DEDICATION

From the very first to all later editions of this book, I have received every encouragement, support, and assistance through discussions and proofreading from my devoted wife Dr Pauline Marjorie Armarego. Her efforts and contributions during the preparation of this eighth edition were very considerable. She was responsible for locating and inserting the DOI and PMID numbers after thousands of references to the original literature. In so doing she amended all errors in faulty references, checked that the science corresponded with the respective reference, and that the numbers indeed allowed the download of the respective original references. In addition to this she proofread the whole manuscript four times on a 24 inch screen on a 'word by word' basis, correcting the typos while keeping an 'eagle eye' on the formatting and the chemistry. Her efforts have saved me more than twelve months of hard work, which are deserving of co-authorship. However, her modesty would not allow me this, but finally conceded me the pleasure of dedicating this edition to her.

Preface to the Eighth Edition

THE INCENTIVE to write the eighth edition came from Ms Fiona Geraghty, Acquisitions Editor, S & T Books, Elsevier Limited who approached me to write an 8th edition of *Purification of Laboratory Chemicals* and proposed an increase in the size of the book by about 200 pages. I accepted because I had many ideas in mind that would improve the book's usefulness, and this was a good opportunity to carry them through. These ideas were conveyed to Ms Geraghty who solicited the views of a few reviewers. Their responses, as well as being uniformly favourable, were also very constructive.

The following propositions were thus implemented in this edition.
(*a*) All Chapters and sections were updated, new information and new substances were inserted in keeping with the original theme of '*purification of commercially available substances*'. In several instances brief synthetic procedures were included because they gave insights into purifying these substances.
(*b*) The empirical formulae and new physical data were inserted for each entry.
(c) Almost all substances now have one or more references to the original literature with their corresponding DOI's (digital object identifiers), PMID (unique PubMed system identifiers), ISBN (International Standard Book Number), and ISSN (International Standard Serial Number) numbers. These will allow users to download the original publications directly from a laptop computer connected to the internet without leaving the laboratory or requiring a comprehensive library.
(*d*) Chapter 3 of the 7th edition was deleted and replaced by sections on *Recent Advances in Physical* and *in Chemical Techniques*, *used in Purification* at the end of Chapters 1 and 2 respectively. The 'Miscellaneous Compounds' section in Chapter 6 (formerly Chapter 7) was renamed 'Physiologically Active Compounds' and the more important active compounds, and many new ones, were located here.
(*e*) Every endeavour was made to state briefly the more common applications where possible, e.g. industrial, agricultural, pharmaceutical, physiological, medical, catalytic etc.
(*f*) The General Index was made more comprehensive.
(*g*) A 20% increase in the Chemical Abstracts Service Registry numbers (CASRNs), and consequently of new substances, was made, providing a total of over 8000 chemical and biochemical substances. It does not include those that were not allocated CASRNs, e.g. allotropic and polymorphic forms, polymer bound reagents, enzymes, some catalysts and some nanomaterials.
The large variety and number of examples of purification procedures described in this book should make it possible to devise appropriate methods for the purification of any number of new substances in hand.

I should like to make the following acknowledgements:
I am gratefully indebted to Professor Jill E. Gready (John Curtin School of Medical Research, ANU) for her continued encouragement and for strongly supporting my Visiting Fellowships in her research group over many years. I am also grateful to Professor David Tremethick (Head of the of Genome Biology Department, John Curtin School of Medical Research, ANU) for his continued encouragement and for supporting my Visiting Fellowship. I thank Professor Martin Banwell FAA (Research School of Chemistry, ANU) for pointing out to me that specific optical rotations are now designated without a degree sign. I have now deleted the degree sign from the thousands of specific rotations in this edition.
I am indebted to Professor Hiroyasu Taguchi (Department of Medical Chemistry, Molecular Neuroscience Research Centre, Shiga University of Medical Science, Japan) for his encouragement and support for this and previous editions of this book, and particularly for allowing me to include data on curcumin and its derivatives, and their use in the diagnostics of Alzheimer's disease. The continued help from Joe Papa BS MS (EXAXOL in Clearwater, Florida, USA) with the preparation and purification of several inorganic compounds, particularly of beryllium and cerium, and trace metal analyses of a large number of commercially available inorganic compounds included in this book, is much appreciated and gratefully acknowledged.

I wish to thank my wife Dr Pauline M. Armarego for her continued help (see Dedication), my daughter Dr Sarah H. Armarego FANZCA, CCP (Aust) (Anaesthetist and Perfusionist, Senior Staff Specialist) for providing and discussing with me information on many physiologically active substances and their medical aspects, and my grand daughter Ms Gemma M. M. Armarego (University student in Nursing and Paramedics) for providing me with a long list of drugs that she uses in her profession, many of which have been included in this book.
Finally, I thank the ANU library and its staff, both on campus and at the ANU Print Repository, for their prompt and unfailing assistance.

W.L.F. Armarego *September 2016*

PREFACE

Preface to the First Edition

WE BELIEVE that a need exists for a book to help the chemist or biochemist who wishes to purify the reagents she or he uses. This need is emphasised by the previous lack of any satisfactory central source of references dealing with individual substances. Such a lack must undoubtedly have been a great deterrent to many busy research workers who have been left to decide whether to purify at all, to improvise possible methods, or to take a chance on finding, somewhere in the chemical literature, methods used by some previous investigators.

Although commercially available laboratory chemicals are usually satisfactory as supplied, for most purposes in scientific and technological work, it is also true that for many applications further purification is essential.

With this thought in mind, the present volume sets out, first, to tabulate methods, taken from the literature, for purifying some thousands of individual commercially available chemicals. To help in applying this information, two chapters describe the more common processes currently used for purification in chemical laboratories and give fuller details of new methods which appear likely to find increasing application for the same purpose. Finally, for dealing with substances not separately listed, a chapter is included setting out the usual methods for purifying specific classes of compounds.

To keep this book to a convenient size, and bearing in mind that its most likely users will be laboratory-trained, we have omitted manipulative details with which they can be assumed to be familiar, and also detailed theoretical discussion. Both are readily available elsewhere, for example in Vogel's very useful book **Practical Organic Chemistry** (Longmans, London, 3rd ed., 1956), or Fieser's **Experiments in Organic Chemistry** (Heath, Boston, 3rd ed., 1957).

For the same reason, only limited mention is made of the kinds of impurities likely to be present, and of the tests for detecting them. In many cases, this information can be obtained readily from existing monographs.

By its nature, the present treatment is not exhaustive, nor do we claim that any of the methods taken from the literature are the best possible. Nevertheless, we feel that the information contained in this book is likely to be helpful to a wide range of laboratory workers, including physical and inorganic chemists, research students, biochemists, and biologists. We hope that it will also be of use, although perhaps to only a limited extent, to experienced organic chemists.

We are grateful to Professor A. Albert and Dr D.J. Brown for helpful comments on the manuscript.

D.D.P., W.L.F.A. & D.R.P.
1966

Preface to the Second Edition

SINCE the publication of the first edition of this book, there have been major advances in purification procedures. Sensitive methods have been developed for the detection and elimination of progressively lower levels of impurities. Increasingly stringent requirements for reagent purity have gone hand-in-hand with developments in semiconductor technology, in the preparation of special alloys and in the isolation of highly biologically active substances. The need to eliminate trace impurities at the micro- and nanogram levels has placed greater emphasis on ultrapurification technique. To meet these demands the range of purities of laboratory chemicals has become correspondingly extended. Purification of individual chemicals thus depends more and more critically on the answers to two questions-Purification from what, and to what permissible level of contamination. Where these questions can be specifically answered, suitable methods of purification can usually be devised.

Several periodicals devoted to ultrapurification and separations have been started. These include "Progress in Separation and Purification" (vol. 1) Ed. E.S. Perry, Wiley-Interscience, New York, vols. 1-4, 1968-1971, and **Separation and Purification Methods**, Ed. E.S.Perry and C.J.van Oss, Marcel Dekker, New York, vol. 1, 1973. Nevertheless, there still remains a broad area in which a general improvement in the level of purity of many compounds can be achieved by applying more or less conventional procedures. The need for a convenient source of information on methods of purifying available laboratory chemicals was indicated by the continuing demand for copies of this book even though it had been out of print for several years.

We have sought to revise and update this volume, deleting sections that have become more familiar or less important, and incorporating more topical material. The number of compounds in Chapters 3 and 4 have been increased appreciably. Also, further details in purification and physical constants are given for many compounds that were listed in the first edition.
We take this opportunity to thank users of the first edition who pointed out errors and omissions, or otherwise suggested improvements or additional material that should be included. We are indebted to Mrs S.Schenk who emerged from retirement to type this manuscript.

D.D.P., W.L.F.A. & D.R.P.
1980

Preface to the Third Edition

THE CONTINUING demand for this monograph and the publisher's request that we prepare a new edition are an indication that **Purification of Laboratory Chemicals** fills a gap in many chemists' reference libraries and laboratory shelves. The present volume is an updated edition that contains significantly more detail than the previous editions, as well as an increase in the number of individual entries and a new chapter.
Additions have been made to Chapters 1 and 2 in order to include more recent developments in techniques (e.g. Schlenk-type, *cf* p. 10), and chromatographic methods and materials. Chapter 3 still remains the core of the book, and lists in alphabetical order relevant information on *ca* 4000 organic compounds. Chapter 4 gives a smaller listing of *ca* 750 inorganic and metal-organic substances, and makes a total increase of ca 13% of individual entries in these two chapters. Some additions have also been made to Chapter 5.
We are currently witnessing a major development in the use of physical methods for purifying large molecules and macromolecules, especially of biological origin. Considerable developments in molecular biology are apparent in techniques for the isolation and purification of key biochemicals and substances of high molecular weight. In many cases something approaching homogeneity has been achieved, as evidenced by electrophoresis, immunological and other independent criteria. We have consequently included a new section, Chapter 6, where we list upwards of 100 biological substances to illustrate their current methods of purification. In this chapter the details have been kept to a minimum, but the relevant references have been included.

The lists of individual entries in Chapters 3 and 4 range in length from single-line entries to *ca* one page or more for solvents such as acetonitrile, benzene, ethanol and methanol. Some entries include information such as likely contaminants and storage conditions. More data referring to physical properties have been inserted for most entries [i.e. melting and boiling points, refractive indexes, densities, specific optical rotations (where applicable) and UV absorption data]. Inclusion of molecular weights should be useful when deciding on the quantities of reagents needed to carry out relevant synthetic reactions, or preparing analytical solutions. The Chemical Abstracts registry numbers have also been inserted for almost all entries and should assist in the precise identification of the substances.

In the past ten years laboratory workers have become increasingly conscious of safety in the laboratory environment. We have therefore in three places in Chapter 1 (pp. 3 and 33, and bibliography p. 52) stressed more strongly the importance of safety in the laboratory. Also, where possible, in Chapters 3 and 4 we draw attention to the dangers involved with the manipulation of some hazardous substances.

The worldwide facilities for retrieving chemical information provided by the Chemical Abstract Service (CAS on-line) have made it a relatively easy matter to obtain CAS registry numbers of substances, and most of the numbers in this monograph were obtained *via* CAS on-line. We should point out that two other available useful files are CSCHEM and CSCORP, which provide, respectively, information on chemicals (and chemical products) and addresses and telephone numbers of the main branch offices of chemical suppliers.

The present edition has been produced on an IBM PC and a Laser Jet printer using the **Microsoft Word (4.0)** word-processing program with a set style sheet. This has allowed the use of a variety of fonts and font sizes which has made the presentation more attractive than in the previous edition. Also, by altering the format and increasing slightly the sizes of the pages, the length of the monograph has been reduced from 568 to 391 pages. The reduction in the number of pages has been achieved in spite of the increase of *ca* 15% of total text.

PREFACE

We extend our gratitude to the readers whose suggestions have helped to improve the monograph, and to those who have told us of their experiences with some of the purifications stated in the previous editions, and in particular with the hazards that they have encountered. We are deeply indebted to Dr M.D. Fenn for the several hours that he has spent on the terminal to provide us with a large number of CAS registry numbers.

This monograph could not have been produced without the expert assistance of Mr David Clarke who has spent many hours loading the necessary fonts in the computer, and for advising one of the authors (W.L.F.A.) on how to use them together with the idiosyncrasies of Microsoft Word.

D.D.P. & W.L.F.A.
1988

Preface to the Fourth Edition

THE AIMS of the first three editions, to provide purification procedures of commercially available chemicals and biochemicals from published literature data, are continued in this fourth edition. Since the third edition in 1988 the number of new chemicals and biochemicals that have been added to most chemical and biochemical catalogues have increased enormously. Accordingly there is a need to increase the number of entries with more recent useful reagents and chemical and biochemical intermediates. With this in mind, together with the need to reorganise and update general purification procedures, particularly in the area of biological macromolecules, as well as the time lapse since the previous publication, this fourth edition of **Purification of Laboratory Chemicals** has been produced. Chapter 1 has been reorganised with some updating, and by using a smaller font it was kept to a reasonable number of pages. Chapters 2 and 5 were similarly altered and have been combined into one chapter. Eight hundred and three hundred and fifty entries have been added to Chapters 3 (25% increase) and 4 (44% increase), respectively, and four hundred entries (310% increase) were added to Chapter 5 (Chapter 6 in the Third Edition), making a total of 5700 entries-all resulting in an increase from 391 to 529 pages, i.e., by *ca* 35%.

Many references to the original literature have been included remembering that some of the best references happened to be in the older literature. Every effort has been made to provide the best references, but this may not have been achieved in all cases. Standard abbreviations, listed on page 1, have been used throughout this edition to optimise space, except where no space advantage was achieved, in which cases the complete words have been written down to improve the flow of the sentences.

With the increasing facilities for information exchange, chemical, biochemical and equipment suppliers are making their catalogue information available on the Internet; e.g., Aldrich-Fluka-Sigma catalogue information is available on the World Wide Web by using the address http://www.sigma.sial.com, and GIBCO BRL catalogue information from http://www.lifetech.com, as well as on CD-ROMS which are regularly updated. Facility for enquiring about, ordering and paying for items is available *via* the Internet. CAS on-line can be accessed on the Internet, and CAS data is available now on CD-ROM. Also biosafety bill boards can similarly be obtained by sending SUBSCRIBE SAFETY John Doe at the address "listserv@uvmvm.uvm.edu", SUBSCRIBE BIOSAFETY at the address "listserv@mitvma.mit.edu", and SUBSCRIBE RADSAF at the address "listserv@romulus.ehs.uiuc.edu"; and the Occupational, Health and Safety information (Australia) is available at the address "http://www.worksafe.gov.au/~wsa1". Sigma-Aldrich provided Material Safety data sheets on CD-ROMs.

It is with much sadness that Dr Douglas D. Perrin was unable to participate in the preparation of the present edition due to illness. His contributions towards the previous editions have been substantial, and his drive and tenacity have been greatly missed.

The Third Edition was prepared on an IBM-PC, and the previous IBM files were converted into Macintosh files. These have now been reformatted on a Macintosh LC575 computer, and all further data to complete the Fourth Edition were added to these files. The text was printed with a Hewlett-Packard 4MV -600dpi Laser Jet printer, which gives a clearer resolution.

I thank my wife Dr Pauline M. Armarego, also an organic chemist, for the arduous and painstaking task of entering the new data into the respective files, and for the numerous hours of proofreading as well as the corrections of typographic errors in the files. I should be grateful to my readers for any comments, suggestions, amendments and criticisms which could, perhaps, be inserted in the second printing of this edition.

W.L.F. Armarego, 30 June 1996

Preface to the Fifth Edition

THE DEMAND for **Purification of Laboratory Chemicals** has not abated since the publication of the fourth edition as evidenced by the number of printings and the sales. The request by the Editor for a fifth edition offered an opportunity to increase the usefulness of this book for laboratory purposes. It is with deep regret that mention should be made that Dr Douglas D. Perrin had passed away soon after the fourth edition was published. His input in the first three editions was considerable, and his presence has been greatly missed. A fresh, new and young outlook was required in order to increase the utility of this book, and it is with great pleasure that Dr Christina L.L. Chai, a Reader in Chemistry and leader of a research group in organic and bio-organic chemistry, has agreed to coauthor this edition. The new features of the fifth edition have been detailed below.

Chapters 1 and 2 have been reorganised and updated in line with recent developments. A new chapter on the Future of Purification has been added. It outlines developments in syntheses on solid supports, combinatorial chemistry as well as the use of ionic liquids for chemical reactions and reactions in fluorous media. These technologies are becoming increasingly useful and popular, so much so that many future commercially available substances will most probably be prepared using these procedures. Consequently, knowledge of their basic principles will be helpful in many purification methods of the future.

Chapters 4, 5 and 6 (3, 4 and 5 in the 4th ed.) form the bulk of the book. The number of entries has been increased to include the purification of many recent commercially available reagents that have become more and more popular in the syntheses of organic, inorganic and bio-organic compounds. Several purification procedures for commonly used liquids, e.g., solvents, had been entered with excessive thoroughness, but in many cases the laboratory worker only requires a simple, rapid but effective purification procedure for immediate use. In such cases a **rapid purification** procedure has been inserted at the end of the respective entry, and should be satisfactory for most purposes. With the increased use of solid phase synthesis, even for small molecules, and the use of reagents on solid support (e.g., on polystyrene) for reactions in liquid media, compounds on solid support have become increasingly commercially available. These have been inserted at the end of the respective entry and have been listed in the General Index together with the above rapid purification entries.

A large number of substances are ionisable in aqueous solutions, and knowledge of their ionisation constants, stated as pK (pKa) values, can be of importance not only in their purification but also in their reactivity. Literature values of the pK's have been inserted for ionisable substances, and where values could not be found they were estimated (pK_{Est}). The estimates are usually so close to the true values as not to affect the purification process or the reactivity seriously. The book will thus be a good compilation of pK values for ionisable substances.

Almost all the entries in Chapters 4, 5 and 6 have CAS (Chemical Abstract Service) Registry Numbers to identify them, and these have been entered for each substance. Unlike chemical names which may have more than one synonymous name, there is only one CAS Registry Number for each substance (with only a few exceptions, e.g., where a substance may have another number before purification, or before determination of absolute configuration). To simplify the method for locating the purification of a substance, a CAS Registry Number Index with the respective page numbers has been included after the General Index at the end of the book. This will also provide the reader with a rapid way to see if the purification of a particular substance has been reported in the book. The brief General Index includes page references to procedures and equipment, page references to abbreviations of compounds, e.g., TRIS, as well as the names of substances for which a Registry Number was not found.

Website references for distributors of substances or/and of equipment have been included in the text. However, since these may be changed in the future we must rely on the suppliers to inform users of their change in website references.

We wish to thank readers who have provided advice, constructive criticism and new information for inclusion in this book. We should be grateful to our readers for any further comments, suggestions, amendments and criticisms which could, perhaps, be inserted in a second printing of this edition. In particular, we thank Professor Ken-chi Sugiura (Graduate School of Science, Tokyo Metropolitan University, Japan) who has provided us with information on the purification of several organic compounds from his own experiences, and Joe Papa BS MS (EXAXOL in Clearwater, Florida, USA) who has provided us not only with his experiences in the purification of many inorganic substances in this book, but also gave us his analytical results on the amounts of other metal impurities at various stages of purification of several salts. We thank them graciously for permission to include their reports in this work. We express our gratitude to Dr William B. Cowden for his generous advice on computer hardware and software over many years and for providing an Apple LaserWriter (16/600PS) which we used to produce the master copy of this book. We also extend our sincere thanks to Dr Bart Eschler for advice on computer hardware and software and for assistance in setting up the computers (iMac and eMac) used to produce this book.

We thank Dr Pauline M. Armarego for assistance in the painstaking task of entering data into respective files, for many hours of proofreading, correcting typographical errors and checking CAS Registry Numbers against their respective entries.

One of us (W.L.F.A) owes a debt of gratitude to Dr Desmond (Des) J. Brown of the Research School of Chemistry, ANU, for unfailing support and advice over several decades and for providing data that was difficult to acquire not only for this edition but also for the previous four editions of this book.

PREFACE

One of us (C.L.L.C) would especially like to thank her many research students (past and present) for their unwavering support, friendship and loyalty, which enabled her to achieve what she now has. She wishes also to thank her family for their love, and would particularly like to dedicate her contribution towards this book to the memory of her brother Andrew who had said that he should have been a scientist.

We thank Mrs. Joan Smith, librarian of the Research School of Chemistry, ANU, for her generous help in many library matters, which has made the tedious task of checking references more enduring.

W.L.F. Armarego & C.L.L. Chai
November 2002

Preface to the Sixth Edition

THERE IS a continuing demand for the **Purification of Laboratory Chemicals** book, to the extent that the 5th edition which was published in early 2003 was carefully translated into Chinese (ISBN 978-7-5025-94367) by Ying-Jie Lin, Wei Liu, Hui-Ping Wang, Xiao-Bo Sun, Qing-Shan Li and Jun-Gang Cao from Jilin University (People's Republic of China) in 2007. In response to the demand, it was timely to update the 5th edition to include the more recently developed purification procedures, as well as add to the list of compounds for purification. The latter comprise some commercially available compounds that have gained usefulness and popularity in the past few years.

The first two chapters have been updated, sections of current interest have been expanded and new sections added. Chapter 3 has been rewritten so that areas of work that have lost popularity have been reduced in size or deleted and sections on recent, and now commonly adopted, technologies have been inserted. Chapters 4, 5 and 6 are now completely reorganized, and each is subdivided into several sections which will make it easier for the reader to locate compounds of similar classification. Chapter 4 is subdivided into aliphatic, alicyclic, aromatic and heterocyclic compounds, Chapter 5 has been subdivided into inorganic and metal-organic compounds, and Chapter 6 has been subdivided into amino acids and peptides, proteins, enzymes, DNA and RNA, carotenoids, carbohydrates, steroids and a miscellaneous section which includes small biologically active substances such as antibiotics, coenzymes, co-factors, lipids, phospholipids, polynucleotides and vitamins. Some useful compounds that have been added recently to commercial catalogues have been included in these three chapters. A large number of derivatives of previous entries with their physical properties and purifications have been inserted together with extensive referencing to the original literature including *Beilstein* references. This resulted in an increase in size of the 5th edition, in text and number of compounds, by over 20%. The purifications of some 7400 substances are described. As in the 5th edition, substance entries are in alphabetical order within subsections and each substance is defined by its Chemical Abstracts Service (CAS) Registry Number. An index of these numbers with their respective page numbers at the end of the book will make it possible to locate the purification of a desired substance readily and to check if the substance is contained in the book. For this purpose we thank Rodney Armarego for setting up a *Macro* on the MacBook Pro computer used for collating the CAS Registry Numbers for the index. There is also a General Index of Contents.

Website references of distributors of substances and/or of equipment have been included in the text. However, since these may change in the future, users should check for current websites of suppliers. The bibliographies have been updated, and websites of a few publishers and book suppliers have been included. Several texts with publication dates older than fifteen years have been deleted except for a few very useful textbooks which are out of print and where recent editions have not been produced. In these cases it is usually possible to obtain used copies from good suppliers of old books, for which there are several websites, e.g. visit Google under "old books suppliers"; also visit websites such as <http//www.abebooks.com>, <http//www.betterworld.com/usedbooks>, <http//www.booksandcollectibles.com.au/index>, <http//www.ebay.com.au/>. Further information for almost every entry in Chapters 4, 5 and 6 of the 6th edition can be obtained from the references to the original literature, which are cited under each entry together with their respective *Beilstein* reference(s).

We thank readers who have provided advice, constructive criticism and new information. We are grateful for any further comments, suggestions, amendments and criticisms which could, perhaps, be inserted in a second printing of this edition. We thank Joe Papa BS MS (EXAXOL in Clearwater, Florida, USA) in particular for sharing his experiences on the purification of several inorganic substances in this and previous editions, and also for allowing us to use his analytical results on the amounts of metal impurities at various stages of purification of several salts.

We thank Dr Pauline M. Armarego for assistance in the painstaking task of entering data into respective files, for many hours of proofreading, correcting typographical errors and checking CAS Registry Numbers against their respective entries.
One of us (W.L.F.A) owes a debt of gratitude to Dr Desmond (Des) J. Brown of the Research School of Chemistry, ANU, for unfailing support and advice over several decades and for providing data that was difficult to acquire not only for this edition but also for the previous five editions of this book.

One of us (C.L.L.C) would like to acknowledge the support and friendship of her many research staff and students (past and present at ANU and A*STAR). She especially thanks Drs Paul Huleatt, Paul Bernardo, Felicity Moore and Brendan Burkett for their unfailing faith in her, through chemical and personal journeys both in Singapore and Australia. The legacy of this book is for Kimberley and Victoria Tse because it is cool to be a scientist!

We thank Mrs Joan Smith, librarian of the Research School of Chemistry, ANU, for her generous help in many library matters which made the tedious task of checking references more enduring.

W.L.F. Armarego & C.L.L. Chai
November 2008

Preface to the Seventh Edition

The sales of the sixth edition, which appeared in April 2009, were high by about October 2009, and one of us (WLFA) was approached by Ms Melanie Benson, Editorial Project Manager of Elsevier Science & Technology Books (who was mainly responsible for the production of the 6th edition), about writing a 7th edition within 2-3 years. In the past, 6-9 years were allowed to lapse between editions. However, the attraction this time, was that we were allowed to increase the size of the work by up to 249 pages. This has given us the opportunity to update all the previous chapters in the light of current thinking on safety (personal and environmental), and to introduce two new chapters. The award of five Nobel Prizes in the past ten years or so in Chemistry and one in Physics, of which three were awarded for work on *Catalysis* and *the catalytic process* (2001, 2005 and 2010), and two for work on *Nanomaterials and Nanotechnology* (1996, 2010) have prompted us to write a new chapter on *Catalysts* and a new chapter on *Nanomaterials and Nanotechnology*. Chemical suppliers have now made commercially available a large number of catalysts as well as many nanomaterials of various sorts. Since the number of commercially available catalysts are currently considerably larger than that of nanomaterials, the chapter on Catalysts is larger than that on Nanomaterials and Nanotechnology, and had to be divided into two parts. The availability, preparation and purification of a large range of these, are presented in these chapters. The other chapters have been updated and expanded, also in keeping with the purpose of all previous editions which is to provide information for the purification of commercially available laboratory materials. Of course, the General Subjects Index and the Chemical Abstracts Registry Numbers (CASRNs) Index increased in size accordingly. Much of the cross referencing is done *via* CASRNs and a page of how to use this book through these is included before Chapter 1 to assist the reader, not only to locate the pages where the required CASRNs are to be found, but also to let the reader know whether a particular substance is included in this work. CASRNs can be readily obtained from chemical catalogues or from SciFinder.

We would like to acknowledge Professor Martin Banwell FAA (Director, Research School of Chemistry, ANU) for his generosity in allowing the use of IT services, and to Dr Emil Mittag (Research School of Chemistry, ANU) for editing and updating the *Macro* program used for making the CASRNs Index.

We are greatly indebted to many people who have made valuable and constructive comments, and indicated errors, in previous editions. The continued help from Joe Papa of BS MS (EXAXOL in Clearwater, Florida, USA) with the preparation and purification of several inorganic compounds, particularly beryllium and cerium, is appreciated and gratefully acknowledged.

One of us (WLFA) owes a debt of gratitude to Professor Jill E. Gready (John Curtin School of Medical Research, ANU) for her continued encouragement and for strongly supporting a Visiting Fellowship over a period of many years.

