalytic Epoxidation of Unfunctionalized Olefins in *Catalytic Asymmetric Synthesis Vol I,* p. 159, Ojima Ed. VCH, NY *1993* (see also Bibliography in Part 2), and for enantioselective hydrolysis of epoxides see Furrow et al. *J Org Chem* **63** 6776 *1998*, DOI: 10.1021/jo981332d.
On a large scale, the brown *R,R-(+)- catalyst* (300-400g) is washed with hot H_2O (2 x 800ml, at 50°), and dried on the filter for 2 hours then under vacuum (50-100mm) at 60-70° for 12 hours, **m 324-326°** (product of acceptable purity has m ~320°), $[\alpha]_D^{23}$ +580 (c 0.01, EtOH), and IR with ν_{max} (KBr) at 1535, 1612, 2950-2958 cm^{-1}. [Larrow et al. *J Org Chem* **59** 1939 *1994*, DOI: 10.1021/jo00086a062.]
The related chiral complexes of **Al(II)-Cl** *[R,R 250611-13-3; S,S 307926-51-8]*, **of Cr(III)-Cl** *[R,R 164931-83-3; S,S 219143-92-7]* and of the **Co(II)-Cl** *[R,R-(+) 176762-62-5; S,S-(-) 188264-84-8]* (Tokunaga et al. *Science* **277** 936 *1977*, DOI: 10.1126/science.277.5328.936; Jacobsen et al. *Tetrahedron Lett* **38** 773 *1997*, DOI: 10.1016/S0040-4039(96)02414-8*)* are similarly prepared and are available commercially. [See also Schaus et al. *J Am Chem Soc* **124** 1307 *2002*, DOI: 10.1021/ja016737l; Brandes & Jacobsen *Tetrahedron Asymm* **23** 3927 *1977*, Gurar et al. *Heterocycles* **48** 1471 *1998*.]

NOTE: It was shown that addition of pyridine *N*-oxides, and particularly 4-(3-phenylpropyl)pyridine-1-oxide (P_3NO, see *[34122-28-6]* in Part 2), stabilise and improve the catalytic activity of Mn(salen) catalysts [Larrow & Jacobsen *J Am Chem Soc* **116** 12129 *1994*, DOI: 10.1021/ja00105a094; Srinivasan et al. *J Am Chem Soc* **108** 2309 *1986*, DOI: 10.1021/ja00269a029; Senanayake *Aldrichimica Acta* **31** 3 *1998*.] Thus in a typical epoxidation MnLCl (0.56mmol, salen Mn catalyst) and P_3NO (2.32mmol) in chlorobenzene (10ml) are added to a 2M solution of NaOCl (26.5mmol) cooled to 0° under N_2, and stirred at 0° for 15 minutes, followed by simultaneous addition of indene (10ml) and further NaOCl (79.5mmol) (syringe pumps) during 30 minutes. The reaction is complete within 1 hour at 0°, and can be performed on a multi-kilogram scale to provide indene epoxide in 89% yield and with an optical purity of 88% e.e. [Senanayake et al. *Tetrahedron Lett* **37** 3271 *1996*, DOI: 10.1016/0040-4039(96)00565-5.]
A *dimeric Jacobsen ligand*, formed by linking two units with a methylene bridge has been prepared and crystallised from CH_2Cl_2/pentane. Its **bis-Mn catalyst** exhibited improved retention in a poly-dimethylsiloxane membrane for the asymmetric epoxidation of olefines [Janssen et al. *Tetrahedron: Asymmetry* **8** 3481 *1997*, DOI: 10.1016/S0957-4166(97)00465-5].

[*(R)*-(+)-2,2'-Bis(diphenylphosphino)-1,1'-binaphthyl]palladium(II) dichloride ([*R*-BINAP]$_2$PdCl$_2$) *[115826-95-4]* **$C_{44}H_{32}Cl_2P_2Pd$, M 800.0, m 255-260° (dec), $[\alpha]_D^{24}$ +682 (c 0.5, $CHCl_3$).** This catalyst is prepared by dissolving a mixture of *R*-BINAP (500mg, 0.803mmol, see *[76189-55-4]*), η-allyl-η-cyclopentadienyl-Pd(II) (84,2mg, 0.396mmol, see [1271-03-0], cf Tatsuno et al. *Inorg Synth* **19** 220 *1979*,. DOI: 10.1002/9780470132500.ch51) in *C_6H_6 (5ml), in a Schlenk tube under N_2 (dried over P_2O_5), and heated at 80° for 3 hours to give a deep red solution which is then evaporated to dryness. The red solid is then dissolved

in CH_2Cl_2 (10ml), filtered and the filtrate is evaporated *in vacuo* down to *ca* 4ml, diluted with Et_2O (40ml) and cooled to 4º whereby red-purple crystals of [*R*-BINAP]$_2$Pd(0) separate, which on washing with cold Et_2O and drying *in vacuo* give analytically pure ***[R-BINAP]$_2$Pd(0)-Et$_2$O*** (480mg, 90%). The 1:1 ratio of Et_2O to Pd is confirmed by ^{1}H NMR spectroscopy. It has ^{1}H NMR (90MHz, *C_6D_6, TMS) with δ_H at 5.88 (t, *J* = 7.6Hz, 8H), 6.19 (t, *J* = 7.3Hz, 4H), 6.8-7.6 (m, 40H), 7.83 (d, *J* = 8.2Hz, 4H), 8.36 (brs, 8H); and the ^{31}P{^{1}H} NMR (36MHz, *C_6D_6, referenced to external 85% H_3PO_4 at δ 0.0) has δ_P at 27.3. This Pd(0) complex catalyses asymmetric arylation in the Heck reaction. ***[R-BINAP]$_2$PdCl$_2$*** is obtained by stirring *R*-BINAP (249mg, 0.40mmol) in *C_6H_6 (4.0ml) with $PdCl_2(MeCN)_2$ (104mg, 0.40mmol) in *C_6H_6 (4.0ml) overnight. The yellow precipitate is collected by filtration, washed with *C_6H_6 and dried *in vacuo*. It is crystallised by dissolving in Me_2CO, layering with hexane and setting aside at ~25º to give red crystals of [*R*-BINAP]$_2$PdCl$_2$ (238mg, 75%, **m 255-260º**) of analytical purity, and suitable for X-ray crystallographic structure determination which confirmed its structure. [Ozawa et al. *Organometallics* **12** 4188 *1993*, DOI: 10.1021/om00034a064; cf. review by Shimizu, Nagasaki & Saito *Tetrahedron* **61** 5405 *2005*, DOI: 10.1016/j.tet.2005.03.022].

Bis(trifluoromethanesulfonyl)amine metal salts [NTf$_2$, bis-(trifluoromethanesulfon)amide metal salts, (CF$_3$SO$_2$)$_2$NMetal] see *[82113-65-3]*. **NTf$_2$** readily forms salts, e.g. with Li, Ba, Ca, Al, Zn, Al and lanthanides, which act as ***Lewis Acids*** in effectively catalysing Diels-Alder reactions [Kobayashi et al. *Chem Lett* 307 *1995*, DOI: 10.1246/cl.2003.654; Handy et al. *Synlett* 565 *1995*, DOI: 10.1055/s-1995-5289] and acylation reactions [Mikami et al. *Synlett* 171 *1996*, DOI: 10.1055/s-1996-5363]. It forms an ***N-trimethylsilyl derivative*** ($TMSNTf_2$ prepared from allylTMS and NTf_2, see above) which catalyses Diels-Alder reactions between methyl acrylate and various dienes [Mathieu & Ghosez *Tetrahedron Lett* **38** 5497 *1997*, DOI: 10.1016/S0040-4039(97)01208-2], as well as Friedel-Crafts acylation reactions of anisole, and allylation and bis-allylation of carbonyl derivatives [Ishii et al. *Synlett* 1145 *1997*, DOI: 10.1055/s-1997-995]. **NTf$_2$** is a weakly coordinating counter ion which confers stability to catalytic metal complexes such as the gold catalyst $[Ph_3PAu(I)]^+$ $[NTf_2]^-$, see *[866395-16-6]*.

***R*(-)- and *S*(+)- 4,12-Bis(diphenylphosphino)-[2.2]-paracyclophane {*R*- and S- PHANEPhos, (*R*)- and (*S*)-5,11-bis(phenylphosphino)-tricyclo[8.2.2.2^{4,7}]hexadeca-hexaene}** *[(R) 364732-88-7; (S) 192463-40-4]* **M $C_{40}H_{34}P_2$, 576.6, m 222-226º, 224-276º, $[\alpha]_D^{25}$ *R* -34, *S* +34 (c 1, $CHCl_3$).** These are chiral ligands for the rhodium precatalysts **(COD)Rh{(*R*)-[2.2]PHANEPhos}$^+$ OTf$^-$** and **(COD)Rh{(*S*)-[2.2]PHANEPhosS}$^+$ OTf$^-$** (see preparation and purification below) which are highly enantioselective in the hydrogenation of dehydroamino acid methyl esters generally, and also of methyl 1-Ac-4-Boc-1,4,5,6-tetrahydropyrazine-1-carboxylate which is difficult to reduce. When they are pre-reduced in MeOH, they form **(MeOH)$_2$Rh{(*R*)-[2.2]PHANEPhos}$^+$ OTf$^-$** whose activity is more pronounced and reduction is complete in less than 60 minutes by passing H_2 gas through the MeOH solution at temperatures between -45º to +50º, with high substrate to catalyst ratios.
The preparations of these ligands (described briefly here for convenience) involve di-bromination of *p*-cyclophane, separation of the *meso*- from the *racemic*- isomers (latter are more soluble in triglyme), reaction of the *rac*-isomer (1 equivalent) with *tert*-BuLi (4.2 equivalents), and $MgBr_2.Et_2O$ (2.3 equivalents) in THF then diphenylphosphinyl chloride (Ph_2POCl, 2.2 equivalents.) to give *rac*-4,12-bis(diphenylphosphinyl)-[2.2]-paracyclophane (76% yield). Optical resolution of this racemate (in $CHCl_3$) with (+)-dibenzoyl-D-tartaric acid (in EtOAc) at 60º, then cooling to ~25º over 18 hours, gives a white precipitate from which the ***R*(-)-*enantiomer*** (>99.5% 'ee') is isolated. The absolute configuration was obtained from the X-ray crystallographic structure determination of the *R*-dibenzoyl-D-tatrate salt (for definition of the ***chiral descriptor notation*** see R.S. Chan, C.K. Ingold and V. Prelog *Angew Chem Int Ed* **5** 385 *1966*, DOI: 10.1002/anie.196603851). From the mother liquors the ***S*(+)-*enantiomer*** (>99.5% 'ee') was isolated by washing the diastereomeric tartrate salt (in $CHCl_3$) with 0.5M aqueous NaOH. They are white solids that are separated by SFC (supercritical fluid chromatography using a 25cm Hewlett Packard Chiracel AD column with 15% MeOH/supercritical CO_2 at 1.0ml/minute) with retention times of 13.0 minutes for the *R*-isomer and 17.8 minutes for the *S*-isomer, and they have $[\alpha]_D^{25}$ -104 and $[\alpha]_D^{25}$ +104 (c 0.1, EtOH) respectively. When *R*-4,12-bis(diphenylphosphinyl)-[2.2]-paracyclophane (4.0g, 6.58mmol) is treated with Cl_3SiH (10ml, 99mmol, *10025-78-2*] in *p*-xylene (80ml), and slowly heated to 140º, kept at this temperature for 18 hours, a further aliquot of Cl_3SiH (5ml, 49.5mmol) is added, and heating is continued for 24 hours, the reduction appears complete. The mixture is then cooled to -10º, quenched with 30% aqueous NaOH (60ml, care violent reaction), extracted with EtOAc (3 x 80ml), the extract is dried ($MgSO_4$), filtered and evaporated to dryness. Degassed MeOH (30ml, by sonication) is added to the residue which

is filtered and dried to give the pure diphosphino ***R-[2.2]PHANEPhos*** as a white solid. It has ^{1}H NMR (400MHz, $CDCl_3$, with residual $CHCl_3$ as reference at δ 7.27) with δ_H at 7.54, (m, 2H), 7.45 (m, 3H), 7.41 (m, 2H), 7.24 (m, 3H), 6.62 (*ortho and meta*, 2H), 6.58 (dd, *J* = 7.6 and 5.0Hz, 1H), 3.13 (m, 1H), 3.03 (*ortho and meta*, 2H), 2.65 (m, 1H); for ^{13}C NMR see references, and ^{31}P NMR (160MHz, $CDCl_3$, referenced to external 85% H_3PO_4 at δ 0.0) with δ_P at -0.53. The enantiomeric ***S-[2.2]PHANEPhos*** is similarly obtained.

Rh(COD){(*R*)-[2.2]PHANEPhosS}$^+$ OTf$^-$ is prepared using Schlenk equipment under N_2 from the red solution of *R*-[2.2]PHANEPhos (630mg, 1.09mmol) and $[(Rh\ COD)]_2^+$ OTf^- (512mg, 1.09mmol, see *12092-47-6* for chloride, cf. Catalysts-Part 2), in CH_2Cl_2 (10ml) which is stirred for 30 minutes, evaporated *in vacuo*, MeO-*t*-Bu (10ml) is added to the residue, sonicated for 30 minutes, stirred vigorously for 30 minutes, filtered and the solid is dried under N_2 to give the orange *R*- precatalyst (860mg, 85%). It has ^{1}H NMR (400MHz, $CDCl_3$, with residual $CHCl_3$ as reference at δ 7.27) with δ_H at 8.58 (m, 2H), 7.85 (m, 1H), 7.31 (m, 2H), 7.59 (m, 1H), 7.43 (m, 1H), 7.36 (m, 2H), 7.19 (m, 2H), 6.55 (br d, *J* = 8.0Hz, 1H), 6.43 (dd, *J* = 8.0 and 4.0Hz, 1H), 4.50 (br s, 2H), 2.77 (m, 1H), 2.67 (m, 1H), 2.54 (m, 1H), 2.48 (m, 1H), 2.20 (om, 3H), 2.03 (m, 1H); for ^{13}C NMR see references; and ^{31}P NMR (160MHz, $CDCl_3$, referenced to external 85% H_3PO_4 at δ 0.0) has δ_P at 32.7 (d, $J_{P\text{-}Rh}$ = 146.1Hz). The enantiomeric ***Rh(COD){(S)-[2.2]PHANEPhosS}$^+$ OTf$^-$*** is similarly prepared. [Pye, Rossen et al. *J Am Chem Soc* **119** 6207 *1997*, DOI: 10.1021/ja970654g.] For the catalytic hydrogenation of β-keto esters to β-hydroxy esters using ***Ru(II){[2.2]PHANEPhos}(trifluoroacetate)$_2$*** with up to 96% 'ee'', see Pye, Rossen et al. *Tetrahedron Lett* **39** 4441 *1998*, DOI: 10.1016/S0040-4039(98)00842-9.

R*(-)- and *S*(+)- 4,12-Bis[di(3,5-xylyl)phosphino)-[2.2]-paracyclophane {*R*- and *S*- xylyl-PHANEPhos, (*R*)- and (*S*)-5,11-bis[di(3,5-xylyl)phenylphosphino)-tricyclo-[8.2.2.2^{4,7}]hexadeca-hexaene}** *[(R) 325168-89-6; (S) 325168-88-5]* **$C_{48}H_{50}P_2$, M 688.9, m 234-238°, $[\alpha]_D^{22}$ *R* -61.0, *S* +61.0 (c 0.1, EtOH).** These chiral ligands are prepared and purified in much the same way as for [2.2]PHANEPhos above except that 3,5-dimethylphenylphosphinyl chloride is used to introduce the phosphorous group into the *p*-cyclophane. When these enantiomers are complexed with ruthenium and chiral ethylenediamine-type bases, they form powerful precatalysts that in the presence of H_2, will catalyse the reduction of a range of simple aromatic, heteroaromatic as well as α,β-unsaturated ketones with high 'ee' values. Only one example, ***R-{[xylyl-PHANEPhos]-Ru$_2$Cl(S,S)-DPEN} is described here. It is prepared from the red solution of $[(C_6H_6)RuCl_2]_2$ (218mg, 0.436mmol, see *[37366-09-9]*), *R*-xylyl-PHANEPhos (0.60mg, 0.871mmol) in dry DMF (6ml) by heating at 100° for 4 hours, to which is then added ***S,S-1,2-diphenylethylene-1,2-diamine*** (185mg, 0.871mmol, *S,S*-DPEN, [29841-69-8]), and heating, and stirring is continued at 100° for 1.5 hours. The mixture is filtered, the filtrate is evaporated *in vacuo*, treated with Et_2O (10ml) and MeOH (100), the yellow catalyst is filtered off, washed with MeOH (12ml) and dried (420mg, 45% yield). It has ^{1}H NMR (400MHz, $CDCl_3$) with δ_H at 1.78 (ddd, *J* = 15.0, 10.5, 4.5Hz, 1H), 2.07 (s, 6H), 2.27 (s, 6H), 2.59 (s, 1H), 2.78 (m, 1H), 4.01 (m, 1H), 4.40 (m, 1H), 4.49 (m, 1H), 6.36 (d, *J* = 8.0Hz), 6.42 (d, *J* = 8.0Hz), 6.60 (m, 2H), 6.79 (m, 1H), 6.96 (m, 2H), 7.06 (s, 1H), 7.13 (m, 3H), 8.04 (m, 2H), 8.21 (m, 1H); and ^{31}P NMR (162MHz, $CDCl_3$, referenced to external 85% H_3PO_4 at δ 0.0) with δ_P at +46.06 (s). The crude catalysts performed equally as well as the ***purified precatalysts***. [Burk et al. *Org Lett* **2** 4173 *2000*, DOI: 10.1021/ol000309n.]