We thank Dr Pauline M. Armarego for assistance in the painstaking task of proofreading and correcting typographical errors as well as checking the General Index and the CASRNs Index.

We thank the ANU library and its staff, both on campus and at the ANU Print Repository, for their prompt and unfailing assistance.

W.L.F. Armarego & C.L.L. Chai
December 2011

HOW THIS BOOK SHOULD BE USED

Substances have been entered in their respective chapters, sections and subsections. In these sections, compounds are listed in alphabetical order according to their more commonly used names. Because compounds can be named in various ways, some alternate names, as well as the commonly used abbreviations and commercial synonyms, have been included in brackets after their entries. Sometimes it may be difficult to find a particular substance; in which case *it is advisable to obtain the page number of the entry from its Chemical Abstracts Registry Number in the 'CASRNs Index' at the end of the book.* This index is the ***gateway*** to the book. CASRNs of substances are readily obtained from 'SciFinder', or better, from any commercial catalogue that sells these compounds, as almost all of these have CASRNs inserted after the names of their products. Some substances that could be formally included in more than one section of the book are entered in the preferred section but are cross-referenced by inserting 'see CASRN' or just the 'CASRN'. Thus the cross-reference is its CASRN. The CASRNs Index provides the page numbers in bold/italic type. If the CASRN of a desired substance is *not* in the CASRN Index, or its full or abbreviated name is *not* in the General Index, then it will not be present in this book. CASRNs are unique for each substance and are internally consistent. They are set up according to a specific formula. Refer to the first page of the CASRNs Index to calculate the formula in order to check whether or not the number is a valid CAS number.

DOIs, PMIDs, ISBNs and ISSNs

The number of references to the original literature has been increased considerably in this edition. Every effort has been made to locate the respective DOIs (Digital Object Identifiers) and these have been inserted after each literature reference. More than 95% of DOIs have been found. If a publication has not yet been allocated a number, is too old, or has altered its name and not been allocated a number, no DOI is recorded. Occasionally in such cases, but not always, it may be possible to download the publication by inserting the full reference title into an internet server, e.g. 'Google Scholar'. Where this is not possible, a copy of the publication will have to be obtained from a national or international library. In some publications, particularly the medical ones, PMID numbers (see Preface) are the alternative means to DOIs for accessing the publication directly from the internet. For books and serials the ISBN and ISSN numbers respectively should be used to access information about them from a server. The usefulness of these numbers is that anyone can access the original literature directly from a laptop or other computer that is connected to the internet from any situation *viz* a laboratory, an office, a library or from home.

WLFA

ABOUT THE AUTHOR

Wilf Armarego was a British Subject born in Alexandria, Egypt, on 23 April 1931, and was educated at British Boys' School (Alexandria), where he matriculated externally (University of London). In 1949 he enrolled as an external free auditor at Farouk 1st University (later, University of Alexandria). He attended some lectures and all practical classes while studying mostly at home. In June 1951 he obtained the *Intermediate BSc* qualification (external, University of London) in Chemistry, Physics and Biology, and two years later in June 1953 succeeded in the University of London External BSc Special Honours degree in Chemistry. In September 1953 he left Egypt for London. He began research training in stereochemistry at Bedford College (University of London) in November 1953 under the tutelage of Professor E. E. Turner FRS, and subsequently submitted a PhD thesis in December 1955. In September 1956 he went to Melbourne, Australia, and was appointed Research Officer at the new ICIANZ Central Research Laboratories where he worked on plant growth substances for 2 years. This was followed by a year as Senior Demonstrator in Organic Chemistry at the University of Melbourne. He joined the Department of Medical Chemistry, John Curtin School of Medical Research (JCSMR), ANU, in January 1960 where he worked until his retirement in December 1996. He was awarded a DSc of the University of London for his work in heterocyclic chemistry at the early age of 36 years. In 1972 he changed his research field to studies of pteridine requiring enzymes associated with a variety of inborn errors of metabolism in children. This involved work on enzyme purification, cloning, mutation, gene expression, kinetics and enzyme mechanisms. He became a naturalised Australian in 1969. Since retirement he has been a Visiting Fellow in the JCSMR. He has written four books,[1-4] in addition to over 140 refereed publications. Awarded FRSC (FRIC 1963), C.Chem, FRACI (1972), A.D. Olle Prize (1968) and Worldwide WHO'sWHO 2014 Professional of the Year, Representing Medical Research.

CHAPTER 1

COMMON PHYSICAL TECHNIQUES USED IN PURIFICATION

INTRODUCTION

Purity is a matter of degree. Other than contaminants such as dust, paper fibres, wax, cork, etc., that may have been inadvertently introduced into the sample during manufacture, all commercially available chemical substances are in some measure impure. Any amounts of unreacted starting material, intermediates, by-products, isomers and related compounds may be present depending on the synthetic or isolation procedures used for preparing the substances. Inorganic reagents may deteriorate because of defective packaging (glued liners affected by sulfuric acid, zinc extracted from white rubber stoppers by ammonia), corrosion or prolonged storage. Organic molecules may undergo changes on storage. In extreme cases the container may be incorrectly labeled or, where compositions are given, they may be misleading or inaccurate for the proposed use. Where any doubt exists, it is usual to check for impurities by appropriate spot tests, or by recourse to tables of physical or spectral properties such as the extensive infrared and NMR libraries published by the Sigma Aldrich Chemical Co.
The important question, then, is not whether a substance is pure but whether a given sample is sufficiently pure for some intended purpose. That is, are the contaminants likely to interfere in the process or measurement that is to be studied. By suitable manipulation it is often possible to reduce levels of impurities to acceptable limits, but absolute purity is an ideal which, no matter how closely approached, can never be attained. A *negative* physical or chemical test indicates only that the amount of an impurity in a substance lies below a certain sensitivity level; no test can demonstrate that a likely impurity is entirely absent.

When setting out to purify a laboratory chemical, it is desirable that the starting material is of the best grade commercially available. Particularly among organic solvents there is a range of qualities varying from *laboratory chemical* to *spectroscopic* and *chromatographic* grades. Many of these are suitable for use as received. With the more common reagents it is usually possible to obtain from the current literature some indications of likely impurities, their probable concentrations and methods for detecting them. However, in many cases complete analyses are not given so that significant concentrations of unspecified impurities may be present.

THE QUESTION OF PURITY

Solvents and substances that are specified as *pure* for a particular purpose may, in fact, be quite impure for other uses. Absolute ethanol may contain traces of benzene, which makes it unsuitable for ultraviolet spectroscopy, or plasticisers which make it unsuitable for use in solvent extraction. See also the section on 'Criteria of Purity' in Chapter 2.
Irrespective of the grade of material to be purified, it is essential that some criteria exist for assessing the degree of purity of the final product. The methods used are preferably those that do not destroy the material, and if they do, denoted with a hash #, it is important that as little material is used as possible since it is not recoverable. The more common methods include:

1. Examination of physical properties such as:
    (a) Melting point, freezing point, boiling point, and the freezing curve (i.e. the variation, with time, in the freezing point of a substance that is being slowly and continuously frozen).

Purification of Laboratory Chemicals.
http://dx.doi.org/10.1016/B978-0-12-805457-4.50001-X,

(b) Density at a specified temperature, and whether it is relative to the density of some other standard, e.g. water at 0.
(c) Refractive index at a specified temperature and wavelength. The sodium D line at 589.26 nm (weighted mean of the D_1 and D_2 lines) is the usual wavelength used but the refractive index values at other wavelengths can often be interpolated from a plot of refractive index versus $1/(\text{wavelength})^2$.
(d) Specific conductivity. (This can be used to detect, for example, water, salts, inorganic and organic acids and bases, in non-electrolytes).
(e) Optical rotation, optical rotatory dispersion and circular dichroism.

2. Empirical analysis, for C, H, N, S, metals, ash, etc.#

3. Chemical tests for particular types of impurities, e.g. for peroxides in aliphatic ethers (with acidified KI), or for water in solvents (quantitatively by the Karl Fischer method, see Fieser and Fieser, *Reagents for Organic Synthesis*, J. Wiley & Sons, NY, Vol 1 pp. 353, 528 *1967*, Library of Congress Catalog Card No 66-27894, also see Karl Fischer titrant or Hydranal –Titrant type 5E [64-17-5]. A number of other formulations for general and specific purposes, in aqueous and non-aqueous solutions, are commercially available [see Sigma-Aldrich Catalogue].

4. Physical tests for particular types of impurities:
Emission and atomic absorption spectroscopy for detecting organic impurities and determining metal ions.
Chromatography, including paper, thin layer, liquid (high, medium and normal pressure), flash and vapour phase.
Electron spin resonance for detecting free radicals.
Other spectroscopic methods (see 5 below).

5. Examination of spectroscopic properties
Nuclear Magnetic Resonance (^{1}H, ^{13}C, ^{31}P, ^{19}F, ^{11}B NMR etc)
Infrared spectroscopy (IR, NIR and Fourier Transform IR)
Ultraviolet (UV), visible and fluorescence spectroscopy
X-ray photoelectron spectroscopy (XPS)
Atomic absorption spectroscopy (AAA)
Mass spectroscopy [electron ionisation (EI), chemical ionisation (CI), electrospray ionisation (ESI), fast atom bombardment (FAB), matrix-associated laser desorption ionisation (MALDI), inductively coupled plasma-mass spectrometry (ICP-MS), etc.#

6. Electrochemical methods (see 'Introduction' in Chapter 6 for macromolecules).

7. Nuclear methods which include a variety of radioactive elements as in organic reagents, complexes or salts.

A substance is usually taken to be of an acceptable purity when the measured property is unchanged by further treatment (especially if it agrees with a recorded value). In general, at least two different methods, such as recrystallisation and distillation, should be used in order to ensure maximum purity. Crystallisation may be repeated (from the same solvent or better from different solvents) until the substance has a constant melting point, and until it distils repeatedly within a narrow specified temperature range. The purified product should have spectroscopic properties which indicate that the traces of impurities left in the sample are of acceptable levels for the intended purpose.
With liquids, the refractive index at a specified temperature and wavelength is a sensitive test of purity. Note however that this is sensitive to dissolved gases such as O_2, N_2 or CO_2. Under favourable conditions, freezing curve studies are sensitive to impurity levels of as little as 0.001 moles percent. Analogous fusion curves or heat capacity measurements can be up to ten times as sensitive as this. With these exceptions, most of the above methods are rather insensitive, especially if the impurities and the substances in which they occur are chemically similar. In some cases, even an impurity comprising many parts per million of a sample may escape detection.
The common methods of purification, discussed below, comprise distillation (including fractional distillation, distillation under reduced pressure, sublimation and steam distillation), crystallisation, extraction, chromatographic, electrophoresis and other methods. In some cases, volatile and other impurities can be removed

simply by heating or application of a vacuum. Impurities can also sometimes be eliminated by the formation of derivatives from which the purified material is regenerated (see Chapter 2).

SOURCES OF IMPURITIES

Some of the more obvious sources of contamination of solvents arise from storage in metal drums and plastic containers, and from contact with grease and screw caps. Many solvents contain water. Others have traces of acidic materials such as hydrochloric acid in chloroform. In both cases this leads to corrosion of the drum and contamination of the solvent by traces of metal ions, especially Fe^{3+}. Grease, for example on stopcocks of separating funnels and other apparatus, e.g. greased ground joints, is also likely to contaminate solvents during extractions and chemical manipulation. Oxygen from the air is a source of contamination by virtue of its ability to produce small or large amounts of oxidation products (see section on the *Solubility of gases in liquids* below).
A much more general source of contamination that has not received the consideration it merits comes from the use of plastics for tubing and containers. Plasticisers can readily be extracted by organic solvents from PVC and other plastics, so that most solvents, irrespective of their grade (including spectrograde and ultrapure), have been reported to contain 0.1 to 5ppm of plasticiser [de Zeeuw et al. *Anal Biochem* **67** 339 *1975*, DOI: 10.1016/0003-2697(75)90303-6]. Where large quantities of solvent are used for extraction followed by evaporation, this can introduce significant amounts of impurity, even exceeding the weight of the genuine extract and giving rise to spurious peaks in gas chromatography, for example of fatty acid methyl esters [Pascaud, *Anal Biochem* **18** 570 *1967*, DOI: 10.1016/0003-2697(67)90116-9]. Likely contaminants are di(2-ethylhexyl)phthalate and dibutyl phthalate, but upwards of 20 different phthalate esters are listed as plasticisers as well as adipates, azelates, phosphates, epoxides, polyesters and various heterocyclic compounds. These plasticisers would enter the solvent during passage through plastic tubing or from storage in containers or from plastic coatings used in cap liners for bottles. Such contamination could arise at any point in the manufacture or distribution of a solvent. The problem with cap liners is avoidable by using corks wrapped in aluminium foil, although even in this case care should be taken because aluminium foil can dissolve in some liquids e.g. benzylamine and propionic acid. Polycarbonate containers invariably leach out the 'estrogenic chemical' **Bisphenol A** (see 'Aromatic Compounds' in Chapter 3) into the liquid in the container [Fiona Case *Chemistry World* **5** (No. 4) 12 *2008*, Rebecca Trager *Chemistry World* **5** (No. 5) 8 *2008*]. Also see issues of the SAGE journal *Toxicology and Industrial Health* first published in 1985.
Solutions in contact with polyvinyl chloride can become contaminated with trace amounts of lead, titanium, tin, zinc, iron, magnesium or cadmium from additives used in the manufacture and moulding of PVC.
N-Phenyl-2-naphthylamine is a contaminant of solvents and biological materials that have been in contact with black rubber or neoprene (in which it is used as an antioxidant). Although this potential carcinogenic naphthylamine was only an artifact of the isolation procedures, it was at first thought to be a genuine component of vitamin K preparations, and of extracts of plant lipids, algae, butter, animal livers, eye tissue and kidney tissue [Brown *Chem Br* **3** 524 *1967*, Wang et al. *Cancer Res* **44** 3098 *1984*, PMID: 6327034].
Most of the above impurities can be removed by prior distillation of the solvent, and care should be taken to avoid further contact with plastic or black rubber materials. When using large volumes of solvents for extraction and chromatographic purification of substances it is imperative that the solvents are of the highest purity because impurities in them could severely contaminate the desired substance after solvent evaporation. This is particularly serious when working which small quantities of material (see above).

PRACTICES TO AVOID IMPURITIES

Cleaning practices

Laboratory glassware and Teflon equipment can be cleaned satisfactorily for most purposes by careful immersion into a solution of sodium dichromate in concentrated sulfuric acid, followed by draining, and rinsing copiously with distilled water. This is an exothermic reaction and should be carried out **very** cautiously in an efficient fume cupboard. [To prepare the ***chromic acid bath***, dissolve 5 g of sodium dichromate (CARE: cancer suspect agent) in 5 ml of water. The dichromate solution is then cooled and stirred while 100 ml of concentrated sulfuric acid is added slowly. Store it in a glass bottle.] Where traces of chromium (adsorbed on the glass) must be avoided, a 1:1 mixture of concentrated sulfuric and nitric acid is a useful alternative. (*Use in a fumehood to remove vapour and with adequate face and body protection.*) Acid washing is also suitable for polyethylene ware, but prolonged contact (some weeks) leads to severe deterioration of the plastic. Alternatively, an alcoholic solution of sodium

hydroxide (***alkaline base bath***) can be used. This strongly corrosive solution (CAUTION: alkali causes serious burns) can be made by dissolving 120g of NaOH in 120 ml of water, followed by dilution to 1 L with 95% ethanol. This solution is conveniently stored in suitable alkali-resistant containers (e.g. Nalgene heavy duty rectangular tanks) with lids. Glassware can be soaked overnight in the base bath and rinsed thoroughly after soaking until the pH of the wash is close to 7. For much glassware, washing with hot detergent solution, using tap water, followed by rinsing well with distilled water and acetone, and heating at 200-300° overnight, is adequate. (Volumetric apparatus should not be heated: after washing it is rinsed with acetone, then pure diethyl ether, and air-dried. Prior to use, equipment can be rinsed with acetone, then with petroleum ether or pure diethyl ether, to remove the last traces of contaminants.) Teflon equipment should be soaked, first in acetone, then in petroleum ether or pure diethyl ether for ten minutes, then dried in a vacuum or flushed with dry nitrogen prior to use.
For trace metal analyses, prolonged soaking of equipment in 1M nitric acid may be needed to remove adsorbed metal ions.
Soxhlet thimbles and filter papers may contain traces of lipid-like materials. For manipulations with highly pure materials, as in trace-pesticide analysis, thimbles and filter papers should be thoroughly extracted with the solvent used for the extractions, followed by pure diethyl ether before use.
Trace impurities in silica gel for TLC can be removed by heating at 300° for 16 hours or by Soxhlet extraction for 3 hours with distilled chloroform, followed by 4 hours extraction with distilled pure diethyl ether and drying in a vacuum.

Silylation of glassware and plasticware

Silylation of apparatus makes it repellant to water and hydrophilic materials. It minimises loss of solute by adsorption onto the walls of the container. The glassware is placed in a desiccator containing dichloromethyl silane (1ml) in a small beaker and evacuated for 5 minutes. The vacuum is turned off and air is introduced into the desiccator, which allows the silylating agent to coat the glassware uniformly. The desiccator is then evacuated, closed and set aside for 2 hours. The glassware is removed from the desiccator and baked at 180° for 2 hours before use.

Silylating mixtures for coating glassware, as well as for silylation reactions, can be readily prepared, e.g. (a) ~5% dimethyldichlorosilane [DMDCS, 75-78-5] in hexane, (b) ~2% dimethyldichlorosilane in 1,1,1-trichloroethane) for coating micro electrodes, (c) 10% hexamethyldisilazane [HMDS, 999-97-3] and 6% trimethylchlorosilane [TMCS, 75-77-4] in 1-chloronaphthalene), (d) ~4% trimethylchlorosilane in *o*-xylene, (e) ~5% dimethyldichlorosilane in *o*-xylene, and (f) ~3% tributylchlorosilane [995-45-9] in 1-chloronaphthalene for coating micropipette electrodes by the dip-and-bake method. A more powerful general silylating mixture consists of *N*-*tert*-butyldimethylsilyl-*N*-methyltrifluoroacetamide [MTBSTFA, 77377-52-7] containing 1% of *tert*-butyl-dimethylchlorosilane [TBDMSCl, 18162-48-6], which is also available commercially.

Plasticware is treated similarly except that it is rinsed well with water before use instead of baking. Note that dichloromethylsilane is highly **TOXIC** and **VOLATILE**, and the whole operation should be carried out in an efficient fume cupboard.
An alternative procedure used for large apparatus is to rinse the apparatus with a 5% solution of dichloromethyl silane in chloroform, followed by several rinses with water before baking the apparatus at 180°/2 hours (for glass) or drying in air (for plasticware). A solution of 2% w/v of dichloromethylsilane in octamethyl cyclooctasilane (Repel-silane ES, Lim et al. *J Nanomater* **2015** 1 *2015*, article ID 561586 DOI: org/10.1155/2015/561586) or octmethylcyclotetrasiloxane [556-67-2] is used to prevent the sticking of polyacrylamide gels, agarose gels and nucleic acids to glass surfaces and these chemicals are available commercially.

SAFETY PRECAUTIONS ASSOCIATED WITH THE PURIFICATION OF LABORATORY CHEMICALS

Although most of the manipulations involved in purifying laboratory chemicals are inherently safe, care is necessary if hazards are to be avoided in the chemical laboratory. In particular there are dangers inherent in the inhalation of vapours and absorption of liquids and low melting solids through the skin. In addition to the toxicity

of solvents there is also the risk of their flammability and the possibility of eye damage. Chemicals, particularly in admixture, may be explosive. Compounds may be carcinogenic or otherwise deleterious to health. Present-day chemical catalogues specifically indicate the particular dangerous properties of the individual chemicals they list, and these should be consulted whenever the use of commercially available chemicals is contemplated. Radioisotopic labeled compounds pose special problems of human exposure and of disposal of laboratory waste. Hazardous purchased chemicals are accompanied by detailed MSDS (Material Safety Data Sheets), which contain information regarding their toxicity, safety handling procedures and the necessary precautions to be taken. These should be read carefully and filed for future reference. In addition, chemical management systems such as Chem-ChemWatch, which include information and videos on hazards, handling and storage of chemicals, are commercially available. There are a number of websites which provide selected safety information: these include the Sigma-Aldrich website <www.sigmaaldrich.com> and other chemical websites, e.g. <www.ilpi.com/msds>.

The most common hazards are:

(1) Explosions due to the presence of peroxides formed by aerial oxidation of ethers and tetrahydrofuran, decahydronaphthalene, acrylonitrile, styrene and related compounds.
(2) Compounds with low flash points (below room temperature). Examples are acetaldehyde, acetone, acetonitrile, benzene, carbon disulfide, cyclohexane, diethyl ether, ethyl acetate and *n*-hexane.
(3) Contact of oxidising agents ($KMnO_4$, $HClO_4$, H_2O_2) with organic liquids.
(4) Toxic reactions with tissues (Me_2SO_4, H_2CrO_4).

The laboratory should at least be well ventilated and safety glasses should be worn, particularly during distillations and manipulations carried out under reduced pressure or at elevated temperatures. With this in mind we have endeavoured to warn users of this book whenever greater than usual care is needed in handling chemicals. As a general rule, however, **all chemicals which users are unfamiliar with should be treated with extreme care and assumed to be highly flammable and toxic.** The safety of others in a laboratory should always be foremost in mind, with ample warning to others whenever a potentially hazardous operation is in progress. Also, unwanted solutions or solvents should never be disposed *via* the laboratory sink. The operator should be aware of the usual means for disposal of chemicals in her/his laboratories, and she/he should remove unwanted chemicals accordingly. **Organic liquids for disposal should be temporarily stored, as is practically possible, in respective containers. Avoid placing all organic liquids in the same container particularly if they contain small amounts of reagents which could react with each other. Halogenated waste solvents should be kept separate from other organic liquids. These containers should be stored in cupboards, preferably made of metal, and separated from containers of common laboratory solvents.**
Laboratory coats, disposable aprons, caps, sleeves, dust/mist respirators and foot protection, hearing protection as well as a variety of safety glasses, goggles, face and body shields should be used when the demand arises and are available commercially (see e.g. the Sigma-Aldrich Labware catalogue).

SOME HAZARDS OF CHEMICAL MANIPULATION IN PURIFICATION AND RECOVERY OF RESIDUES

Performing chemical manipulations calls for some practical knowledge if danger is to be avoided. However, with care, hazards can be kept to an acceptable minimum. A good general approach is to consider every operation as potentially perilous and then to adjust one's attitude as the operation proceeds. A few of the most common dangers are set out below. For a larger coverage of the following sections, and of the literature, the bibliography at the end of this chapter should be consulted.

Perchlorates and perchloric acid. At 160° perchloric acid is an exceedingly strong oxidising acid and a strong dehydrating agent. Organic perchlorates, such as methyl and ethyl perchlorates, are unstable and are violently explosive compounds. A number of heavy-metal perchlorates are extremely prone to explode. The use of anhydrous magnesium perchlorate, *Anhydrone*, *Dehydrite*, as a drying agent for organic vapours is **not** recommended. Desiccators which contain this drying agent should be adequately shielded at all times, preferably in a metal basket, and kept in a cool place, i.e. **never** on a window sill where sunlight can fall on it.
No attempt should be made to purify perchlorates, except for ammonium, alkali metal and alkaline earth salts which, in water or aqueous alcoholic solutions are insensitive to heat or shock. Note that perchlorates react relatively slowly in aqueous organic solvents, but as the water is removed there is the increased possibility of an

explosion. Perchlorate salts, often used in non-aqueous solvents, are explosive in the presence of even small amounts of organic compounds when heated. Hence stringent care should be taken when purifying perchlorates, and direct flame and infrared lamps should be avoided. Tetra-alkylammonium perchlorates should be dried below 50° under vacuum (and protection). Only very small amounts of such materials should be prepared, and stored, at any one time.

Peroxides. These are formed by aerial oxidation or by autoxidation of a wide range of organic compounds, including diethyl ether, allyl ethyl ether, allyl phenyl ether, dibenzyl ether, benzyl butyl ether, *n*-butyl ether, *iso*-butyl ether, *t*-butyl ether, dioxane, tetrahydrofuran, olefins, and aromatic and saturated aliphatic hydrocarbons. They accumulate during distillation and can detonate violently on evaporation or distillation when their concentration becomes high. If peroxides are likely to be present materials should be tested for peroxides before distillation (for tests see entry under 'Ethers' in Chapter 2). Also, distillation should be discontinued when at least one quarter of the residue is left in the distilling flask.

Heavy-metal-containing explosives. Ammoniacal silver nitrate, on storage or treatment, will eventually deposit the highly explosive silver nitride *fulminating silver*. Silver nitrate and ethanol may give silver fulminate (see 'Inorganic Compounds' in Chapter 4), and in contact with azides or hydrazine and hydrazides may form silver azide. Mercury can also form such compounds. Similarly, ammonia or ammonium ions can react with gold salts to form *'fulminating gold'*. Metal fulminates of cadmium, copper, mercury and thallium are powerfully explosive, and some are detonators [Matyáš & Pachman *Fulminates* in *Primary Explosives* Springer Verlag, pp 37-70 *2013*, ISBN 978-3-642-28436-6_3, DOI: 10.1007/978-3-642-28436-6_3]. Heavy-metal-containing solutions, particularly when organic material is present, should be treated with great respect, and precautions towards possible explosion should be taken.

Strong acids. In addition to perchloric acid (see above), extra care should be taken when using strong mineral acids. Although the effects of concentrated sulfuric acid are well known, these cannot be stressed strongly enough. Contact with tissues will leave irreparable damage. **Always dilute the concentrated acid (Oil of Vitriol) by carefully adding the acid down the side of the flask which contains the water, and the process should be carried out under cooling. This solution is not safe to handle until the acid has been thoroughly mixed (care) with the water. Protective face, and body coverage should be used at all times.** Fuming sulfuric acid and chlorosulfonic acid are even more dangerous than concentrated sulfuric acid, and adequate precautions should be taken. Chromic acid cleaning mixture contains strong sulfuric acid and should be treated in the same way; and in addition this mixture is potentially ***carcinogenic***.
Concentrated and fuming nitric acids are also dangerous because of their severe deleterious effects on tissues.

Picric acid. This acid and related nitro compounds, e.g. styphnic acid, are explosive and should **not** be allowed to dry. The acid is generally stored wet by covering the crystals with water. Solutions in ethanol and benzene are used occasionally. They should be stored in the cold (to minimise evaporation), and a rubber or plastic stopper (**not a ground glass stopper, because twisting the stopper could cause any dry substance on the side of the stopper to explode due to heat produced by friction**) should be used. **Note** that picric acid and picrates stain skin proteins in a yellow colour that is not readily washed off. This can be avoided by wearing rubber gloves.

Reactive halides and anhydrides. Substances like acid chlorides, low-molecular-weight anhydrides and some inorganic halides (e.g. PCl_3) can be **highly toxic and lachrymatory, affecting mucous membranes and lung tissues. Utmost care should be taken when working with these materials. Work should be carried out in a very efficient fume cupboard.**

Salts and organic esters of some inorganic acids. In addition to the dangers of perchlorate salts, other salts such as nitrates, azides, diazo salts, organic nitrates, organic azides and picrates (see above) can be hazardous, and due care should be taken when these are dried. Organic nitrites are dangerous as they affect the heart rate. Large quantities should never be prepared or stored for long periods.

Solvents. The flammability of low-boiling organic liquids cannot be emphasised strongly enough. These invariably have very low flash points and can ignite spontaneously. Special precautions against explosive flammability should be taken when recovering such liquids. Care should be taken with small volumes (*ca* 250ml) as well as large volumes (> 1L), and the location of all the fire extinguishers, and fire blankets, in the immediate

vicinity of the apparatus should be checked. Fire extinguishers should be operational and checked on a regular basis and the dates noted. The following flammable liquids (in alphabetical order) are common fire hazards in the laboratory: acetaldehyde, acetone, acrylonitrile, acetonitrile, benzene, carbon disulfide, cyclohexane, diethyl ether, ethyl acetate, hexane, low-boiling petroleum ether, tetrahydrofuran and toluene. Toluene should always be used in place of benzene wherever possible due to the potential *carcinogenic* effects of the liquid and vapour of the latter. The drying of flammable solvents with sodium or potassium metal and metal hydrides poses serious potential fire hazards, and adequate precautions should be stressed.

Safety is an issue that goes hand in hand with 'Green Science', and cannot be emphasised enough. It should be the first consideration when planning a scientific operation. Safety issues should never be considered a *nuisance*, or an aspect which hampers procedures. This is no longer a *local* or a *regional* issue, but is becoming more and more a *global* problem. It is true that it means more effort should be put in planning an operation, but this is something that the worker should get used to. It is totally *unacceptable* today, and certainly will be in the future, not to take **safety** very seriously.
Questions to be addressed include:

Could this procedure be carried out in a safer way with respect not only to the operator but also to those around her/him?
How does it affect the immediate as well as the extended environment around the operation?
Could the operation be performed in an alternative way that can better satisfy these criteria?
Safety now goes well beyond the laboratory and all should be consciously aware of the consequences of a potentially unsafe situation.

SAFETY DISCLAIMER

Experimental chemistry is a very dangerous occupation, and extreme care and adequate safety precautions should be taken at all times. Although we have stated the safety measures that have to be taken under specific entries, these are by no means exhaustive and some may have been unknowingly or accidentally omitted. The experimenter without prior knowledge or experience must seek further safety advice on reagents and procedures from experts in the field before undertaking the purification of any material. Chemical Suppliers should provide detailed safety documentation for every chemical they list. If for some reason this has not been provided, the purchaser should demand that the respective safety details be forwarded by the Suppliers. ***We take no responsibility whatsoever if any mishaps occur when using any of the procedures described in this book.***

METHODS OF PURIFICATION OF REAGENTS AND SOLVENTS

Many methods exist for the purification of reagents and solvents. A number of these methods are routinely used in synthetic as well as analytical chemistry and biochemistry. These techniques, outlined below, will be discussed in greater detail in the respective sections in this chapter. It is important to note that more than one method of purification may need to be implemented in order to obtain compounds of highest purity.
Common methods of purification are:

Solvent Extraction and Distribution
Distillation
Recrystallisation
Sublimation
Electrophoresis
Chromatography

For substances contaminated with water or solvents, drying with appropriate absorbents and desiccants may be sufficient.

SOLVENT EXTRACTION AND DISTRIBUTION

Extraction of a substance from suspension or solution into another solvent can sometimes be used as a purification process. Thus, organic substances can often be separated from inorganic impurities by shaking an aqueous solution

or suspension with suitable immiscible solvents such as benzene, carbon tetrachloride, chloroform, diethyl ether, diisopropyl ether or petroleum ether. After several such extractions, the combined organic phase is dried and the solvent is evaporated. Grease from the glass taps of conventional separating funnels is invariably soluble in the solvents used. Contamination with grease can be very troublesome particularly when the amounts of material to be extracted are very small. Instead, the glass taps should be lubricated with the extraction solvent; or better, the taps of the extraction funnels should be made of the more expensive material *Teflon*. Immiscible solvents suitable for extractions are given in Table 1. Addition of electrolytes (such as ammonium sulfate, calcium chloride or sodium chloride) to the aqueous phase helps to ensure that the organic layer separates cleanly and also decreases the extent of extraction of water into the latter. Emulsions can also be broken up by filtration (with suction) through Celite, or by adding a little diethyl ether, octyl alcohol or some other paraffinic alcohol. The main factor in selecting a suitable immiscible solvent is to find one in which the material to be extracted is readily soluble, whereas the substance from which it is being extracted is not. The same considerations apply irrespective of whether it is the substance being purified, or one of its contaminants, that is taken into the new phase. (The second of these processes is described as washing.)

Common examples of washing with aqueous solutions include the following:

Removal of acids from water-immiscible solvents by washing with aqueous alkali, sodium carbonate or sodium bicarbonate.

Removal of phenols from similar solutions by washing with aqueous alkali.

Removal of organic bases by washing with dilute hydrochloric or sulfuric acids.

Removal of unsaturated hydrocarbons, of alcohols and of ethers from saturated hydrocarbons or alkyl halides by washing with cold concentrated sulfuric acid.

This process can also be applied to purification of the substance if it is an acid, a phenol or a base, by extracting into the appropriate aqueous solution to form the salt which, after washing with pure solvent, is again converted to the free species and re-extracted. Paraffin hydrocarbons can be purified by extracting them with phenol (in which aromatic hydrocarbons are highly soluble) prior to fractional distillation.

For extraction of solid materials with a solvent, a *Soxhlet* extractor is commonly used. This technique is applied, for example, in the alcohol extraction of dyes to free them from insoluble contaminants such as sodium chloride or sodium sulfate.

Acids, bases and amphoteric substances can be purified by taking advantage of their ionisation constants (see below).

The recovery of some fifty more commonly used solvents from water, other solvents, residues etc. have been discussed, together with information on their behaviour before and after use, by I.M. Smallwood in the *Solvent Recovery Handbook*, Blackwood Science Publ Ltd, *2001*, ISBN 9780632056477.

DISTILLATION

One of the most widely applicable and most commonly used methods of purification of liquids or low melting solids (especially of organic chemicals) is fractional distillation at atmospheric, or some lower, pressure. Almost without exception, this method can be assumed to be suitable for all organic liquids and most of the low-melting organic solids. For this reason it has been possible, e.g. in Chapter 3, to omit many procedures for purification of organic chemicals when only a simple fractional distillation is involved—the suitability of such a procedure is implied from the boiling point.

The boiling point of a liquid varies with the 'atmospheric' pressure to which it is exposed. A liquid boils when its vapour pressure is the same as the external pressure on its surface, its normal boiling point being the temperature at which its vapour pressure is equal to that of a standard atmosphere (760.000mm Hg = 101.325 kPa). Lowering the external pressure lowers the boiling point. For most substances, boiling point and vapour pressure are related by an equation of the form,

$$\log p = A + B/(t + 273),$$

where p is the pressure in mmHg, t is in ^{o}C, and A and B are constants. Hence, if the boiling points at two different pressures are known, the boiling point at another pressure can be calculated from a simple plot of log p *versus* $1/(t + 273)$. For organic molecules that are not strongly associated, this equation can be written in the form,

$$\log p = 8.586 - 5.703\ (T + 273)/(t + 273)$$

where *T* is the boiling point in ºC at 760mm Hg. Tables 2A and 2B give computed boiling points over a range of pressures. Some examples illustrate its application. Ethyl acetoacetate, **b** 180º (with decomposition) at 760mm Hg has a predicted **b** of 79º at 16mm (where it is stable); the experimental value is 78º. Similarly 2,4-diaminotoluene, **b** 292º at 760mm, has a predicted **b** of 147º at 8mm; the experimental value is 148-150º. For self-associated molecules the predicted **b** are lower than the experimental values. Thus, glycerol, **b** 290º at 760mm, has a predicted **b** of 146º at 8mm: the experimental value is 182º.

Similarly an estimate of the boiling points of liquids at reduced pressure can be obtained using a nomogram (see Fig. 1).

For pressures near 760mm, the change in boiling point is given approximately by

$$\delta t = a(760 - p)(t + 273)$$

where $a = 0.00012$ for most substances, but $a = 0.00010$ for water, alcohols, carboxylic acids and other associated liquids, and $a = 0.00014$ for very low-boiling substances such as nitrogen or ammonia [Crafts *Chem Ber* **20** 709 *1887*, DOI: 10.1002/cber.188702001162]. When all the impurities are non-volatile, simple distillation is adequate purification. The observed boiling point remains almost constant and approximately equal to that of the pure material. Usually, however, some of the impurities are appreciably volatile, so that the boiling point progressively rises during the distillation because of the progressive enrichment of the higher-boiling components in the distillation flask. In such cases, separation is effected by fractional distillation using an efficient column. [For further reading see section on 'Variation of Boiling Points with Pressure' in *CRC—Handbook of Chemistry and Physics 96th Edition*, *2015-2016*, William M. Haynes (Editor–in-Chief) CRC Press, Taylor & Francis Publishing Group, Boca Raton, Florida, USA, ISBN-10: 1482260964; ISNB-13: 978-1482260960.]

Techniques

The distillation apparatus consists basically of a distillation flask, usually fitted with a vertical fractionating column (which may be empty, or packed with suitable materials such as glass helices or stainless-steel wool) to which is attached a condenser leading to a receiving flask. The bulb of a thermometer projects into the vapour phase just below the region where the condenser joins the column. The distilling flask is heated so that its contents are steadily vaporised by boiling. The vapour passes up into the column where, initially, it condenses and runs back into the flask. The resulting heat transfer gradually warms the column so that there is a progressive movement of the vapour phase-liquid boundary up the column, with increasing enrichment of the more volatile component. Because of this fractionation, the vapour finally passing into the condenser (where it condenses and flows into the receiver) is commonly that of the lowest-boiling components in the system. The conditions apply until all of the low-boiling material has been distilled, whereupon distillation ceases until the column temperature is high enough to permit the next component to distil. This usually results in a temporary fall in the temperature indicated by the thermometer.

Distillation of liquid mixtures

The principles involved in fractional distillation of liquid mixtures are complex but can be seen by considering a system which approximately obeys *Raoult's law*. (This law states that the vapour pressure of a solution at any given temperature is the sum of the vapour pressures of each component multiplied by its mole fraction in the solution.) If two substances, A and B, having vapour pressures of 600mm Hg and 360mm Hg, respectively, were mixed in a molar ratio of 2:1 (i.e. 0.666:0.333 mole ratio), the mixture would have (ideally) a vapour pressure of 520mm Hg (i.e. 600 x 0.666 + 360 x 0.333, or 399.6 + 119.88 mm Hg) and the vapour phase would contain 77% (399.6 x 100/520) of A and 23% (119.88 x 100/520) of B. If this phase was now condensed, the new liquid phase would, therefore, be richer in the volatile component A. Similarly, the vapour in equilibrium with this phase is still further enriched in A. Each such liquid-vapour equilibrium constitutes a 'theoretical plate'. The efficiency of a fractionating column is commonly expressed as the number of such plates to which it corresponds in operation. Alternatively, this information may be given in the form of the height equivalent to a theoretical plate, or HETP. The number of theoretical plates and equilibria between liquids and vapours are affected by the factors listed to achieve maximum separation by fractional distillation in the section below on techniques.

In most cases, systems deviate to a greater or lesser extent from Raoult's law, and vapour pressures may be greater

or less than the values calculated. In extreme cases (e.g. azeotropes), vapour pressure-composition curves pass through maxima or minima, so that attempts at fractional distillation lead finally to the separation of a constant-boiling (azeotropic) mixture and one (but not both) of the pure species if either of the latter is present in excess.

Elevation of the boiling point by dissolved solids. Organic substances dissolved in organic solvents cause a rise in boiling point which is proportional to the concentration of the substance, and the extent of rise in temperature is characteristic of the solvent. The following equation applies for dilute solutions and non-associating substances:

$$\frac{M\,\Delta t}{c} = K$$

where M is the molecular weight of the solute, Δt is the elevation of boiling point in ^{o}C, c is the concentration of solute in grams for 1000gm of solvent, and K is the *Ebullioscopic Constant* (molecular elevation of the boiling point) for the solvent. K is a fixed property (constant) for the particular solvent. This has been very useful for the determination of the molecular weights of organic substances in solution.

The efficiency of a distillation apparatus used for purification of liquids depends on the difference in boiling points of the pure material and its impurities. For example, if two components of an ideal mixture have vapour pressures in the ratio 2:1, it would be necessary to have a still with an efficiency of at least seven plates (giving an enrichment of $2^7 = 128$) if the concentration of the higher-boiling component in the distillate was to be reduced to less than 1% of its initial value. For a vapour pressure ratio of 5:1, three plates would achieve as much separation. In a fractional distillation, it is usual to reject the initial and final fractions, which are likely to be richer in the lower-boiling and higher-boiling impurities respectively. The centre fraction can be further purified by repeated fractional distillation.

To achieve maximum separation by fractional distillation:

1. The column must be flooded initially to wet the packing. For this reason it is customary to operate a still at reflux for some time before beginning the distillation.

2. The reflux ratio should be high (i.e. the ratio of drops of liquid which return to the distilling flask and the drops which distil over), so that the distillation proceeds slowly and with minimum disturbance of the equilibria along the column.

3. The hold-up of the column should not exceed one-tenth of the volume of any one component to be separated.

4. Heat loss from the column should be prevented, but if the column is heated to offset this, its temperature must not exceed that of the distillate in the column.

5. Heat input to the still-pot should remain constant.

6. For distillation under reduced pressure there must be careful control of the pressure to avoid flooding or cessation of reflux.

Types of distillation

The distilling flask. To minimise superheating of the liquid (due to the absence of minute air bubbles or other suitable nuclei for forming bubbles of vapour), and to prevent bumping, one or more of the following precautions should be taken:

(a) The flask is heated uniformly over a large part of its surface, either by using an electrical heating mantle or, by partial immersion in a bath above the boiling point of the liquid to be distilled (Table 3).

(b) Before heating begins, small pieces of unglazed fireclay or porcelain (porous pot, boiling chips), pumice, diatomaceous earth, or platinum wire are added to the flask. These act as sources of air bubbles.

(c) The flask may contain glass siphons or boiling tubes. The former are inverted J-shaped tubes, the end of the shorter arm being just above the surface of the liquid. The latter comprise long capillary tubes sealed above the lower end.

(d) A steady slow stream of inert gas (e.g. N_2, Ar or He) is passed through the liquid.

(e) The liquid in the flask is stirred mechanically. This is especially necessary when suspended insoluble material is present.

For simple distillations a Claisen flask is often used. This flask is, essentially, a round-bottomed flask to the neck of which is joined another neck carrying a side arm. This second neck is sometimes extended so as to form a Vigreux column [a glass tube in which have been made a number of pairs of indentations which almost touch each other and which slope slightly downwards. The pairs of indentations are arranged to form a spiral of glass inside the tube].

For heating baths, see Table 3. For distillation apparatus on a macro, semi-micro or micro scale see Aldrich and other glassware catalogues. Alternatively, visit some useful websites for suppliers of laboratory glassware, e.g. <www.wheatonsci.com>; <www.sigmaaldrich.com> and <www.kimble-kontes.com>.

Types of columns and packings. A slow distillation rate is necessary to ensure that equilibrium conditions operate and also that the vapour does not become superheated so that the temperature rises above the boiling point. Efficiency is improved if the column is heat insulated (either by vacuum jacketing or by lagging) and, if necessary, heated to just below the boiling point of the most volatile component. Efficiency of separation also improves with increase in the heat of vaporisation of the liquids concerned (because fractionation depends on heat equilibration at multiple liquid-gas boundaries). Water and alcohols are more easily purified by distillation for this reason.
Columns used in distillation vary in their shapes and types of packing. Packed columns are intended to give efficient separation by maintaining a large surface of contact between liquid and vapour. Efficiency of separation is further increased by operation under conditions approaching total reflux, i.e. under a high reflux ratio. However, great care must be taken to avoid flooding of the column during distillation. The minimum number of theoretical plates for satisfactory separation of two liquids differing in boiling point by δt is approximately $(273 + t)/3\delta t$, where t is the average boiling point in °C.

Some of the commonly used *columns* are:

Bruun column. A type of all-glass bubble-cap column.

Bubble-cap column. A type of plate column in which inverted cups (bubble caps) deflect ascending vapour through reflux liquid lying on each plate. Excess liquid from any plate overflows to the plate lying below it and ultimately returns to the flask. (For further details, see Bruun & West *Ind Eng Chem Anal Ed* **9** 247 *1937*, DOI: 10.1021/ac50109a023). Like most plate columns, it has a high through-put, but a relatively low number of theoretical plates for a given height.

Dufton column. A plain tube, into which fits closely (preferably ground to fit) a solid glass spiral wound round a central rod. It tends to choke at temperatures above 100° unless it is lagged (Dufton *J Soc Chem Ind* (London) **38** 45T *1919*, DOI: 10.1002/jctb.5000380406).

Hempel column. A plain tube (fitted near the top with a side arm) which is almost filled with a suitable packing, which may be of rings or helices.

Oldershaw column. An all-glass perforated-plate column. The plates are sealed into a tube, each plate being equipped with a baffle to direct the flow of reflux liquid, and a raised outlet which maintains a definite liquid level on the plate and also serves as a drain on to the next lower plate [see Oldershaw *Ind Eng Chem (Anal Ed)* **11** 265 *1941*, DOI: 10.1021/i560092a026].

Podbielniak column. A plain tube containing 'Heli-Grid' Nichrome or Inconel wire packing. This packing provides a number of passage-ways for the reflux liquid, while the capillary spaces ensure very even spreading of the liquid, so that there is a very large area of contact between liquid and vapour while, at the same time, channelling and flooding are minimised. A column 1m high has been stated to have an efficiency of 200-400 theoretical plates (for further details, see Podbielniak *Ind Eng Chem (Anal Ed)* **13** 639 *1941*, DOI: 10.1021/i560097a020; Mitchell & O'Gorman *Anal Chem* **20** 315 *1948*, DOI: 10.1021/ac60016a012).

Stedman column. A plain tube containing a series of wire-gauze discs stamped into flat, truncated cones and welded together, alternatively base-to-base and edge-to-edge, with a flat disc across each base. Each cone has a hole, alternately arranged, near its base, vapour and liquid being brought into intimate contact on the gauze surfaces (Stedman *Can J Research B* **15** 383 *1937*, DOI: 10.1139/cjr37b-044).

Todd column. A column (which may be a Dufton type, fitted with a Monel metal rod and spiral, or a Hempel type, fitted with glass helices) which is surrounded by an open heating jacket so that the temperature can be adjusted to be close to the distillation temperature (Todd *Ind Eng Chem (Anal Ed)* **17** 175 *1945*, DOI: 10.1021/i560139a016).

Vigreux column. A glass tube in which have been made a number of pairs of indentations which almost touch each

other and which slope slightly downwards. The pairs of indentations are arranged to form a spiral of glass inside the tube.

Widmer column. A Dufton column, modified by enclosing within two concentric tubes the portion containing the glass spiral. Vapour passes up the outer tube and down the inner tube before entering the centre portion. Thus flooding of the column, especially at high temperatures, is greatly reduced (Widmer *Helv Chim Acta* **7** 59 *1924*, DOI: 10.1002/hlca.19240070107).

The packing of a column greatly increases the surface of liquid films in contact with the vapour phase, thereby increasing the efficiency of the column, but reducing its capacity (the quantities of vapour and liquid able to flow in opposite directions in a column without causing flooding). Material for packing should be of uniform size, symmetrical shape, and have a unit diameter less than one-eighth that of the column. (Rectification efficiency increases sharply as the size of the packing is reduced but so, also, does the hold-up in the column.) It should also be capable of uniform, reproducible packing.

The usual ***packings*** are:

(a) **Rings.** These may be hollow glass or porcelain (Raschig rings), of stainless steel gauze (Dixon rings), or hollow rings with a central partition (Lessing rings) which may be of porcelain, aluminium, copper or nickel.

(b) **Helices.** These may be of metal or glass (Fenske rings), the latter being used where resistance to chemical attack is important (e.g. in distilling acids, organic halides, some sulphur compounds, and phenols). Metal single-turn helices are available in aluminium, nickel or stainless steel. Glass helices are less efficient, because they cannot be tamped to ensure uniform packing.

(c) **Balls.** These are usually glass of uniform diameter, but can be made of stainless steel.

(d) **Wire packing.** For use of 'Heli-Grid' and 'Heli-Pak' packings. see references given for the Podbielniak column. For Stedman packing, see entry under Stedman column.

Types of condensers:

Air condenser. A glass tube such as the inner part of a Liebig condenser. Used for liquids with boiling points above 90°. Can be of any length.

Allihn condenser. The inner tube of a Liebig condenser is modified by having a series of bulbs to increase the condensing surface. Further modifications of the bubble shapes give the Julian and Allihn-Kronbitter (glass-jacketed) condensers.

Bailey-Walker condenser. A type of all-metal condenser fitting into the neck of extraction apparatus and being supported by the rim. Used for high-boiling liquids.

Coil condenser. An open tube, into which is sealed a glass coil or spiral through which water circulates. The tube is sometimes also surrounded by an outer cooling jacket.

Double surface condenser. A tube in which the vapour is condensed between an outer and inner water-cooled jacket after impinging on the latter. Very useful for liquids boiling below 40°.

Friedrichs condenser. A 'cold-finger' type of condenser sealed into a glass jacket open at the bottom and near the top. The cold finger is formed into glass screw threads.

Graham condenser. A type of coil condenser.

Hopkins condenser. A cold-finger type of condenser resembling that of Friedrichs.

Liebig condenser. An inner glass tube surrounded by a glass jacket through which water is circulated.

Othmer condenser. A large-capacity condenser which has two coils of relatively large bore glass tubing inside it, through which the water flows. The two coils join at their top and bottom.

West condenser. A Liebig condenser with a light-walled inner tube and a heavy-walled outer tube, with only a narrow space between them.

Wiley condenser. A condenser resembling the Bailey-Walker type.

[For more information see: https://en.wikipedia.org/wiki/Condenser_(laboratory)]

Vacuum distillation. This expression is commonly used to denote a distillation under reduced pressure lower than that of the normal atmosphere. As the boiling point of a substance depends on the pressure, it is often possible to distil materials at a temperature low enough to avoid partial or complete decomposition by lowering the pressure, even if they are unstable when boiled at atmospheric pressure.

Sensitive or high-boiling liquids should invariably be distilled or fractionally distilled under reduced pressure. The apparatus is essentially as described for distillation except that ground joints connecting the different parts of the apparatus should be air tight by using grease, or better *Teflon sleeves*. For low, moderately high, and very high temperatures Apiezon L, M and T greases, respectively, are very satisfactory. Alternatively, it is often preferable to avoid grease and to use thin Teflon sleeves in the joints. The distillation flask, must be supplied with a capillary bleed (which allows a fine stream of air, nitrogen or argon into the flask), and the receiver should be of the fraction collector type. When distilling under vacuum it is very important to place a loose packing of glass wool above the liquid to buffer sudden boiling of the liquid. The flask should **not** be more than two-thirds full of liquid. The vacuum must have attained a steady state, i.e. the liquid has been completely degassed, before the heating

source is applied, and the temperature of the heat source must be raised *very slowly* until boiling is achieved.
If the pump is a filter pump off a high-pressure water supply, its performance will be limited by the temperature of the water because the vapour pressure of water at 10°, 15°, 20° and 25° is 9.2, 12.8, 17.5 and 23.8 mm Hg, respectively. The pressure can be measured with an ordinary manometer. For vacuums in the range of 10^{-2} mm Hg to 10 mm Hg, rotary mechanical pumps (oil pumps) are used and the pressure can be measured with a Vacustat McLeod-type gauge. If still higher vacuums are required, for example for high vacuum sublimations, a mercury diffusion pump is suitable. Such a pump can provide a vacuum up to 10^{-6} mm Hg. For better efficiencies, the diffusion pump can be backed up by a mechanical pump. In all cases, the mercury pump is connected to the distillation apparatus through several traps to remove mercury vapours. These traps may operate by chemical action, for example the use of sodium hydroxide pellets to react with acid vapours, or by condensation, in which case empty tubes cooled in solid carbon dioxide-ethanol or liquid nitrogen (contained in wide-mouthed Dewar flasks) are used.
Special oil or mercury traps are available commercially, and a liquid-nitrogen (**b** -209.9°C) trap is the most satisfactory one to use between these and the apparatus. It has an advantage over liquid air or oxygen in that it is non-explosive if it becomes contaminated with organic matter. Air should **not** be sucked through the apparatus before starting a distillation because this will cause liquid oxygen (**b** –183°C) to condense in the liquid nitrogen trap, and this is potentially explosive (especially in mixtures with organic materials). Due to the potential lethal consequences of liquid oxygen/organic material mixtures, care must be exercised when handling liquid nitrogen. Hence, it is advisable to degas the system for a short period before the trap is immersed into the liquid nitrogen (which is kept in a Dewar flask).

Spinning-band distillation. Factors which limit the performance of distillation columns include the tendency to flood (which occurs when the returning liquid blocks the pathway taken by the vapour through the column) and the increased hold-up (which decreases the attainable efficiency) in the column that should, theoretically, be highly efficient. To overcome these difficulties, especially for distillation under high vacuum of heat sensitive or high-boiling highly viscous fluids, spinning band columns are commercially available. In such units, the distillation columns contain a rapidly rotating, motor-driven, spiral band, which may be of polymer-coated metal, stainless steel or platinum. The rapid rotation of the band in contact with the walls of the still gives intimate mixing of descending liquid with ascending vapour while the screw-like motion of the band drives the liquid towards the still-pot, helping to reduce hold-up. There is very little pressure drop in such a system, and very high throughputs are possible, with high efficiency. For example, a 765-mm long 10-mm diameter commercial spinning-band column is reported to have an efficiency of 28 plates and a pressure drop of 0.2 mm Hg for a throughput of 330ml/hour. The columns may be either vacuum jacketed or heated externally. The stills can be operated down to 10^{-5} mm Hg. The principle, which was first used commercially in the Podbielniak Centrifugal Superfractionator, has also been embodied in descending-film molecular distillation apparatus.

Steam distillation. When two immmiscible liquids distil, the sum of their (independent) partial pressures is equal to the atmospheric pressure. Hence in steam distillation, the distillate has the composition

$$\frac{\text{Moles of substance}}{\text{Moles of water}} = \frac{P_{substance}}{P_{water}} = \frac{760 - P_{\text{water}}}{P_{water}}$$

where the *P*'s are vapour pressures (in mm Hg) in the boiling mixture.

The customary technique consists of heating the substance and water in a flask (to boiling), usually with the passage of steam, followed by condensation and separation of the aqueous and non-aqueous phases in the distillate. Its advantages are those of selectivity (because only some water-insoluble substances, such as naphthalene, nitrobenzene, phenol and aniline are volatile in steam) and of ability to distil certain high-boiling substances well below their boiling point. It also facilitates the recovery of a non-steam-volatile solid at a relatively low temperature from a high-boiling solvent such as nitrobenzene. The efficiency of steam distillation is increased if superheated steam is used (because the vapour pressure of the organic component is increased relative to water). In this case the flask containing the material is heated (without water) in an oil bath and the steam passing through it is superheated by prior passage through a suitable heating device (such as a copper coil heated electrically or an oil bath).

Azeotropic distillation. In some cases two or more liquids form constant-boiling mixtures, or azeotropes. Azeotropic mixtures are most likely to be found with components which readily form hydrogen bonds or are otherwise highly associated, especially when the components are dissimilar, for example an alcohol and an aromatic hydrocarbon, but have similar boiling points.