{1,2-Bis[(4*S*)-4-isopropyl-2-oxazolin-2-yl]benzene}zinc(II) Chloride *[131380-93-3]* **$C_{18}H_{24}N_2O_2ZnCl_2$, M 436.7, m 202°.** The zinc complex is obtained by adding a solution of the free ligand (300mg, 1mmol, see *[131380-80-8]*) in dry THF (5ml) to a solution of fused anhydrous $ZnCl_2$ (136mg, 1mmol, dried by melting in high vacuum and cooling under argon] in dry THF (10ml) and collecting the crystals, but if crystals are not readily formed, evaporate to dryness and recrystallise the residue from EtOH to give the colourless complex (420mg, 98%). It has IR (KBr) with ν_{max} at 1655 (C=N) cm^{-1}; the ^{1}H NMR (300MHz, CD_3CN) has δ at 0.84 (d, *J* = 6.9Hz, 6H, $CH(CH_3)_2$), 0.95 (d, *J* = 7.1Hz, 6H, $CH(CH_3)_2$), 2.52-2.62 (m, 2H, $CH(CH_3)_2$), 4.50-4.62 (m, 6H, OCH_2CHN), 7.77-7.81 (m, 2H, 4-H and 5-H), 7.85-7.89 (m, 2H, 3-H and 6-H) from TMS; for the ^{13}C NMR see reference. [Bolm et al. *Chem Ber* **124** 1173 *1991*, DOI: 10.1002/cber.19911240532.] Like many chiral bis(oxazolin-2-yl) complexes it can be involved in a variety of metal catalysed asymmetric synthesis such as allylation, aziridination, cyclopropanation, Diels-Alder and retro Diels Alder, Mukaiyama aldol condensation and hydrosilylation [see reviews by Ghosh et al. *Tetrahedron: Asymmetry* **9** 1 *1998*, DOI: 10.1016/S0957-4166(97)00593-4; Pflatz *Acta Chem Scand* **50** 189 *1996*, DOI: 10.3891/acta.chem.scand.50-0189; Johnson & Evans *Acc Chem Res* **33** 325 *2000*, DOI: 10.1021/ar960062n; Jørgensen et al. *Acc Chem Res* **32** 605 *1999*, DOI: 10.1021/ar970347f.]

1,3-Bis(2,4,6-trimethylphenyl)-imidazol-2-ylidenegold(I) chloride (IMesAuCl) *[852445-81-9]* **$C_{21}H_{25}N_2AuCl$, M 537.8, m ~280-286°.** The gold complex is prepared by adding Ag_2O (0.5mmol) to $IMes^+$ Cl^- (1mmol) in CH_2Cl_2 and the suspension is stirred for 3 hours at ~25° whereby it became clear; then a solution of $Au(Me_2S)Cl$ (1mmol, see *[29892-37-3]*) in CH_2Cl_2 is added dropwise and stirred for a further 4 hours. After filtration through Celite, the filtrate is evaporated to a small volume and hexane is added to allow the complex to separate. It is collected and dried (49% yield). Its ^1H NMR (400MHz, $CDCl_3$, TMS) has δ_H at 7.08 (s, 2H), 6.97 (bs, 4H), 2.33 (s, 6H), 2.09 (s, 12H), for ^{13}C NMR and HRMS-FAB see reference. It catalyses the intramolecular [4+2] cycloadditions of 1-en-6-ynes, or aralkynes with alkenes, in the presence of $AgSbF_6$; also the related ***1-methyl-3-(2,4,6-trimethylphenyl)-imidazol-2ylgold(I) chloride*** is almost equally effective [Nieto-Oberhuber *J Am Chem Soc* **127** 6178 *2005*, DOI: 10.1021/ja042257t]. [For X-ray structure of dimeric PF_6 salt see Hu et al. *Organometallics* **23** 755 *2004*, DOI: 10.1021/om0341855.]
The saturated 4,5-dihydro- analogue **1,3-bis(2,4,6-trimethylphenyl)-imidazolin-2-ylidenegold(I) chloride (ISMeAuCl)** *[852445-82-0]* **$C_{21}H_{227}N_2AuCl$, M 539.9,** behaves in much the same manner as IMesAuCl, chemically and catalytically. It has recently been shown that both IMesAuCl and SIMesAuCl can be made by metal exchange from the cheaper respective IMesCuCl and SIMesCuCl (see below) in 71-90% yields. Thus a mixture of $[AuCl(SMe_2)]$ (0.4-0.47mmol, *[29892-37-3]*) and [CuCl(NHC)] (1 equivalent) in CH_2Cl_2 (5ml) is stirred at 40° for 1-2 hours, then filtered through Celite and the solvent is removed *in vacuo*. CH_2Cl_2 (3ml) and petroleum ether (10ml) are added to the residue, the ***almost pure Au complex*** is filtered off, washed with petroleum ether (3 x 5ml) until colourless, and dried *in vacuo*. Their catalytic activities from these different preparations are the same. [Furst & Cazin *Chem Commun* **46** 6924 *2010*, DOI: 10.1039/C0CC02308F.]

Chloro[(1,1'-biphenyl-2-yl)di-*tert*-butylphosphine]gold(I) (JohnPhos-gold(I) chloride, JohnPhos-AuCl) *[854045-93-5]* **$C_{20}H_{27}PAuCl$, M 530.8, m 237-240°.** The gold complex is made from sodium tetrachloroaurate(III) dihydrate *[13874-02-7]* or hydrogen tetrachloroaurate(III) [see *16961-25-4]* (1 mmol) in H_2O and the yellow solution is cooled in ice, to which is added ***bis(2-hydroxyethyl)sulfide*** [see *111-48-8*] (3mmol) dropwise over ~45 minutes with stirring. Then a solution of JohnPhos *[224311-51-7]* (1mmol) in EtOH is added dropwise, whereby the gold complex separates as a white solid which is filtered off (43% yield), washed with MeOH and dried *in vacuo*. The ^1H NMR (400MHz, $CDCl_3$) has δ_H at 7.87 (td, J = 7.7, 1.7Hz, 1H), 7.51 (m, 5H), 7.31 (m, 1H), 7.13 (dd, J = 8.0, 1.0Hz, 2H), 1.41 (d, J = 15.6Hz, 18H); the ^{31}P NMR (160MHz, $CDCl_3$) has δ_P at 63.11; and for ^{13}C NMR and HRMS-ESI see references. [Nieto-Oberhuber et al. *J Am Chem Soc* **127** 6168 *2005*, Al-Sa'Ady et al. *Inorg Synth* **23** 191 *1985*, DOI: 10.1002/9780470132548.ch39.]
The acetonitrile complex salt derivative ***(acetonitrile)(2-biphenyl)-di-tert-butylphosphinogold(I) hexafluoro-antimonate*** *[866641-66-9]* **M 772.1,** has **m 198-203°(dec).** It catalyses a highly efficient intramolecular addition of β-ketoamide to unactivated olefins leading to highly substituted lactams in the presence of AgOTf (e.g. *N*-allyl *N*-benzyl benzoylacetamide to *cis*-3-benzoyl-1-benzyl-4-methylpyrrolidin-2-one in 99% yield [Zhou & Che *J Am Chem Soc* **129** 5828 *2007*, DOI: 10.1021/ja070027j]. JohnPhos-AuCl and related complexes, in the presence of $AgSbF_6$ (see SbF_6^- salts), catalyse intramolecular [4+2] cycloadditions of 1,3-enynes or arylalkynes and alkenes very efficiently [Nieto-Oberhuber et al. *J Am Chem Soc* **127** 6178 *2005*, DOI: 10.1021/ja042257t].

Chloro[2-dicyclohexyl(2',4',6'-tri-isopropylbiphenyl)phosphine]gold(I) [X-Phos-gold(I) chloride, X-Phos-AuCl)] *[854045-94-6]* **$C_{33}H_{49}PAuCl$, M 709.1, m 243-250°.** This complex is prepared in much the same way as JohnPhos-AuCl but using a solution containing 1mmol of X-Phos *[564483-18-7]* in EtOH instead and giving a 61% yield of the X-Phos-AuCl as a white solid. The ^1H NMR (400MHz, $CDCl_3$) has δ_H at 7.57-7.55 (m,2H), 7.23 (m, 1H), 7.05 (s, 2H), 2.95 (hept, J = 7.0Hz, 1H), 2.21 (hept, J = 6.7Hz, 2H), 2.05-2.01 (m, 4H), 1.83-1.71 (m, 6H), 1.67-1.61 (m, 2H), 1.53-1.42 (m, 3H), 1.35 (s, 3H), 1.34 (s, 3H), 1.28 (s, 3H), 1.26 (s, 3H), 1.23-1.13 (m, 7H), 0.92 (s, 3H), 0.91 (s, 3H); the ^{31}P NMR (160MHz, $CDCl_3$) has δ_P at 38.48; and for ^{13}C NMR and HRMS-ESI see references. [Nieto-Oberhuber et al. *J Am Chem Soc* **127** 6178 *2005*, DOI: 10.1021/ja042257t; Al-Sa'Ady et al. *Inorg Synth* **23** 191 *1985*, DOI: 10.1002/9780470132548.ch39.] Its catalytic activities are similar to those of JohnPhos-AuCl above.

Chloro(triphenylphosphine)gold(I) *[14243-64-2]* **$[(C_6H_5)_3P]AuCl$, M 495.7, m 240-241°, 242-243°.** Ph_3PAuCl is prepared under argon by adding a solution of hydrogen tetrachloroaurate (2.0g, 5.87mmol, $H[AuCl_4].nH_2O$, n ~3, 'brown gold chloride' see *[16903-35-8]*) in EtOH (10ml), which has been filtered to remove any insoluble Au-containing material, to a stirred solution of Ph_3P (3.08g, 11.7mmol) in absolute EtOH

(50ml of 100%, warm if necessary to dissolve). The solution immediately becomes colourless and after stirring for 15 mnutes the white microcrystalline solid is collected (fritted glass filter, porosity 4), washed with EtOH (2 x 5ml), then Et_3O (3 x 15ml), and dried *in vacuo* (0.1mm) to give the analytically pure complex (1.9-2.3g 67-80%, or up to 92% if equipment is thoroughly dried, solvents degassed, and working in an strict inert atmosphere). It (~1.g) crystallises from CH_2Cl_2 (10ml) by slow addition of *n*-pentane (60ml) and cooling to -25º to give small slender white needles within a few minutes, and it also crystallises from $CHCl_3$ solution by addition of heptane. [Braunstein et al. *Inorg Synth* **27** 218 *1990*, DOI: 10.1002/9780470132586.ch42; Bruce et al. *Inorg Synth* **26** 324 *1986*, DOI: 10.1002/9780470132579.ch59; cf. JohnPhos-AuCl above.]. Ph_3PAuCl has also been prepared by adding Ph_3P (1.5g) in Me_2CO (5ml) to a solution of $HAuCl_4$ (1g, 0.5mol equivalents, 'chlorogold(III) acid' see *[16903-35-8]*) in Me_2CO at 20º. The volume of the solution is reduced to *ca* 5ml and the complex that separates (1.2g, 83%) is collected and dried or crystallised as before [Burgess et al. *JCS Dalton Trans* 1661 *1983*, DOI: 10.1039/DT9830001661]. ***Alternatively***, to the orange solution of sodium tetrachloroaurate(III).$2H_2O$ (1mmol, *[13874-02-7]*) dissolved in $2H_2O$, cooled in ice, is slowly added 2,2'-thiodiethanol {3mmol, i.e. bis(2-hydroxyethyl)sulfide *[see 111-48-8]*} at 0º during ~45 minutes, followed dropwise by a solution of the Ph_3P ligand (1mmol, or other PX_3 ligand) in EtOH which causes a white solid to separate. This is filtered off, washed with MeOH, and dried *in vacuo* (0.1mm) to give Ph_3PAuCl (or other PX_3AuCl) as a white solid in ~88% yield. It is recrystallised as described above. [Li et al. *J Org Chem* **73** 4323 *2008*, DOI: 10.1021/jo8003875]. The ^1H NMR (400MHz, $CDCl_3$) has δ_H at 2.03-1.93 (m, 9H), 1.89-1.85 (m, 6H), 1.75-1.72 (m, 3H), 1.52-1.41 (m, 6H), 1.35-1.21 (m, 9H); the ^{31}P NMR (160MHz, $CDCl_3$) has δ_P at 57.12 (34.224ppm reported also at 300MHz, $CDCl_3$, from external H_3PO_4); and for ^{13}C NMR and HRMS-ESI see references. [Nieto-Oberhuber et al. *J Am Chem Soc* **127** 6178 *2005*, DOI: 10.1021/ja042257t; Al-Sa'Ady et al. *Inorg Synth* **23** 191 *1985*, DOI: 10.1002/9780470132548.ch39; Li et al. *J Org Chem* **73** 4323 *2008*, DOI: 10.1021/jo8003875.] Its catalytic activities are similar to those of JohnPhos-AuCl above. It has also been used in the cyclisation of *O*-propargyl carbamates to alkylideneoxazolidiones at room temperature, *via* a 5-exo-digonal pathway [Ritter et al. *Synlett* 3309 *2006*, DOI: 10.1055/s-2006-951555]. It is soluble in Me_3CO, CH_2Cl_2, $CHCl_3$, $*C_6H_6$ and THF, but **not** in EtOH or hexane, and is used for the preparation of a variety of Ph_3PAu salts and cluster complexes. It is stable indefinitely in air, and note that ^{31}P NMR studies of Ph_3PAuCl showed no change in the chemical shift (at 33.8ppm in THF) after bubbling O_2 through the solution of 24 hours, indicating how stable it is compared with cationic Ph_3PAu^+ species in the presence of O_2 [Liu et al. *J Am Chem Soc* **128** 11332 *2006*, DOI: 10.1021/ja062610q]. X-Ray crystallography showed that the molecule of Ph_3PAuCl is linear with a P-Au-Cl angle of 179.68º and Au-P distance of 2.235Å [Baenziger et al. *Acta Cryst* **B32** 962 *1976*, DOI: 10.1107/S0567740876004330].

Chlorotris(triphenylphosphine)rhodium(I) (Wilkinson's catalyst) *[14694-95-2]* **$[(C_6H_5)_3P]_3RhCl$, M 925.2, m 138º(dec), 140º(dec), 157-158º(dec).** It is prepared by adding PPh_3 (12g, recrystallised from EtOH to remove any PPh_3O) in hot EtOH (350ml) to $RhCl_3.3H_2O$ (2g) in 95% EtOH (70ml) in a flask purged with N_2, refluxed in the presence of N_2 for 2 hours, and the red solid that is formed is collected on a sintered glass funnel and washed with small volumes of dry Et_2O (50ml) to give the catalyst (6.25g, 88%). It forms dark burgundy crystals from hot EtOH after refluxing for 30 minutes. When the solution is heated for only 5 minutes, orange crystals are formed. Heating the orange crystals in EtOH yields red crystals. Crystallisation from Me_2CO gives the orange crystals. The dimorphic forms have similar IR spectra, but the X-ray diffraction patterns are slighly different. Excess of PPh_3 can be recovered by adding H_2O to the EtOH filtrates from recrystallisation and, collecting it on standing for 2-3 days. [Osborne et al. *J Chem Soc (A)* 1711 *1966*, DOI: 10.1039/J19660001711; Osborn et al. *Inorg Synth* **10** 67 *1967*, DOI: 10.1002/9780470132418.ch12; Bennett & Donaldson *Inorg Chem* **16** 655 *1977,* DOI: 10.1021/ic50169a033.] The solubilities are: in CH_2Cl_2 ~2% (25º), in toluene 0.2% (25º), but less so in Me_2CO, MeOH, BuOH and AcOH, and insoluble in petroleum ethers and cyclohexane. It reacts with donor solvents e.g. pyridine, DMSO and MeCN. Solutions of $RhCl[(PPh_3)_3]$ are ***air sensitive*** absorbing O_2, and as well as the solid, should be stored under O_2-free N_2 or argon. On heating solutions in $*C_6H_6$, toluene or methyl ethyl ketone the chlorine-bridged ***dimer $[(PPh_3)_3RhCl_2Rh(PPh_3)_3]$*** is formed as salmon-red crystals which absorb oxygen even in the solid state, but can be converted to the ***monomer*** in refluxing EtOH containing PPh_3. Red solution of $RhCl[(PPh_3)_3]$ absorb H_2 reversibly at 760mm/25º, become yellow in colour, and are effective in catalysing the reduction of C-C double bonds and triple bonds, often in a selective manner. [Osborn et al. *Inorg Synth* **28** 77 *1990*, DOI: 10.1002/9780470132593.ch17.] The stoichiometric and catalytic reactions of $RhCl[(PPh_3)_3]$ were reviewed by Jardine [*Prog Inorg Chem* **28** 63 *1981*, DOI: 10.1002/ 9780470166291.ch2].

In the presence of 1.5 mol of Et_2Zn, 1 mol of 4-phenylbut-3-ene-2-one (and related α-ene-ones) reacts with 1.7mol of CF_3Cl in THF at 5° to give 4-phenyl-3-(trifluoromethyl)butan-2-one (and related ketones) in moderate yields in the presence of catalytic amounts of $RhCl[(PPh_3)_3]$ (~0.02mol) [Sato, Omote, Ado and Kumadaki *Org Synth* **83** 177 *2006*, DOI: 10.15227/orgsyn.083.0177]. § This catalyst is also available commercially on a styrene-divinylbenzene polymer support. It catalyses efficient cross-coupling of activated alkenyl tosylates with aromatic boronic acids [Wu et al. *Eur J Org Chem* 5260 *2006*, DOI: 10.1002/ejoc.200600469], and the cleavage of allyl phenolic ethers to phenols in the presence of DABCO [Aristegul et al. *Org Lett* **8** 5927 *2006*, DOI: 10.1021/ol062297x]. [See Fieser **1** 140, **2** 448, **3** 325, **4** 559, **5** 736, **6** 652, **8** 109, **9** 113, **15** 90, **16** 86.]

Chromium (III) acetylacetonate [Cr(acac)$_3$] *[21679-31-2]* **$(C_5H_7O_2)_3Cr$, M 349.3, m 212-216°, 216°, b 340°, pK^{25} 4.0 (see chromic chloride).** Purify it by dissolving 6g in hot $*C_6H_6$ (20ml) and adding petroleum ether (75ml) slowly. Cool to room temperature then chill on ice, filter off and dry in air to give 2.9g. It also crystallises from EtOH. It is soluble in heptane, $*C_6H_6$, toluene and pentane-2,4-dione at 20-40°. It forms a 1:2 complex with $CHCl_3$. [Fernelius et al. *Inorg Synth* **5** 130 *1957*, DOI: 10.1002/9780470132364.ch35; Steinbach & Burns *J Am Chem Soc* **80** 1839 *1958*, DOI: 10.1021/ja01541a018; *Beilstein* **1** H 782, **1** II 836, **1** IV 3673.] $Cr(acac)_3$ catalyses the oxidation of methacrylic acid esters in the presence of H_2O_2 which provides a new route to pyruvic esters [Inoue et al. *Chem Lett (Jpn)* **18** 99 *1989*, DOI: 10.1246/cl.1989.99]. **Potential carcinogen**.

Cobalt Oxazoline Palladacycles (COPs) are organocobalt-palladium complexes which catalyse the asymmetric rearrangements of non-chiral allylic trichloroacetamidates with very high enantiomeric selectivity (>90%) to provide chiral allylic amines [it is an aza-Claisen rearrangement, '***The Overman Rearrangement***' Overman & Carpenter *Org React* **66** *2005*, DOI: 10.1002/0471264180.or066.01; Kirsch, Overman and Watson *J Org Chem* **69** 8101 *2004*, DOI: 10.1021/jo0487092]; and in the presence of phenols stereospecific cross-coupling also occurs to provide chiral phenoxyallyl ethers with very high (>90%) enantiomeric selectivity [Kirsch, Overman and White *Org Lett* **9** 911 *2007*, DOI: 10.1021/ol070110b; Overman & Carpenter *Org React* **66** *2005*, DOI: 10.1002/0471264180.or066.01].

(*S*)-(+)-COP-OAc dimer catalyst {*S*(COP-OAc)$_2$, di-μ-acetobis[η^5-(*S*)-(*pR*)-2-(2'-(4'-methylethyl)-oxazolinyl)cyclopentadienyl, 1-*C*-3'-*N*)(η^4-tetraphenylcyclobutadiene)cobalt]dipalladium]} *[222400-03-5]* **$C_{82}H_{72}N_2O_6Co_2Pd_2$, M 1512-2, m 189-194° (250-257° dec.), $[\alpha]_D^{24}$ +942 (c 0.215, $CHCl_3$).** This COP is prepared in a Schlenk flask flushed with argon containing (η^5-(*S*)-2-(4'-methylethyl)-oxazolinyl-cyclopentadienyl)-(η^4-tetraphenylcyclo-butadiene)cobalt (9.6g, 16.2mmol, see *[22240-02-4]*) in glacial acetic acid (96ml) to which is added palladium(II) acetate (3.6g, 16.2mmol, must be recrystallised from $*C_6H_6$), and the red solution is heated at 95° for 30 minutes when an orange precipitate separates. After cooling to ~25°, the solid is collected, washed with glacial acetic acid (50ml) and dried *in vacuo* to give ***almost analytically pure*** *S*-(COP-Ac)$_2$ (8.9g, 73%) as mustard coloured crystals. It has IR (thin film) with ν_{max} at 3061, 2961, 1583 (C=N), 1501, 1417 (acetate bridge), 1366, 1181, 1069 cm^{-1}; ^{1}H NMR (500MHz, $CDCl_3$) with δ_H at -0,01 (d, *J* = 6.6Hz, 3H, C*H*$_3$), 0.46 (d, *J* = 7.1Hz, 3H, C*H*$_3$), 1.72-1,81 (m, 1H, C*H*), 1.96 (s, 3H, C*H*$_3$), 2.98 (td, *J* = 9.0, 3.1Hz, 1H, C*H*), 3.36 (t, *J* = 9.0Hz, 1H, C*H*$_2$), 4.08 (dd, *J* = 8.6, 3.9Hz, 1H, C*H*$_2$), 4.23 (t, *J* = 2.4Hz, 1H, C*H*), 4.62 (d, *J* = 1.4Hz, 1H, C*H*), 4.68 (d, *J* = 2.0Hz, 1H, C*H*), 7.20-7.29 (m, 12H, ArH), 7.64 (m, 8H, ArH); see ^{13}C NMR in refs.

The **(*R*)-(-)-COP-OAc dimer enantiomer** *[849592-74-1]* **$C_{82}H_{72}N_2O_6Co_2Pd_2$, M 1512.2, m 241-251° dec.** is prepared in the same way but using the enantiomeric starting material. [Stevens & Richards *Organometallics* **18** 1346 *1999*, DOI: 10.1021/om980812s; Anderson et al. *Org Synth* **84** 148 *2007*, DOI: 10.15227/orgsyn.084.0148.] The reactions of trichloroacetimidate derivatives of *Z*-2-alken-1-ols with phenolic nucleophiles in the presence of chiral COP-OAc dimer catalysts provide 3-aryloxy-1-alkenes in high yields (63-90%) and high enantiomeric purity (90-97% 'ee'); and are compatible with the presence of base-labile substituents in either reactant [Kirsch, Overman and White *Org Lett* **9** 911 *2007*, DOI: 10.1021/ol070110b].

(*S*)-(+)-COP-Cl dimer catalyst {*S*(COP-Cl)$_2$, di-μ-chlorobis[η^5-(*S*)-(*pR*)-2-(2'-(4'-methylethyl)-oxazolinyl)cyclopentadienyl, 1-*C*-3'-*N*)(η^4-tetraphenylcyclobutadiene)cobalt]dipalladium]} *[581093-92-7]* **$C_{78}H_{66}Cl_2N_2O_2Co_2Pd_2$, M 1464.98, m 204-205°, $[\alpha]_D^{20}$ +1201 (c 0.1, CH_2Cl_2).** It is obtained from the above *S*-(COP-OAc)$_2$ (8.9g, 5.9mmol) in acetone (59ml) by stirring vigorously at ~25° with aqueous NaCl (2M, 30ml) to give a homogeneous mixture until the reaction is complete (~4 hours, checked periodically by sampling a filtered aliquot and examining the ^{1}H NMR spectra). The yellow complex which separates is filtered off, washed

with H_2O (125ml) then Me_2CO (20ml) and dried *in vacuo* to give almost pure $(COP\text{-}Cl)_2$ (8.2g, 95%) as a mustard coloured solid. It can be purified further by filtering a solution in CH_2Cl_2 through a short plug of Celite and eluting with CH_2Cl_2 to give an ***analytically pure*** orange solid (97% recovery) which exists as a ***1.0:0.7 mixture of dimers***. It has IR (thin film) with ν_{max} at 3061, 2961, 1602, 1502, 1370, 1185 cm^{-1}; the ^1H NMR (500MHz, $CDCl_3$) has δ_H at 0.70-0.74 (m, 6H, C*H*$_3$), 0.76 (d, *J* = 6.8Hz, 3H, C*H*$_3$), 0.80 (d, *J* = 7.0Hz, 3H, C*H*$_3$), 2.20-2.33 (m, 2H, C*H*), 3.03-3.15 (m, 2H, C*H*), 3.34 (t, *J* = 9.0Hz, 1H, *CH*$_2$), 3.43 (t, *J* = 8.9Hz, 1H, C*H*$_2$), 4.16-4.22 (m, 2H, C*H*$_2$), 4.28 (t, *J* = 2.5Hz, 1H, C*H*), 4.40 (t, *J* = 2.5Hz, 1H, C*H*), 4.70 (d, *J*= 2.0Hz, 1H, C*H*), 4.73 (d, *J* = 2.0Hz, 1H, C*H*), 4.98 (d, *J* = 1.5Hz, 1H, C*H*), 4.99 (d, *J* = 1.5Hz, 1H, C*H*), *7*.16-7.22 (m, 12H, ArH), *7*.23-7.30 (m, 12H, ArH), 7.58-7.62 (m, 8H, ArH), 7.66-7.71 (m, 8H, ArH); and for ^{13}C NMR see ref. The enantiomeric purity was determined by conversion into the acetylacetonate derivative ***COP-acac*** (see below) and the enantiopurity was shown to be >99% by HPLC [Diacel Chiralpak AD-H (0.46cm x 25cm) column, with1.0ml/minute flow rate and eluted with 95:5 hexanes:*iso*-PrOH]. The retention time for *S*-COP-acac is 5.1 minutes whereas that of *R*-COP-acac would have been ~3.1 minutes [Anderson, Kirsch and Overman *Org Synth* **84** 148 *2007,* DOI: 10.15227/orgsyn.084.0148.]

(*R*)-(-)-COP-Cl dimer catalyst {*R*(COP-Cl)$_2$, di-μ-chlorobis[η^5-(*R*)-(*pR*)-2-(2'-(4'-methylethyl)-oxazolinyl)cyclopentadienyl, 1-*C*-3'-*N*)(η^4-tetraphenylcyclobutadiene)cobalt]dipalladium]} *[612065-00-6]* **$C_{78}H_{66}Cl_2N_2O_2Co_2Pd_2$, M 1464.98, m 205-208°, $[\alpha]_D^{20}$ +1240 (c 0.1, CH_2Cl_2)** is obtained and purified as for its *S*-enantiomer above but using the *R*-enantiomeric intermediates. These planar chiral COP-Cl dimers catalyse the [3+3]-sigmatropic rearrangements of a wide range of non-chiral *E*-allylic trichloroacetim**idates** into the corresponding transposed chiral allylic trichloroacet**amides** (from which the free base can be obtained) in high yields and very high enantioselectivities [Anderson & Overman *J Am Chem Soc* **125** 12412 *2003*, DOI: 10.1021/ja037086r; Anderson, Overman and Watson *Org Synth* **82** 134 *2005*, DOI: 10.15227/orgsyn.082.0134]. The reactions of trichloroacetimidate derivatives of *Z*-2-alken-1-ols with phenolic nucleophiles in the presence of chiral COP-Cl dimer catalysts yield 3-aryloxy-1-alkenes in high yield (63-90%) and high enantiomeric purity (90-97% 'ee'); and are compatible with the presence of base-labile substituents in either reactant [Kirsch, Overman and White *Org Lett* **9** 911 *2007*, DOI: 10.1021/ol070110b].

(*S*)-(+)-COP-acac monomer catalyst {acetylacetonato[η^5-(*S*)-(*pR*)-2-(2'-(4'-methylethyl)-oxazolinyl)cyclopentadien-yl,1-*C*-3'-*N*)-(η^4-tetraphenylcyclobutadiene)cobalt]palladium]} *[805315-09-7]* **$C_{44}H_{40}NO_3CoPd$, M 796.1, m 100-104°(dec.), $[\alpha]_D^{28}$ +246.1, $[\alpha]_{577}^{28}$ +250.2, $[\alpha]_{546}^{28}$ +175.5, $[\alpha]_{435}^{28}$ -59.8, $[\alpha]_{405}^{28}$ -91.4 (c 1.00, $CHCl_3$).** (*S*)-(+)-COP-acac is obtained as a monomer from the above dimer *S*-$(COP\text{-}OAc)_2$ (1.0g, 0.66mmol), sodium acetonylacetonate (954mg, 6.8mmol, see *[15435-71-9]*), Me_2CO (6.6ml) and H_2O (3.3ml) by stirring vigorously for 24 hours at ~25°. The mixture is then extracted with CH_2Cl_2 (10ml), the extract is separated, dried ($MgSO_4$), filtered and concentrated to give almost pure (*S*)-(+)-COP-acac (1.0g, quantitative) as an orange solid. It can be further purified by filtering through a silica-gel column and eluting with *iso*-PrOH:hexanes (5:95) and evaporating the orange band to give an analytically pure complex. See above *S*$(COP\text{-}Cl)_2$ for HPLC data; and it has R_F 0.59 (silica gel, hexanes-EtOAc, 80:20). It has IR (thin film) with ν_{max} at 3058, 2960, 1597, 1579, 1508, 1399, 1265, 1183, 1067 cm^{-1}; the ^1H NMR (400MHz, $CDCl_3$) has δ_H at 7.64 (d, *J*= 7.6Hz, 8H), 7.20-7.30 (m, 12H), 5.26 (s, 1H), 5.17 (s, 1H), 4.89 (d, *J* = 1.6Hz, 1H), 4.47 (s, 1H), 4.27 (dd, *J* = 8.4, 5.6Hz, 1H), 3.67 (t, *J* = 9.0Hz, 1H), 3.29-3.31 (m, 1H), 2.26-2.27 (m, 1H), 2.00 (s, 3H), 1.94 (s, 3H), 0.84 (d, *J* = 7.6Hz, 3H), 0.82 (d, *J* = 8.0Hz, 3H); and for ^{13}C NMR see references. [Kirsch et al. *J Org Chem* **69** 8101 *2004*, DOI: 10.1021/jo0487092; Anderson et al. *Org Synth* **84** 148 *2007*, DOI: 10.15227/orgsyn.084.0148.].

The isomer, **(*R*)-(-)-COP-acac monomer catalyst {acetylacetonato[η^5-(*R*)-(*pR*)-2-(2'-(4'-methyl-ethyl)-oxazolinyl)cyclopentadien-yl,1-*C*-3'-*N*)-(η^4-tetraphenylcyclobutadiene)cobalt]palladium]}** *[CASRN is the same as preceding S-(+)-enantiomer]* **$C_{44}H_{40}NO_3CoPd$, M 796.1, m 100-104°(dec), $[\alpha]_D^{28}$ -246.1, $[\alpha]_{577}^{28}$ -250.2, $[\alpha]_{546}^{28}$ −175.5, $[\alpha]_{435}^{28}$ +59.8, $[\alpha]_{405}^{28}$ +91.4 (c 1.00, $CHCl_3$)** can be obtained and purified as for its *S*-enantiomer above but using the *R*-enantiomeric intermediates. These monomeric COPs catalyse the asymmetric rearrangements of non-chiral allylic trichloro-acetim**idates** into chiral transposed allylic trichloroacet**amides** in good yield with high asymmetric induction (>90% 'ee'). These are more soluble catalysts than the COP dimers, and because they are soluble in a much wider variety of solvents, the reactions can be carried out at high substrate concentrations (e.g. at ~2.6M) [Kirsch et al. *J Org Chem* **69** 8101 *2004*, DOI: 10.1021/jo0487092.]. The reactions of trichloroacetimidate derivatives of *Z*-2-alken-1-ols with phenolic nucleophiles in the presence of

chiral COP-acac monomer catalysts yield 3-aryloxy-1-alkenes in high yield (63-90%) and high enantiomeric purity (90-97% 'ee'); and are compatible with the presence of base-labile substituents in either reactant [Kirsch, Overman and White *Org Lett* **9** 911 *2007*, DOI: 10.1021/ol070110b].

(*S*)-(+)-COP-hfacac {hexafluoroacetylacetonato[η^5-(*S*)-(*pR*)-2-(2'-(4'-methylethyl)oxazolinyl)-cyclopentadienyl,1-*C*-3'-*N*)(η^4-tetraphenylcyclobutadiene)cobalt]palladium]} *[805315-08-6]* **$C_{44}H_{34}F_6NO_3$ CoPd, M 904.0, m 108-110°(dec.) $[\alpha]_D^{28}$ +271.2, $[\alpha]_{577}^{28}$ +277.6, $[\alpha]_{546}^{28}$ +214.8, $[\alpha]_{435}^{28}$ -57.7, $[\alpha]_{405}^{28}$ -86.8 (c 1.02, $CHCl_3$).** (*S*)-(+)-COP-hfacac is obtained as a monomer from the above dimer *S*-(COP-OAc)$_2$ (1.0g, 0.66mmol), sodium hexafluoroacetonylacetonate (1.6g, 6.8mmol, see *[22466-49-5]*), Me_2CO (6.6ml) and H_2O (3.3ml) by stirring vigorously at ~25° for 9-11 hours (check periodically by sampling a filtered aliquot and examining the ^1H NMR spectra until completion). The solid that separates is filtered off, washed with H_2O (10-20ml) and dried *in vacuo* over P_2O_5 to give (*S*)-(+)-COP-hfacac monomer (1.1g, 91%). A pure sample can be obtained by filtration through a short plug of silica gel with CH_2Cl_2 as eluent (in an 89% yield). It has R_F 0.63 (silica gel, hexanes-EtOAc, 80:20). It has IR (thin film) with ν_{max} at 3061, 2964, 1629, 1598, 1509, 1475, 1258, 1208, 1150 cm^{-1}; the ^1H NMR (500MHz, $CDCl_3$) has δ_H at 7.54-7.56 (m, 8H, Ar*H*), 7.19-7.29 (m, 12H, Ar*H*), 5.95 (s, 1H, C*H*), 4.68 (d, *J* = 2.3Hz, 1H, C*H*), 4.90 (d, *J* = 2.3, 1H, C*H*), 4.53 (t, *J* = 2.3Hz, 1H, C*H*), 4.33 (*J* = 8.6, 5.3Hz, 1H, CH_2), 3.72 (t, *J*= 9.4Hz, 1H, CH_2), 3.45 (td, *J* = 9.4, 5.1Hz, 1H, C*H*), 2.05-2.08 (m, 1H, C*H*), 0.83 (d, *J* = 7.0Hz, 3H, CH_3), 0.79 (d, *J* = 6.9Hz, 3H, CH_3); and the ^{13}C NMR (125MHz, $CDCl_3$) has δ_C at 14.9, 18.4, 29.3, 65.3, 72.3, 76.7, 78.9, 84.1, 84.8, 87.7, 90.1, 97.6, 116.6, 118.8, 126.5, 127.9, 128.9, 135.5, 173.3, 173.6, 174.1. [Kirsch et al. *J Org Chem* **69** 8101 *2004*, DOI: 10.1021/jo0487092; Anderson et al. *Org Synth* **84** 148 *2007*, DOI: 10.15227/orgsyn.084.0148.]