Examples where the boiling point of the distillate is a minimum (less than either pure component) include:
Water with ethanol, *n*-propanol and isopropanol, *tert*-butanol, propionic acid, butyric acid, pyridine,
methanol with methyl iodide, methyl acetate, chloroform,
ethanol with ethyl iodide, ethyl acetate, chloroform, benzene, toluene, methyl ethyl ketone,
benzene with cyclohexane,
acetic acid with toluene.
Although less common, azeotropic mixtures are known which have higher boiling points than their components. These include water with most of the mineral acids (hydrofluoric, hydrochloric, hydrobromic, perchloric, nitric and sulfuric) and formic acid. Other examples are acetic acid-pyridine, acetone-chloroform, aniline-phenol, and chloroform-methyl acetate.
The following azeotropes are important commercially for drying ethanol:

ethanol 95.5% (by weight) - water 4.5%	**b** 78.1º
ethanol 32.4% - benzene 67.6%	**b** 68.2º
ethanol 18.5% - benzene 74.1% - water 7.4%	**b** 64.9º

Materials are sometimes added to form an azeotropic mixture with the substance to be purified. Because the azeotrope boils at a different temperature, this facilitates separation from substances distilling in the same range as the pure material. (Conversely, the impurity might form the azeotrope and be removed in this way.) This method is often convenient, especially where the impurities are isomers or are otherwise closely related to the desired substance. Formation of low-boiling azeotropes also facilitates distillation.
One or more of the following methods can generally be used for separating the components of an azeotropic mixture:

1. By using a chemical method to remove most of one species prior to distillation. (For example, water can be removed by suitable drying agents; aromatic and unsaturated hydrocarbons can be removed by sulfonation).
2. By redistillation with an additional substance which can form a ternary azeotropic mixture (as in the ethanol-water-benzene example given above).
3. By selective adsorption of one of the components. (For example, of water on to silica gel or molecular sieves, or of unsaturated hydrocarbons onto alumina).
4. By fractional crystallisation of the mixture, either by direct freezing or by dissolving in a suitable solvent.

Kügelrohr distillation. The Aldrich Kügelrohr Distillation Apparatus (see Aldrich-Sigma Labware catalogue) is made up of small glass bulbs (*ca* 4-5cm diameter) that are joined together *via* Quickfit joints at each pole of the bulbs. The liquid (or low melting solid) to be purified is placed in the first bulb of a series of bulbs joined end to end, and the system can be evacuated. The first bulb is heated in a furnace (e.g. Büchi Kügelrohr micro distillation oven from Sigma-Aldrich Labware catalogue) at a high temperature whereby most of the material distils into the second bulb (which is outside of the furnace). The second bulb is then moved into the furnace and the furnace temperature is reduced by *ca* 5º whereby the liquid in the second bulb distils into the third bulb (at this stage the first bulb is now out at the back of the furnace, and the third and subsequent bulbs are outside the front of the furnace). The furnace temperature is lowered by a further *ca* 5º, and the third bulb is moved into the furnace. The lower boiling material will distil into the fourth bulb. The process is continued until no more material distils into the subsequent bulb. The vacuum (if applied) and the furnace are removed, the bulbs are separated and the various fractions of distillates are collected from the individual bulbs. For volatile liquids, it may be necessary to cool the receiving bulb with solid CO_2 held in a suitable container (a Kügelrohr distillation apparatus with an integrated cooling system is available). This procedure is used for preliminary purification and the distillates are then redistilled or recrystallised.

Isopiestic or isothermal distillation. This technique can be useful for the preparation of metal-free solutions of volatile acids and bases for use in trace metal studies. The procedure involves placing two beakers, one of distilled water and the other of a solution of the material to be purified, in a desiccator. The desic-

cator is sealed and left to stand at room temperature for several days. The volatile components distribute themselves between the two beakers whereas the non-volatile contaminants remain in the original beaker. This technique has afforded metal-free pure solutions of ammonia, hydrochloric acid and hydrogen fluoride.

RECRYSTALLISATION

Techniques

The most commonly used procedure for the purification of a solid material by recrystallisation from a solution involves the following steps:

(a) The impure material is dissolved in a suitable solvent, by shaking or vigorous stirring, at or near the boiling point, to form a near-saturated solution.
(b) The hot solution is filtered to remove any insoluble particles. To prevent crystallisation during this filtration, a heated filter funnel can be used, or the solution can be diluted with more of the solvent.
(c) The solution is then allowed to cool so that the dissolved substance crystallises out.
(d) The crystals are separated from the mother liquor, either by centrifuging or by filtering, under suction, through a sintered glass, a Hirsch or a Büchner, funnel. Usually, centrifugation is preferred because of the greater ease and efficiency of separating crystals and mother liquor, and also because of the saving of time and effort, particularly when very small crystals are formed or when there is entrainment of solvent.
(e) The crystals are washed free from mother liquor with a little fresh cold solvent, then dried.

If the solution contains extraneous coloured material likely to contaminate the crystals, this can often be removed by adding some activated charcoal (decolorising carbon) to the hot, but not boiling, solution which is then shaken frequently for several minutes before being filtered. (The large active surface of the carbon makes it a good adsorbent for this purpose.) In general, the cooling and crystallisation steps should be rapid so as to give small crystals which occlude less of the mother liquor. This is usually satisfactory with inorganic material, so that commonly the filtrate is cooled in an ice-water bath while being vigorously stirred. In many cases, however, organic molecules crystallise much more slowly, so that the filtrate must be set aside to cool to room temperature or left in the refrigerator. It is often desirable to subject material that is very impure to preliminary purification, such as steam distillation, Soxhlet extraction, or sublimation, before recrystallising it. A greater degree of purity is also to be expected if the crystallisation process is repeated several times, especially if different solvents are used. The advantage of several crystallisations from different solvents lies in the fact that the material sought, and its impurities, are unlikely to have similar solubilities because solvents and temperatures are varied.

For the final separation of solid material, sintered-glass discs are preferable to filter paper. Sintered glass is unaffected by strongly acidic solutions or by oxidising agents. Also, with filter paper, cellulose fibres are likely to become included in the sample. The sintered-glass discs or funnels can be readily cleaned by washing in freshly prepared *chromic acid cleaning mixture*. This mixture is made by adding 100ml of concentrated sulfuric acid slowly with stirring to a solution of 5g of sodium dichromate (CARE: cancer suspect) in 5ml of water. (The mixture warms to about 70°, and sulfuric acid becomes hot when water is added to it; see p 3).

For materials with very low melting points it is sometimes convenient to use dilute solutions in acetone, methanol, pentane, diethyl ether or $CHCl_3/CCl_4$. The solutions are cooled to -78° in a dry-ice/acetone bath, to give a slurry which is filtered off through a precooled Büchner funnel. Experimental details, as applied to the purification of nitromethane, are given by Parrett and Sun [*J Chem Educ* **54** 448 *1977*, DOI: 10.1021/ed054p448].

Where substances vary little in solubility with temperature, *isothermal crystallisation* may sometimes be employed. This usually takes the form of a partial evaporation of a saturated solution at room temperature by leaving it under reduced pressure in a desiccator.

However, in rare cases, crystallisation is not a satisfactory method of purification, especially if the impurity forms crystals that are *isomorphous* with the material being purified. In fact, the impurity content may even be greater in such recrystallised material. For this reason, it still remains necessary to test for impurities and to remove or adequately lower their concentrations by suitable chemical manipulation prior to recrystallisation.

Filtration. Filtration removes particulate impurities rapidly from liquids and is also used to collect insoluble or crystalline solids which separate or crystallise from solution. The usual technique is to pass the solution, cold or hot, through a fluted filter paper in a conical glass funnel.

If a solution is hot and needs to be filtered rapidly, a Büchner funnel and flask are used and filtration is performed

under a slight vacuum (water pump), the filter medium being a circular cellulose filter paper wet with solvent. If filtration is slow, even under high vacuum, a pile of about twenty filter papers, wet as before, are placed in the Büchner funnel and, as the flow of solution slows down, the upper layers of the filter paper are progressively removed. *Alternatively*, a filter aid, e.g. Celite, Florisil or Hyflo-supercel, is placed on top of a filter paper in the funnel. When the flow of the solution (under suction) slows down, the upper surface of the filter aid is scratched gently. Filter papers with various pore sizes are available covering a range of filtration rates. Hardened filter papers are slow filtering, but they can withstand acidic and alkaline solutions without appreciable hydrolysis of the cellulose (see Table 4). When using strong acids it is preferable to use glass micro fibre filters, which are commercially available (see Tables 4 and 5).

Freeing a solution from extremely small particles [e.g. for optical rotatory dispersion (ORD) or circular dichroism (CD) measurements] requires filters with very small pore size. Commercially available (Millipore, Gelman, Nucleopore) filters other than cellulose or glass include nylon, Teflon, and polyvinyl chloride, and the pore diameter may be as small as 0.01micron (see Table 5). Special containers are used to hold the filters, through which the solution is pressed by applying pressure, e.g. from a syringe. Some of these filters can be used to clear strong sulfuric acid solutions (and remove bacteria from contaminated water).
As an alternative to the Büchner funnel for collecting crystalline solids, a funnel with a sintered glass-plate under suction may be used. Sintered-glass funnels with various porosities are commercially available and can be easily cleaned with warm chromic or nitric acid (see above).

When the solid particles are too fine to be collected on a filter funnel because filtration is extremely slow, separation by **centrifugation** should be used. Bench-type centrifuges are most convenient for this purpose. The solid is placed in the centrifuge tube, the tubes containing the solutions on opposite sides of the rotor should be balanced accurately (at least within 0.05 to 0.1g), and the solutions are spun at maximum speed for as long as it takes to settle the solid (usually *ca* 3-5minutes). The solid is washed (by shaking) with cold solvent by centrifugation, and finally twice with a pure volatile solvent in which the solid is insoluble, also by centrifugation. After decanting the supernatant, the residue is dried in a vacuum, at elevated temperatures if necessary. In order to avoid 'spitting' and contamination with dust while the solid in the centrifuge tube is dried, the mouth of the tube is covered with aluminium foil and held fast with a tight rubber band near the lip. The flat surface of the aluminium foil is then perforated in several places with a pin, and the tube and contents are dried in a vacuum desiccator over a desiccant.

Solvents

Choice of solvents. The best solvents for recrystallisation have the following properties:

(a) The material is much more soluble at higher temperatures than it is at room temperature or below.
(b) Well-formed (but not large) crystals are produced.
(c) Impurities are either very soluble or only sparingly soluble.
(d) The solvent must be readily removed from the purified material.
(e) There must be no reaction between the solvent and the substance being purified.
(f) The solvent must not be inconveniently volatile or too highly flammable. (These are reasons why diethyl ether and carbon disulfide are not commonly used in this way.)

The following generalisations provide a rough guide to the selection of a suitable solvent:

(a) Substances usually dissolve best in solvents to which they are most closely related in chemical and physical characteristics. Thus, hydroxylic compounds are likely to be most soluble in water, methanol, ethanol, acetic acid or acetone. Similarly, petroleum ether might be used with water-insoluble substances. However, if the resemblance is too close, solubilities may become excessive.
(b) Higher members of homologous series approximate more and more closely to their parent hydrocarbon.
(c) Polar substances are more soluble in polar than in non-polar solvents.

Although Chapters 3 to 7 provide details of the solvents used for recrystallising a large portion of commercially available laboratory chemicals, they cannot hope to be exhaustive, nor are they necessarily the best choice, but they are the solvents reported in the literature. In other cases where it is desirable to use this process, it is necess-

ary to establish whether a given solvent is suitable. This is usually done by taking only a small amount of material in a small test-tube and adding enough solvent to cover it. If it dissolves readily in the cold or on gentle warming, the solvent is unsuitable. Conversely, if it remains insoluble when the solvent is heated to boiling (adding more solvent if necessary), the solvent is again unsuitable. If the material dissolves in the hot solvent but does not crystallise readily within several minutes of cooling in an ice-salt mixture, another solvent should be tried.

Water

The properties and purification of water are described in the 'Inorganic Compounds' section of Chapter 4. Fluka (Riedel-de Haën) supply purified water prepared specifically for a variety of uses, e.g. LC-MS, HPLC, gradient elution, for cell biology which is freed from *enterotoxins* by *ultrafiltration* and autoclaving, for organic and for inorganic trace analysis, for residue analysis and other analytical purposes. Some of these have been prepared by *reverse osmosis*, or ultrafiltration, under clean room conditions and filtered through 0.2μm membranes into bottles of high purity glass under inert gas. They have a limited shelf life once opened most probably because O_2 from the air dissolves readily in the water. The solubility of O_2 in 100ml of water is ~1.02ml (0.455mM) at 0°, 0.68ml (0.282mM) at 20°, 0.63ml (0.258mM) at 25°, 0.63ml (0.237mM) at 30°, and 0.12ml (0.033mM) at 100°, all at ~760mmHg in equilibrium with air (see Tables 25-28). This is in comparison with the concentration of O_2 of 0.23mM in 0.1M Tris HCl buffer at pH 7.2 and 25° in equilibrium with air at 760mmHg. Routinely, water is best purified by redistilling it twice in an all glass apparatus, storing it under N_2 or He in stoppered glass containers and, if necessary, preferably subjected to ultrafiltration through a single or multistage 0.2μm membrane system or to reverse osmosis (visit <www.millipore.com>). If oxygen-free water is required, N_2 or argon should be bubbled through a sintered glass frit in the highly purified water for 2-3hours, and stoppered immediately. It is best to use a glass container from which the water can be withdrawn without it coming into contact with air. Note that boiling and distilling water, and condensing it in an inert atmosphere should de-gas it.

Petroleum ethers are commercially available fractions of refined petroleum and are sold in fractions of about 20° boiling ranges. This ensures that little of the hydrocarbon ingredients boiling below the range is lost during standing or boiling when recrystallising a substance. Petroleum ethers with boiling ranges (at 760mm pressure) of 35—60°, 40—60°, 60—80°, 80—100°, and 100—120° are generally free from unsaturated and aromatic hydrocarbons. The lowest boiling petroleum ether commercially available has **b** 30-40°/760mm and is mostly *n*-pentane. The purer spectroscopic grades are almost completely free from olefinic and aromatic hydrocarbons. ***Petroleum spirit*** (which is sometimes used synonymously with petroleum ether or light petroleum) is usually less refined petroleum, and ***ligroin*** is used for fractions boiling above 100°. The lower boiling fractions consist of mixtures of *n*-pentane (**b** 36°), *n*-hexane (**b** 68.5°) and *n*-heptane (**b** 98°), and some of their isomers in varying proportions. For purification see petroleum ether b 35-60° in 'Aliphatic Compounds', Chapter 3, which is typical.

Solvents commonly used for recrystallisation, and their boiling points, are given in Table 6.

For comments on the toxicity and use of **benzene** see the 'Introduction' pages of Chapters 3, 4 and 6.

Mixed Solvents. Where a substance is too soluble in one solvent and too insoluble in another, for either to be used for recrystallisation, it is often possible (provided the solvents are miscible) to use them as a mixed solvent system. (In general, however, it is preferable to use a single solvent if this is practicable.) Table 7 contains many of the common pairs of miscible solvents.

Several procedures with mixed solvents have been used successfully for crystallisation. These include the following:

(a) The material is dissolved in the solvent in which it is more soluble at room temperature, then the second solvent (heated to near boiling) is added cautiously to the cold solution until a slight turbidity persists or crystallisation begins. The turbidity is cleared by warming or by adding several drops of the first solvent, and the clear solution is allowed to cool slowly for crystallisation to occur. The supernatant is decanted off carefully (do not disturb the crystals unduly) and more of the second solvent is added to the clear decanted supernatant until turbidity begins again, and is set aside for further crystals to form. The procedure is repeated until no more crystals separate.

(b) A variation of the procedure in (a) is simply to precipitate the material in a microcrystalline form from solution in one solvent at room temperature, by adding a little more of the second solvent also at room temperature, filtering off the crystals, adding a little more of the second solvent and repeating the process. This ensures, at least in the first or last precipitation, a material which contains as little as possible of the impurities, which may also be precipitated in this way. With inorganic salts or metal salts of organic acids, the first solvent is commonly water

and the second solvent is alcohol or acetone. With salts of organic bases and inorganic acids, e.g. hydrochloride, or salts of organic acids and organic bases, the first solvent is usually an alcohol or acetone, in which the salt is very soluble and the second solvent is dry diethyl ether.
(c) A very concentrated solution of the compound in the first solvent in one beaker, and a second beaker containing the second solvent in which the compound is insoluble are placed in a desiccator. As the vapours of the two solvents equilibrate in the desiccator, and crystals separate in the first beaker that contains the compound.
(d) This procedure is best carried out in a cold room (at *ca* 4º). A strong solution of the solid in the solvent in which it is very soluble is *layered* carefully with the second solvent. As the second solvent diffuses and dissolves into the solution, crystals begin to form at the 'interface'. When separation of crystals is complete and the solvent mixture is homogeneous, another layer of the second solvent is applied and the process is repeated.
Seeding is well known to initiate the crystallisation process. A good way to procure seed crystals is to dissolve the crystals in the minimum amount of solvent, place the solution in a watch glass, then blow a fine stream of dry N_2 or argon gently over the surface of the solution until seed crystals are formed. *Alternatively*, the inert gas is allowed to evaporate all the solvent, and the residual crystals or fine powder are used for seeding. The seeds are applied in the above procedures at the appropriate time, e.g. when first turbidity appears, or placed onto the tip of a glass rod which is then rubbed against the sides of the container of the solution until crystallisation begins.

Recrystallisation from the melt. A crystalline solid melts when its temperature is raised sufficiently for the thermal agitation of its molecules or ions to overcome the restraints imposed by the crystal lattice. Usually, impurities weaken crystal structures, and hence lower the melting points of solids (or the freezing points of liquids). If an impure material is melted and cooled slowly (with the addition, if necessary, of a trace of solid material near the freezing point to avoid supercooling), the first crystals that form will usually contain less of the impurity, so that fractional solidification by partial freezing can be used as a purification process for solids with melting points lying in a convenient temperature range (or for more readily frozen liquids). Some examples of cooling baths that are useful in recrystallisation are summarised in Table 8. In some cases, impurities form higher melting eutectics with substances to be purified, so that the first material to solidify is less pure than the melt. For this reason, it is often desirable to discard the first crystals and also the final portions of the melt. Substances having similar boiling points often differ much more in melting points, so that fractional solidification can offer real advantages, especially where ultrapurity is sought. For further information on this method of recrystallisation, consult the earlier editions of this book as well as references by Schwab and Wichers (*J Res Nat Bur Stand* **25** 747 *1940*, DOI: 10.6028/jres.025.001). This method works best if the material is already nearly pure, and hence tends to be a final purification step.

Zone refining. Zone refining (or zone melting) is a particular development for fractional solidification and is applicable to all crystalline substances that show differences in the concentrations of impurities in liquid and solid states at solidification. The apparatus used in this technique consists essentially of a device in which the crystalline solid to be purified is placed in a glass tube (set vertically) which is made mechanically to move slowly upwards while it passes through a fixed coil (one or two turns) of heated wire. A narrow zone of molten crystals is formed when the tube is close to the heated coil. As the zone moves away from the coil the liquid crystallises, and a fresh molten zone is formed below it at the coil position. The machine can be set to recycle repeatedly. At its advancing side, the zone has a melting interface with the impure material whereas on the upper surface of the zone there is a constantly growing face of higher-melting, resolidified purer material. This leads to a progressive increase in impurity in the liquid phase which, at the end of the run, is discarded from the bottom of the tube. Also, because of the progressive increase in impurity in the liquid phase, the resolidified material contains correspondingly less of the impurites. For this reason, it is usually necessary to make several zone-melting runs before a sample is satisfactorily purified. This is also why the method works most successfully if the material is already fairly pure. In all these operations the zone must travel slowly enough to enable impurities to diffuse or be convected away from the area where resolidification is occurring.
The technique finds commercial application in the production of metals of extremely high purity (tubes other than glass are used in these cases, and impurities can be reduced down to 10^{-9} ppm), in purifying refractory oxides, and in purifying organic compounds, using commercially available equipment. Criteria for indicating that definite purification is achieved include elevation of melting point, removal of colour, fluorescence or smell, and a lowering of electrical conductivity. Difficulties likely to be found with organic compounds, especially those with low melting points and low rates of crystallisation, are supercooling and, because of surface tension and contraction, the tendency of the molten zone to seep back into the recrystallised areas. The method is likely to be

useful in cases where fractional distillation is not practicable, either because of unfavourable vapour pressures or ease of decomposition, or where super-pure materials are required. The method has been used for the latter purpose for purifying anthracene, benzoic acid, chrysene, morphine, 1,8-naphthyridine and pyrene to name a few. [See E.F.G.Herington, *Zone Melting of Organic Compound*s, Wiley & Sons, NY, 1963; W.Pfann, *Zone Melting*, 2nd edn, Wiley, NY, 1966; H.Schildknecht, *Zonenschmelzen*, Verlag Chemie, Weinheim, 1964; W.R.Wilcox, R.Friedenberg and Back *Chem Rev* **64** 187 *1964*, DOI: 10.1021/cr60228a006; M.Zief and W.R.Wilcox (Eds), *Fractional Solidification*, Vol I, M Dekker Inc. NY, 1967.]

SUBLIMATION

Sublimation differs from ordinary distillation because the vapour condenses to a solid instead of a liquid. Usually, the pressure in the heated system is diminished by pumping, and the vapour is condensed (after travelling a relatively short distance) onto a cold finger or some other cooled surface. This technique, which is applicable to many organic solids, can also be used with inorganic solids such as aluminium chloride, ammonium chloride, arsenious oxide and iodine to name a few. In some cases, passage of a stream of inert gas over the heated substance secures adequate vaporisation and reduces oxidation. This procedure has the added advantage of removing occluded solvent used for recrystallising the solid.

CHROMATOGRAPHY

Chromatography is often used with advantage for the purification of small, and large, amounts of complex organic mixtures. Chromatography techniques all rely on the differential distribution of the various components in the solution, between the mobile phase and the stationary phase. The mobile phase can either be a gas or a liquid, whereas the stationary phase can either be a solid or a non-volatile liquid adsorbed on a solid surface.
The major chromatographic techniques can also be categorised according to the nature of the mobile phase used - vapour phase chromatography for when a gas is the mobile phase and liquid chromatography for when a liquid is the mobile phase.
The suppliers of chromatography equipment for every need are too numerous to list here but can be viewed on the internet under 'Chromatography products'. Details and orders can be obtained from the respective websites listed at the end of the section on HPLC below.

Vapour phase chromatography (GC or gas-liquid chromatography)

The mobile phase in vapour phase chromatography is a gas (e.g. hydrogen, helium, nitrogen or argon), and the stationary phase is a non-volatile liquid impregnated onto a porous material. The mixture to be purified is injected into a heated inlet whereby it is vaporised and taken into the column by the carrier gas. It is separated into its components by partition between the liquid on the porous support and the gas. For this reason vapour-phase chromatography is sometimes referred to as gas-liquid chromatography (g.l.c). Vapour phase chromatography is very useful for the resolution of a mixture of volatile compounds. This type of chromatography uses either packed or capillary columns. Packed columns have internal diameters of 3-5 mm with lengths of 2-6 metres. These columns can be packed with a range of materials including firebrick derived materials (chromasorb P, for separation of non-polar hydrocarbons) or diatomaceous earth (chromasorb W, for separation of more polar molecules such as acids, amines). Capillary columns have stationary phase bonded to the walls of long capillary tubes. The diameters of capillary columns are less than 0.5 mm, and the lengths of these columns can go up to 50 metres! These columns have much superior separating capabilities than the packed columns. Elution times for equivalent resolutions with packed columns can be up to ten times shorter. It is believed that almost any mixture of compounds can be separated using one of the four stationary phases, OV-101, SE-30, OV-17 and Carbowax-20M. Capillary columns for analysis in gas chromatography are now routinely used. An extensive range of packed and capillary columns is available from chromatographic specialists such as Supelco, Alltech, Hewlett-Packard, Phenomenex (for stainless steel capillary columns see <phenomenex.com>, etc. (see above and at the end of the section on HPLC below). Some typical liquids used for stationary phases in gas chromatography are listed in Table 9.
Although gas chromatography is routinely used for the analysis of mixtures, this form of chromatography can also be used for separation/purification of substances. This is known as preparative GC. In preparative GC, suitably packed columns are used, and as substances emerge from the column, they are collected by condensing the vapour

of these separated substances in suitable traps. The carrier gas blows the vapour through these traps; hence these traps have to be very efficient. Improved collection of the effluent vaporised fractions in preparative work is attained by strong cooling, increasing the surface of the traps by packing them with glass wool, and/or by applying an electrical potential which neutralises the charged vapour and causes it to condense.
When the gas chromatograph is attached to a mass spectrometer, a very powerful analytical tool (*gas chromatography-mass spectrometry*; **GC-MS**) is produced. Gas chromatography allows the separation of mixtures but does not allow the definitive identification of unknown substances, whereas mass spectrometry is good for the identification of individual compounds of the mixtures of compounds. This means that with GC-MS, both separation *and* identification of substances in mixtures can be achieved. The spectrometer can be connected to a computer that has a library from which the mass peaks can be compared and is a very powerful analytical tool. Because of the relatively small amounts of material required for mass spectrometry, a splitting system is inserted between the column and the mass spectrometer. This enables only a small fraction of the effluent to enter the spectrometer; the rest of the effluent is usually collected or vented to the air. See p 29 below for **GC-MS-MS**.
For more detail on apparatus and chromatographic columns see http://www.sigmaaldrich.com/analytical-chromatography/gas-chromatography.html and websites at the end of the section on HPLC below.

Liquid chromatography

In contrast to vapour phase chromatography, the mobile phase in liquid chromatography is a liquid. In general, there are four main types of liquid chromatography: *adsorption*, *partition*, *ion-chromatography*, and *gel filtration*.

Adsorption chromatography is based on the difference in the extent to which substances in solution are adsorbed onto a suitable surface. The main techniques in adsorption chromatography are TLC (thin layer chromatography), paper and column chromatography.