Enantiomer **(*R*)-(-)-COP-hfacac {hexafluoroacetylacetonato[η^5-(*R*)-(*pR*)-2-(2'-(4'-methylethyl)-oxazolinyl)-cyclopentadienyl,1-*C*-3'-*N*)(η^4-tetraphenylcyclobutadiene)cobalt]palladium]}** *[CASRN is given the same as preceding S-(+)-enantiomer]* **$C_{44}H_{34}F_6NO_3$ CoPd, M 904.0, m 108-110°(dec.), $[\alpha]_D^{28}$ -271.2, $[\alpha]_{577}^{28}$ -277.6, $[\alpha]_{546}^{28}$ −214.8, $[\alpha]_{435}^{28}$ +57.7, $[\alpha]_{405}^{28}$ +86.8 (c 1.02, $CHCl_3$)** can be obtained and purified as for its *S*-enantiomer above but using the *R*-enantiomeric intermediates. These COP-hfacac complexes, like the related COP-acac complexes, are monomeric and more soluble than the dimeric COPs above. They can be used in a variety of solvents, e.g. THF, MeCN, which allow catalytic asymmetric allylacetimidate rearrangements to be performed at high concentrations and using as little as 1 mole% of catalyst. [Anderson et al. *Org Synth* **84** 148 *2007*, DOI: 10.15227/orgsyn.084.0148; Kirsch, Overman and Watson *J Org Chem* **69** 8101 *2004*, DOI: 10.1021/jo0487092]. The reactions of trichloroacetimidate derivatives of *Z*-2-alken-1-ols with phenolic nucleophiles in the presence of chiral COP-acac catalysts yield 3-aryloxy-1-alkenes in high yield (63-90%) and high enantiomeric purity (90-97% 'ee'); and are compatible with the presence of base-labile substituents in either reactant [Kirsch, Overman and White *Org Lett* **9** 911 *2007*, DOI: 10.1021/ol070110b].

Copper(I) [1,3-bis(2,6-di-*iso*-propylphenyl)imidazol-2-ylidene] chloride [1,3-bis(2,6-di-*iso*-propyl-phenyl)imidazol-2-ylidene copper(I) chloride, (IPr)=CuCl] *[578743-87-0]* **$C_{27}H_{36}ClN_2Cu$, M 487.59, m >300°.** This ***NHC (N-heterocyclic carbene)*** precatalyst is readily prepared in analytical purity in a Schlenk flask and under an argon atmosphere. Dry THF (100ml) is added to a mixture of freshly prepared Cu(I)Cl (1.0g, 10.1mmol), 1,3-bis(2,6-di-*iso*-propylphenyl)imidazolinium chloride (4.29g, 10.1mmol, IPr.HCl see *[250285-32-6]*) and Na *tert*-butoxide (0.97g, 10.1mmol), and stirred mechanically under argon at ~25° for 20 hours. The mixture is then filtered through a plug of Celite, and the filtrate is evaporated *in vacuo* to give the complex as a white powder (4.59g, 9.40mmol, 94%), m >300°. Suitable crystals were grown from CH_2Cl_2/hexane solutions and subjected to single-crystal diffraction studies. The molecular structure was as expected with the imidazole C2, Cu and Cl atoms in the same plane, with the C2-Cu bond length of 1.953Å, the Cu-Cl bond length 2.089Å, and the C2—Cu—Cl angle of 180.00°, i.e. is linear. [Kaur et al. *Organometallics* **23** 1157 *2004*, DOI: 10.1021/om034285a]. It has IR (neat on a DiComp probe) with ν_{max} at 2968, 2927, 2871, 1680, 1647, 1470, 1457, 809, 764, and 743 cm^{-1}; the ^1H NMR (500MHz, Me_2CO-d_6, downfield from TMS) has δ_H at 7.26 (s, 2H), 7.57-7.54 (dd, *J* = 15.5 and 8.0Hz, 2H), 7.43-7.41 (d, *J* = 8.0Hz, 4H), 2.70-2.65 (m, 4H), 1.32-1.31 (d, *J* = 7.0Hz, 12H), 1.27-1.25 (d, *J* = 6.5 Hz, 12H); and for ^{13}CNMR and HRMS (EI) see ref. has: found 389.2962, and calculated for $C_{14}H_{16}O$: 389.2951 (M -CuCl) [Jurkauskas et al. *Org Lett* **5** 2417 *2003*, DOI: 10.1021/ol034560p.]**(IPr)=CuCl** catalyses the conjugate reduction of α,β-unsaturated carbonyl compounds with catalytic amounts of the Cu complex, *tert*-BuONa and poly(methylhydrosiloxane) as the stoichiometric reduct-

ant in >81% yields [Jurkauskas et al. *Org Lett* **5** 2417 *2003*, DOI: 10.1021/ol034560p], it catalyses the methenylation of a variety of aliphatic and aromatic aldehydes and ketones in the presence of trimethylsilyldiazomethane ($TMSCHN_2$), Ph_3P and 2-propanol efficiently, and is a cheaper alternative to the corresponding rhodium catalyst [Lebel et al. *J Org Chem* **72** 144 *2007*, DOI: 10.1021/jo061781a], it catalyses the efficient hydrosilylation of ketones with Et_3SiH to yield the corresponding saturated triethylsilylethers [Kaur et al. *Organometallics* **23** 1157 *2004*, DOI: 10.1021/om034285a]. It catalyses the transfer of the ':$CHCO_2Et$' group (from ethyl diazoacetate) to saturated and unsaturated substrates, e.g. olefins, amines or alcohols, in very high yields [Fructos et al. *J Am Chem Soc* **126** 10846 *2004*, DOI: 10.1021/ja047284y], and has been used for the total synthesis of (-)-Angelastin A by catalysing the aziridiylation (using TsN=IPh) *[55962-05-5]*) of a difficult rather electron-deficient cyclopentene intermediate [Trost & Dong *J Am Chem Soc* **128** 6054 *2006*, DOI: 10.1021/ja061105q].

NOTE: More recently it has been shown that the above IPr=CuCl (IPrCuCl) and its 4,5-dihydro-derivative SIPrCuCl, are readily prepared by refluxing ~1.9-2.3mmol of 1,3-bis-(2,6-diisopropylphenyl)imidazolium chloride (IPrCl, see *[250285-32-6]*) or 1,3-bis-(2,6-diisopropylphenyl)imidazoliniuum chloride (SIPrCl, see [25278-25-0]) with Cu_2O (~1.4-1.5mmol, ~95% purity, *ca* 0.65 equivalents) for 24 hours, then excess of Cu_2O is removed to provide the following respective yields in the solvents indicated: IPrCuCl (78% from toluene, 88% conversion; 94% from H_2O with 96% conversion; 74% from dioxane) or SIPrCuCl (88% from toluene, 99% conversion; 72% from H_2O, 78% conversion). [Cazin and coworkers: Citadelle et al. *JCS Dalton Trans* **39** 4489 *2010*, DOI: 10.1039/C0DT00128G; Son and coworkers: Chun et al. *Organometallics* **29** 1518 *2010*, DOI: 10.1021/om900768w].

Similarly the analogous **[1,3-bis(2,4,6-trimethylphenyl)imidazol-2-ylidene copper(I) chloride, [(IMes)=CuCl]** and the ***4,5-dihydro derivative*** **[1,3-bis(2,4,6-trimethylphenyl)imidazolin-2-ylidene copper(I) chloride [(SIMes)=CuCl**, **S** is for saturated**]** can be prepared from the respective ***IMesCl*** an ***SIMesCl*** with 0.65 equivalents of Cu_2O by refluxing in toluene for 24 hours (in 86% and 71% yields respectively, with 100% conversion), and by refluxing in H_2O for 24 hours (in 98% and 99% yields respectively, with 100% conversion). [Cazin and coworkers: Citadella et al. *JCS Dalton Trans* **39** 4489 *2010*, DOI: 10.1039/C0DT00128G]. These are slightly less catalytically specific than the **IPr** analogues because the latter have slightly greater steric hindrance.

Copper(I) bis-[1,3-bis(2,6-di-*iso*-propylphenyl)imidazol-2-ylidene] tetrafluoroborate [$(IPr)_2Cu^+$ BF_4^-] *[886061-48-9]* **$C_{54}H_{72}N_4CuBF_4$, M 927.5, m >300°.** This copper catalyst is prepared in an oven dried septum screw capped vial (in a glove box) by mixing tetrakis(acetonitrile)copper (I) tetrafluoroborate (186mg, 0.5mmol), IPr.Cl (157mg, 0.5mmol, see *[250285-32-6]*) and *ter*-BuONa (96mg, 1mmol), sealing, then injecting THF (10ml) and stirring outside the box at ~25° for 6 hours. The mixture is filtered through a plug of Celite (THF), and the Cu complex salt is precipitated by adding excess hexane, filtered off, and dried *in vacuo* to give the pure white *tetrafluoroborate* (452mg, 92%). It has ^1H NMR (400MHz, Me_2CO-d_6) with δ at 7.54 (t containing a singlet at 7.55, *J* = 7.5 Hz, 8H, *p*-C*H* + NC*H*), 7.25 (d, *J* = 7.5 Hz, 8H, *m*-C*H*), 2.40 (septet, *J* = 6.8Hz, 8H, C*H*(CH_3)$_2$), 1.04 (d, *J* = 6.8Hz, 24H, CH_3), 0.94 (d, *J* = 6.8Hz, 24H, CH_3); and for ^{13}CNMR see references. The ***hexafluorophosphate salt*** is similarly prepared in 96% yield starting from tetrakis(acetonitrile)copper (I) hexafluorophosphate *[64443-05-6]*. The structure of these salts was shown by X-ray crystal analysis (crystals grown from CH_2Cl_2-methyl *tert*-butyl ether solution) to consist of two ***N-heterocyclic carbenes (NHCs)*** attached to one Cu atom. These salts are air- and moisture- stable and are highly active catalysts for the hydroxysilylation of ketones with varying steric constraints, aldehydes and enolisable aldehydes, and esters in THF at ~25°, in the presence of Et_3SiH and *ter*-BuONa in >90% yields [Díez-González et al. *Organometallics* **25** 2355 *2006*, DOI: 10.1021/om0600487].

Diacetato[*(R)*-(+)- and *(S)*-(−)- 2,2'-Bis(diphenylphospheno)-1,1'-binaphthyl]ruthenium(II) [*R*- and *S*-(BINAP)$_2$ Ru(II) (OAc)$_2$] *[(R) 325146-81-4 diacetato, (S) 261948-85-0 diacetato*; *(R) 132071-87-5 dichloro*, *(S) 134524-84-8*; *dichloro]* **$C_{48}H_{38}O_4P_2Ru$, M 841.8, m 185-187°(dec,), 186-188°(dec.), 188-190°(dec.), *R*-λ_{max} 335nm (Δε/mol^{-1}.dcm^3.cm^{-1} +4.5) and λ_{max} 450nm (Δε/mol^{-1}. dcm^3.cm^{-1} +2.5); *S*- λ_{max} 335nm (Δε/mol^{-1}.dcm^3.cm^{-1} -4.5) and λ_{max} 450nm (Δε/mol^{-1} dcm^3 cm^{-1} -2.5); (c 6.5 x 10^{-5} M, CH_2Cl_2).** Typically, the *S-enantiomer* is prepared in a Schlenk tube under dry argon, by dissolving (*S*)-BINAP (1.37g, 2.20mmol, see [76189-56-5]) and $[RuCl_2(COD)]_n$ (0.56g, 2.0mmol, calc based on monomer weight, see [50982-12-2] in dry toluene (55ml) containing Et_2NH (1.2ml, 8.6mmol), and the brown suspension is refluxed with stirring for 12 hours. The clear reddish brown solution is cooled to ~25°, the solvent is removed *in vacuo* and the

brown solid residue is dissolved in CH_2Cl_2 (40ml), filtered through a Celite pad and the filtrate is evaporated *in vacuo*. A solution of anhydrous NaOAc (0.88g, 11mmol) in *t*-BuOH (107ml) is added to the residue, stirred under reflux for 12 hours in an argon atmosphere, the solvent is removed *in vacuo* and the residue is extracted with absolute Et_2O (3 x 20ml) and evaporated again *in vacuo*. The brown residue is extracted several times with absolute EtOH (70ml total) and evaporated *in vacuo* to give a yellow-brown solid (1.58g) which is recrystallised from toluene (12ml)/hexane (30ml) mixture to afford purer complex (1.23g, 68% yield). This sample is pure enough for providing good catalytic activity for asymmetric hydrogenations. Analytical purity (to give 0.9g, 50%, 188-190º dec.) can be achieved by further recrystallisation from toluene (14ml)/hexane (13ml), and another amount (0.3g, 17%) can be recovered from the mother liquors by evaporation and recrystallisation of the residue (from 8ml of toluene and 10ml of hexane). Crystals of analytical material were subjected to X-ray structure determination that gave the required ***absolute configuration*** of the complex, and the circular dichroism spectrum of it and its enantiomer were consistent with the X-ray structure. It has IR (CH_2Cl_2) with ν_{max} at 1452, 1518 cm^{-1}; and ^1H NMR (400MHz, $CDCl_3$, TMS) with δ_H at 1.80 (s, 2 $OCOCH_3$), 6.47-7.84 (m, aromatic H); and for $^{13}C\{^1H\}$ NMR see references. The ***R-enantiomer*** can be prepared and purified in the same way.
The enantiomers of this complex catalyse the asymmetric hydrogenation of pro-chiral ketones and olefins in high yields and 'ee' values. [Ohta, Takaya and Noyori *Inorg Chem* **27** 566 *1988*, DOI: 10.1021/ic00276a025; Kumobyashi et al. *Synlett* 1055 *2001*, DOI: 10.1055/s-2001-14625] RhBINAP complexes with ligands other than acetate, e.g. Cl_2 (see *dichloro* in title of entry), $*C_6H_6$, $(OCO\text{-}t\text{-}Bu)_2$, $(OCOCMe{=}CHMe)_2$ also catalyse asymmetric hydrogenations, isomerisations and asymmetric Heck reactions [Shimizu, Nagasaki and Saito *Tetrahedron* **61** 5405 *2005*, DOI: 10.1016/j.tet.2005.03.022.] An excellent asymmetric hydrogenation catalyst for α-(acylmino)acrylic acids to give the corresponding ***chiral α-aminoacylpropionic acids*** with high 'ee'-ratios is **(*S*)-[(BINAP)$Rh^+(OMe)_2$] ClO_4^-**. It is obtained (together with norbornane) when a solution of ***(S)-[(BINAP)Rh^+(norbornadiene)] ClO_4^-*** in MeOH is exposed to H_2 at room temperature. Exactly 2mols are absorbed, and it is isolated as deep red prisms whose ^1H NMR (CD_2Cl_2, TMS) has δ_H at 7,50 (m) and 6.82 (BINAP), 3.42 (s, CH_3O); and ^{31}PNMR (CD_3OD with 5% H_3PO_4 in CD_3OD as external standard) has δ at 53.1 (d, $J_{Rh\text{-}P}$ = 206Hz)]. It loses MeOH *in vacuo* to give an ***equally active catalyst***. [Myashita et al. *J Am Chem Soc* **102** 7932 *1980*, DOI: 10.1021/ja00547a020.]

Dichloro(1,5-cyclooctadiene)palladium(II) [Pd(COD)Cl_2] *[12107-56-1]* **$C_8H_{12}PdCl_2$, M 285.5, m 210º (dec).** This air-stable catalyst can be prepared by adding 1,5-cyclooctadiene (3ml, 2.2mol, *[111-78-4]*) to a cooled and filtered solution of $PdCl_2$ (2.0g, 1 mol) and concentrated HCl (150ml, warm) in EtOH (150ml), whereby the yellow complex separates immediately. After keeping for 10 minutes the solid is filtered off, washed with Et_2O (3 x 30ml) and dried *in vacuo* (3.1g, 96%). The yellow powder is recrystallised by boiling in CH_2Cl_2 (200ml), and evaporating until the onset of crystals. ***Dibromo(1,5-cyclooctadiene)palladium(II) [Pd(COD)Br_2)]*** *[12145-47-0]* **$C_8H_{12}PdBr_2$, M 374.4, m 213º (dec)**, is obtained from the dichloride and NaBr in Me_2CO, or as above from $PdCl_2$/HCl in the presence of NaBr before adding the diene. [Drew et al. *Inorg Synthesis,* Coll Vol **28** 346 *1990*, DOI: 10.1002/9780470132593.ch89; **13** 47 *1972* DOI: 10.1002/9780470132449.ch11.] ***Alternatively***, a solution of sodium chloropalladite tetrahydrate (2g) in MeOH (75ml) and the diene (2ml) can be used, and the pale orange-yellow complex is collected after 1 hour and is recrystallised from glacial AcOH.
[Pd(COD)Br_2] can also be prepared from the dichloride (0.45g) and LiBr (0.1g) in Me_2CO (20ml), boiled under reflux for 2 hours, filtered and the filtrate is evaporated to dryness in a vacuum (15mm), the residue is washed with H_2O, dried (0.22g) and is recrystallised from AcOH (orange-red needles). [Chatt et al. *J Chem Soc* 3413 *1957*, DOI: 10.1039/JR9570003413.] The ***dichloro-complex*** is sparingly soluble in cold EtOH and $*C_6H_6$, but is more soluble in hot $*C_6H_6$, $CHCl_3$, Me_2CO, MeEtCO, $(EtO)_2CO$, tetrahydrothiophene 1,1-dioxide (sulfolane) and nitrobenzene. It reacts with Me_2SO to form ***Pd(II)Cl_2(Me_2SO)$_2$***. The IR (Nujol) has ν_{max} at 1489, 1419, 1337, 1088, 999, 867, 825, 794, 768 325 and 295 cm^{-1}; and the ^1H NMR ($CDCl_3$) has δ at 2.69 (CH_2 protons) and 6.32 (CH=CH protons). The ***dibromo-complex*** is similarly ***air-stable*** and has similar solubilities in solvents, and for IR (Nujol) see references. The ^1H NMR ($CDCl_3$) has δ at 2.60 (CH_2 protons) and 6.32 (C_2H_2=CH protons).

Dichloro(1,5-cyclooctadiene)platinum(II) [Pt(COD)Cl_2]* *[12080-32-9]* **$C_8H_{12}PtCl_2$, M 374.2, m 220-278º (dec), 285º (dec).** The colourless air-stable dichloro-complex is obtained by adding 1,5-cyclooctadiene* (6ml) to a warm solution (75º) of hydrated chloroplatinic acid (5g) in AcOH (15ml), stirring, and cooling to ~25º then diluting with H_2O (50ml), and the black suspension is kept at ~25º for 1 hour. The black solid is collected,

washed with H_2O (50ml), Et_2O (100ml), then suspended in CH_2Cl_2 (400ml), heated to boiling and kept at this temperature for 5 minutes. The solution is cooled, mixed with chromatographic grade silica gel (5g) and allowed to settle. The supernatant should be colourless, otherwise portions (~1g) of silica gel should be added until the supernatant is colourless. The solid is filtered off, washed with CH_2Cl_2 (2x 50ml) and the combined CH_2Cl_2 solutions (~500ml) are evaporated until crystallisation (75ml) occurs. The hot CH_2Cl_2 solution is then poured into petroleum ether (b 60-70°) producing a fine white powder which is collected, washed with petroleum ether (50ml) and dried (2.55g, 80%). Recrystallisation in the same way (dissolving in boiling CH_2Cl_2 and evaporating till crystallisation sets in) yields white macroscopic crystals. It also crystallises from AcOH (charcoal) as white needles. Its solubilities in solvents are similar to those of Pd(COD)Cl_2 above, i.e. being insoluble in most organic solvents except boiling CH_2Cl_2, $CHCl_3$ and AcOH, and decomposes slowly in Me_2SO (cf. related Pd compound above). Its IR (Nujol) has ν_{max} at 1334, 1179, 1333, 1009, 1083, 871, 834, and 782 cm^{-1}; and the ^1H NMR ($CDCl_3$) has δ at 2.71 (CH_2 protons) and 5.62 ($J_{Pt\text{-}H}$ = 65Hz, CH=CH protons). [Drew et al. *Inorg Synthesis*, Coll Vol **28** 346 *1990*, DOI: 10.1002/9780470132593.ch89; **13** 47 *1972*, DOI: 10.1002/9780470132449.ch11.]

Dibromo(1,5-cyclooctadiene)platinum(II) [Pt(COD)Br$_2$] *[12145-48-1]* **$C_8H_{12}PtBr_2$, M 463.1, m 220-278° (dec)** can be obtained from sodium chloroplatinate hydrate (4g), diene (4ml) and LiBr (2g) in EtOH (80-100ml), kept at ~20° for 2 days, and the precipitate is crystallised from AcOH (charcoal) in pale yellow needles. It is slightly more soluble than the chloro-analogue in organic solvents. [Chatt et al. *J Chem Soc* 2496 *1957*, DOI: 10.1039/JR9570002496; *Beilstein* 5 IV 404.]

* ***Dichloro(1,3,5,7-cyclooctatetraene)Platinum(II)***, ***dichloro(dicyclopentadiene)Platinum(II)*** **and** ***dichloro(2,5-norbornadiene)Platinum(II)*** have been prepared successfully by this procedure using the respective alicycles.

Dichloro[(1,2,3,6,7,10,11,12-η)-2,6,10-dodecatriene-1,12-diyl]ruthenium(IV), [(dichloro-2,6,10-dodecatrienylene-ruthenium(IV)] *[12170-97-7]* **$C_{12}H_{18}RuCl_2$, M 334.2, decomposes >200° with part melting at 220°.** This complex is much more stable than the corresponding Ni complex, and is prepared by bubbling butadiene for 7 hours through a solution of $RuCl_3$. $3H_2O$ (0.43g, *[13815-94-6]*) in 2-methoxyethanol (25ml) at 90° in a hot water bath. The deep red solution deposits yellow-brown prisms when cooled. These are filtered off and recrystallised from CH_2Cl_2/petroleum ether (b 40-60°) to give the ***analytically pure complex*** (0.30g, 54.5%) as orange crystals. The IR shows a medium intensity band at ν = 1522 cm^{-1} assigned to the *trans* C=C co-ordinated to the Ru atom; the ^1H NMR (60MHz, $CDCl_3$/TMS) has δ at ~5.4 (m, w = 65Hz, 6H, vinylic and non terminal allylic H), 4.9 (d, *J* = 7.5Hz, 2H, terminal allylic H), 3.76 (d, *J* = 11.2Hz, 2H, terminal allylic H), 3.1 (m, w = 20Hz, 4H, methylene H) and 2.37 (m, w = 35Hz, 4H, methylene H); and the measured molecular weight (osmometry in 1.45% *C_6H_6 solution) is 340. [Nicholson & Shaw *J Chem Soc (A)* 807 *1966*, DOI: 10.1039/J19660000807.] The ^1H NMR is consistent with a Ru atom enveloped by dodeca-2,6,10-triene and co-ordinated to the two terminal allylic double bonds, i.e. butadiene trimerised about the metal atom, and this structure is confirmed by an X-Ray determination. This showed that Ru is bipyramidal, with the Cl atoms at the apices of the pyramids with three co-ordinate bonds (to the allylic and the C6=C7 double bonds) in the central plane. [Lydon et al. *Proc Chem Soc* p 421 (first page 385) *1964*, DOI: 10.1039/ PS9640000385].

The ***dichloro-dodecatriene-ruthenium complex*** is a highly efficient catalyst for the *one-pot* internal redox process that converts allylic alcohols (RC=C-C(OH) into carbonyl compounds (RC-C-C=O, ketones or aldehydes) in the presence of $CsCO_3$ under N_2 with high yields and turnover frequencies (TOF) in THF or H_2O [Cadierno et al. *Chem Commun* 232 *2004*, DOI: 10.1039/B313069J; see also van der Drift et al. *J Organomet Chem* **650** 1 *2002*, DOI: 10.1016/S0022-328X(02)01150-6]. It is also an efficient catalyst for the de-protection of *N*-allylic and *N*-diallylic substrates (with ~3mol% of Ru) in aqueous solution at 90° under N_2 in very high yields (typically >95%) to give the free amine and propionaldehyde (allyl product); and can be carried out on a preparative scale [Cadierno et al. *Chem Commun* 4086 *2005*, DOI: 10.1039/B506788J].

Dichloro(η^5-pentamethylcyclopentadienyl)iridium(III) dimer {di-μ-chloro-dichlorobis(η^5-pentamethylcyclopentadienyl)diiridium (III), [Rh(η^5-C_5Me_5)Cl_2]$_2$} *[12354-84-6]* **$C_{20}H_{30}Ir_2Cl_4$, M 796.7, m >230°.** The complex is prepared by stirring $IrCl_3$. xH_2O (10g, 26mmol), pentamethylcyclopentadiene (5g, 36mmol, Cp' see [4045-44-7]) and MeOH (300ml), purging the apparatus with N_2 for 5 minutes then refluxing the solution also under N_2 for 48 hours. After cooling to room temperature the orange crystals are filtered off in air through a glass sinter, the filtrate is concentrated *in vacuo* to ~50ml and cooled to give a second crop of crystals which are combined with the first crop, washed with Et_2O (3 x 50ml) and air dried. The ***Ir-dimer*** (10.7g, 85%) can be obt-

ained as an orange microcrystalline solid in analytical purity by recrystallisation using the minimum volume of $CHCl_3$ to dissolve it, filtering off insoluble material if present, and adding slowly twice that volume of hexane. The complex is stable in air at room temperature without obvious decomposition for several years. It is soluble in chlorinated solvents, much less so in Me_2CO, EtOH or hydrocarbon solvents, but is somewhat soluble in H_2O. The halogen atoms undergo metathesis and can be replaced by PF_6 and MeCN to form complexes such as $[Ir(\eta^5\text{-}C_5Me_5)(NCMe)_3]\ [PF_6]_2$. Its reactions can be studied by following the ^1H NMR ($CDCl_3$) signal of the single C_5Me_5 resonance at δ 1.73s. [White et al. *Inorg Synth* **29** 228 *1992*, DOI: 10.1002/9780470132609.ch53.] The ***Ir-dimer*** directly catalyses the C3 alkylation of a variety of indoles using aliphatic and benzylic alcohols in >80% yields [Grigg et al. *Tetrahedron* **65** 4375 *2009*, DOI: 10.1016/j.tet.2009.03.065]. It is used as a precursor of *N*-3-substituted-*N*-1-pyrimidyl-imidazolinium-Ir-pentamethyl-cyclopentadiene which catalyses transfer hydrogenation from isoPrOH to ketones, e.g. cyclohexanone, and imines, e.g. benzylideneaniline, to form the respective alcohols and amines [Gnanamgari et al. *Organometallics* **28** 321 *2009*, DOI: 10.1021/om800821q]. It has also been used as a precursor to efficient phosphine-free 'Ir-Cp' chiral catalysts, e.g. with *N*-sulfonyl *S*,*S*-1,2-diphenylethylenediamine, for the hydrogenation of 2-substituted quinolines to give chiral 2-substituted 1,2,3,4-tetrahydroquinolines in >90% yields and >99%'ee' [Li et al. *Org Lett* **10** 5265 *2008*, DOI: 10.1021/ol802016w].

Dichloro(η^5-pentamethylcyclopentadienyl)rhodium(III) dimer {di-μ-chloro-dichlorobis(η^5-pentamethyl-cyclopentadienyl)dirhodium (III), $[Rh(\eta^5\text{-}C_5Me_5)Cl_2]_2$} *[12354-85-7]* $C_{20}H_{30}Rh_2Cl_4$, M 618.1, m >230°. The complex is readily prepared by stirring $RhCl_3.3H_2O$ (10g, 42mmol), pentamethylcyclopentadiene (6g, 44mmol, Cp' see *[4045-44-7]*) and MeOH (300ml), purging the apparatus with N_2 for 5 minutes then refluxing the solution also under N_2 for 48 hours. After cooling to room temperature the dark red crystals are filtered off in air through a glass sinter, the filtrate is concentrated *in vacuo* to ~50ml and cooled to give a second crop of crystals which are combined with the first crop, washed with Et_2O (3 x 50ml) and air dried to give the ***Rh-dimer*** (11.25g, 95%). It can obtained in ***analytical purity*** by recrystallisation using the minimum volume of $CHCl_3$ to dissolve it, filtering off insoluble material if present, and adding slowly twice that volume of hexane. The complex is ***stable in air*** at room temperature without obvious decomposition for several years. It is soluble in chlorinated solvents, much less so in Me_2CO, EtOH or hydrocarbon solvents, and is somewhat soluble in H_2O. The halogen atoms undergo metathesis and can be replaced by PF_6 and MeCN to form complexes such as ***$[Rh(\eta^5\text{-}C_5Me_5)(NCMe)_3][PF_6]_2$***. Its reactions can be studied by following the ^1H NMR ($CDCl_3$) signal of the single C_5Me_5 resonance at δ 1.60s. [White et al. *Inorg Synth* **29** 228 *1992*, DOI: 10.1002/ 9780470132609.ch53.] .] In the presence of base the rhodium dimer is a good catalyst for the hydrogenation of olefins [Gill et al. *JCS Dalton Trans* 617 *1978*, DOI: 10.1039/DT9780000617], for hydrosilylation of olefins [Millan et al. *J Mol Catal* **26** 89 *1984,* DOI: 10.1016/0304-5102(84)85022-1; Millan et al. *JCS Chem Commun* 673 *1981*, DOI: 10.1039/C39810000673], and for the disproportionation of aldehydes [Cook et al. *JCS Dalton Trans* 2342 *1981*, DOI: 10.1039/DT9810002342].

Dicobalt octacarbonyl (cobalt carbonyl) *[10210-68-1]* **$(CO)_8Co_2$, M 341.9, m 51°, 51-52° (dec), d 1.87.** $Co_2(CO)_8$ has been identified as the cobalt catalyst in hydroformylation, hydrogenation and homologation reactions involving H_2 and CO (synthesis gas). The earlier preparation [Gilmont et al. *Inorg Synth* **2** 238 *1946*, DOI: 10.1002/9780470132333.ch76] has been improved due to the availability of steel pressure vessels and CO under pressure. Thus ***Raney Co*** (4 to 6g) was placed with Et_2O (145ml) under CO at 3200psi in a steel pressure bomb and heated with shaking for 5 or 6 hours at 150°. The pressure during the heating process dropped from 4900 to 4300psi and then to 2200psi when the bomb was cooled to ~25°. The insoluble material was removed by centrifugation, and the reddish-brown clear solution (160ml, which includes washings and transfers) contained 8.9g of $Co_2(CO)_8$. It is kept in a closed pressure-adjusted Pyrex bottle and aliquots siphoned as required because it decomposes slowly to liberate CO in an open vessel and should be stored in the cold. The solubility of the catalyst in Et_2O at ambient temperture is 7.5g per 100ml of solution. Cobalt on Kieselguhr 'Co-100 powder' that contains 12 to 15% of Co can be substituted for ***Raney Co***. [Adkins & Kresk *J Am Chem Soc* **70** 383 *1948*, DOI: 10.1021/ja01181a119.] The above preparation can also be carried out in $*C_6H_6$ which has the advantage of being less volatile than Et_2O, and in which reactions could be carried out at lower temperatures. It has been kept at a concentration of 1.0×10^{-2} M in 50ml of $*C_6H_6$. [Adkins & Kresk *J Am Chem Soc* **71** 3051 *1949*, DOI: 10.1021/ja01177a032.] It forms orange-brown ***air-sensitive*** crystals on recrystallisation from *n*-hexane under a carbon monoxide atmosphere. It has been sublimed *in vacuo* (orange platelets*)*, and is available commercially as a solid moistened with 5-10% of hexane. It is insoluble in H_2O, but soluble in organic solvents

such as alcohols, Et_2O, $*C_6H_6$, CS, slowly decomposed by HCl, and H_2SO_4, but rapidly by HNO_3. [Wender et al. *J Am Chem Soc* **71** 4160 *1949*, DOI: 10.1021/ja01180a520; Ojima et al. *J Am Chem Soc* **109** 7714 *1987*, DOI: 10.1021/ja00259a020; see Hileman in *Preparative Inorganic Reactions,* Ed. Jolly, Vol **1** p101 *1987*].
Carbon monoxide is **VERY POISONOUS** as it complexes with haemoglobin. Great care should be exercised when using the catalyst as well as CO, and all operations should be carried out in an efficient fume cupboard. The **TOXIC LEVEL** of CO is 50ppm (~55mg/m^3). **The ANTIDOTE should be at hand and always available in laboratories using CO; and staff should be trained to administer it.** On completion of reactions the autoclave should be filled with H_2 at 1000-1300psi and heated at 110-135º for 45 minutes where cobalt compounds are transformed to the metal. If the product of reaction does not contain oxidisable compounds, the mixture is heated in air on a steam bath when copious evolution of CO occurs and the metal is deposited as a cobalt mirror. A third procedure to decompose $Co_2(CO)_8$ and related CO compounds is to shake or stir the mixture with dilute H_2SO_4 until evolution of gas ceases. [Wender et al. *J Am Chem Soc* **72** 4375 *1950*, DOI: 10.1021/ja01166a012.]

2,6-Di-*iso*-propylphenylimino-neophylidene[(*S*)-(-)-BIPHEN]molybdenum(VI) {(*S*)-Schrock-Hoveyda Catalyst; Mo(*N*-2,6-di-*iso*-$Pr_2C_6H_3$)(CHCMe$_2$Ph)(*syn*-(*S*)(-)-*tert*-Bu_2Me_4(BIPHEN); molybdenum, [(*S- or R-)* 3,3'-bis(1,1'-dimethylethyl)-5,5',6,6'-tetramethyl[1,1'-biphenyl]-2,2'-diolato(2-)-κO,κO']][2,6-bis(1-methylethyl)benzenaminato(2-)](2-methyl-2-phenylpropylidene)- } *[(S) 205815-80-1; (R) 329735-77-5; (RS) 300344-02-9]* **$C_{46}H_{61}NO_2Mo$, M 755.9.** The key intermediate is ***2,6-di-iso-propylphenylimino-neophylidene-bistriflate-dimethoxyethane-molybdenum (VI) complex*** *{molybdenum, [2,6-bis(1-methylethyl)benzene-aminato(2-)][1,2-dimethoxy-κO)ethane][2-methyl-2-phenylpropylidene)bis(1,1,1-trifluoromethanesulfonato-κO)-*; [Mo(=N-2,6-isoPr$_2$C$_6$H$_3$)(=CHMePh)-(OTf)$_2$-DME] *[126949-63-1]* which is prepared in three steps. ***Firstly*** (preferred method)**:** A solution of $MoO_2Cl_2(THF)_2$ (10.2g, 29.0mmol, see *[13637-68-8, 556907-19-8; 12081-12-8]*) in DME (200ml) at -30º is stirred vigorously while the following are added sequentially (i) a solution of 2,6-lutidine (12.4g, 116mmol) in DME (10ml at -30º) during 3-5 minutes, (ii) a solution of Me_3SiCl (31.5g, 290mmol, see [75-77-4]) in DME (40ml, at -30º) over a period of 3-5 minutes, and (iii) a solution of 2,6-di-*iso*-propylaniline (10.3g, 58mmol, see *[24544-04-5]*) in DME (15ml at -30º) during 15 minutes. The colour of the solution alters from pale yellow to bright red-orange to deep red-orange as a solid separated. The mixture is stirred as it warmed to room temperature during 6 hours. The mixture is then heated to 50º for 5 hours, filtered through Celite, to remove 2,6-lutidine hydrochloride, which is washed with Et_2O until the washings are clear; all filtrates are combined and evaporated *in vacuo* to give ***bis(2,6-di-iso-propylphenylimino)dichloro-dimethoxyethane molybdenum*** **[Mo(=N-2,6-isoPr$_2$C$_6$H$_3$)$_2$Cl$_2$DME]** (16.7g, 27.5 mmol, 95%) as a brick red solid which is almost of analytical purity (elemental C, H, N and Cl for $MoC_{28}H_{44}Cl_2N_2O_2$), and used in the next step. Its ^{1}H NMR (400MHz, C_6D_6, TMS) has δ at 7.01 (d, 4, arom H_m), 6.89 (t, 2, arom H_p), 4.29 (sept, 4, C***H***Me$_2$), 3.44 (s, 6, ***Me***OCH$_2$CH$_2$O***Me***), 3.18 (s, 4, MeOC***H***$_2$C***H***$_2$OMe), 1.25 (d, 24, CH***Me***$_2$) and for ^{13}C NMR see references. ***Secondly*****:** Neophyl magnesium chloride (100ml, 0.5M, 50mmol, see *[35293-35-7]*) in Et_2O is added dropwise to a stirred solution of the preceding complex [Mo(=N-2,6-isoPr$_2$C$_6$H$_3$)$_2$Cl$_2$DME] (15.1g, 25mmol) in Et_2O (250ml) at -30º (all the complex need not have dissolved). The colour of the solution alters from red to orange as $MgCl_2$ separates, the mixture is allowed to thaw to 25º and is stirred at this temperature for 3 hours. The mixture is filtered through Celite, the filtrate is concentrated *in vacuo*, kept at -40º to provide orange crystals (usually three crops) of ***almost analytically pure*** (elemental C, H and N for $MoC_{44}H_{60}N_2$) ***bis(2,6-di-iso-propylphenylimino)-bis(neophyl) molybdenum*** **[Mo((=N-2,6-isoPr$_2$C$_6$H$_3$)$_2$(-CH$_2$C Me$_2$Ph)$_2$]** (14.3g, 80%). The yellow residue is extracted with chilled (~0º) toluene (100ml), filtered, evaporated *in vacuo*, and the dark yellow residue is recrystallised from Et_2O to provide the desired ***almost analytically pure*** (elemental C, H, and N for $MoC_{28}H_{39}F_6NO_8S_2$) key intermediate ***2,6-di-iso-propylphenylimino-neophylidene-bis(triflate)-dimethoxy-ethane molybdenum(IV) complex*** **[Mo(=N-2,6-isoPr$_2$C$_6$H$_3$)(=CHMePh)(OTf)$_2$DME]** (5.94g, 76%, in three crops). Its ^{1}H NMR (400MHz, C_6D_6, TMS) has δ at 14.45 (s, 1H, C***H***CMe$_2$Ph), 7.57 (d, 2H, aromatic), 7.18 (t, 2H, aromatic), 6.97-6.89 (m, 4H, aromatic), 3.84 (sept, 2H, C***H***Me$_2$), 3.73 (s, 3H, OC***H***$_3$), 3.18 (M, 2H, OC***H***$_2$), 2.84-2.78 (m, 5H,

OC***H***$_3$, OC***H***$_2$), 1.91 (s, 6H, CHC***Me***$_2$Ph), 1.37 (d, 6H, CH***Me***$_2$), 1.21 (d, 6H, CH***Me***$_2$) and the ^{13}C NMR (100MHz, C_6D_6, TMS) has δ at 328.4, 152.1, 151.8, 148.7, 130.6, 128.7, 126.6, 124.3, 72.8, 70.0, 65.7, 61.9, 58.8, 31.1, 28.3, 25.6, 22.8. [Schrock et al. *J Am Chem Soc* **112** 3875 *1990*, DOI: 10.1021/ja00166a023.]