Thin layer chromatography **(TLC)**. In thin layer chromatography, the mobile phase, i.e. the solvent, creeps up the stationary phase (the absorbent) by capillary action. The adsorbent (e.g. silica, alumina, cellulose) is spread on a rectangular glass plate (or solid inert plastic sheet or aluminium foil). Some adsorbents (e.g. silica) are mixed with a setting material (e.g. $CaSO_4$) by the manufacturers which causes the film to set hard on drying. The adsorbent can be activated by heating at 100-110º for a few hours. Other adsorbents (e.g. celluloses) adhere on glass plates without a setting agent. Thus some grades of absorbents have prefixes; e.g. prefix G means that the absorbent can cling to a glass plate and is used for TLC (e.g. silica gel GF_{254} is for TLC plates which have a dye that fluoresces under 254nm UV light). Those lacking this binder have the letter H after any coding and is suitable for column chromatography e.g. silica gel 60H. The materials to be purified or separated are spotted in a solvent close to the lower end of the plate and allowed to dry. The spots will need to be placed at such a distance so as to ensure that when the lower end of the plate is immersed in the solvent, the spots are a few mm above the eluting solvent. The plate is placed upright in a tank containing the eluting solvent. Elution is carried out in a closed tank to ensure equilibrium. Good separations can be achieved with square plates if a second elution is performed at right angles to the first using a second solvent system. For rapid work, plates of the size of microscopic slides or even smaller are used which can decrease the elution time and cost without loss of resolution. The advantage of plastic backed and aluminium foil backed plates is that the size of the plate can be made as required by cutting the sheet with scissors or a sharp guillotine. Visualisation of substances on TLC can be carried out using UV light if they are UV absorbing or fluorescing substances or by spraying or dipping the plate with a reagent that gives coloured products with the substance (e.g. iodine solution or vapour gives brown colours with amines), or with dilute sulfuric acid (organic compounds become coloured or black when the plates are heated at 100º if the plates are of alumina or silica, but not cellulose). (see Table 10 for some methods of visualisation.) Some alumina and silica powders are available with fluorescent materials in them, in which case the whole plate fluoresces under UV light. Non-fluorescing spots are thus clearly visible, and fluorescent spots invariably fluoresce with a different colour. The colour of the spots can be different under UV light at 254nm from light at 365nm. Another useful way of showing up non-UV absorbing spots is to spray the plate with a 1-2% solution of Rhodamine 6G in acetone. Under UV light the dye fluoresces and reveals the non-fluorescing spots. For preparative work, if the material in the spot or fraction is soluble in ether or petroleum ether, the desired substance can be extracted from the absorbent with these solvents which leave the water soluble dye behind.
TLC can be used as an analytical technique, or as a guide to establishing the progress of a reaction, conditions for column chromatography or as a preparative technique in its own right.
The thickness of the absorbent on the TLC plates can be between 0.2mm to 2mm or more. In preparative work, the thicker plates are used and hundreds of milligrams of mixtures can be purified conveniently and quickly. The spots or areas are easily scraped off the plates and the desired substances extracted from the absorbent with the

required solvent. For preparative TLC, non-destructive methods for visualising spots and fractions are required. As such, the use of UV light is very useful. If substances are not UV active, then a small section of the plate (usually the right or left edge of the plate) is sprayed with a visualising agent while the remainder of the plate is kept covered.

Thin layer chromatography has been used successfully with ion-exchange celluloses as stationary phases and various aqueous buffers as mobile phases. Also, gels (e.g. Sephadex G-50 to G-200 superfine) have been adsorbed on glass plates and are good for fractionating substances of high molecular weights (1500 to 250,000). With this technique, which is called *thin layer gel filtration* (**TLG**), molecular weights of proteins can be determined when suitable markers of known molecular weights are run alongside (see Chapter 6).

Commercially available pre-coated plates with a variety of adsorbents are generally very good for quantitative work because they are of a standard quality. Plates of a standardised silica gel 60 (as medium porosity silica gel with a mean porosity of 6mm) released by Merck have a specific surface of 500 m^2/g and a specific pore volume of 0.75 ml/g. They are so efficient that they have been called *high performance thin layer chromatography* (**HPTLC**) plates (Ripphahn & Halpaap *J Chromatogr* **112** 81 *1975*, DOI: 10.1016/S0021-9673(00)99944-8). In another variant of thin layer chromatography the adsorbent is coated with an oil as in gas chromatography thus producing *reverse-phase thin layer chromatography* (**R-P TLC**). R-P TLC plates e.g. silica gel RP-18 are available from Fluka and Merck.

A very efficient form of chromatography makes use of a circular glass plate (rotor) coated with an adsorbent (silica, alumina or cellulose). As binding to a rotor is needed, the sorbents used may be of a special quality and/or binders are added to the sorbent mixtures. For example, when silica gel is required as the absorbent, silica gel 60 PF-254 with calcium sulfate (Merck catalog 7749) is used. The thickness of the absorbent (1, 2 or 4 mm) can vary depending on the amount of material to be separated. The apparatus used is called a **Chromatotron** (available from Harrison Research, USA). The glass plate is rotated by a motor, and the sample followed by the eluting solvent is allowed to drip onto a central position on the plate. As the plate rotates the solvent elutes the mixture, centrifugally, while separating the components in the form of circular bands radiating from the central point. The separated bands are usually visualised conveniently by UV light and as the bands approach the edge of the plate, the eluent is collected. The plate with the adsorbent can be re-used many times if care is employed in the usage, and hence this form of chromatography utilises less absorbents as well as solvents.

Recipes and instructions for coating the rotors are available from the Harrison website <http://www.harrisonresearch.com/chromatotron/>. In addition, information on how to regenerate the sorbents and binders is also included.

Paper chromatography. This is the technique from which thin layer chromatography was developed. It uses cellulose paper (filter paper) instead of the TLC adsorbent and does not require a backing like the plastic sheet in TLC. It is used in the **ascending procedure** (like in TLC) whereby a sheet of paper is hung in a jar, and the materials to be separated are spotted (after dissolving in a suitable solvent and drying) near the bottom of the sheet which dips into the eluting solvent just below the spots. As the solvent rises up the paper the spots are separated according to their adsorption properties. A variety of solvents can be used, the sheet is then dried in air (fume cupboard), and can then be run again with the solvent running at right angles to the first run to give a two-dimensional separation. The spots can then be visualised as in TLC or can be cut out and analysed as required. A **descending procedure** had also been developed where the material to be separated is spotted near the top of the paper and the top end is made to dip into a tray containing the eluting solvent. The whole paper is placed in a glass jar, and the solvent then runs down the paper causing the materials in the spots to separate also according to their adsorption properties and to the eluting ability of the solvent. This technique is much cheaper than TLC and is still used (albeit with thicker cellulose paper) with considerable success for the separation of protein hydrolysates for sequencing analysis and/or protein identification. However, modern and more efficient technologies are available for analysing proteins and their hydrolysates although the equipment is expensive. (Whatman papers for chromatography and electrophoresis are available also from Sigma-Aldrich Labware.)

Column Chromatography. The substances to be purified are usually placed on the top of the column and the solvent is run down the column. Fractions are collected and checked for compounds using TLC (UV and/or other means of visualisation). The adsorbent for chromatography can be packed dry and solvents to be used for chromatography are used to equilibrate the adsorbent by flushing the column several times until equilibration is achieved. *Alternatively*, the column containing the adsorbent is packed wet (slurry method), and pressure is applied at the top of the column until the column is well packed (i.e. the adsorbent is settled).

Graded Adsorbents and Solvents. Some materials used in columns for adsorption chromatography are grouped in Table 11 in an approximate order of effectiveness. Other adsorbents sometimes used include barium carbonate, calcium sulfate, calcium phosphate, charcoal (usually mixed with Kieselguhr or

other forms of diatomaceous earth, for example, the filter aid Celite) and cellulose. The alumina can be prepared in several grades of activity (see below).
In most cases, adsorption takes place most readily from non-polar solvents such as petroleum ether and least readily from polar solvents such as alcohols, esters, and acetic acid. Common solvents, arranged in approximate order of increasing eluting ability are also given in Table 11. Eluting power roughly parallels the dielectric constants of solvents. The series also reflects the extent to which the solvent binds to the column material, thereby displacing the substances that are already adsorbed. This preference of alumina and silica gel for polar molecules explains, for example, the use of percolation through a column of silica gel for the following purposes:— drying of ethylbenzene, removal of aromatics from 2,4-dimethylpentane and of ultraviolet absorbing substances from cyclohexane. Mixed solvents are intermediate in strength, and so provide a finely graded series. In choosing a solvent for use as an eluent it is necessary to consider the solubility of the substance in it and the ease with which it can subsequently be removed.

Preparation and Standardisation of Alumina. The activity of alumina depends inversely on its water content, and a sample of poorly active material can be rendered more active by leaving for some time in a round bottomed flask heated up to about 200° in an oil bath or a heating mantle while a slow stream of a dry inert gas is passed through it. *Alternatively*, it is heated to red heat (380-400°) in an open vessel for 4-6 hours with occasional stirring and then cooled in a vacuum desiccator: this material is then of grade I activity. Conversely, alumina can be rendered less active by adding small amounts of water and thoroughly mixing for several hours. Addition of about 3% (w/w) of water converts grade I alumina to grade II.
Used alumina can be regenerated by repeated extraction, first with boiling methanol, then with boiling water, followed by drying and heating. The degree of activity of the material can be expressed conveniently in terms of the scale due to Brockmann and Schodder (*Chem Ber* **74** 73 *1941*, DOI: 10.1002/cber.19410740113).

Alumina is normally slightly alkaline. A (less strongly adsorbing) neutral alumina can be prepared by making a slurry in water and adding 2M hydrochloric acid until the solution is acid to Congo red. The alumina is then filtered off, washed with distilled water until the wash water gives only a weak violet colour with Congo red paper, and dried.
Alumina used in TLC can be recovered by washing in ethanol for 48 hours with occasional stirring, to remove binder material and then washed with successive portions of ethyl acetate, acetone and finally with deionised water. Fine particles are removed by siphoning. The alumina is first suspended in 0.04M acetic acid (30min), then in distilled water (2 x 30min) and siphoning off after each wash. The process is repeated 7-8 times. It is then dried and activated at 200° [Vogh & Thomson *Anal Chem* **53** 1345 *1981*, DOI: 10.1021/ac00232a010].

Preparation of other adsorbents

Silica gel can be prepared from commercial water-glass by diluting it with water to a density of 1.19 and, while keeping it cooled to 5°, adding concentrated hydrochloric acid with stirring until the solution is acid to thymol blue. After standing for 3 hours, the precipitate is filtered off, washed on a Büchner funnel with distilled water, then suspended in 0.2M hydrochloric acid. The suspension is set aside for 2-3days, with occasional stirring, then filtered, washed well with water and dried at 110°. It can be activated by heating up to about 200° as described for alumina.
Powdered commercial silica gel can be purified by suspending and standing overnight in concentrated hydrochloric acid (6ml/g), decanting the supernatant and repeating with fresh acid until the latter remains colourless. After filtering with suction on a sintered-glass funnel, the residue is suspended in water and washed by decantation until free of chloride ions. It is then filtered, suspended in 95% ethanol, filtered again and washed on the filter with 95% ethanol. The process is repeated with anhydrous diethyl ether before the gel is heated for 24 hours at 100° and stored for another 24 hours in a vacuum desiccator over phosphorus pentoxide.
To buffer silica gel for flash chromatography (see later), 200g of silica is stirred in 1L of 0.2M NaH_2PO_4 for 30 minutes. The slurry is then filtered with suction using a sintered glass funnel. The silica gel is then activated at 110°C for 16 hours. The pH of the resulting silica gel is ~4. Similar procedures can be utilized to buffer the pH of the silica gel at various pHs (up to pH ~8: pH higher than this causes degradation of silica) using appropriate phosphate buffers.
Commercial silica gel has also been purified by suspension of 200g in 2L of 0.04M ammonia, and stood for 5 minutes before siphoning off the supernatant. The procedure was repeated 3-4 times, before rinsing with distilled water and drying, and activating the silica gel in an oven at 110° [Vogh & Thomson, *Anal Chem* **53** 1345 *1981*,

DOI: 10.1021/ac00232a010]. Although silica gel is not routinely recycled after use (due to fear of contamination as well as the possibility of reduced activity), the costs of using new silica gel for purification may be prohibitive. In these cases, recycling may be achieved by stirring the used silica gel (1 kg) in a mixture of methanol and water (2L MeOH/4L water) for 30-40 minutes. The silica gel is filtered (as described above) and reactivated at 110ºC for 16 hours.

Diatomaceous earth (Celite 535 or 545, Hyflo Super-cel, Dicalite, Kieselguhr) is purified before use by washing with 3M hydrochloric acid, then water, or it is made into a slurry with hot water, filtered at the pump and washed with water at 50º until the filtrate is no longer alkaline to litmus. Organic materials can be removed by repeated extraction at 50º with methanol or chloroform, followed by washing with methanol, filtering and drying at 90-100º.

Charcoal is generally satisfactorily activated by heating gently to red heat in a crucible or quartz beaker in a muffle furnace, finally allowing to cool under an inert atmosphere in a desiccator. Good commercial activated charcoal is made from wood, e.g. *Norit* (from Birch wood), *Darco* and *Nuchar*. If the cost is important, then the cheaper *animal charcoal* (bone charcoal) can be used. However, this charcoal contains calcium phosphate and other calcium salts and cannot be used with acidic materials. In this case the charcoal is boiled with dilute hydrochloric acid (1:1 by volume) for 2-3 hours, diluted with distilled water and filtered through a fine grade paper on a Büchner flask, washed with distilled water until the filtrate is almost neutral, and dried first in air, then in a vacuum, and activated as above. To improve the porosity, charcoal columns are usually prepared in admixture with diatomaceous earth.

Cellulose for chromatography is purified by sequential washing with chloroform, ethanol, water, ethanol, chloroform and acetone. More extensive purification uses aqueous ammonia, water, hydrochloric acid, water, acetone and diethyl ether, followed by drying in a vacuum. Trace metals can be removed from filter papers by washing for several hours with 0.1M oxalic, citric acid, or 0.1M EDTA solution, followed by repeated washing with distilled water.

Supelco supply a variety of 'solvent desorption tubes', which are cartridges that remove specific impurities (e.g. LpDNPH cartridges which contain a high purity silica adsorbent coated with 2,4-dinitrophenylhydrazine and remove carbonyl compounds; ozone scrubbers which eliminate ozone). Other cartridges such as the 'ORBO charcoal' cartridges contain various beds such as *activated coconut charcoal, activated petroleum charcoal, HBr on petroleum charcoal or 4-tert-butyl catechol on charcoal* and are used for specific or for general purposes. Other ORBO cartridges contain activated silica gel and coated silica gel, Florisil, Carboxen, Carbosieve and carbon-coated traps, as well as a variety of ORBO porous polymers, polyurethane, and glass fibre coated with 1-(2-pyridyl)piperazine (which is specific for sampling diisocyanates). They also supply filter cartridges for trapping aerosols and particulate forms of semivolatiles.

Flash Chromatography (FC and HPFC)

A faster method of separating components of a mixture is *flash chromatography* (see Still et al. *J Org Chem* **43** 2923 *1978*, DOI: 10.1021/jo00408a041). Flash chromatography has become an extremely useful and popular means of purification of small as well as large quantities of compounds. In flash chromatography the eluent flows through the column under a pressure of *ca* 1 to 4 atmospheres. The lower end of the chromatographic column has a relatively long taper closed with a tap. The upper end of the column is connected through a ball joint to a tap. *Alternatively*, a specially designed chromatographic column with a solvent reservoir can also be used (for an example, see the Aldrich Chemical Catalog-glassware section). The tapered portion is plugged with cotton, or quartz wool and *ca* 1 cm length of fine washed sand (the latter is optional). The adsorbent is then placed in the column as a dry powder or as a slurry in a solvent and allowed to fill to about one-third of the column. A fine grade of adsorbent is required in order to slow the flow rate at the higher pressure, e.g. Silica 60, 230 to 400 mesh with particle size 0.040-0.063mm (e.g. from Merck). The top of the adsorbent is layered with *ca* 1 cm length of fine washed sand. The mixture in the smallest volume of solvent is applied at the top of the column and allowed to flow into the adsorbent under gravity by opening the lower tap momentarily. The top of the column is filled with eluent, the upper tap is connected by a tube to a nitrogen supply from a cylinder, or to compressed air, and turned on to the desired pressure (monitor with a gauge). The lower tap is turned on and fractions are collected rapidly until the level of eluent has reached the top of the adsorbent (do not allow the column to run dry). If further elution is desired then both taps are turned off, the column is filled with more eluting solvent and the process repeated. The top of the column can be modified so that gradient elution can be performed. *Alternatively*, an apparatus for producing the gradient is connected to the upper tap by a long tube and placed high above the column in order to produce the required hydrostatic pressure. Much better resolution is obtained by dry loading

the sample for purification rather than loading the sample as a solution. Flash chromatography is more efficient and gives higher resolution than conventional chromatography at atmospheric pressure and is completed in a relatively shorter time. A successful separation of components of a mixture by TLC using the same adsorbent is a good indication that flash chromatography will give the desired separation on a larger scale.

Very elaborate equipment is now available for FC and HPFC (high-performance flash chromatography), which may include a pump, facility for gradient elution, UV detection and fraction collection of effluent. A large variety of columns (disposable cartridges) with packings such as silicate, carbon, reverse phases for a wide range of applications are commercially available. In addition a plethora of cartridges are available for preliminary purification, prior to FC or HPFC, packed with adsorbents which can remove specific impurities, e.g. unwanted reaction products such as aldehydes or ketone which may be suspected by-products and/or starting materials. [see Supelco online catalog http://sigma-aldrich.dirxion.com/WebProject.asp?BookCode=chr09flx#; Sigma Aldrich: http://www.sigmaaldrich.com/analytical-chromatography/analytical-chromatography-catalog.html; Biotage: *Synthesis and Purification* Catalogue and the *Analytical Sample Preparation* Catalogue contain details on available FC and HPFC equipment, accessories and consumables, as well as means of optimising purification, see <www.biotage.com>.]

Paired-ion Chromatography (PIC)

Mixtures containing ionic compounds (e.g. acids and/or bases), non-ionisable compounds, and zwitterions can be separated successfully by paired-ion chromatography (PIC). It utilises the 'reverse-phase' technique (Eksborg & Schill *Anal Chem* **45** 2092 *1973*, DOI: 10.1021/ac60334a019). The stationary phase is lipophilic, such as μ-BONDAPAK C_{18} or any other adsorbent that is compatible with water. The mobile phase is water or aqueous methanol containing the acidic or basic counter ion. Thus the mobile phase consists of dilute solutions of strong acids (e.g. 5mM 1-heptanesulfonic acid) or strong bases (e.g. 5 mM tetrabutylammonium phosphate) that are completely ionised at the operating pH values which are usually between 2 and 8. An equilibrium is set up between the neutral species of a mixture in the stationary phase and the respective ionised (anion or cation) species which dissolve in the mobile phase containing the counter ions. The extent of the equilibrium will depend on the ionisation constants of the respective components of the mixture, and the solubility of the unionised species in the stationary phase. Since the ionisation constants and the solubility in the stationary phase will vary with the water-methanol ratio of the mobile phase, the separation may be improved by altering this ratio gradually (gradient elution) or stepwise. If the compounds are eluted too rapidly, the water content of the mobile phase should be increased, e.g. by steps of 10%. Conversely, if components do not move, or move slowly, the methanol content of the mobile phase should be increased by steps of 10%.

The application of pressure to the liquid phase in liquid chromatography generally increases the separation (see HPLC). In PIC also, improved efficiency of the column is observed if pressure is applied to the mobile phase (Wittmer et al. *Anal Chem* **47** 1422 *1975*, DOI: 10.1021/ac60358a072). [See the Fluka (Riedel-deHaën) catalogue and Supelco catalogue, <http://sigma-aldrich.dirxion.com/WebProject.asp?BookCode=chr09flx#> for IPC reagents for the separation of cations and anions.]

Ion-exchange Chromatography

Ion-exchange chromatography involves an electrostatic process which depends on the relative affinities of various types of ions for an immobilised assembly of ions of opposite charge. The mobile phase is an aqueous buffer with a fixed pH or an aqueous mixture of buffers in which the pH is continuously increased or decreased as the separation may require. This form of liquid chromatography can also be performed at high inlet pressures of liquid with increased column performances.

Ion-exchange Resins. An ion-exchange resin is made up of particles of an insoluble elastic hydrocarbon network to which is attached a large number of ionisable groups. Materials commonly used comprise synthetic ion-exchange resins made, for example, by crosslinking polystyrene to which has been attached non-diffusible ionised or ionisable groups. Resins with relatively high crosslinkage (8-12%) are suitable for the chromatography of small ions, whereas those with low cross linkage (2-4%) are suitable for larger molecules. Applications to hydrophobic systems are possible using aqueous gels with phenyl groups bound to the rigid matrix (Phenyl-Superose/Sepharose, Pharmacia-Amersham or merged companies) or neopentyl chains (Alkyl-Superose, Biosciences merged companies suppliers). (Superose is a cross-linked agarose-based medium with an almost uniform bead size.) These groups are further distinguishable as strong [$-SO_2OH$, $-NR_3^+$] or weak [-OH, $-CO_2H$, $-PO(OH)_2$, $-NH_2$]. Their charges are counterbalanced by diffusible ions, and the operation of a column depends on its ability and selectivity to replace these ions. The exchange that takes place is primarily an electrostatic process

but adsorptive forces and hydrogen bonding can also be important. A typical sequence for the relative affinities of some common anions (and hence the inverse order in which they pass through such a column) is the following, obtained using a quaternary ammonium (strong base) anion-exchange column:

Fluoride < acetate < bicarbonate < hydroxide < formate < chloride < bromate < nitrite < cyanide < bromide < chromate < nitrate < iodide < thiocyanate < oxalate < sulfate < citrate.

For an amine (weak base) anion-exchange column in its chloride form, the following order has been observed:

Fluoride < chloride < bromide = iodide = acetate < molybdate < phosphate < arsenate < nitrate < tartrate < citrate < chromate < sulfate < hydroxide.

With strong cation-exchangers (e.g. with SO_3H groups), the usual sequence is that polyvalent ions bind more firmly than mono- or di- valent ones, a typical series being as follows:

$Th^{4+} > Fe^{3+} > Al^{3+} > Ba^{2+} > Pb^{2+} > Sr^{2+} > Ca^{2+} > Co^{2+} > Ni^{2+} = Cu^{2+} > Zn^{2+} = Mg^{2+} > UO_2^{+} = Mn^{2+} > Ag^{+} > Tl^{+} > Cs^{+} > Rb^{+} > NH_4^{+} = K^{+} > Na^{+} > H^{+} > Li^{+}$.

Thus, if an aqueous solution of a sodium salt contaminated with heavy metals is passed through the sodium form of such a column, the heavy metal ions will be removed from the solution and will be replaced by sodium ions from the column. This effect is greatest in dilute solution. Passage of sufficiently strong solutions of alkali metal salts or mineral acids readily displaces all other cations from ion-exchange columns. (The regeneration of columns depends on this property.) However, when the cations lie well to the left in the above series it is often advantageous to use a complex-forming species to facilitate removal. For example, iron can be displaced from ion-exchange columns by passage of sodium citrate or sodium ethylenediaminetetraacetate. Some of the more common commercially available resins are listed in Table 12.

Ion-exchange resins swell in water to an extent which depends on the amount of crosslinking in the polymer, so that columns should be prepared from the wet material by adding it as a suspension in water to a tube already partially filled with water. (This also avoids trapping air bubbles.) The exchange capacity of a resin is commonly expressed as mg equiv/ml of wet resin. This quantity is pH-dependent for weak-acid or weak-base resins but is constant at about 0.6-2.0 for most strong-acid or strong-base types.

Apart from their obvious applications to inorganic species, sulfonic acid resins have been used in purifying amino acids, aminosugars, organic acids, peptides, purines, pyrimidines, nucleosides, nucleotides and polynucleotides. Thus, organic bases can be applied to the H^+ form of such resins by adsorbing them from neutral solution and, after washing with water, they are eluted sequentially with suitable buffer solutions or dilute acids. *Alternatively*, by passing alkali solution through the column, the bases will be displaced in an order that is governed by their pK values. Similarly, strong-base anion exchangers have been used for aldehydes and ketones (as bisulfite addition compounds), carbohydrates (as their borate complexes), nucleosides, nucleotides, organic acids, phosphate esters and uronic acids. Weakly acidic and weakly basic exchange resins have also found extensive applications, mainly in resolving weakly basic and acidic species. For demineralisation of solutions without large changes in pH, mixed-bed resins can be prepared by mixing a cation-exchange resin in its H^+ form with an anion-exchange resin in its OH^- form. Commercial examples include Amberlite MB-1 (IR-120 + IRA-400) and Bio-Deminrolit (Zeo-Karb 225 and Zerolit FF). The latter is also available in a self-indicating form.

Ion-exchange Celluloses and Sephadex. A different type of ion-exchange column that finds extensive application in biochemistry for the purification of proteins, nucleic acids and acidic polysaccharides derives from cellulose by incorporating acidic and basic groups to give ion-exchangers of controlled acid and basic strengths. Commercially available cellulose-type resins are listed in Tables 13 and 14. AG 501 x 8 (Bio-Rad) is a mixed-bed resin containing equivalents of AG 50W-x8 H^+ form and AG 1-x8 HO^- form, and Bio-Rex MSZ 501 resin. A dye marker indicates when the resin is exhausted. Removal of unwanted cations, particularly of the transition metals, from amino acids and buffer can be achieved by passage of the solution through a column of Chelex 20 or Chelex 100. The metal-chelating abilities of the resin reside in the bonded iminodiacetate groups. Chelex can be regenerated by washing in two bed volumes of 1M HCl, two bed volumes of 1M NaOH and five bed volumes of water.

Ion-exchange celluloses are available in different particle sizes. It is important that the amounts of ‘fines’ are kept to a minimum otherwise the flow of liquid through the column can be extremely slow to the point of no liquid flow. Celluloses with a large range of particle sizes should be freed from 'fines' before use. This is done by suspending the powder in the required buffer and allowing it to settle for one hour and then decanting the ‘fines’. This separation appears to be wasteful, but it is necessary for reasonable flow rates without applying high pressure

at the top of the column. Good flow rates can be obtained if the cellulose column is packed dry whereby the 'fines' are evenly distributed throughout the column. Wet packing causes the 'fines' to rise to the top of the column, which thus becomes clogged.

Several ion-exchange celluloses require recycling before use, a process that must be applied for recovered celluloses. Recycling is done by stirring the cellulose with 0.1M aqueous sodium hydroxide, washing with water until neutral, then suspending in 0.1M hydrochloric acid and finally washing with water until neutral. When regenerating a column it is advisable to wash with a salt solution (containing the required counter ions) of increasing ionic strength up to 2M. The cellulose is then washed with water and recycled if necessary. Recycling can be carried out more than once if there are doubts about the purity of the cellulose and when the cellulose had been used previously for a different purification procedure than the one to be used. The basic matrix of these ion-exchangers is cellulose and it is important not to subject them to strong acid (> 1M) and strongly basic (> 1M) solutions.

When storing ion-exchange celluloses, or during prolonged usage, it is important to avoid growth of microorganisms or moulds which slowly destroy the cellulose. Good inhibitors of microorganisms are phenyl mercuric salts (0.001%, effective in weakly alkaline solutions), chlorohexidine (Hibitane at 0.002% for anion exchangers), 0.02% aqueous sodium azide or 0.005% of ethyl mercuric thiosalicylate (Merthiolate); these are most effective in weakly acidic solutions for cation exchangers. Trichlorobutanol (Chloretone, at 0.05% is only effective in weakly acidic solutions) can be used for both anion and cation exchangers. Most organic solvents (e.g. methanol) are effective antimicrobial agents but only at high concentrations. These inhibitors must be removed by washing the columns thoroughly before use because they may have adverse effects on the material to be purified (e.g. inactivation of enzymes or other active preparations).

Sephadex. Other carbohydrate matrices such as *Sephadex* are a bead form of cross-linked gels (based on dextran) which have more uniform particle sizes. Their advantages over the celluloses include faster and more reproducible flow rates and they can be used directly without removal of 'fines'. *Sephadex*, which can also be obtained in a variety of ion-exchange forms (see Table 14) consists of beads of a cross-linked dextran gel which swells in water and aqueous salt solutions. The smaller the bead size, the higher the resolution that is possible but the slower the flow rate. Typical applications of Sephadex gels are the fractionation of mixtures of polypeptides, proteins, nucleic acids, polysaccharides and for desalting solutions.