The **Schrock-Hoveyda catalyst** is prepared in a glove box or in Schlenk equipment under an argon or N_2 atmosphere by adding solid KH (360mg, 9mmol, 3 equivalents) in portions to a stirred solution of H_2[*S*-BIPHEN] (1.06g, 3mmol, see [*R- 329735-68-4*, *S- 205927-03-3*, *RS- 101203-31-0*] in Part 2) in THF (100ml), whereby H_2 gas evolves while the K_2[BIPHEN] salt is being formed. After stirring for 18 hours at ~25°, the suspension is filtered through Celite to remove excess of KH, and the key intermediate above [Mo(=N-2,6-isoPr$_2$C$_6$H$_3$)(=CHMePh)(OTf)$_2$DME] (2.24g, 2.83mmol, 0.94 equivalents) is added as a solid during 2 minutes. The mixture is stirred for 3 hours at ~25°, the volatiles are removed *in vacuo*, and the residual red powder is treated with *C_6H_6 (40ml), and the slurry is filtered through Celite to remove insoluble CF_3SO_3K and washed with *C_6H_6 until the washings are no longer red in colour. The red *C_6H_6 solutions are combined, evaporated *in vacuo*, and the spongy red solid is recrystallised from Et_2O (~4ml) to give the desired catalyst, mainly in the *syn* configuration at the alkylidene group, as dark orange red crystals (1.35g, 64%). Its ^{1}H NMR (400MHz, *C_6D_6, TMS) has δ at 10.98 (s, 1H, J_{CH} = 123Hz, *syn* alkylidene C=C***H***CMe$_2$Ph), 7.42 (m, 3H, biphenyl and Ph C***H***s), 7.16 (m, 3H, biphenyl and Ph C***H***s), 7.05 (br t, *J* = 7.6Hz, 1H, aromatic), 6.92 (s, 3H, aromatic), 3.70 (heptet, *J* = 7.0Hz, 2H, *iso*-C***H***Me$_2$), 2.13 (s, 3H), 2.15 (s, 3H), 1.85 (s, 3H), 1.74 (s, 3H), 1.66 (s, 3H) {these signals 2.13—1.66 ppm are from 4 biphenyl-***Me***s and one methyl from C***Me***MePh}, 1.59 (s, 9H, *tert*-C***Me***$_3$), 1.54 (s, 9H, *tert*-C***Me***$_3$), 1.14 (d, *J* = 7.0Hz, 6H, *iso*-CH***Me***$_2$), 1.13 (s, 3H, CMe***Me***Ph), 0.90 (d, *J* = 7.0Hz, 6H, *iso*-CH***Me***$_2$), and for ^{13}C{^{1}H} NMR see references. [Alexander et al. *J Am Chem Soc* **120** 4041 *1998*, DOI: 10.1021/ja974353i.]

See also a ***slightly modified preparation*** in which the red spongy powder is dissolved in Et_2O (18ml), transferred to a 20ml vial, kept uncapped in a well purged glovebox (with N_2) until the volume decreased to 5ml, the red solution is decanted from the red crystal blocks which were washed with cold Et_2O and dried *in vacuo* to provide a 72% yield of ***analytically pure*** (elemental C, H, and N for $MoC_{46}H_{61}NO_2$) ***syn-(S)-catalyst***. The X-ray crystal structure proved the absolute configuration of the biphenolate ligand. Related complexes in which the 2,6-di-*iso*-propylphenylimino ligand is replaced by various other ligands have been similarly prepared. [Alexander et al. *Organometallics* **19** 3700 *2000*, DOI: 10.1021/om000336h.] Schrock-Hoveyda catalysts with *R*-BIPHEN and *racemic*-BIPHEN also form red crystals, and have been similarly prepared. All are ***air and moisture sensitive***, *and have to be stored cold and in the dark*. NMR data revealed that the *syn*-alkylidene conformer predominates in solution with a ***syn-anti* exchange rate** of ~1 s^{-1}. However, evidence from ROM (ring-opening metathesis) polymerisation suggests that reactions with the *anti* conformer are catalytically more active than with the *syn* conformer by some orders of magnitude [Oskam & Schrock *J Am Chem Soc* **115** 11831 *1993*, DOI: 10.1021/ja00078a023].

The related catalyst where the *tert*-buyl groups in the biphenol ligand are replaced by 1-adamantyl groups **Mo(*N*-2,6-di-*iso*-Pr$_2$C$_6$H$_3$)(CHCMe$_2$Ph)(*syn*-(*S*)(-)-*tert*-Bu$_2$Me$_4$(BIAD))** has been prepared in 54% yield as orange crystals from the above key intermediate [Mo(=N-2,6-isoPr$_2$C$_6$H$_3$)(=CHMePh)(OTf)$_2$DME] and (*S*)-H$_2$(BIAD) (see in Part 2) except that benzylpotassium was used instead of KH to prepare the phenolate salt. X-ray crystallography of the catalyst also confirmed the ***S- absolute configuration of (-)-H$_2$(BIAD)***). [Alexander et al. *Organometallics* **19** 3700 *2000*, DOI: 10.1021/om000336h; and for the X-ray crystallographic structures of related Mo-2,2'-dihydroxy-1,1'-biaryls see Totland et al. *Macromolecules* **29** 6114 *1996*, DOI: 10.1021/ma960351r.]

These and related ***chiral molybdenum complexes*** are remarkable catalysts that effect efficient asymmetric enantioselective ring-closing olefin metathesis (RCM) [Alexander et al. *J Am Chem Soc* **120** 4041 *1998*, DOI: 10.1021/ja974353i; Weatherhead et al. *Tetrahedron Lett* **41** 9553 *2000*, DOI: 10.1016/S0040-4039(00)01690-7], ring-opening metathesis/cross metathesesis (ROM/CM) [La et al. *J Am Chem Soc* **123** 7767 *2001*, DOI: 10.1021/ja010684q], as well as ring-opening olefin metathesis (ROM) polymerisation [Totland et al. *Macromolecules* **29** 6114 *1996*, DOI: 10.1021/ma960351r] reactions. These complexes catalyse olefin metathesis reactions in which the starting olefin is a racemic mixture, and in the reaction process ***kinetic resolution*** occurs, whereby the products, and any unreacted starting material, are of one chirality, i.e. the asymmetric centre in the racemic mixture is converted into one enantiomer at the expense of the other enantiomer. The above Mo-(*S*)-[BIPHEN] complex also catalyses efficient and enantioselective ***desymmetrisation*** reactions, e.g. (±)-3-allyloxy-2,4-dimethylpenta-1,4-diene and its I,5-dimethyl derivative (4-allyloxy-3,5-dimethyl-hepta-2,5-diene) are cyclised to 2-(prop-2'en-2'yl)-3(*R*)-methyl-2,5-dihydrofuran and 2-(but-2-en-2-yl)-3(*R*)-methyl-2,5-dihydro-furan in the absence of solvent, 1-2 mol% catalyst, at 22° in 5 minutes

in 85% and 93% yields, and 93% 'ee' and 99% 'ee' respectively [La et al. *J Am Chem Soc* **120** 9720 *1998*, DOI: 10.1021/ja9821089]. [For olefin metathesis review see Grubbs *Tetrahedron* **60** 7117 *2004*, DOI:10.1016/j.tet.2004.05.124; and R.H. Grubbs (Ed.), *Handbook of Metathesis*, Vols 1-3, Wiley-VCH, *2003*. ISBN 3527306161.]

However, when recrystallised from EtOH or Et_2O it has **m 179°** [Hantzsch & Desch *Justus Liebigs Ann Chem* **323** 1 *1902*, DOI: 10.1002/jlac.19023230102]. Recrystallisation from absolute EtOH also gives material with **m 159.5°** [Emmert & Jacob *Chem Ber* **67** 286 *1934*, DOI: 10.1002/cber.19340670225]. Dry it for 1 hour at 120°. [*Beilstein* **1** I 404, **1** II 836, **1** IV 3675; for applications see Fieser **4** 268, **6** 304.] Fe(acac)$_3$ catalyses a large variety of chemical reactions such as aromatic substitution, cross-coupling, Friedel-Crafts etc [see B. Pleitker (ed), *Iron Catalysis in Organic Chemistry* Wiley-VCH, *2008*, ISBN 978-3-527-31927].

Ferrous (II) acetylacetonate [Fe(acac)$_2$, iron(II) bis(2,4-pentadionate)] *[14024-17-0]* **($C_5H_7O_2)_2Fe$, M 254.1, m 175°.** For its catalytic properties see B. Pleitker (ed), *Iron Catalysis in Organic Chemistry* Wiley-VCH, *2008*, ISBN 978-3-527-31927, and for the preparation see Chapter 4, 'Metal-Organic Compounds'. [*Beilstein* **1** III 3122, **1** IV 3676]

Iridium(I) bis(1,5-cyclooctadiene) tetrafluoroborate complex [bis(1,5-cyclooctadiene)iridium (I) tertrafluoroborate, Ir(COD)$_2^+$. BF_4^-] *[35138-23-9]* **($C_8H_{12})_2Ir^+$. BF_4^-, M 495.4, m ~190° (dec).** This dark red iridium complex is prepared and purified exactly as for the corresponding Rh(COD)$_2^+$.BF_4^- [*35138-22-8*, below] from the dimer {[Ir(COD)Cl]$_2$ *[12112-67-3]* below, Herde et al. *Inorg Synth* **15** 18 *1974*, DOI: 10.1002/9780470132463.ch5]} with COD and $AgBF_4$ in 93% yield. [Schenck et al. *Inorg Chem* **24** 2334 *1985*, DOI: 10.1021/ic00209a003.]

Iridium(I) chloride 1,5-cyclooctadiene complex dimer {chloro(1,5-cyclooctadiene)iridium dimer, di-μ-chlorobis[(1,2,5,6-η)-1,5-cyclooctadiene]diiridium (I), [Ir(COD)Cl]$_2$} *[12112-67-3]* **($C_{16}H_{24})Ir_2Cl_2$, M 671.7, m 205°(dec).** The complex is an orange-red, air-stable solid that is soluble in *C_6H_6 and $CHCl_3$, less so in Me_2CO and insoluble in Et_2O. It can be prepared from $IrCl_3.3H_2O$ (3g) in 95% EtOH (34ml), H_2O (17ml) and cycloocta-1,5-diene (6ml), through which is bubbled (with magnetic stirring) a slow stream of N_2 while boiling under reflux for 24 hours, during which time a brick-red product precipitates. The mixture is cooled and Ir(COD)Cl]$_2$ is filtered off, washed with ice-cold MeOH to remove unreacted COD and dried *in vacuo* at 25° for 8 hour (yield 1.5g, 72%, decomp >200°). [Herde et al. *Inorg Synth* **15** 18 *1974*, DOI: 10.1002/9780470132463.ch5.] *Alternatively*, to a mixture of H_2O (100ml), isoPrOH (35ml) and 1,5-cyclooctadiene (18ml) is added $(NH_4)_2IrCl_6$ (20g), and the mixture is refluxed under N_2 for 18 hours when the colour changes to orange-red, and a red or orange solid separated on cooling. This is filtered off (frit), and washed with EtOH (2 x 5ml at 0°) to give the ***complex in high purity*** (14.0g, 92%). Recrystallisation (if required) is best carried out by slowly adding an equal volume of EtOH to a saturated stirred solution of the solid in CH_2Cl_2, followed by gentle removal of half of the mixed solvent under reduced pressure. The stirred solution is cooled spontaneously to -30° during the process and the complex is filtered off, washed with EtOH (2 x 5ml at 0°) and dried *in vacuo*. It is identified by the characteristic IR bands (Nujol) at 907, 970, 980 and 1002 cm^{-1}; and the vinyl CH resonance in the ^{1}H NMR ($CDCl_3$) spectrum at δ 4.3. [Crabtree et al. *Synth React Inorg Met-Org Chem* **12** 407 *1982*, DOI:10.1080/00945718208063124.] [Fieser **5**, 113.] It is the metal complex precursor with allyamines for asymmetric allylic substitutions; for resting state and kinetic studies see Markovic and Hartwig [*J Am Chem Soc* **129** 11680 *2007*, DOI: 10.1021/ja074584h].

Iridium(I) (1,5-cyclooctadiene)-η^5-(indenyl) {(1,5-cyclooctadiene)-η^5-(indenyl)iridium (I), [(COD)(C_9H_7)Ir(I)], [(Ind)Ir(I) (COD)]} *[102525-11-1]* **($C_9H_7)Ir(C_8H_{12})$, M 414.5, m 126-131°.** The complex is obtained by adding solid indenyllithium (0.73g, 5.98mmol) to a solution of the preceding dimer [Ir(COD)Cl]$_2$ (2.0g, 2.98mmol) in THF (50ml) and stirring at ~20° for 1 hour. The solvent is removed *in vacuo*, extracted with pentane (6 x 50ml) and the combined extracts are slowly evaporated to deposit pale yellow crystals (2.15g, 86%).

It has ^{1}H NMR (200MHz) with δ at 1.65-1.86 (m, 8H, COD CH_2), 3.99 (m, 4H, COD C*H*), 5.00 (d, 2H, indenyl H1/H3), 5.76 (t, 1H, indenyl H2), 6.98-7.16 (m, 4H, indenyl H4-H7); and ^{13}C NMR (50MHz) with δ at 34.36 (COD *C*H_2), 51.35 (COD *C*H), 72.80 (indenyl C1/C3), 85.15 (indenyl C2), 110.23 (indenyl C8/C9), 121.75 and 124.89 (indenyl C4-C7). [Merola & Kacmarcik *Organometallics* **8** 778 *1989*, DOI: 10.1021/om00105a031; Abad *Inorg Chim Acta* **121** 213 *1986*, DOI: 10.1016/S0020-1693(00)84522-3; Crabtree et al. *Synth React Inorg Met-Org Chem* **12** 407 *1982*, DOI: 10.1080/00945718208063124; Naderer et al. *Organomet Chem* **518** 181 *1996*, DOI:10.1016/0022-328X(96)06144-X.] [Uson et al. *Inorg Synth* **23** 126 *1985*, DOI: 10.1002/9780470132548.ch25.] **[(Ind)Ir(I) (COD)]** is a powerful C-H activation catalyst for preparing phenols from arenes in the presence of pinacolborane and bis(diphenylphosphino)ethane that borylate arenes to the intermediate pinacol arylboryl esters which are then converted to the respective phenols by reaction with ***oxone*** [$2KHSO_5.KHSO_4.K_2SO_4$] in Me_2CO at 25° within ~7 minutes in 51 to 88% yields depending on the substituents [Maleczka et al. *J Am Chem Soc* **125** 7792 *2003*, DOI: 10.1021/ja0349857.]