Sephadex ion-exchangers, unlike celluloses, are available in narrow ranges of particle sizes. These are of two medium types**,** the G-25 and G-50, and their dry bead diameter sizes are *ca* 50 to 150 microns. They are available as cation and anion exchange Sephadex. One of the disadvantages of using Sephadex ion-exchangers is that the bed volume can change considerably with alteration of pH. *Ultragels* also suffer from this disadvantage to a varying extent, but ion-exchangers of the bead type have been developed e.g. *Fractogels, Toyopearl*, which do not suffer from this disadvantage.

Sepharose (e.g. *Sepharose CL and Bio-Gel A*) is a bead form of agarose gel which is useful for the fractionation of high molecular weight substances, for molecular weight determinations of large molecules (molecular weight > 5000), and for the immobilisation of enzymes, antibodies, hormones and receptors usually for affinity chromatography applications. In preparing any of the above for use in columns, the dry powder is evacuated, then mixed under reduced pressure with water or the appropriate buffer solution. *Alternatively*, it is stirred gently with the solution until all air bubbles are removed. Because some of the wet powders change volumes reversibly with alteration of pH or ionic strength (see above), it is imperative to make allowances when packing columns (see above) in order to avoid overflowing of packing when the pH or salt concentrations are altered.

Cellex CM ion-exchange cellulose can be purified by treatment of 30-40g (dry weight) with 500ml of 1mM cysteine hydrochloride. It is then filtered through a Büchner funnel and the filter cake is suspended in 500ml of 0.05M NaCl/0.5M NaOH. This is filtered and the filter cake is resuspended in 500ml of distilled water and filtered again. The process is repeated until the washings are free from chloride ions. The filter cake is again suspended in 500ml of 0.01M buffer at the desired pH for chromatography, filtered, and the last step repeated several times.

Cellex D and other anionic celluloses are washed with 0.25M NaCl/0.25M NaOH solution, then twice with deionised water. This is followed with 0.25M NaCl and then washed with water until chloride-free. The *Cellex* is then equilibrated with the desired buffer as above.

Crystalline Hydroxylapatite is a structurally organised, highly polar material which, in aqueous solution (in buffers) strongly adsorbs macromolecules such as proteins and nucleic acids, permitting their separation by virtue of the interaction with charged phosphate groups and calcium ions, as well by physical adsor-

ption. The procedure therefore is not entirely ion-exchange in nature. Chromatographic separations of singly and doubly stranded DNA are readily achievable, whereas there is negligible adsorption of low-molecular-weight species.

Gel Filtration

The gel-like, bead nature of wet Sephadex enables small molecules such as inorganic salts to diffuse freely into it while, at the same time, protein molecules are unable to do so. Hence, passage through a Sephadex column can be used for complete removal of salts from protein solutions. Polysaccharides can be freed from monosaccharides and other small molecules because of their differential retardation. Similarly, amino acids can be separated from proteins and large peptides.

Gel filtration using Sephadex G-types (50 to 200) is essentially useful for fractionation of large molecules with molecular weights above 1000. For Superose, the range is given as 5000 to 5 x 10^6. Fractionation of lower molecular weight solutes (e,g, ethylene glycols, benzyl alcohols) can now be achieved with Sephadex G-10 (up to Mol.Wt 700) and G-25 (up to Mol.Wt 1500). These dextrans are used only in aqueous solutions. In contrast, Sephadex LH-20 and LH-60 (prepared by hydroxypropylation of Sephadex) are used for the separation of small molecules (Mol.Wt less than 500) using most of the common organic solvents as well as water.

Sephasorb HP (ultrafine, prepared by hydroxypropylation of crossed-linked dextran) can also be used for the separation of small molecules in organic solvents and water, and in addition it can withstand pressures up to 1400 psi making it useful in HPLC. These gels are best operated at pH values between 2 and 12, because solutions with high and low pH values slowly decompose them (see further in Chapter 6).

Supelco (see catalogue) supply a variety of SUPELCOGEL columns (for small molecule separations), TSK-GEL columns (for large molecules separation) and guard columns for gel permeation chromatography. They have columns of the latter type (e.g. TSL-GEL column G4000SW) which can separate globular proteins of 20—10,000 x 10^3 Daltons in molecular weight. They also supply 'Ascentis HPLC Applications CDs' containing a comprehensive library of their columns and possible applications.

High Performance Liquid Chromatography (HPLC)

When pressure is applied at the inlet of a liquid chromatographic column the performance of the column can be increased by several orders of magnitude. This is partly because of the increased speed at which the liquid flows through the column and partly because fine column packings which have larger surface areas can be used. Because of the improved efficiency of the columns, this technique has been referred to as high performance, high pressure, or high speed liquid chromatography and has found great importance in chemistry and biochemistry.

The equipment consists of a hydraulic system to provide the pressure at the inlet of the column, a column, a detector, data storage and output, usually in the form of a computer. The pressures used in HPLC vary from a few psi to 4000-5000 psi. The most convenient pressures are, however, between 500 and 1800psi. The plumbing is made of stainless steel or non-corrosive metal tubing to withstand high pressures. Plastic tubing and connectors are used for low pressures, e.g. up to ~500psi. Increase of temperature has a very small effect on the performance of a column in liquid chromatography. Small variations in temperatures, however, do upset the equilibrium of the column, hence it is advisable to place the column in an oven at ambient temperature in order to achieve reproducibility. The packing (stationary phase) is specially prepared for withstanding high pressures. It may be an adsorbent (for adsorption or solid-liquid HPLC), a material impregnated with a high boiling liquid (e.g. octadecyl sulfate, in *reverse-phase* or *liquid-liquid or paired-ion* HPLC), an ion-exchange material (in *ion-exchange* HPLC), or a highly porous non-ionic gel (for high performance *gel filtration* or *permeation*). The mobile phase is water, aqueous buffers, salt solutions, organic solvents or mixtures of these.

Detectors. The more commonly used detectors for column chromatography in general have UV, visible, diode array or fluorescence monitoring for light absorbing substances in the effluent, and refractive index monitoring and evaporative light scattering for transparent compounds in the effluent. UV detection is not useful when molecules do not have UV absorbing chromophores, and solvents for elution should be carefully selected when UV monitoring is used so as to ensure the lack of background interference in detection. The sensitivity of the refractive index monitoring is usually lower than the light absorbing monitoring by a factor of ten or more. It is also difficult to use a refractive index monitoring system with gradient elution of solvents. When substances have readily oxidised and reduced forms, e.g. phenols, nitro compounds, heterocyclic compounds etc. then electrochemical detectors are useful. These detectors oxidise and/or reduce these substances and make use of this process to provide a peak on the recorder. The cells of the monitoring devices are very small (*ca* 5 μl) and the detection is very good. The volumes of the analytical columns are quite small (*ca* 2ml for a 1 metre column)

hence the result of an analysis is achieved very quickly. Larger columns have been used for preparative work and can be used with the same equipment. Most machines have solvent mixing chambers for solvent gradient or ion gradient elution. The solvent gradient (for two solvents) or pH or ion gradient can be adjusted in a linear, increasing or decreasing exponential manner. Splitters can be used, whereby very small volumes of the effluent are directed through the detectors so that the whole effluent does not pass through the detector.

Columns for HPLC. In general two different types of HPLC columns are available. Prepacked columns are those with metal casings with threads at both ends onto which capillary connections are attached. The cartridge HPLC columns are cheaper and are used with cartridge holders. As the cartridge is fitted with a groove for the holding device, no threads are necessary and the connection pieces can be reused.

A large range of HPLC columns (including guard columns, i.e. small pre-columns) are available from Supelco < http://sigma-aldrich.dirxion.com/WebProject.asp?BookCode=chr09flx#>, Waters <www.waters.com>, Agilent Technologies <www.chem.agilent.com>, Phenomenex <www.phenomenex.com>, YMC <www.ymc.co.jp/en/>, Merck <www. merck.de>, SGE <www.sge.com>, GE Healthcare <www.gehealthcare.com>, and other leading companies. It is not possible to list the range of columns here that are commercially available because the numbers are too large and include prepared columns for the type of chromatography described below in the *Other Types of Liquid Chromatography* such as Monolithic Chromatography and UPLC (see below). Also, in this range of columns are columns with chiral bonded phases capable of separating enantiomeric mixtures. The number of these, on the other hand, is relatively smaller and some *chiral* columns are listed in Table 15.

Other Types of Liquid Chromatography

New stationary phases for specific purposes in chromatographic separation are being continually developed. *Charge transfer adsorption chromatography* makes use of a stationary phase which contains immobilised aromatic compounds and permits the separation of aromatic compounds by virtue of the ability to form charge transfer complexes (sometimes coloured) with the stationary phase. The separation is caused by the differences in stability of these complexes (Porath & Caldwell *J Chromatogr A* **133** 180 *1977*, DOI: 10.1016/S0021-9673(00)89219-5).

In *metal chelate adsorption chromatography* a metal is immobilised by partial chelation on a column which contains bi- or tri- dentate ligands. Its application is in the separation of substances which can complex with the bound metals and depends on the stability constants of the various ligands (Porath et al. *Nature* **258** 598 *1975*, DOI: 10.1038/258598a0; Lönnerdal et al. *FEBS Lett* **75** 89 *1977*, DOI: 10.1016/0014-5793(77)80059-8).

An application of chromatography which has found extensive use in biochemistry and has brought a new dimension in the purification of enzymes is *affinity chromatography*. A specific enzyme inhibitor is attached by covalent bonding to a stationary phase (e.g. AH-Sepharose 4B for acidic inhibitors and CH-Sepharose 4B for basic inhibitors, Phenyl-Sepharose for hydrophobic proteins), and will strongly bind only the specific enzyme which is inhibited or preferentially bound, allowing all other proteins to flow through the column. The enzyme is then eluted with a solution of high ionic strength (e.g. 1M sodium chloride) or a solution containing a substrate or reversible inhibitor of the specific enzyme. (The ionic medium can be removed by gel filtration using a mixed-bed gel.) Similarly, an immobilised lectin may interact with the carbohydrate moiety of a glycoprotein. The most frequently used matrixes are cross-linked (4-6%) agarose and polyacrylamide gel. Many adsorbents are commercially available for nucleotides, coenzymes and vitamins, amino acids, peptides, lectins and related macromolecules and immunoglobulins. Considerable purification can be achieved by one passage through the column and the column can be reused several times.

The affinity method may be *biospecific*, for example as an antibody-antigen interaction, or chemical as in the chelation of boronate by *cis*-diols, or of unknown origin as in the binding of certain dyes to albumin and other proteins.

Hydrophobic adsorption chromatography takes advantage of the hydrophobic properties of substances to be separated and has also found use in biochemistry (Hoftsee *Biochem Biophys Res Commun* **50** 751 *1973*, DOI: 10.1016/0006-291X(73)91308-9; Jennissen & Heilmayer Jr *Biochemistry* **14** 754 *1975*, DOI: 10.1021/bi00675a017). Specific covalent binding with the stationary phase, a procedure that was called *covalent chromatography*, has been used for the separation of compounds and for immobilising enzymes on a support: the column was then used to carry out specific bioorganic reactions (Mosbach *Method Enzymol* **44** 1976; A.Rosevear et al. *Immobilised Enzymes and Cells: A Laboratory Manual*, Adam Hilger, Bristol, 1987, ISBN 085274515X). See Bibliography for further literature.

More recently ***Monolithic Chromatography*** has been introduced which is a new type of high-performance liquid chromatography in which the columns are a 'one-piece porous solid', or *monolith*, instead of particles. These columns take a variety of forms for use in adsorption, ion exchange (weak and strong, cation and anion), reverse phase, and are for use in the separation of small and large molecules. The mobile phase in these columns flows

through the whole of the stationary phase. [P. Wang ed., *Monolithic Chromatography and its Modern Applications* ILM Publications, pp 648 *2010*, ISBN 9781906799038, 1906799032; and for columns see BIA Separations <www.biaseparations.com>.

Ultra performance Liquid chromatography **(UPLC)** affords a considerable improvement by bringing high performance liquid chromatography to a new level. Great improvements in analysis and purification of amino acids, peptides, proteins, oligonucleotides and glycans can be accomplished. This has been achieved by packing columns with smaller sized particles (1.7-1.8μm) and applying pressures of ~15,000psi (~1030 bar) to the mobile phase. NanoACQUITY UPLC trapping and nanoflow columns have been specifically designed for use on Waters nanoACQUITY systems that can be integrated with MS components [see www.waters.com].

Automated column chromatography

Most of the above methods of column chromatography have been, or can be, automated. Devices are available for the automated injection of samples to columns which are useful for analytical evaluation of samples, for repeated analyses, or for repeated separations to obtain larger amounts of material. The specific fractions of the effluent can be collected. Equipment for these purposes can be obtained from several of the supplier listed at the end of the HPLC section above with the corresponding websites. GC systems coupled with mass spectrometers (GC-MS) and HPLC systems coupled to mass spectrometers (LC-MS) are extremely important methods for the separation and identification of substances. These are invariably linked to a computer with internal libraries of mass spectral data which are useful for identifying peaks; and the libraries can be continually updated (see above). With more elaborate equipment LC-MS-MS, where the peaks from the first spectrometer are further analysed by a second mass spectrometer, provide a wealth of information. If not for the costs involved in GC-MS, GC-MS-MS, LC-MS and LC-MS-MS equipment, these systems would be more commonly found in analytical and research laboratories. [For further reading see Bibliography.]

ELECTROPHORESIS

Ionisable substances such as organic and inorganic acids, bases and salts migrate to their respective electrodes (anode or cathode) if a voltage is applied. When they are placed onto a matrix, e.g. paper or gel, then their rate of migration to the electrodes will vary with the charge, nature and structure of the substance. This phenomenon is known as electrophoresis and is very useful for separating and purifying substances. Capillary techniques have been adapted to electrophoresis and 'capillary electrophoresis', and 'capillary zone electrophoresis' are finding wide use for identification, separation and isolation of ionisable substances (see text in the Bibliography under 'electrophoresis' and the 'Introduction' in Chapter 6). The method is used extensively for biological substances, e.g. proteins, polypeptides, DNA, RNA, (see Introduction in Chapter 6) but has been used to a limited extent for identifying and purifying small molecules. Elaborate equipment is available commercially which contains essentially an electrolytic cell and a power supply which provides variable voltage for the process. The use of paper (Whatman of various thicknesses) as the matrix on a flat bed or in a vertical descending mode has been completely superseded with polyacrylamide or agarose flat bed gels. These are routinely used mainly for the separation of proteins and nucleic acids. Also capillary electrophoresis (CE) is now widely used for the analysis and detection of biological substances and drugs. It is used for the separation and purification of carbohydrates, nucleic acids, proteins, peptides and for chiral analysis and separation and detection of drugs [see Bibliography].

DRYING

Removal of Solvents

Where substances are sufficiently stable, removal of solvent from recrystallised materials presents no problems. The crystals, after filtering at the pump (and perhaps air-drying by suction), are heated in an oven above the boiling point of the solvent (but below the melting point of the crystals), followed by cooling in a desiccator. Where this treatment is inadvisable, it is still often possible to heat to a lower temperature under reduced pressure, for example in an Abderhalden pistol. This device consists of a small chamber which is heated externally by the vapour of a boiling solvent. Inside this chamber, which can be evacuated (pump) is placed a small boat containing the sample to be dried and also a receptacle with a suitable drying agent. Convenient liquids for use as boiling liquids in an Abderhalden pistol, and their boiling temperatures, are given in Table 16. *Alternatively* an electrically heated drying pistol can also be used. In cases where heating above room temperature cannot be used, drying must be carried out in a vacuum desiccator containing suitable absorbents. For example, hydrocarbons, such as cyclohexane and petroleum ether, can be removed by using shredded paraffin wax, and acetic acid and other acids can be absorbed by pellets of sodium or potassium hydroxide. However, in general, solvent removal is less of a problem than ensuring that the water content of solids and liquids is reduced below an acceptable level.

Removal of Water

Methods for removing water from solids depend on the thermal stability of the solids or the time available. The safest way is to dry in a vacuum desiccator over concentrated sulfuric acid, phosphorus pentoxide, silica gel, calcium chloride, or some other desiccant. Where substances are stable in air and melt above 100°, drying in an air oven may be adequate. In other cases, use of an Abderhalden pistol may be satisfactory.

Often, in drying inorganic salts, the final material that is required is a hydrate. In such cases, the purified substance is left in a desiccator to equilibrate above an aqueous solution having a suitable water-vapour pressure. A convenient range of solutions used in this way is given in Table 17.

Removal of water from gases may be by physical or chemical means, and is commonly by adsorption on to a drying agent in a low-temperature trap. The effectiveness of drying agents depends on the vapour pressure of the hydrated compound - the lower the vapour pressure the less the remaining moisture in the gas.

The most usually applicable of the specific methods for detecting and determining water in organic liquids is due to Karl Fischer. (See J.Mitchell & D.M.Smith, *Aquametry*, 2nd Ed, J Wiley & Sons, New York, *1977-1984*, ISBN 0471022640; Fieser & Fieser, *Reagents for Organic Synthesis*, J.Wiley & Sons, NY, Vol 1, 528 *1967*, ISBN 0271616X), also see Karl Fischer titrant or Hydranal –Titrant Type 5E [64-17-5] and other types in the Aldrich catalogue <http://www.sigmaaldrich.com/analytical-chromatography/titration/hydranal.html>. Other techniques include electrical conductivity measurements and observation of the temperature at which the first cloudiness appears as the liquid is cooled (applicable to liquids in which water is only slightly soluble). Addition of anhydrous cobalt (II) iodide (blue) provides a convenient method (colour changing to pink on hydration) for detecting water in alcohols, ketones, nitriles and some esters. Infrared absorption measurements of the broad band for water near 3500 cm^{-1} can also sometimes be used for detecting water in non-hydroxylic substances.

Cartridges for the removal not only water from solvents or solutions but other specific impurities, e.g. acids, amines, aldehydes, are now commercially available [see supplies listed at the end of the HPLC section together with their respective websites]. For further useful information on mineral and drying agents, go to the SigmaAldrich website <sigmaaldrich.com>, under technical library (Aldrich) for technical bulletin AL-143.

Intensity and Capacity of Common Desiccants

Drying agents are conveniently grouped into three classes, depending on whether they combine with water reversibly, they react chemically (irreversibly) with water, or they are molecular sieves. The first group varies in their drying intensity with the temperature at which they are used, depending on the vapour pressure of the hydrate that is formed. This is why, for example, drying agents such as anhydrous sodium sulfate, magnesium sulfate or calcium chloride should be filtered off from the liquids before the latter are heated. The intensities of drying agents belonging to this group fall in the sequence:

P_2O_5 >> BaO > $Mg(ClO_4)_2$, CaO, MgO, KOH (fused), conc H_2SO_4, $CaSO_4$, Al_2O_3 > KOH (pellets), silica gel, $Mg(ClO_4)_2.3H_2O$ > NaOH (fused), 95% H_2SO_4, $CaBr_2$, $CaCl_2$ (fused) > NaOH (pellets), $Ba(ClO_4)_2$, $ZnCl_2$, $ZnBr_2$ > $CaCl_2$ (technical) > $CuSO_4$ > Na_2SO_4, K_2CO_3.

Where large amounts of water are to be removed, a preliminary drying of liquids is often possible by shaking with concentrated solutions of sodium sulfate or potassium carbonate, or by adding sodium chloride to salt out the organic phase (for example, in the drying of lower alcohols), as long as the drying agent does not react (e.g. $CaCl_2$ with alcohols and amines, see below).

Drying agents that combine irreversibly with water include the alkali metals, the metal hydrides (discussed in Chapter 2), and calcium carbide.

Suitability of Individual Desiccants

Alumina. (Preheated to 175° for about 7 hours). Mainly as a drying agent in a desiccator or as a column through which liquid is percolated.

Aluminium amalgam. Mainly used for removing traces of water from alcohols *via* refluxing followed by distillation.

Barium oxide. Suitable for drying organic bases.

Barium perchlorate. Expensive. Used in desiccators (*covered with a metal guard*). Unsuitable for drying solvents or organic material where contact is necessary, because of the danger of **EXPLOSION**

Boric anhydride. (Prepared by melting boric acid in an air oven at a high temperature, cooling in a desiccator, and powdering.) Mainly used for drying formic acid.

Calcium chloride (anhydrous). Cheap. Large capacity for absorption of water, giving the hexahydrate below 30°, but is fairly slow in action and not very efficient. Its main use is for preliminary

drying of alkyl and aryl halides, most esters, saturated and aromatic hydrocarbons and ethers. Unsuitable for drying alcohols and amines (which form addition compounds), fatty acids, amides, amino acids, ketones, phenols, or some aldehydes and esters. Calcium chloride is suitable for drying the following gases: hydrogen, hydrogen chloride, carbon monoxide, carbon dioxide, sulfur dioxide, nitrogen, methane, oxygen, also paraffins, ethers, olefins and alkyl chlorides.

Calcium hydride. See Chapter 2.

Calcium oxide. (Preheated to 700-900º before use.) Suitable for alcohols and amines (but does not dry them completely). Need not be removed before distillation, but in that case the head of the distillation column should be packed with glass wool to trap any calcium oxide powder that might be carried over. Unsuitable for acidic compounds and esters. Suitable for drying gaseous amines and ammonia.

Calcium sulfate (anhydrous). (Prepared by heating the dihydrate or the hemihydrate in an oven at 235º for 2-3 hours; it can be regenerated.) Available commercially as *Drierite*. It forms the hemihydrate, $2CaSO_4.H_2O$, so that its capacity is fairly low (6.6% of its weight of water), and hence is best used on partially dried substances. It is very efficient (being comparable with phosphorus pentoxide and concentrated sulfuric acid). Suitable for most organic compounds. Solvents boiling below 100º can be dried by direct distillation from calcium sulfate.

Copper (II) sulfate (anhydrous). Suitable for esters and alcohols. Preferable to sodium sulfate in cases where solvents are sparingly soluble in water (for example, benzene or toluene). The colourless to fawn coloured powder turns blue as it absorbs water

Lithium aluminium hydride. See Chapter 2.

Magnesium amalgam. Mainly used for removing traces of water from alcohols by refluxing the alcohol in the presence of the Mg amalgam followed by distillation.

Magnesium perchlorate (anhydrous). (Available commercially as *Dehydrite*. Expensive.) Used in desiccators. Unsuitable for drying solvents or any organic material where contact is necessary, because of the danger of **EXPLOSION**.

Magnesium sulfate (anhydrous). (Prepared from the heptahydrate by drying at 300º under reduced pressure.) More rapid and effective than sodium sulfate but is slightly acidic. It has a large capacity, forming $MgSO_4.7H_2O$ below 48º. Suitable for the preliminary drying of most organic compounds.

Molecular sieves. See below.

Phosphorus pentoxide. Very rapid and efficient, but difficult to handle and should only be used after the organic material has been partially dried, for example with magnesium sulfate. Suitable for anhydrides, alkyl and aryl halides, ethers, esters, hydrocarbons and nitriles, and for use in desiccators. Not suitable with acids, alcohols, amines or ketones, or with organic molecules from which a molecule of water can be eliminated. Suitable for drying the following gases: hydrogen, oxygen, carbon dioxide, carbon monoxide, sulfur dioxide, nitrogen, methane, ethane and paraffins. It is available on a solid support with an indicator under the name *Sicapent* (from Merck). The colour changes in Sicapent depend on the percentage of water present (e.g. in the absence of water, Sicapent is colourless but becomes green with 20% water and blue with 33% w/w water). When the quantity of water in the desiccator is high, a crust of phosphoric acid forms a layer over the phosphorus pentoxide powder and decreases its efficiency. The crust can be removed with a spatula to expose the dry powder and restore the desiccant property.

Potassium (metal). Properties and applications are similar to those for sodium but as the reactivity is greater than that of sodium, the hazards are greater than those of sodium. **Handle with extreme care**.

Potassium carbonate (anhydrous). Has a moderate efficiency and capacity, forming the dihydrate. Suitable for an initial drying of alcohols, bases, esters, ketones and nitriles by shaking with them, then filtering off. Also suitable for salting out water-soluble alcohols, amines and ketones. Unsuitable for acids, phenols, thiols and other acidic substances.

Potassium hydroxide. Solid potassium hydroxide is very rapid and efficient. Its use is limited almost entirely to the initial drying of organic bases. *Alternatively*, sometimes the base is shaken first with a concentrated solution of potassium hydroxide to remove most of the water present. Unsuitable for acids, aldehydes, ketones, phenols, thiols, amides and esters. Also used for drying gaseous amines and ammonia.

Silica gel. Granulated silica gel is a commercially available drying agent for use with gases, in desiccators, and (because of its chemical inertness) in physical instruments (pH meters, spectrometers, balances). Its drying action depends on physical adsorption, so that silica gel must be used at room temperature or below. By incorporating cobalt chloride into the material it can be made self indicating (blue when dry, pink when wet), re-drying in an oven at 110º being necessary when the colour changes from blue to pink.

Sodium (metal). Used as a fine wire or as chips, for more completely drying ethers, saturated hydrocarbons and aromatic hydrocarbons which have been partially dried (for example with calcium chloride or magnesium sulfate). Unsuitable for acids, alcohols, alkyl halides, aldehydes, ketones, amines and esters. Reacts violently if water is present and can cause a fire with highly flammable liquids.

Sodium hydroxide. Properties and applications are similar to those for potassium hydroxide.

Sodium-potassium alloy. Used as lumps. Lower melting than sodium, so that its surface is readily renewed by shaking. Properties and applications are similar to those for sodium.

Sodium sulfate (anhydrous). Has a large capacity for absorption of water, forming the decahydrate below 33º, but drying is slow and inefficient, especially for solvents that are sparingly soluble in water. It is suitable for the preliminary drying of most types of organic compounds.

Sulfuric acid (concentrated). Widely used in desiccators. Suitable for drying bromine, saturated hydrocarbons, alkyl and aryl halides. Also suitable for drying the following gases: hydrogen, nitrogen, carbon dioxide, carbon monoxide, chlorine, methane and paraffins. Unsuitable for alcohols, bases, ketones or phenols. Also available on a solid support with an indicator under the name *Sicacide* (from Merck) for desiccators. The colour changes in Sicacide depends on the percentage of water present (e.g. when dry Sicacide is red-violet but becomes pale violet with 27% water and pale yellow to colourless with 33% w/w water).

For convenience, many of the above drying agents are listed in Table 18 under the classes of organic compounds for which they are commonly used.

Molecular sieves

Molecular sieves are types of adsorbents composed of crystalline zeolites (sodium and calcium aluminosilicates). By heating them, water of hydration is removed, leaving holes of molecular dimensions in the crystal lattices. These holes are of uniform size and allow the passage into the crystals of small molecules, but not of large ones. This *sieving* action explains their use as very efficient drying agents for gases and liquids. The pore size of these sieves can be modified (within limits) by varying the cations built into the lattices. The four types of molecular sieves currently available are:

Type 3A sieves. A crystalline potassium aluminosilicate with a pore size of about 3 Angstroms. This type of molecular sieves is suitable for drying liquids such as acetone, acetonitrile, methanol, ethanol and 2-propanol, and drying gases such as acetylene, carbon dioxide, ammonia, propylene and butadiene. The material is supplied as beads or pellets.

Type 4A sieves. A crystalline sodium aluminosilicate with a pore size of about 4 Angstroms, so that, besides water, ethane molecules (but not butane) can be adsorbed. This type of molecular sieves is suitable for drying chloroform, dichloromethane, diethyl ether, dimethylformamide, ethyl acetate, cyclohexane, benzene, toluene, xylene, pyridine and diisopropyl ether. It is also useful for low pressure air drying. The material is supplied as beads, pellets or powder.