Iridium(I) *μ*-chloro-bis(cyclooctene) dimer {di-*μ*-chlorotetrakis(cyclooctene)diiridium(I), $[Ir(COE)_2Cl]_2$ *[12246-51-4]* **$C_{32}H_{56}Ir_2Cl_2$, M 896.1, m 150°(dec), 160-165°(dec).** This solid yellow iridium complex is air sensitive and decomposes to a dark green solid that eventually turns black. However, it can be stored *in vacuo* in a desiccator for prolonged periods of time. It is preferable to store it in aliquots in sealed ampoules under an inert atmosphere or in a vacuum. It is soluble in Me_2CO, $CHCl_3$ and $*C_6H_6$, but it oxidises more readily in solution than in the solid state, and the necessary precautions to strictly exclude air should be exercised.
It is prepared by stirring (stirrer bar) a mixture of $IrCl_3.3H_2O$ (2.0g), *iso*-propanol (22ml), H_2O (8ml) and cyclooctene (40ml), while a slow stream of dry N_2 is bubbled through the solution, and refluxed at 78° for 3 hours. During this time the colour of the solution changes from dark red to orange-yellow and the complex separates from the solution which is cooled to ~25°. It is collected rapidy by filtration, washed rapidly with ice-cold MeOH to remove excess of cyclohexene (this is done preferably in a dry box under N_2). Drying *in vacuo* at 25° for 4 hours gives pure di-*μ*-chlorotetrakis(cyclooctene)diiridium(I) (1.5g, 59%), which decomposes at 150° and has the correct elemental analysis for C, H, Cl and Ir. [Herde et al. *Inorg Synth* **15** 18 *1974*, DOI: 10.1002/9780470132463.ch5; Herdé & Senoff *Inorg Nucl Chem Lett* **7** 1029 *1971*, DOI: 10.1016/0020-1650(71)80023-5.] By using $(NH_4)_3IrCl_6$ (6g) suspended in an oxygen-free suspension of *iso*-PrOH (30ml) and H_2O (90ml), and cyclooctene (12ml), and refluxing with stirring for 3-4 hours under N_2, followed by cooling, an orange oil which solidifies is formed and is collected, washed with cold EtOH, and allowed to crystallise from EtOH, collected, dried *in vacuo*, all under N_2, to give the ***[Ir(COE)$_2$Cl]$_2$*** (80-92% yield) as yellow needles. It should be stored under N_2 at room temperature. [Van Der Ent et al. *Inorg Synth* **28** 90 *1989*, DOI: 10.1002/9780470132593.ch23.]
Although this compound is air sensitive, with the correct stoichiometry, it forms a less sensitive stable tris-boryl complex with pinacolborane (Bpin) and 4,4'-di-*tert*-butyl-2,2'-dipyridine (dtbpy) which has been crystallised, and its X-ray analysis shows that it has the composition ***[Ir(dtbpy)(COE)(Bpin)$_3$]***‡. These complexes are catalytically active in the C-H borylation of arenes. Thus dissolution of the latter complex in $*C_6D_6$ (or $*C_6H_6$) provided $*C_6D_5$-Bpin within minutes at room temperature and in 80% yield. Kinetic studies revealed a ***kinetic isotope effect*** k_H/k_D of 3.8. The iridium complexes containing dtbpy are easily prepared and are air-stable. The reaction of bis(pinacolato)diboron (***B$_2$pin$_2$***) and ½$[IrCl(COE)_2]_2$/dtbpy (5 mol% of Ir) in 60 equivalents of $*C_6H_6$ at 25° for 4.5 hours gives ***Ph-Bpin*** in 83% yield; and with ½$[IrCl(COE)_2]_2$/dtbpy (0.02 mol% of Ir) at 100° for 16 hours gives ***Ph-Bpin*** in 80% yield with 8000 turnovers. These catalysts provide a simple and direct route for the synthesis of arylboronates—which were previously obtained by transmetalation with aryl lithium or arylmagesium reagents and trialkylborates. [Ishiyama et al. *J Am Chem Soc* **124** 390 *2002*, DOI: 10.1021/ja0173019; cf. Ishiyama et al. *Angew Chem Int Ed* **41** 3056 *2002*, DOI: 10.1002/1521-3773(20020816)41.]
‡***[Ir(dtbpy)(COE)(Bpin)$_3$]*** is prepared in a dry box under N_2: a glass flask containing a mixture of $[Ir(COE)_2Cl]_2$ (350mg, 390mmol), dtbpy (209mg, 778mmol) and B_2pin_2 (494mg, 1.95mmol), to which is added mesitylene (or xylene) (50ml) and heated with very slow stirring at 50° for 5 hours. The solvent is evaporated off at ~25°, the residue is dissolved in Et_2O and allowed to evaporate slowly at ~25° to afford red cubes (blocks) of the complex in 28% yield (52mg). Its ^{1}H NMR (400MHz, cyclohexane-d_{12}) has δ at 1.15 (s, 12H), 1.17 (s, 12H), 1.18 (s, 12H), 1.33 (m, 12H), 1.41 (s, 18H). 3.74 (d, 2H, *J* = 10.8Hz), 7.09 (dd, 2H, *J* = 6.4, 2.0Hz), 7.93, (s, 2H), 9.45 (d, 2H, *J* = 6.4Hz) from Me_4Si; and its ^{11}B NMR (128MHz, $CDCl_3$) has δ at 37 from external BF_3OEt_2. [Ishiyama et al. *J Am Chem Soc* **124** 390 *2002*, DOI: 10.1021/ja0173019.]

Iridium(I) (methoxy)(1,5-cyclooctadiene) dimer {bis(η^4–1,5-cyclooctadiene) di-μ-methoxy diiridium (I) dimer, [(COD)(OMe)Ir(I)]$_2$} *[12148-71-9]* [$(C_8H_{12})(CH_3O)Ir]_2$, M 662.9, m 154-179º (dec). Deoxygenated solvents should be used and reactions should be carried out under N_2 or argon. The methoxylated catalyst is prepared in Schlenk equipment in an inert atmosphere by adding a suspension of $[Ir(COD)Cl]_2$ (148mg, 222mmol, *[12112-67-3]*) in MeOH (10ml) to KOH (25mg, 445mmol) in MeOH (5ml), whereby the colour becomes orange-red and a yellow crystalline solid is formed. Stir for 30 minutes then add H_2O (40ml), collect the solid, wash it with H_2O (6 x 5ml), and dry it over P_2O_5 *in vacuo* to give ***[Ir(COD)(OMe)]$_2$*** (124mg, 85%, decomposing at 145-155º becoming black at 155º) as a yellow air-stable solid. It is soluble in chlorinated solvents to give solutions that are air sensitive. It is soluble in MeOH, Me_2CO, hexane, $*C_6H_6$ and Et_2O but insoluble in H_2O. For IR see references; the ^1H NMR ($CDCl_3$) has δ at 3.57 (8H, vinyl), 2.22 (8H, allylic H), 1.45 (8H, allylic H) and 3.28 (sharp singlet, 6H, MeO). [Uson et al. *Inorg Synth* **23** 126 *1981*, DOI: 10.1002/9780470132548.ch25.] ***Alternatively***, **[Ir(COD)(OMe)]$_2$** can be prepared by boiling $[Ir(COD)Cl]_2$ (1g) in MeOH (40ml) under reflux with anhydrous Na_2CO_3(0.6g) for 1 hour, filtering hot, cooling, and the yellow plates of the desired complex are filtered off, washed with MeOH and dried *in vacuo*. [cf. Rhodium analogue in Chatt & Venanzi *J Chem Soc* 4735 *1957*, DOI: 10.1039/JR9570004735.] It has been used successfully, by preparing it *in situ*, on adding NaOMe to the solution containing $Ir(COD)Cl]_2$ (see below).

[Ir(I) (OMe)(COD)]$_2$, like the preceding complex, is a powerful C-H activation catalyst for preparing phenols from arenes in the presence of pinacolborane and 3,3'-di-*tert*-butyl-1,1'-bipyridyl which borylates arenes to the intermediate pinacol arylboryl esters which are then converted to the respective phenols by reaction with ***oxone*** [$2KHSO_5.KHSO_4.K_2SO_4$] in Me_2CO at 25º within 7 minutes in ~70% yields depending on the substituents [Maleczka et al. *J Am Chem Soc* **125** 7792 *2003*, DOI: 10.1021/ja0349857.] The catalyst, prepared *in situ*, in the presence of bipyridines has been used as in the previous reference for borylation of arenes in high yields and should be useful for preparing arylboronates [Ishiyama et al. *Angew Chem Int Ed* **41** 3056 *2002*, DOI: 10.1002/1521-3773(20020816)41.]

Iridium(III) (1,1,1,5,5,5-trifluoroacetylacetonato)(bis-cyclooctene) [(hfacac)(COE)$_2$Ir] *[58616-58-3]* **($C_{16}H_{28}$)($C_5H_2F_6O_2$)Ir, M 620.7, m 96-97º.** It is prepared by adding ***Tl(hfacac)***† (600mg) to a suspension of $[Ir(COE)_2Cl]_2$ (920mg, see above) in pentane (100ml) at ~ 25º, and stirring for 3 hours then filtering. The red filtrate is concentrated to 10ml, kept at -30º for 24 hours and the red crystals of ***[(hfacac)(COE)$_2$Ir]*** (786.5g, 70%) are collected and dried *in vacuo* to give ***analytically pure complex*** (C and H). It is a ***monomeric*** complex in $*C_6H_6$ and for IR see references. The ^1H NMR (60MHz, $CDCl_3$, TMS) has δ at 6.26 (s, 1H), 2.8-2.4 (br m, 4H), 2.3-1.8 (br m, 8H), 1.7-1.3 (br m, 16H).

(Acac)(COE)$_2$Ir is similarly prepared from Tl(acac) *{[25955-51-6], M 303.5, m 134º obtained as for Tl(hfacac) below}* and $[Ir(COE)_2Cl]_2$ in 86% yield forming orange-yellow crystals with **m 114-115º, M 512.6**, and for IR (KBr) see refs. The ^1H NMR (60MHz, $CDCl_3$, TMS) has δ at 5.43 (s, 1H), 1.92 (s, 6H), 2.4-1.7 (br m, 8H), 1.7-1.0 (br m, 20H). [Diversi et al. *J Organomet Chem* **125** 253 *1977*, DOI: 10.1016/S0022-328X(00)89444-9.]

†**Thallium 1,1,1,5,5,5-hexafluoroacetylacetonate [Tl(hfacac)]** is obtained from a solution of thallous ethoxide (8g, prepared as in Fieser **2** 407; see *[20398-06-5]* in Chapter 4, 'Metal-Organic Compounds'] in EtOH (60ml) reacted with hexafluoroacetylacetone (6.7g, [see *1522-22-1*]) at ~ 25º/30 minutes; the solvent was removed *in vacuo,* the residue washed with pentane and dried. The ***Tl(hfacac)*** (11.8g, 95%) was thus obtained as a microcrystalline solid. [Ingrosso et al. *J Organomet Chem* **84** 75 *1975*, DOI: 10.1016/S0022-328X(00)88776-8.]

Iron(0) 2,2'-bipyridine [bpyFe(0)] *[bpy*Fe(1^+) *500295-31*; *bpy*Fe(2^+) *73871-24-6*; *bpy*Fe(3^+) *51232-88-3]* **(C_5H_5N)$_2$Fe, M 214.0.** This iron catalyst mediates ***ene-carbocyclisations*** such as formal [4+4] ene reactions of trienes [Takacs & Anderson *J Am Chem Soc* **109** 2200 *1987*, DOI: 10.1021/ja00241a059; Takacs et al. *Tetrahedron* **46** 5507 *1990*, DOI: 10.1016/S0040-4020(01)87749-8], regio- and chemo- selective diene to olefin cross coupling reactions [Takacs et al. *Organometallics* **5** 2395 *1986*, DOI: 10.1021/om00142a044], and stereoselective and regiocontrolled formation of substituted tetrahydropyrans [Takacs et al. *Tetrahedron Lett* **28** 5627 *1987*, DOI: 10.1016/S0040-4039(00)96797-2]. The 'active bpyFe(0) catalyst' is prepared *in situ* from $Fe(acac)_2$ (see *[14024-17-0]*) generated by a minimum of 3.0 equivalents of Et_3Al and $Fe(acac)_3$ (see *[14024-18-1]*, in $*C_6H_6$ at 0º), and 2,2'-bipyridine (1:1 with respect to Fe, sublimed at 65º/0.01mm) to which is added the olefin(s) at or near room temperature. [The $Fe(acac)_3$ is recrystallised from EtOH or $*C_6H_6$/hexanes, dried at 25º/0.01mm, or sublimed at 100º/0.05mm.] Prior to the reduction of the iron, 1.1 equivalents of 2,2'-bipyridine and 10 equivalents of 'addend' (furan or 2-methylfuran) are added to the $Fe(acac)_3$ in $*C_6H_6$. After

reduction, the substrate(s) are added and the reaction is allowed to proceed at 25° and monitored. The 'addend' is added mainly to slow down the disproportionation of the active bpyFe(0) into inactive bpy_2(Fe(0) and Fe_{metal} [Takacs et al. *Tetrahedron* **46** 5507 *1990*, DOI: 10.1016/S0040-4020(01)87749-8]. **Note:** The catalytically active 1:1 complex bpyFe(0) has not been isolated, but is assumed to be in solution and is most probably stabilised in solution by coordinating with some entity such as ethylene (derived from Et_3Al), or perhaps even furan or methylfuran as these are required for its stability.
The reduction of $FeCl_3$ by 3.1 equivalents of *iso*-PrMgBr in the presence of 1.1 equivalents of 2.2'-bipyridine and 2,3-dimethylbutadiene yields an active catalyst by forming the ***bpyFe(0)2,3-butadiene complex*** *[104714-94-5]* in which the olefin may be involved in the reaction [Takacs et al. *Organometallics* **5** 2395 *1986*, DOI: 10.1021/om00142a044]. Carbocyclisations are also mediated by Pd, Ni, Co, and Rh complexes [bibliography : Takacs et al. *Tetrahedron* **46** 5507 *1990*, DOI: 10.1016/S0040-4020(01)87749-8]. The Fe(0) valence is **dubious**.

(2,3-*O*-Isopropylidene)-2,3-dihydroxy-1,4-bis-(diphenylphosphino)butane (DIOP) *[4R,5S-(-)- 32305-98-9, 4S,5R-(+)- 37002-48-5]* **$C_{31}H_{32}O_2P_2$, M 498.5, m 88-89°, 88-90°, $[\alpha]_D^{19}$ (-) and (+) 26 (c 2.3, $CHCl_3$), also 4*R*,5*S*- has $[\alpha]_D^{22}$ (-) 12.3 (c 4.6, $*C_6H_6$), pK_{Est} ~0.0.** These are quite stable in air and have been recrystallised from $*C_6H_6$/petroleum ether. After 2 recrystallisations from EtOH, they are generally pure by TLC on silica gel using Me_2CO/hexane as solvent. The optical purity can be determined by GC [Chiral Select 1000 column 15m x 0.25mm using He carrier gas (1ml/minute); or Chirasil-L-Val fused silica 25m x 0.25mm] or by HPLC using an (*S,S*)-Whelk-01 column (5.0µm, 25cm x 0.46cm). [Details of the general preparation of **DIOP** are described under **3,4-O-isopropylidene-(3*S*,4*S*)-dihydroxy-(2*R*,5*R*)-bis(diphenylphosphino)hexane (*RSSR*-dimeDIOP**, see *[258873-45-9]*) in Part 2. The rhodium(I) complexes described below catalyse the asymmetric hydrogenation of β-substituted α-acetamidoacrylic acids to the corresponding chiral α-amino acid derivatives with high stereoselectivity. [Kagan *J Am Chem Soc* **94** 6429 *1972*, DOI: 10.1021/ja00773a028.]
The DIOP derived catalysts used are **$Rh(I)^+$(DIOP)(COD) X^-** where X^- **is Cl^-, BF_4^-, SbF_6^-** or **PF_6^-** and are prepared *in situ* by reaction of $Rh(I)^+(COD)_2$ X^- with the DIOP ligand in a solvent (CH_2Cl_2, MeOH, $PhCH_3$, THF or $*C_6H_6$), using a DIOP/Rh ratio of <2 (preferably 1.1:1.0) to avoid the formation of $Rh(I)^+(DIOP)_2$ which exhibits very little, if any, catalytic activity due to its inability to coordinate with the olefinic substrate. A **typical hydrogenation** is carried out in a Fisher-Porter tube which is filled (in a dry-box) with the enamide substrate (0.25mmol), the appropriate solvent (5ml), and pre-formed $Rh(I)^+$(DIOP)(COD) X^- [Rh precursor, $Rh(I)^+(COD)_2$ X^- (0.005mol) in the appropriate solvent (3ml), DIOP (0.055ml of 0.1M solution in, e.g. $PhCH_3$, 0.0055mmol) and stir for 10 minutes]. After sealing, the tube is removed from the dry-box, placed behind a proper body shield, and *ca* five vacuum/refilling cycles of H_2 are performed. Hydrogenation is performed at room temperature, with the desired pressure of H_2 (1.1 to 50 bar, usually ~30psi), and is stirred vigorously for ~10 hours (but could be up to 60 hours). The reaction is completed by releasing the H_2, the catalyst is filtered off through a short silica column, and the filtrate is worked up in the appropriate manner. [Kagan *J Am Chem Soc* **94** 6429 *1972*, DOI: 10.1021/ja00773a028; Li & Zhang *J Org Chem* **65** 5871 *2000*, DOI: 10.1021/jo0004613; Yan & RajanBabu *Org Lett* **26** 4137 *2000*, DOI: 10.1021/ol006591f.] A variety of DIOP derivatives have been synthesised and tested as ligands with pre-Rh catalyst salts having different X^- counter ions in several solvents. The combination which gaves high yields and 'ee' excesses of ~98% was the all-equatorial ***3,4-O-isopropylidene-(3S,4S)-dihydroxy-(2R,5R)-bis(diphenylphosphino)hexane***, i.e. *RSSR*-dimeDIOP, X^- = BF_4^- and $Rh(I)^+(COD)_2$ BF_4^- [35138-22-8], in CH_2Cl_2, at 20-40psi and 10 hours [Yan & RajanBabu *Org Lett* **26** 4137 *2000*, DOI: 10.1021/ol006591f]. Other examples of the application of Rh-catalysed reactions requiring the DIOP ligand include regioselective hydroformylation of methyl *N*-aminoacrylate [and involving RhH(CO)(DOP)] [Gladiali & Pinna *Tetrahedron: Asymmetry* **1** 693 *1990*, DOI: 10.1016/S0957-4166(00)82375-7], 1,4-disilylation of α,β-unsaturated ketones [Matsumoto et al. *Tetrahedron* **50** 335 *1994*, DOI: 10.1016/S0040-4020(01)80758-4], the Heck reaction with alkenyl iodides [Sato et al. *Tetrahedron* **50** 371 *1994*, DOI: 10.1016/S0040-4020(01)80761-4], as well as the asymmetric hydrogenation of enamides [Morimoto et al. *Tetrahedron: Asymmetry* **6** 23 *1995*, DOI: 10.1016/0957-4166(94)00342-9; Morimoto et al. *Tetrahedron: Asymmetry* **6** 75 *1995*, DOI: 10.1016/0957-4166(94)00355-F].