Type 5A sieves. A crystalline calcium aluminosilicate with a pore size of about 5 Angstroms, these sieves adsorb larger molecules than type 4A. For example, as well as the substances listed above, propane, butane, hexane, butene, higher *n*-olefins, *n*-butyl alcohol and higher *n*-alcohols, and cyclopropane can be adsorbed, but not branched-chain C_6 hydrocarbons, cyclic hydrocarbons such as benzene and cyclohexane, or secondary and tertiary alcohols, carbon tetrachloride or boron trifluoride. This is the type generally used for drying gases, though organic liquids such as THF and dioxane can be dried with this type of molecular sieves.

Type 13X sieves. A crystalline sodium aluminosilicate with a pore size of about 10 Angstroms which enables many branched-chain and cyclic compounds to be adsorbed, in addition to all the substances removed by type 5A sieves.

They are unsuitable for use with strong acids but are stable over the pH range 5-11.

Because of their selectivity, molecular sieves offer advantages over silica gel, alumina or activated charcoal, especially in their very high affinity for water, small polar molecules and unsaturated organic compounds. Their relative efficiency is greatest when the impurity to be removed is present at low concentrations. Thus, at 25º and a relative humidity of 2%, type 5A molecular sieves adsorb 18% by weight of water, whereas for silica gel and alumina the figures are 3.5 and 2.5% respectively. Even at 100º and a relative humidity of 1.3%, molecular sieves adsorb about 15% by weight of water.

The greater preference of molecular sieves for combining with water molecules explains why this material can be used for drying ethanol and why molecular sieves are probably the most universally useful and efficient drying agents. Percolation of ethanol with an initial water content of 0.5% through a 144 cm long column of type 4A molecular sieves reduced the water content to 10ppm. Similar results have been obtained with pyridine.

The main applications of molecular sieves to purification comprise:

1. Drying of gases and liquids containing traces of water.
2. Drying of gases at elevated temperatures.
3. Selective removal of impurities (including water) from gas streams.

(For example, carbon dioxide from air or ethene; nitrogen oxides from nitrogen; methanol from diethyl ether. In general, carbon dioxide, carbon monoxide, ammonia, hydrogen sulfide, mercaptans, ethane, ethene, acetylene (ethyne), propane and propylene are readily removed at 25°. In mixtures of gases, the more polar ones are preferentially adsorbed).

The following applications include the removal of straight-chain from branched-chain or cyclic molecules. For example, type 5A sieves will adsorb *n*-butyl alcohol but not its branched-chain isomers. Similarly, it separates *n*-tetradecane from benzene, or *n*-heptane from methylcyclohexane.

The following liquids have been dried with molecular sieves: acetone, acetonitrile, acrylonitrile, allyl chloride, amyl acetate, benzene, butadiene, *n*-butane, butene, butyl acetate, *n*-butylamine, *n*-butyl chloride, carbon tetrachloride, chloroethane, 1-chloro-2-ethylhexane, cyclohexane, dichloromethane, dichloroethane, 1,2-dichloropropane, 1,1-dimethoxyethane, dimethyl ether, 2-ethylhexanol, 2-ethylhexylamine, *n*-heptane, *n*-hexane, isoprene, isopropyl alcohol, diisopropyl ether, methanol, methyl ethyl ketone, oxygen, *n*-pentane, phenol, propane, *n*-propyl alcohol, propylene, pyridine, styrene, tetrachloroethylene, toluene, trichloroethylene and xylene. In addition, the following gases have been dried: acetylene, air, argon, carbon dioxide, chlorine, ethene, helium, hydrogen, hydrogen chloride, hydrogen sulfide, nitrogen, oxygen and sulfur hexafluoride.

After use, molecular sieves can be regenerated by heating at between 300°–350° for several hours, preferably in a stream of dry inert gas such as nitrogen or preferably under vacuum, then cooling in a desiccator. Special precautions must be taken before regeneration of molecular sieves used in the drying of flammable solvents.

However, care must be exercised in using molecular sieves for drying organic liquids. Appreciable amounts of impurities were *formed* when samples of acetone, 1,1,1-trichloroethane and methyl-*t*-butyl ether were dried in the liquid phase by contact with molecular sieves 4A [Connett *Lab Pract* **21** 545 *1972*, ISSN: 0023-6853 (Print) 0023-6853 (Linking)]. Other, less reactive types of sieves may be more suitable but, in general, it seems desirable to perform a preliminary test to establish that no unwanted reactions take place. Useful comparative data for Type 4A and 5A sieves are in Table 19. With the advent of nanotechnology, nanoparticles are finding use as porous materials for a variety of purposes [see J.A. Schwartz & C. Contescu (Eds), *Surfaces of Nanoparticles & Porous Materials*, Marcel Dekker Inc, *1999*. ISBN 9780824719333].

PROPERTIES USEFUL IN PURIFICATION

Spectroscopic

Spectroscopic instruments of one sort or another are generally available in laboratories and useful for providing some idea of the purity of the specimen in question. Among these are IR, UV-VIS, fluorescence, NMR and mass spectrometers.

Infrared spectra [IR or FT(Fourier Transformed)-IR with frequency range of ν from ~ 600 to 3400 cm^{-1}], generally of the solid ground in a large excess of KBr, or in a mull by grinding into an oil, e.g. Nujol, or in solution, e.g. $CHCl_3$, provide a 'fingerprint' of the substance. The KBr spectrum, or the spectrum of a film between NaCl plates if the substance is a liquid, are more useful as they give detailed information without interfering signals from Nujol or solvent which may mask important signals. Since the IR spectra consist of several signals many of which are sharp, impurities show up clearly. However, if the impurities are less than say 10% it may be difficult to say how impure the sample is, or what impurities are present in it. On the other hand, if the sample is very pure then its spectrum will be superimposable on that of the pure authentic sample.

Ultraviolet Spectra (with wavelength range of λ form ~ 200 to 400 mμ) are measured in dilute solution and are generally broad bands. Although the broadness of the bands make it difficult to identify impurities, the values of the molecular absorption extinction coefficients ε ($M^{-1}cm^{-1}$) at all wavelengths, but usually measured at the peaks

or troughs, are characteristics of the substance in the particular solvent used, and would be different if the sample was impure . Glass cuvettes cannot be used as they are not transparent to UV radiation, and quartz cells should be used. However, quartz cells need only have quartz on the two opposite faces of the four sided cuvette through which the light passes; the other two faces being made of glass. Similarly in the *visible* spectra (wavelength range of λ form ~ 400 to 800 mμ) the ε values are characteristic of the substance in the solvent used. In this case the cheaper glass cuvettes may be used as they are transparent to visible light.

Fluorescence Spectra are measured in the wavelength range similar to the *visible* range, but from light that is scattered at right angles to the incident excitation (UV) wavelength. Thus at a set excitation wavelength λ_{ex}, the fluorescence spectrum is scanned and the peak maximum λ_{em} and its ε_{em} are recorded. In this case the cuvettes must have quartz faces on all four sides, as the UV light has to go through adjacent sides of the cell. This spectroscopy is useful as sometimes impurities in a sample may fluoresce at a particular wavelength. Generally, dyes have fluorescent properties and are identified in this way. Substances with strongly fluorescing properties have found considerable use in biology. Here they have been tagged to biological molecules and their movement into particular tissues and cells has been traced through their fluorescence. Table 20 lists a number of *Fluorochromes* which have found many applications in analytical chemistry (by tagging to non-fluorescent compounds) and in biology. By selecting a mixture of two fluorochromes it is possible to obtain a desired emission wavelength. In this case the emitted fluorescence energy from the excitation of the first fluorochrome is transferred to the second fluorochrome to provide the desired fluorescence.

For other than macromolecules it is important that *at least* the ^{1}H NMR spectrum and/or the mass spectrum of the substance should be measured routinely. These measurements require no more than one to three milligrams of material and provide a considerable amount of information about the substance. The ^{1}H NMR and ^{13}C NMR spectra are measured to assess the purity of hydrogen and carbon containing samples. The use of very high magnetic field NMR spectrometers is especially useful for detecting impurities in such samples. The signals and their relative heights can provide valuable information not only about the extent of the impurities, but also some indications about the nature of the impurities. A variety of NMR solvents are available for dissolving the samples, and the hydrogen atoms of the solvents are replaced by deuterium which does not interfere with the ^{1}H or ^{13}C spectra. However, deuteration is generally just under 100% and signals from residual H in the solvent may appear in the spectrum and need to be identified. Similarly ^{13}C signals from solvents also should be identified. Common solvents and reagents that contain trace impurities will also show minor signals in the NMR spectra. The ^{1}H NMR signals of trace impurities in some common organic solvents (including water) and some reagents are presented in Tables 21 and 22. Similarly presented in Table 23 are the ^{13}C NMR signals of some common solvents and reagents. In some instances these minor signals have been very useful as internal standards for reporting the chemical shifts of substances, thus avoiding contamination from other added standards, particularly if the samples need to be used for further studies. The NMR spectra of other nuclei such as ^{11}B and ^{31}P are currently also measured routinely for boron and phosphorus containing compounds. Since the compounds invariably have only a small number of these atoms in their molecules, boron or phosphorus containing impurities are readily identified in the ^{11}B or ^{31}P NMR spectra.

References in the bibliography at the end of this chapter to the Aldrich-Sigma catalogues of NMR, IR and mass spectral data for a large number of the compounds are listed. These collections of spectra are extremely useful for identifying compounds and impurities. If the material appears to have several impurities, these spectra should be valuable for identifying the impurities as much as possible. Preliminary chromatographic (e.g. TLC) and spot tests could be devised to monitor the material and its impurities. Purification methods can then be devised to remove these impurities, and a monitoring method will have already been established.

Ionisation Constants — pK

When substances ionise, their neutral species produce positive and negative species. The ionisation constants are those constant values (equilibrium constants) for the equilibria between the charged species and the neutral species, or species with a larger number of charges (e.g. between mono and dications). These ionisation constants are given as **pK** values where **pK = -log K**, and **K** is the dissociation constant for the equilibrium between the species [Albert and Serjeant, *The Determination of Ionisation Constants*, A Laboratory Manual, 3rd Edition, Chapman & Hall, New York, London, 1984, ISBN 0412242907].

The advantage of using pK values (instead of K values) is that theory (and practice) states that the pK values of the ionisable substances are numerically equal to the pH of the solution at which the concentrations of the ionised and

the neutral species are equal. For example acetic acid has a pK^{25} value of 4.76 at 25º in H_2O; then at pH 4.76 the aqueous solution contains equal amounts of acetic acid [AcOH] and acetate anion [AcO^-], i.e. [AcOH]/[AcO^-] of 50/50. At pH 5.76 (pK + 1) the solution contains [AcOH]/[AcO^-] of 10/90, at pH 6.76 (pK + 2) the solution contains [AcOH]/[AcO^-] of 1/99 etc; conversely at pH 3.76 (pK - 1) the solution contains [AcOH]/[AcO^-] of 90/10, and at pH 2.76 (pK - 2) the solution contains [AcOH]/[AcO^-] of 99/1.

One can readily appreciate the usefulness of pK value in purification procedures, e.g. as when purifying acetic acid. If acetic acid is placed in aqueous solution and the pH adjusted to 7.76 {[AcOH]/[AcO^-] with a ratio of 0.1/99.9}, and extracted with say diethyl ether, neutral impurities will be extracted into diethyl ether leaving almost all the acetic acid in the form of AcO^- in the aqueous solution. If then the pH of the solution is adjusted to 1.67 where the acid is almost all in the form AcOH, almost all of it will be extracted into diethyl ether.
Aniline will be used as a second example. It has a pK^{25} of 4.60 at 25º in H_2O. If it is placed in aqueous solution at pH 1.60 it will exist almost completely (99.9%) as the anilinium cation. This solution can then be extracted with solvents e.g. diethyl ether to remove neutral impurities. The pH of the solution is then adjusted to 7.60 whereby aniline will exist as the free base (99.9%) and can be extracted into diethyl ether in order to give purer aniline.

See Table 24 for the pH values of selected buffers.

A knowledge of the pK allows the adjustment of the pH without the need of large excesses of acids or base. In the case of inorganic compounds, knowledge of the pK is useful for adjusting the ionic species for making metal complexes which could be masked or extracted into organic solvents [Perrin and Dempsey, *Buffers for pH and Metal ion Control*, Chapman & Hall, New York, London, 1974, ISBN 0412117002], or for obtaining specific anionic species in solution e.g. $H_2PO_4^-$, HPO_4^{2-} or PO_4^{3-}.

The **pK** values that have been entered in Chapters 3, 4 and 6 have been collected directly from the literature or from compilations of literature values for organic bases [Perrin, *Dissociation Constants of Organic Bases in Aqueous Solution*, Butterworths, London, 1965, Supplement 1972, ISBN 040870408X; Albert and Serjeant, *The Determination of Ionisation Constants*, A Laboratory Manual, 3rd Edition, Chapman & Hall, London, New York, 1984, ISBN 0412242907]; organic acids [Kortum, Vogel and Andrussow, *Dissociation Constants of Organic Acids in Aqueous Solution,* Butterworth, London, 1961; Serjeant and Dempsey, *Dissociation Constants of Organic Acids in Aqueous Solution,* Pergamon Press, Oxford, New York, 1979, ISBN 0080223397; and inorganic acids and bases [Perrin, *Ionisation Constants of Inorganic Acids and Bases in Aqueous Solution*, Second Edition, Pergamon Press, Oxford, New York, 1982, ISBN 0080292143; J Russel and R Cohen *Acid dissociation constant* Bookvika Publishing *2015*, ISBN 10: 5513329530, ISBN 13: 9785513329534]. Where literature values were not available, values have been predicted and assigned **pK_{Est} ~**. Most predictions should be so close to true values as to make very small difference for the purposes intended in this book. The success of the predictions, i.e. how close to the true value, depends on the availability of pK values for closely related compounds because the effect of substituents or changes in structures are generally additive [Perrin, Dempsey and Serjeant, *pKa Prediction for Organic Acids and Bases*, Chapman & Hall, London, New York, 1981, ISBN 041222190X].

All the pK values in this book are pKa values, the acidic pK, i.e. dissociation of H^+ from an acid (AH) or from a conjugate base (BH^+). Occasionally pKb values are reported in the literature but these can be converted using the equation **pKa + pKb = 14**. For strong acids e.g. sulfuric acid, and strong bases, e.g. sodium hydroxide, the pK values lie beyond the 1 to 11 pH scale and have to be measured in strong acidic and basic media. In these cases appropriate scales e.g. the H_o (for acids) and H_- (for bases) have been used [see Katritzky & Waring, *J Chem Soc* 1540 *1962*, DOI: 10.1039/JR9620001540]. These values will be less than 1 (and negative) for acids and >11 for bases. They are rough guides to the strengths of acids and bases. Errors in the stated pK and pK_{Est} ~ values can be judged from the numerical values given. Thus pK values of 4.55, 4.5 and 4 mean that the respective errors are better than ± 0.05, ± 0.3 and ± 0.5. Values taken from the literature are written as **pK**, and all the values that were estimated because they were not found in the literature are written as **pK_{Est}**.

pK and Temperature

The temperatures at which the literature measurements were made are given as superscripts, e.g. pK^{25}. Where no temperature is given, it is assumed that the measurements were carried out at room temperature, e.g. 15—25º. No temperature is given for estimated values (**pK_{Est} ~**), and these have been estimated from data at room temperature.

The variation of pK with temperature is given by the equation:

$$- \delta(pK)/ \delta T = (pK + 0.052\Delta S^o)/T$$

where T is in degrees Kelvin and ΔS^o is in Joules deg^{-1} mol^{-1}. The $- \delta(pK)/dT$ in the range of temperatures between 5 to 70° is generally small (e.g. between ~0.0024 and ~0.04), and for chemical purification purposes is not a seriously deterring factor. It does, however, vary with the compound under study because ΔS^o varies from compound to compound. The following are examples of the effect of temperature on pK values: for imidazole the pK values are 7.57 (0°), 7.33 (10°), 7.10 (20°), 6.99 (25°), 6.89 (30°), 6.58 (40°) and 6.49 (50°); and for 3,5-dinitrobenzoic acid they are 2.60 (10°), 2.73 (20°), 2.85 (30°), 2.96 (40°) and 3.07 (40°); and for *N*-acetyl-β-alanine they are 4.4788 (5°), 4.4652 (10°), 4.4564 (15°), 4.4488 (20°), 4.4452 (25°), 4.4444 (30°), 4.4434 (35°) and 4.4412 (40°).

pK and solvent

All stated pK values in this book are for data in dilute aqueous solutions unless otherwise stated, although the dielectric constants, ionic strengths of the solutions and the method of measurement, e.g. potentiometric, spectrophotometric etc., are not given. Estimated values are also for dilute aqueous solutions whether or not the material is soluble enough in water. Generally the more dilute the solution the closer is the pK to the real thermodynamic value. The pK in mixed aqueous solvents can vary considerably with the relative concentrations and with the nature of the solvents. For example the pK^{25} values for *N*-benzylpenicillin are 2.76 and 4.84 in H_2O and H_2O/EtOH (20:80) respectively; the pK^{25} values for (-)-ephedrine are 9.58 and 8.84 in H_2O and $H_2O/MeOCH_2CH_2OH$ (20:80), respectively; and for cyclopentylamine the pK^{25} values are 10.65 and 4.05 in H_2O and H_2O/EtOH (50:50) respectively. pK values in acetic acid or aqueous acetic acid are generally lower than in H_2O.

The dielectric constant of the medium affects the equilibria where charges are generated in the dissociations e.g. $AH \leftrightarrows A^- + H^+$ and therefore affects the pK values. However, its effect on dissociations where there are no changes in total charge such as $BH^+ \leftrightarrows B + H^+$ is considerably less, with a slight decrease in pK with decreasing dielectric constant.

A selection of pKa values for inorganic acids and inorganic bases is displayed in Table 24a, and a selection of pKa values for organic acids and for organic bases is compiled in Tables 24b and 24c respectively.

Solubilities of Gases in Liquids

There are two ways to define the solubilites of gases in water.

The first is the *Bunsen coefficient* (β), which is the ratio of the volume of gas corrected to STP (0°C and 1atm, i.e. 760mmHg) that dissolves in unit volume of solvent at the temperature of the experiment in equilibrium with the gas at 1atm.

The second is the *Ostwald coefficient* (*l*) which is the ratio of the volume of gas that dissolves in unit volume of solvent at the temperature of the experiment in equilibrium with the gas at 1atm. The latter is a more convenient ratio to use because no correction for volume is required. Note that the volume of an ideal gas occupied by one molecular weight in grams of element or compound is ~22.4L at STP (e.g. 32g of oxygen occupy 22.4L at STP). The discussion will be limited to the solubilites of oxygen, nitrogen and air (which behave almost as ideal gases) in water, water containing salts, and in some organic solvents. Generally the solubility of these three gases in water decreases with increase of temperature and can be 'boiled out' of the liquid. Their solubilities in organic liquids, on the other hand, generally increase with increase of temperature. The presence of salts in water tends to decrease the solubilities of these gases, i.e. a salting out effect, and increase in pressure increases their solubilities. These properties have to be noted in liquid chromatography at atmospheric and at high pressures. They become important when purifying small amounts of compounds by crystallisation or chromatography when large amounts of solvents are used. One must be wary of the presence of oxygen in solution, particularly in the presence of organic matter. Also the formation of reactive oxygen species e.g. 'singlet' oxygen, superoxide and hydroxyl radicals, especially in the presence of trace metals such as iron, and/or of ultraviolet light can result in the formation of impurities.

The composition of air is: 78.08% of N_2, 20.95% of O_2, 0.03% of CO_2, 0.93% of Ar and less than 0.01% of other gases. Although the partial pressure of O_2 in air at 1atm is ~0.20, it has a higher solubility in H_2O than N_2. At STP the solubility of O_2 by volume in H_2O is 34.9% when in equilibrium with excess of air. Thus by successively dissolving air in H_2O, expelling it, and redissolving the expelled air six to seven times it is possible to increase the concentration of oxygen by volume in the expelled air to 90%. The (β) values for O_2 and N_2 in H_2O at STP are

0.028 and 0.014 respectively. There are 55.5 moles of H_2O in 1L of H_2O, so the molar ratios of O_2 to H_2O can be calculated. Note that the concentration of O_2 in liquids is higher when the liquids are in equilibrium with excess O_2 than when they are with excess of air.
The solubility coefficients (β) and/or (*l*) of some gases in liquids are given in Tables 25—28. Tables of the solubilities of HCl and NH_3 (g/100g of solution) at 760mm (Table 29) and the boiling points of some useful gases at 760mm (Table 30) are included.

MISCELLANEOUS TECHNIQUES

Freeze-pump-thaw and purging

Volatile contaminants, e.g. traces of low boiling solvent residue or oxygen, in liquid samples or solutions can be very deleterious to the samples on storage. These contaminants can be removed by repeated freeze-pump-thaw cycles. This involves freezing the liquid material under high vacuum in an appropriate vessel (which should be large enough to avoid contaminating the vacuum line with liquid that has bumped) connected to the vacuum line *via* efficient liquid nitrogen traps. The frozen sample is then thawed until it liquefies, kept in this form for some time (*ca* 10-15minutes), refreezing the sample and the cycle repeated several times without interrupting the vacuum. This procedure applies equally well to solutions, as well as purified liquids, e.g. as a means of removing oxygen from solutions for NMR and other measurements. If the presence of nitrogen, helium or argon, is not a serious contaminant then solutions can be freed from gases, e.g. oxygen, carbon dioxide, and volatile impurities by purging with N_2, He or Ar at room, or slightly elevated, temperature. The gases used for purging are then removed by freeze-pump-thaw cycles or simply by keeping in a vacuum for several hours. Special NMR tubes with a screw cap thread and a PTFE valve (Wilmad) are convenient for freeze thawing of NMR samples. *Alternatively*, NMR tubes with 'J Young' valves (Wilmad) can also be used.

Vacuum lines, Schlenk and glovebox techniques

Manipulations involving materials sensitive to air or water vapour can be carried out by these procedures. Vacuum line methods make use of quantitative transfers, and **P**(pressure)-**V**(volume)-**T**(temperature) measurements, of gases, and trap-to-trap separations of volatile substances.
It is usually more convenient to work under an inert-gas atmosphere using **Schlenk** type apparatus. The *principle* of Schlenk methods involve all-glass tubes, flasks or vessels which have standard ground-glass joints with one or more side-arms, one of which may have a tap. The system can be purged by evacuating and flushing with an inert gas (usually dry nitrogen, or in some cases, argon or helium), repeating the process until the contaminants, e.g. O_2, H_2O or CO_2 in the vapour phases have been diminished to acceptable limits. Many of the reactions using Schlenk equipment require anhydrous conditions and in this case the equipment should be heated in an oven slightly above 100° for 1 to 2 hours (preferably with dry N_2, He or argon flushing), and allowed to cool to room temperature in the presence of a desiccant. A large range of Schlenk glassware is commercially available. Schlenk equipment in which refluxing of liquids is possible without contact with the atmosphere outside of the apparatus is available commercially. With these, and tailor-made pieces of glassware, inert atmospheres can be maintained during transfer of material, crystallisation, reflux, filtration, and sublimation. Where addition of a solid sample should be made, an L-tube, or a small bulb with a bent neck, with a glass joint is used in which the solid is placed, and can be transferred to the main reaction vessel by simply rotating the tube or bulb. In the case of a liquid, a separating funnel with an equalising tube can be used to allow equilibration of pressure. Also, liquids can be injected, *via* a syringe through 'Sure/Seal' caps which can be stretched over, or insert nicely into, the ground joint necks of the main reaction container.
Syringe techniques have been developed for small volumes, while for large volumes or where much manipulation is required, dryboxes (*glove boxes*) or dry chambers should be used. Disposable glove bags (e.g. Atmosbags see Sigma-Aldrich Labware of various dimensions) with two or four hands which can be sealed, purged and inflated with an inert gas are available and are relatively cheap and disposable. They are useful not only for handling moisture-sensitive substances, but also for toxic materials.

ADVANCES IN PHYSICAL TECHNIQUES USED IN PURIFICATION

The development, and sophistication of instrumentation keep advancing with the avalanching discoveries and applications of ever developing electronics and computer capabilities. These directly and/or indirectly impact on instruments used for the separation and purification of laboratory chemicals. It is beyond the scope of this work to elaborate in any detail on this. Suffice it to say that a large majority of instruments used are in some way or another integrated with computers which not only use programs to configure the instruments but also to process and store the output information. The amount of information produced by some instruments cannot possibly be

stored and processed manually as is evident in instruments that have become available in past few years. UV-VIS, IR, NIR, MS, NMR and fluorescence spectrometers as well as spectropolarimeters and CD-ORD spectrometers, whether stand alone or bench-top type, are now mostly interfaced with computers which have in addition to programs for driving the instruments, files with libraries so that direct comparisons can be made with spectra of known substances. Among the useful new technologies that are continually appearing is one that allows three phases to be studied together in intact living organisms. Developed by André J. Simpson and coworkers [Mobarhan et al. *Chem Sci* Advance Article 17 Apr *2016*, DOI: 10.1039/C6SC00329J], the novel NMR technique '***Comprehensive Multiphase Nuclear Magnetic Resonance (CM-NMR)***' makes use of an integrated probe to study solution-, gel-, and solid-state molecular movement together. It can be applied to living animals, it can deliver oxygen effectively for long periods enabling long in-depth study, the various phases (i.e. metabolites in solution, in soft tissue and in solid skeletal tissue) can be fully differentiated using a range of spectral editing methods, and using ^{13}C isotopic labelling and multi-dimensional NMR to assign metabolites and structural components *in vivo*. This technique has great potential for studying insoluble biological substances in membranes, muscle and bone that cannot be studied in solution-phase by NMR. Essential information may be gained by this technique about proteins which crystallise into solid fibres as in Alzheimer and Parkinson brains, and the chemistry traffic across biological interfaces. [See also Richard Massey *Chemistry World* **13(**9) 25 *2016*.] Great strides have been made recently in the development and production of automated instruments that synthesise and sequence proteins, DNA and RNA; so much so that the sequencing of the human genome which was completed by several laboratories in five years can now be completed on one instrument in one laboratory in only a few months. There has been a continual need in laboratory work to scale down the quantities used, not only because of cost and waste byproducts but also because of speed in providing the required results. Developments in the field of microfluidics are addressing this problem with increasing success (see following).

Laboratory on a chip/microfluidics. Within the past ten years great strides have been made in *miniaturization* in the wake of tremendous developments in *Nanotechnology* (see Chapter 7) and the silicon chip. This has led to the science and technology of microfluidics that manipulate such small volumes as 10^{-9} to 10^{-18} litres which require channels and chambers with dimensions of radii of hundreds to tens of micrometres. The possibilities of carrying out analytical procedures of chromatography in gas and liquid phases, capillary electrophoresis, microseparations combined with sensitive optical laser and/or electronic detection, and more, are slowly coming to fruition. *Micro chips* or microfluidic chemostats of the order of a few centimeters square to which inlet and outlet tubes can be connected and which have the electronics to open and shut intricate plumbing, mixing, and pneumatic-type valves designed for particular purposes are now already in use. The *chips* require fine tubes, special reservoirs, and pumps to move the fluids, and are made for various uses. There are already manufacturers who will custom-make *chips* to satisfy a variety of demands. The development of lithography and associated microelectronics and microelectrochemical systems (MEMS) originally on silicon and glass chips have found general use in microfluidics, but are slowly replaced by plastic or polymer materials for the platform. Some polymers such as poly(dimethylsiloxane) (PDMS) are optically transparent obviating the use of silicon. They are more malleable, more compressible and cheaper to machine to desired specifications. However, in some instances silicon chips are found to have advantages, as for example where organic fluids cause the plastic materials to swell or dissolve slowly.