Lanthanide trifluoromethanesulfonate (triflate) salts. These behave mostly as water-tolerant ***Lewis acids*** which catalyse a variety of organic functional group transformations. The lanthanide triflates below have been prepared and purified by the general procedure described here unless otherwise stated. The salts are prepared by adding excess of lanthanide (III) or (IV) oxide (>99% purity, 30mmol) to an aqueous solution of trifluoro

methanesulfonic acid (50% v/v, 21.2ml) and heating to boiling for 30 minutes to 1 hour (*alternatively*, at 100° for 2 hours). The mixture is filtered to remove any unreacted oxide. The water is then removed under a vacuum. The resulting hydrated salt is dried by heating under vacuum at 180° to 200° for 48 hours (200°/0.5mm for 40 hours was also reported). These salts are quite ***hygroscopic*** and all manipulations of reactions using these salts should be carried out using Schlenk equipment or glove boxes under an inert atmosphere (N_2, He or argon) to prevent contamination with H_2O that will lead to the formation of insoluble lanthanide hydroxides, and to maximise the activity of the catalyst. [Forsberg et al. *J Org Chem* **52** 1017 *1987*, DOI: 10.1021/jo00382a009; Kobayashi & Hachiya *J Org Chem* **59** 3590 *1994*, DOI: 10.1021/jo00092a017.]

Cerium(IV) trifluoromethanesulfonate **[cerium triflate, $Ce(OSO_2CF_3)_4$ H_2O, $Ce(OTf)_4$ H_2O]** *[698999-65-4]* **$(CF_3SO_3)_4Ce$. xH_2O, M 736.4 (anhydrous), slowly decomposes above 120° to give trivalent cerium species.** Preparation of $Ce(OTf)_4$ from CeO_4 or $Ce(OH)_4$ and trifluoromethanesulfonic acid as above for lanthanide triflates is usually unsuccessful. It is best prepared by adding, with vigorous stirring, a solution of K_2CO_3 (17.3g, 120mmol) in H_2O (95ml) to a solution of cerium(IV) ammonium nitrate (27.4g, 50mmol) *[16774-21-3]* in H_2O (80ml), whereupon a pale yellow carbonate separates. This is filtered off and washed several times with H_2O. CF_3SO_3H (triflic acid, 17.7ml, 200mmol) is slowly added at 0° to this 'wet' cerium(IV) carbonate whereby it dissolves, and the resulting orange coloured solution is evaporated under reduced pressure, and the residue is dried *in vacuo* at 70° for 10 hours to give ***Ce(OTf)$_4$*** as a yellow powder (36.2g). [**Note** that a 'wet' carbonate is important as very dry carbonate does not react readily with triflic acid at 0°.] The IR (KBr) has characteristic bands at $\nu_{S=O}$ 1230 and $\nu_{C\text{-}F}$ 1010 cm^{-1} and it analyses as a ***monohydrate*** (by Karl Fischer). The salt is ***hygroscopic*** and should be stored under N_2 and preferably in aliquots in sealed containers. It is soluble in H_2O, EtOH, THF, 1,2-dimethoxyethane and dioxane, but almost insoluble in hexane, $*C_6H_6$ and $CHCl_3$. It has very good oxidising ability, thus converting benzylic alcohols to aldehydes or ketones, and benzylic type CH_2 to CO, e.g. substituted toluenes to their corresponding benzaldehydes, ethylbenzene to acetophenone and diphenylmethane to benzophenone in high yields. [Imamoto et al. *Chem Lett* 1445 *1990*, DOI: 10.1246/cl.1990.1445]. ***Ce(OTf)$_4$*** is an efficient catalyst for the ring opening of epoxides with high regio and stereo selectivity. Ring opening, e.g. of styrene oxides (phenyloxiranes), yields essentially *trans* products with the OH, OR or OAc entering groups (when H_2O, alcohols or AcOH are used) attacking the 'benzylic carbon' atom, and with high optical purity when the reaction is carried out at ~-10° [e.g. *R*(+)-styrene oxide provides *S*(+)-PhCH(OMe)CH_2OH]. Ring opening of thiiranes with H_2O, alcohols or AcOH also yield *trans* products that dimerise to the corresponding dithianes. [Iranpoor et al. *Synth Commun* **28** 347 *1998*, DOI: 10.1080/00397919808005728; cf. Vougioukas & Kagan *Tetrahedron Lett* **28** 6065 *1987*, DOI: 10.1016/S0040-4039(00)96865-5.]

Gadolinium(III) trifluoromethanesulfonate *[52093-29-5]* **$(CF_3SO_3)_3Gd$, M 604.5, decomposes > 120°.** $Gd(OTf)_3$ is prepared by the above general method. If suspect, then add aqueous triflic acid (50% v/v) and proceed as above. It catalyses the aminolysis of epoxides in an extraordinarily efficient manner in aprotic solvents (e.g. toluene, CH_2Cl_2) with complete *trans* stereoselectivity and high regioselectivity [Chini et al. *Tetrahedron Lett* **35** 433 *1994*, DOI: 10.1016/0040-4039(94)85073-9]. It also catalyses the reactions between nitriles and amines to yield a variety of amidines which, depending on the amine, can be used to prepare cyclic amidines, pyrimidines and *s*-triazines [Forsberg et al. *J Org Chem* **52** 1017 *1987*, DOI: 10.1021/jo00382a009]. It is a water-tolerant ***Lewis acid*** used in aldol reactions of silyl enol-ethers and aldehydes in ~79-89% yields (see below) [Kobayashi & Hachiya *J Org Chem* **59** 3590 *1994*, DOI: 10.1021/jo00092a017].

Hafnium(IV) trifluoromethanesulfonate hydrate *[161337-67-3]* **$(CF_3SO_3)_4Hf$. H_2O, M 774.8 (anhydrous), m >350°.** $Hf(OTf)_4$ is prepared by the general method described above. If suspect, then add aqueous triflic acid (50% v/v) and proceed as in the general method above. It is an efficient catalyst in the Fries rearrangement of acyloxy benzene or naphthalene derivatives, and for the regioselective direct acylation of phenol and naphthol derivatives with acid chlorides [Kobayashi et al. *Tetrahedron Lett* **37** 2053 *1996*, DOI: 10.1016/0040-4039(96)00216-X]. It is an excellent and recyclable catalyst for mono-nitration of *o*-nitrotoluene [Waller et al. *Tetrahedron Lett* **39** 1641 *1998*, DOI: 10.1016/S0040-4039(97)10861-9].

Neodymium(III) trifluoromethanesulfonate **[$Nd(OTf)_3$]** *[34622-08-7]* **$(CF_3SO_3)_3Nd$, M 698.3, decomposes > 120°.** $Nd(OTf)_3$ is prepared by the general method described above. If suspect, then add aqueous triflic acid (50% v/v) and proceed as above. It catalyses the aminolysis of epoxides in an extraordinarily efficient manner in aprotic solvents (e.g. toluene, CH_2Cl_2) with complete *trans* stereoselectivity and high regioselectivity [Chini et al. *Tetrahedron Lett* **35** 433 *1994*, DOI: 10.1016/0040-4039(94)85073-9]. It also catalyses the reactions between nitriles and amines to yield a variety of amidines, which, depending on the amine, can be used to prepare cyclic amidines, pyrimidines and *s*-triazines [Forsberg et al. *J Org Chem* **52** 1017

1987, DOI: 10.1021/ jo00382a009]. It is a ***water-tolerant Lewis acid*** used in aldol reactions of silyl enol-ethers and aldehydes in ~83-85% yields (see below) [Kobayashi & Hachiya *J Org Chem* **59** 3590 *1994*, DOI: 10.1021/jo00092a017].

Ytterbium(III) trifluoromethanesulfonate hydrate **[$Yb(OTf)_3$ x H_2O]** *[252976-51-5]* **$(CF_3SO_3)_3Yb.xH_2O$, M 620.3 (anhydr), decomposes > 120°.** $Yb(OTf)_3$ is prepared by the general method described above. If suspect, then add aqueous triflic acid (50% v/v) and proceed as above. It can be recrystallised from $MeCN/CH_2Cl_2$. It has IR (KBr) bands at 3650, 3350, 2300, 1650, 1300, 1040 cm^{-1}; and ^{13}C NMR (270MHz, D_2O) at δ 122.4 (q, J = 317Hz) using sodium 2,2-dimethyl-2-silapentane-5-sulfonate) as internal standard.
It catalyses the aminolysis of epoxides in an extraordinarily efficient manner in aprotic solvents (e.g. toluene, CH_2Cl_2) with complete *trans* stereoselectivity and high regioselectivity [Chini et al. *Tetrahedron Lett* **35** 433 *1994*, DOI: 10.1016/0040-4039(94)85073-9]. It also catalyses the *trans* addition of indole (at position 3) to epoxides (e.g. to phenoxymethyloxirane) in >50% yields at 60° (42 hours) under pressure (10 Kbar) and was successfully applied for an enantioselective synthesis of ***(+)-diolmycin A2*** [Kotsuki *Tetrahedron Lett* **37** 3727 *1996*, DOI: 10.1016/0040-4039(96)00670-3]. Of the ten lanthanide triflates, $Yb(OTf)_3$ gave the highest yields (> 90%, see above)) of condensation products by catalytically activating formaldehyde, and a variety of aldehydes, in hydroformylations and aldol reactions, respectively, with trimethylsilyl enol-ethers in THF at room temperature. ***All the lanthanide triflates can be recovered from these reactions for re-use***. [Kobayashi & Hachiya *J Org Chem* **59** 3590 *1994*, DOI: 10.1021/jo00092a017.]

Methyltrioxorhenium (MTO, trimethylrhenium(VII) trioxide, Me_3ReO_3) *[70197-13-6]* **$C_3H_6ReO_3$, M 249.2, m 110°, 111°, pK_8^{25} 7.53.** MTO is an ***air-stable*** carbon-rhenium oxide which is prepared from tetramethylrhenium oxide (Me_4ReO, [*53022-70-1*]) or trimethylrhenium dioxide (Me_3ReO_2, *[56090-01-8]*) (100mg) in a 1L evacuated bulb, and dry air is admitted up to a pressure of ~760mm (atmospheric). After a few days long needles of Me_3ReO_3 are formed, and after 4 weeks in excess of 50% yields of the trioxide are obtained. These crystals can be ***resublimed*** to analytical purity *in vacuo* (at ~25°/1mm or 65°/0.001mm), have a sharp melting point (110°), are not decomposed in the gas phase <300°. ***Alternatively on a larger scale*****,** silver tetraoxorhenate (14.0g, 39mmol, $AgReO_4$ *[7784-00-1]*) is dissolved in MeCN (150ml) followed by addition of Me_3SiCl (10.8ml, 85mmol, TMSCl [75-77-4]) whereby a white precipitate of AgCl separates and the solution becomes orange in colour. The suspension is treated with Me_4Sn (6.0ml, 43mmol, *[594-27-4]*), stirred for 24 hours, filtered into a Schlenk sublimation tube (~ 0.75L) and evaporated in a vacuum (20mbar), using a liquid N_2 trap (for volatile Sn compounds). A cold finger is then inserted into the tube and the Me_3SnCl *[1066-45-1]* is sublimed out at ~25°/20mbar; this compound is removed and the vacuum is increased to 0.01mbar when MTO sublimes out as a yellow-white crystalline solid. Traces of ***toxic Sn compounds*** may be present in this MTO (causing a pungent odour), but are removed by spreading it on filter paper in a fume hood for 1-3 hours, and the purity is checked by elemental analysis. MTO (7.8g) is thus obtained in 80% yield. Similar results are obtained on a 100g scale. The recovered Me_3SnCl can be converted to $SnMe_4$ by methylating with MeMgCl (23% in THF). High-purity MTO can be obtained by recrystallisation from CH_2Cl_2/hexane (73%). The white solid turns grey on standing without alteration in its activity, but this can be minimised by storing it away from light under N_2. ***Note*** that the Sn compounds are **HIGHLY TOXIC, and all work should be carried out in an efficient fume cupboard**. [Herrmann & Kratzer *Inorg Synth* **33** 111 *2002*, DOI: 10.1002/0471224502.ch2; Herrmann et al. *Angew Chem Int Ed* **36** 2652 *1997*, DOI: 10.1002/anie.199726521.]
MTO forms colourless needles that develop a greyish tint on prolonged storage in light. It differs from methylperrhenate in being stable to hydrolysis by H_2O. It is soluble in MeCN, $*C_6H_6$, $CHCl_3$, EtOH and H_2O, but sparingly soluble in CS_2 and hexane. Its MS has parent ion peaks of $MeReO_3^+$ at 248 and 250 mass units for the species containing ^{185}Re and ^{187}Re in a ratio consistent with the relative isotopic abundances. The UV/VIS (Et_2O) has λ_{max} (ε) at 260nm (1400, $Lmol^{-1}cm^{-1}$) and 232nm (1900, $Lmol^{-1}cm^{-1}$). ^1H, ^{13}C and ^{17}O NMR ($CDCl_3$, 25°) spectroscopy shows signals with δ_H at 2.61 (sharp), δ_C at 19.03 (^2J = 138Hz, C-H) and δ_O at 829 respectively; and the IR (hexachlorobutadiene mull) has ν_{max} at 1360ms (*CH deformation*), 2895 and 2980 (*CH stretching*) cm^{-1}; the IR in gaseous state (at 70°) has ν_{max} at 1003w(*ReO_3 sym str*), 985w, 975vs, 962vs(*ReO_3 antisym str*), 743mw(*CH_3-rock*), 574w(*Re-C*), 324w(*ReO_3 deformation*) cm^{-1}, and the IR (argon matrix) has ν_{max} at 1000ms(*ReO_3 sym str*), 970vs and 966m(*ReO_3 antisym str*), 566w(*Re-C*) cm^{-1}. Its Raman spectrum in CS_2 has ν_{max} at 999s(*ReO_3 sym str*) cm^{-1}, and in the solid state it has ν_{max} at 999s(*ReO_3 sym str*), 964m(*ReO_3 antisym str*), 530m(*Re-C*), 330m and 242m(*ReO_3 deformation*) cm^{-1}. [Beattie & Jones *Inorg Chem* **18** 2318 *1979*, DOI: 10.1021/ic50198a056.]

MTO is a ***catalytic oxygen carrier*** in conjunction with an oxidant, e.g. H_2O_2, UHP (urea-H_2O_2 complex). For example 3.7mmol of 3,4,6-tri-*O*-acetyl-D-glucal in MeOH is oxidised by 7.4mmol of H_2O_2 in the presence of a catalytic amount of MTO (3.6 x 10^{-2}mmol) at ~25º in 2 hours to give the corresponding β-D-*gluco*- and α-D-*manno*- pyranosides (2:1) in 78% isolated yields *via* the intermediate epoxide. [Boyd et al. *Green Chem* **5** 679 *2003*.] ***MTO*** is a versatile oxidation catalyst and very effective in olefin epoxidation, olefin isomerisation, olefin metathesis, Baeyer-Villiger oxidation of ketones to lactones, aromatic oxidation to *p*-quinones, and in Diels-Alder reactions [Summarised in Herrmann *J Organomet Chem* **500** 149 *1995*, DOI: 10.1016/0022-328X(95)00518-U]. It is a catalytic oxidant for the conversion of imines to nitrones [Soldaini et al. *Org Lett* **9** 473 *2007*, DOI: 10.1021/ol062862w; Baldwin & Long *Org Lett* **6** 1653 *2004*, DOI: 10.1021/ol049505a], and catalyses the efficient and stereospecific desulfurisation of thiirane (episulfides) by Ph_3P at ~25º, and more so if MTO is pre-treated with H_2S, probably due to the formation of Re(V)S species as the active catalyst [Jacob & Espenson *JCS Chem Commun* 1003 *1999*, DOI: 10.1039/A901708I].

Molybdenum dioxo bis(2,4-dipentandionato-κO2,κO4) [bis(acetylacetonato)dioxomolybdenum (IV), dioxobis(2,4-pentadionato)molybdenum (IV), MoO_2 (acac)$_2$] *[17524-05-9]* **$C_{10}H_{14}O_6Mo$, M 326.2, m 179º, 184-185º, 184º (dec).** This complex is readily prepared by dissolving powdered ammonium *para*molybdate {$(NH_4)_6Mo_7O_{24}$ $4H_2O$, 3.0g, 2.4mmol, see *[12054-85-2]*) in 15% aqueous NH_3 (6.0ml, or 6.0.ml of 58%) with stirring. The clear solution (but if some solid remains undissolved, it will dissolve when nitric acid is finally added) is treated with 2,4-pentanedione (7.0ml, 6.8mmol) with stirring and the colour turns yellow. Concentrated HNO_3 (5.0ml, d 1.42) is slowly added with stirring to the mixture which warms up and the colour turns greenish yellow. The yellow complex separates as the mixture is allowed to cool to room temperature. After ~ 0.5 hours the solid is filtered off washed well with H_2O, then with EtOH, and dried *in vacuo* to give a 72% yield (4.0g) of the complex which can be increased to 93% if the hot solution is kept in a freezer at -10º in 18 hours. It can be recrystallised by dissolving ~2.0g in hot 2,4-pentanedione (6.0ml) at ~90º then keeping at -10º in 18 hours. The yellow crystals are filtered off with suction, washed with EtOH and dried *in vacuo* to give 1.8g of product. ***Note*** that if all the 2,4-pentanedione is not removed the crystals slowly develop a reddish tint. It decomposes slowly when stored in air or under fluorescent light, and turns blue. However, it is stable when stored *in vacuo* or under N_2. It is insoluble in H_2O, but slightly soluble in EtOH, $CHCl_3$, CH_2Cl_2 and soluble in MeCN. [Chakravorti et al. *Inorg Synth* **29** 129 *1992*, DOI: 10.1002/9780470132609.ch31; and from MoO_3 and 2,4-pentanedione see Fernelius et al. *Inorg Synth* **6** 147 *1960*, DOI: 10.1002/9780470132371.ch46.] Its IR (KBr) has ν_{max} at 1560, 1500, 1350, 1260, 1015, 930 (Mo=O symm), 900 (Mo=O antisymm), 795, 665, 570 and 445 cm^{-1}; the ^1H NMR (CD_2Cl_2, TMS) has δ at 2.12, 2.14 and 5.83; and for ^{13}C NMR see references.