Microfluidic devices have already found uses for sampling, identifying and assaying in the purification of chemicals and biochemical, the *chips* being connected to instruments used in chromatographic, electrophoretic, spectroscopic and monitoring devices. These in turn transfer their data to computers which process and/or store the data. It should be pointed out that the physics of the movement of fluids under pressure through such fine tubes as are present in the *chips* is quite different from the turbulent type that is found in millimeter and larger diameter tubes. In this case fluids are allowed to move and mix by running the fluid layers together in *laminar flow* movement [see Squires & Quake in 'Microfluidics: Fluid physics at the nanoliter scale' *Rev Mod Phys* **77** 977 *2005*, DOI: 10.1103/ RevModPhys.77.977]. *Alternatively*, when the fluids are ionic as with aqueous solutions the microchannels to be used should have fixed charges on the inner walls (e.g. as with silica or surface oxidised PDMS) and an electrical potential is applied, so the fluid moves as a plug which is characteristic of electro-osmotic flow (EOF, see Santiago in 'Electro-osmotic flows in microchannels with finite inertial and pressure forces' *Anal Chem* **73** 2353 *2001*, DOI: 10.1021/ac0101398].
Apart from the applications made above, microfluidic devices have been made for screening conditions under

which proteins crystallise. These devices allow conditions of solvent concentrations and mix, temperature and its gradient to be specifically altered until crystals can be viewed within the wells in the microchannels [see Hansen et al. 'A robust and scalable microfluidic metering method that allows protein crystal growth by free interface diffusion' *Proc Natl Acad Sci USA* **99** 16531 *2002*, DOI: 10.1073/pnas.262485199; and Zheng et al. 'A droplet-based, composite PDMS/glass capillary microfluidic system for evaluating protein crystallization conditions by microbatch and vapor-diffusion methods with on-chip diffraction' *Angew Chem Int Ed* **43** 2508 *2004*, DOI: 10.1002/anie.200490056]. Appropriate microchips have been constructed for use in chemical syntheses can be carried out on a chip. For example, Snyder and coworkers [*Angew Chem Int Ed* **88** 1 *2006*, DOI: 10.1002/hlca.200490304] have described versatile modular microreaction systems for chemical syntheses which could involve homogeneous and heterogeneous catalysis, require moderate reaction times, can rapidly optimise conditions, can be cleaned for re-use, and can be later scalable from milligram to ton production amounts. A complex reaction sequence has been devised by Quake and coworkers [Lee et al. *Science* **310** 1793–1796 *2005*, DOI: 10.1126/science.1118919] for the synthesis, as an example, of the [^{18}F]-labeled molecular imaging probe 2-deoxy-2-[^{18}F]-fluoro-D-glucose {[^{18}F]FDG} using an integrated microfluidic chip. It involves the following five reaction steps: (i) concentration of a dilute aqueous solution of F^- ions by passage through a miniaturised ion-exchange column in the presence of K_2CO_3 to then form a complex with a cryptant [Kryptofix (K222)], (ii) solvent exchange from H_2O to dry MeCN, in the separate concentration circuit that is connected to the reaction loop, where (iii) fluorination of the sugar precursor (1,3,4,5-tetraacetyl-D-mannose-2-triflate) by the KryptofixK^+F^- complex to produced 1,3,4,5-tetraacetyl-D-glucose-2-fluoride which is followed by (iv) solvent exchange back to H_2O and finally (v) hydrolysed in 3.0N aqueous HCl to give nanogram amounts of [^{18}F]FDG. The movement of fluids in the various channels is visualised by using different food dyes in the fluids. The actual size of the reaction platform is *ca* 20 x 20 mm. See 'Nanotechnology', Chapter 7, for examples of microfluidics for preparing and purifying nanomaterials for example from CdSe, PbS, Au, Pt, Ag, Au and TiO_2.

The possibilities are almost infinite. A quick glance at any issue of the periodical *Lab Chip* reveals that large users of this technology are in the field of medical (and veterinary) diagnosis, screening, routine pathology, microbiology, etc, as new diseases and treatments are discovered and developed. The pharmaceutical industry will continuously exploit the need and use for *micro labchips* for drug evaluation, throughput screening as well as in drug synthesis and analysis. Mention should also be made that this technology furthers our knowledge of fluidics in science and engineering at the micro and nano scale.

There are manufacturers who will make *chip-platforms* to order and the cost can drop considerably if large disposable numbers are to be supplied. Some instrument manufacturers such as those that make DNA and RNA sequencers make their own *chips* for their requirements. Some research laboratories also make their own *chips* to meet their new needs. Once used, *chips* become contaminated and are invariable discarded because of difficulties in getting them pristinely clean, although some may be designed for re-use after appropriate treatment.

The bibliography in this field is ever increasing and new journals and periodicals are being published. The Royal Society of Chemistry (London) started a new journal entitled 'Laboratory on a Chip' abbreviated *Lab Chip* in 2001 and has a current Impact Factor of 6.115. A quick glance at the papers published in this journal reveals much about the various applications of this technology (a few titles are listed in 'selected publications' below). The ISSN and date of first issue of relevant periodicals include: *ACS Chem Mater* (ISSN: 0897-4756; *1989*), *Biomicrofluidics* (ISSN: 1932-1058; *2007*); *Microfluidics and Nanofluidics* (ISSN: 1613-4982; *2004*); *BioChip Journal* (ISSN: 1976-0280 print; 2092-7843 online; *2010*); *Biomedical Microdevices: bioMEMS and Biomedical Nanotechnology* (ISSN: 1387-2176 print; 1572-8781 online; *1998*), *International Journal of Biomedical Nanoscience and Nanotechnology* (IJBNN) (ISSN: 1756-0799 print; 1756-0802 online; *2010*); *Environmental Nanotechnology, Monitoring and Management* (ISSN: 2215-1532, open access; *2014*); *European Journal of Nanomedicine* (ISSN: 1662-596X; 2008). However, some papers in this field will also be found in journals on nanoscience, nanotechnology, e.g. in the journal *Nanoscale* (Impact Factor 7.349; ISSN: 2040-3364, first published in *2009* by the Royal Society of Chemistry, London), as well as in science journals such as *Nature*, *Science, PNAS,* the American Chemical Society and Royal Society of Chemistry publications.

CHEMICAL AND BIOCHEMICAL SOURCES

Apart from wishing to obtain a pure substance there are many reasons for wanting to purify a substance. For example the substance may have been in the store for too long and has deteriorated to a smaller or larger extent and needs to be used. Large quantities may be required, so bulk amounts, less pure but of cheaper grade could serve the purpose if they can be purified readily and cheaply. The cost consideration is very important. Substances that are available commercially can be of varying grades of purity and the purer the grade the higher the price. Biological substances may be only available in crude form, e.g. acetone powders for enzymes. There are a large number of suppliers of substances for chemical, biochemical and for biological requirements and they are continually improving quality, increasing their range and introducing recently developed substances. The following is a website list of the more commonly used suppliers from which almost all the substances and equipment described in this book can be purchased. The list also contains suppliers of laboratory ware as well as of scientific instruments. The list is not exhaustive.

For high purity inorganic compounds, NIST Traceable inorganic reference standards/calibrants and aqueous standard solutions for ICP, ICP-MS, AA, GFAA and IC visit <www.exaxol.com>. Note that all the trace metal analyses in the 'Inorganic Compounds' section of Chapter 4 are by courtesy of Joe Papa (EXAXOL see Preface).

TABLES

TABLE 1. SOME COMMON IMMISCIBLE OR SLIGHTLY MISCIBLE PAIRS OF SOLVENTS AT AMBIENT TEMPERATURES

Acetonitrile with hexane, heptane, iso-octane, cyclohexane.

Benzene with water, brine and aqueous solutions generally.

Butanol with water, brine and aqueous solutions generally.

Carbon tetrachloride with ethanolamine, ethylene glycol, formamide, water or brine.

Chloroform with glycerol, ethylene glycol, water, aqueous solutions generally

Cyclohexane with alohols, dimethyl formamide, dimethyl sulfoxide, glycerol, pyridine.

Cyclopropyl methyl ether same as ethyl ether but less so.

Dimethyl formamide or **dimethyl acetamide** with cyclohexane, pentane, petroleum ether, xylene.

Dimethyl sulfoxide with ethyl ether, pentane, petroleum ethers, cyclohexane, xylene.

Ethyl acetate with aqueous solutions generally or petroleum ethers.

Ethyl ether with ethanolamine, dimethyl sulfoxide, ethylene glycol, glycerol, water or aqueous solutions generally.

Ethanol with carbon disulfide, petroleum ethers, cyclohexanes

Glyerol with benzene, ether, chloroform, carbon tetrachloride, carbon disulfide, petroleum ethers, oils

Iso-octane with acetonitrile, dimethyl formamide, dimethyl sulfoxide, methanol, water.

Methanol with carbon disulfide, hexane, heptane, cyclohexane or petroleum ethers.

***N*-Methylpyrrolidone** with petroleum ethers, cyclohexanes.

Petroleum ether(s) with aniline, benzyl alcohol, dimethyl formamide, dimethyl sulfoxide, formamide, phenol or water and aqeuous solutions generally.

Phenol with petroleum ethers, cyclohexanes.

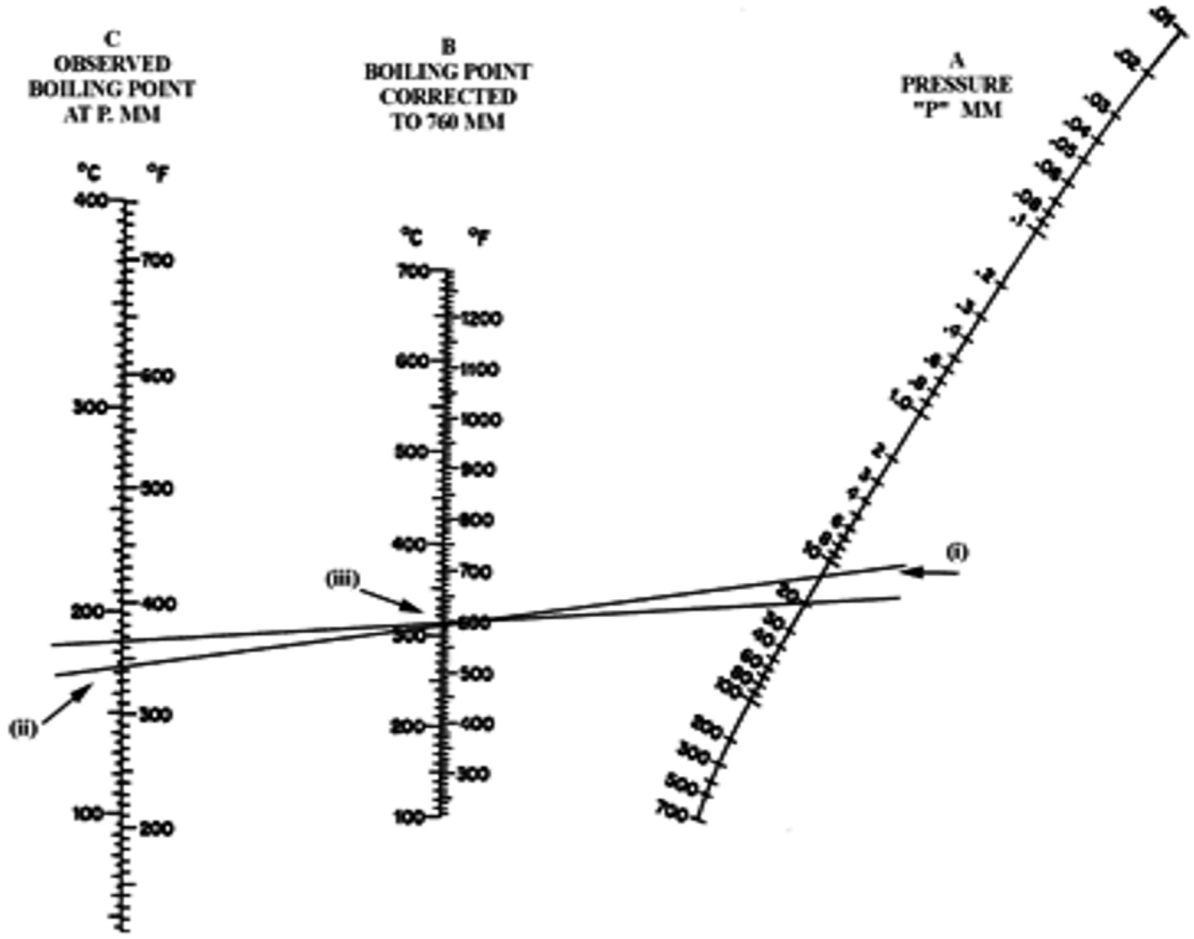
Pyridine with petroleum ethers, hexanes.

Toluene with water, brine, aqueous solutions generally, glycerol but less so than benzene.

Water with aniline, benzene, benzyl alcohol, carbon disulfide, carbon tetrachloride, chloroform, cyclohexane, cyclohexanol, cyclohexanone, diethyl ether, ethyl acetate, isoamyl alcohol, methyl ethyl ketone, nitromethane, tributyl phosphate or toluene.

Xylene with water, brine, aqueous solutions generally, glycerol, dimethyl formamide, dimethyl sulfoxide.

FIGURE 1: NOMOGRAM



How to use Figure 1:
You can use a nomogram to estimate the boiling points of a substance at a particular pressure. For example, the boiling point of 4-methoxybenzenesulfonyl chloride is 173ºC/14mm. Thus to find out what the boiling point of this compound will be at 760mm (atmospheric), draw a point on curve A (pressure) at 14mm (this is shown in (i). Then draw a point on curve C (observed boiling point) corresponding to 173º (or as close as possible). This is shown in (ii). Using a ruler, find the point of intersection on curve B, drawing a line between points (i) and (ii). This is the point (iii) and is the boiling point of 4-methoxybenzenesulfonyl chloride (i.e. approx. 310ºC) at atmospheric pressure. If you want to distil 4-methoxybenzenesulfonyl chloride at 20mm, then you will need to draw a point on curve A (at 20mm). Using a ruler, find the point of intersection on curve C drawing through the line intersecting (iii, curve B, i.e. 310ºC) and the point in curve A corresponding to 20mm. You should have a value of 185ºC; that is, the boiling point of 4-methoxybenzenesulfonyl chloride is estimated to be at 185ºC at 20mm.

TABLE 2A. PREDICTED EFFECT OF PRESSURE ON BOILING POINT*

	Temperature in degrees Centigrade									
760 mmHg	0	20	40	60	80	100	120	140	160	180

800.0	1	21	41	61	81	101	122	142	162	182

* *How to use the Table*: Take as an example a liquid with a boiling point of 80°C at 760mm Hg. The Table gives values of the boiling points of this liquid at pressures from 0.1 to 800mm Hg. Thus at 50mm Hg this liquid has a boiling point of 19°C, and at 2mm Hg its boiling point would be -30°C.

TABLE 2B. PREDICTED EFFECT OF PRESSURE ON BOILING POINT*

	Temperature in degrees Centigrade

400.0	178	197	216	235	254	273	292	311	330	350	369
500.0	185	205	224	244	263	282	302	321	340	360	379
600.0	192	211	231	251	270	290	310	329	349	368	388
700.0	197	217	237	257	277	296	316	336	356	376	396
750.0	200	220	239	259	279	299	319	339	359	279	399
770.0	200	220	241	261	281	301	321	341	361	381	401
800.0	202	222	242	262	282	302	322	342	262	382	403

* *How to use the Table*: Taking as an example a liquid with a boiling point of 340ºC at 760mm Hg, the column headed 340ºC gives values of the boiling points of this liquid at each value of pressures from 0.1 to 800mm Hg. Thus, at 100mm Hg its boiling point is 258ºC, and at 0.8mm Hg its boiling point will be 130ºC.

TABLE 3. HEATING BATHS

Up to 100°	Water baths
-20 to 200°	Glycerol or di-*n*-butyl phthalate
Up to about 200°	Medicinal paraffin
Up to about 250°	Hard hydrogenated cotton-seed oil (**m** 40-60°) or a 1:1 mixture of cotton-seed oil and castor oil containing about 1% of hydroquinone.
-40 to 250° (to 400° under N_2)	D.C. 550 silicone fluid
Up to about 260°	A mixture of 85% orthophosphoric acid (4 parts) and metaphosphoric acid (1 part)
Up to 340°	A mixture of 85% orthophosphoric acid (2 parts) and metaphosphoric acid (1 part)
60 to 500°	Fisher bath wax (highly unsaturated)
73 to 350°	Wood's Metal*
250 to 800°	Solder*
350 to 800°	Lead*

* In using metal baths, the container (usually a metal crucible) should be removed while the metal is still molten.

TABLE 6. COMMON SOLVENTS USED IN RECRYSTALLISATION

Acetic acid (118°)	*Cyclohexane (81°)	*Methanol (64.5°)
*Acetone (56°)	Dichloromethane (41°)	*Methyl ethyl ketone (80°)
Acetylacetone (139°)	*Diethyl ether (34.5°)	Methyl isobutyl ketone (116°)
Acetonitrile (82°C)	Dimethyl formamide (76°/39mm)	Nitrobenzene (210°)
*Benzene (80°)	*Dioxane (101°)	Nitromethane (101°)
Benzyl alcohol (93°/10mm)	*Ethanol (78°)	*Petroleum ether (various)
n-Butanol (118°)	2-Ethoxyethanol (cellosolve 135°)	Pyridine (115.5°)
Butyl acetate (126.5°)	*Ethyl acetate (78°)	Pyridine trihydrate (93°)
n-Butyl ether (142°)	Ethyl benzoate (98°/19mm)	*Tetrahydrofuran (64-66°)
γ-Butyrolactone (206°)	Ethylene glycol (68°/4mm)	Toluene (110°)
Carbon tetrachloride (77°)	Formamide (110°/10mm)	Trimethylene glycol (59°/11mm)
Chlorobenzene (132°)	Glycerol (126°/11mm)	Water (100°)
Chloroform (61°)	Isoamyl alcohol (131°)	Xylenes (*o* 143-145°, *m* 138-139°, *p* 138°)

***Highly flammable, should be heated or evaporated on steam or electrically heated water baths only (preferably under nitrogen). None of these solvents should be heated over a naked flame.**

TABLE 7. PAIRS OF MISCIBLE SOLVENTS

Acetic acid: with chloroform, ethanol, ethyl acetate, acetonitrile, petroleum ether, or water.
Acetone: with benzene, butyl acetate, butyl alcohol, carbon tetrachloride, chloroform, cyclohexane, ethanol, ethyl acetate, methyl acetate, acetonitrile, petroleum ether or water.
Ammonia: with ethanol, methanol, pyridine.
Aniline: with acetone, benzene, carbon tetrachloride, ethyl ether, *n*-heptane, methanol, acetonitrile or nitrobenzene.
Benzene: with acetone, butyl alcohol, carbon tetrachloride, chloroform, cyclohexane, ethanol, acetonitrile, petroleum ether or pyridine.
Butyl alcohol: with acetone or ethyl acetate.
Carbon disulfide: with petroleum ether.
Carbon tetrachloride: with cyclohexane.
Chloroform: with acetic acid, acetone, benzene, ethanol, ethyl acetate, hexane, methanol or pyridine.
Cyclohexane: with acetone, benzene, carbon tetrachloride, ethanol or diethyl ether.
Diethyl ether: with acetone, cyclohexane, ethanol, methanol, methylal (dimethoxymethane), acetonitrile, pentane or petroleum ether.
Dimethyl formamide: with benzene, ethanol or ether.
Dimethyl sulfoxide: with acetone, benzene, chloroform, ethanol, diethyl ether or water.
Dioxane: with benzene, carbon tetrachloride, chloroform, ethanol, diethyl ether, petroleum ether, pyridine or water**.**
Ethanol: with acetic acid, acetone, benzene, chloroform, cyclohexane, dioxane, ethyl ether, pentane, toluene, water or xylene.
Ethyl acetate: with acetic acid, acetone, butyl alcohol, chloroform, or methanol.
Glycerol: with ethanol, methanol or water.
Hexane: with benzene, chloroform or ethanol.
Methanol: with chloroform, diethyl ether, glycerol or water.
Methylal: with diethyl ether.
Methyl ethyl ketone: with acetic acid, benzene, ethanol or methanol.
Nitrobenzene: with aniline, methanol or acetonitrile.
Pentane: with ethanol or diethyl ether.
Petroleum ether: with acetic acid, acetone, benzene, carbon disulfide or diethyl ether.
Phenol: with carbon tetrachloride, ethanol, diethyl ether or xylene.
Pyridine: with acetone, ammonia, benzene, chloroform, dioxane, petroleum ether, toluene or water.
Toluene: with ethanol, diethyl ether or pyridine.
Water: with acetic acid, acetone, ethanol, methanol, or pyridine.
Xylene: with ethanol or phenol.

TABLE 8. MATERIALS FOR COOLING BATHS

Temperature	Composition	Temperature	Composition
0º	Crushed ice	-72º	Solid CO_2 with ethanol
-5º to -20º	Ice-salt mixtures	-77º	Solid CO_2 with chloroform or acetone
Up to -20º	Ice-MeOH mixtures	-78º	Solid CO_2 (powdered; CO_2 snow)
-33º	Liquid ammonia	100º	Solid CO_2 with diethyl ether
-40º to -50º	Ice (3.5-4 parts) - $CaCl_2 \cdot 6H_2O$ (5 parts)	-196º	liquid nitrogen (see footnote*)

Alternatively, the following liquids can be used, partially frozen, as cryostats, by adding solid CO_2 from time to time to the material in a Dewar-type container and stirring to make a slush:

13º	*p*-Xylene	-55º	Diacetone
12º	Dioxane	-56º	*n*-Octane
6º	Cyclohexane	-60º	Di-isopropyl ether
5º	Benzene	-73º	Trichloroethylene or isopropyl acetate
2º	Formamide	-74º	*o*-Cymene or *p*-cymene
-8.6º	Methyl salicylate	-77º	Butyl acetate
-9º	Hexane-2,5-dione	-79º	Isoamyl acetate
-10.5º	Ethylene glycol	-83º	Propylamine
-11.9º	*tert*-Amyl alcohol	-83.6º	Ethyl acetate
-12º	Cycloheptane or methyl benzoate	-86º	Methyl ethyl ketone
-15º	Benzyl alcohol	-89º	*n*-Butanol
-16.3º	*n*-Octanol	-90º	Nitroethane
-18º	1,2-Dichlorobenzene	-91º	Heptane
-22º	Tetrachloroethylene	-92º	*n*-Propyl acetate
-22.4º	Butyl benzoate	-93º	2-Nitropropane or cyclopentane
-22.8º	Carbon tetrachloride	-94º	Ethyl benzene or hexane
-24.5º	Diethyl sulfate	-94.6º	Acetone
-25º	1,3-Dichlorobenzene	-95.1º	Toluene
-29º	*o*-Xylene or pentachloroethane	-97º	Cumene
-30º	Bromobenzene	-98º	Methanol or methyl acetate
-32º	*m*-Toluidine	-99º	Isobutyl acetate
-32.6º	Dipropyl ketone	-104º	Cyclohexene
-38º	Thiophene	-107º	Isooctane
-41º	Acetonitrile	-108º	1-Nitropropane
-42º	Pyridine or diethyl ketone	-116º	Ethanol or diethyl ether
-44º	Cyclohexyl chloride	-117º	Isoamyl alcohol
-45º	Chlorobenzene	-126º	Methylcyclohexane
-47º	*m*-Xylene	-131º	*n*-Pentane
-50º	Ethyl malonate or *n*-butylamine	-160º	Isopentane
-52º	Benzyl acetate or diethylcarbitol		

For other organic materials used in low temperature slush-baths with liquid nitrogen see R.E.Rondeau [*J Chem Eng Data* **11** 124 *1966*, DOI: 10.1021/je60028a037]. ***NOTE**: Use high quality pure nitrogen; do not use liquid air or liquid nitrogen that has been in contact with air for a long period (due to the dissolution of oxygen in it) as this could EXPLODE in contact with organic matter.

TABLE 9. LIQUIDS FOR STATIONARY PHASES IN GAS CHROMATOGRAPHY*

Material	Temp.	Retards
Dimethylsulfolane	0-40º	Olefins and aromatic hydrocarbons
Di-*n*-butyl phthalate	0-40º	General purposes
Squalane	0-150º	Volatile hydrocarbons and polar molecules
Silicone oil or grease	0-250º	General purposes
Diglycerol	20-120º	Water, alcohols, amines, esters, and aromatics
Dinonyl phthalate	20-130º	General purposes
Polydiethylene glycol succinate	50-200º	Aromatic hydrocarbons, alcohols, ketones, esters
Polyethylene glycol	50-200º	Water, alcohols, amines, esters and aromatics
Apiezon grease	50-200º	Volatile hydrocarbons and polar molecules
Tricresyl phosphate	50-250º	General purposes

* See Suppliers at the end of section on HPLC and E.F. Barry and R.L. Grob, *Columns for Gas Chromatography*, J. Wiley and Sons NY, *2007*, ISBN 9780471740438.

TABLE 10. METHODS OF VISUALISATION OF TLC SPOTS

Reagent	Compound	Preparation	Observations
Iodine	General	Iodine crystals in a closed chamber or spray 1% methanol solution of Iodine	Brown spots which may disappear upon standing.
H_2SO_4	General	50% solution, followed by heating to 150ºC	Black or coloured spots
Molybdate	General	5% $(NH_4)_6Mo_7O_{24}$ + 0.2% $Ce(SO_4)_2$ in 5% H_2SO_4, followed by heating to 150ºC.	Deep blue spots
Vanillin	General	0.5g vanillin, 0.5 ml H_2SO_4, 9 ml ethanol	various coloured spots
Ammonia	phenols	Ammonia vapour in a closed chamber	various coloured spots
$FeCl_3$	phenols, enols	1% aqueous $FeCl_3$	various coloured spots
2,4-DNP	aldehydes, ketones	0.5% 2,4-dinitrophenylhydrazine/2M HCl	red to yellow spots
HCl	aromatic acids and amines	HCl vapour in a closed chamber	various coloured spots
Ninhydrin	amino acids, and amines	0.3% ninhydrin in *n*-BuOH with 3% AcOH, followed by heating to 125ºC/10 min	blue spots
$PdCl_2$	S and Se compds	0.5% aq. $PdCl_2$ + few drops of conc. HCl	red and yellow spots
Anisaldehyde	carbohydrates	0.5 ml anisaldehyde in 0.5 ml conc H_2SO_4 + 95% EtOH + a few drops of AcOH Heat at 100-110ºC for 20-30 minutes	various blue spots

TABLE 11. GRADED ADSORBENTS AND SOLVENTS FOR CHROMATOGRAPHY

Adsorbents (decreasing effectiveness)	**Solvents** (increasing eluting ability)
Fuller's earth (hydrated aluminosilicate)	Petroleum ether, b. 40-60°.
Magnesium oxide	Petroleum ether, b. 60-80°.
Charcoal	Carbon tetrachloride.
Alumina	Cyclohexane.
Magnesium trisilicate	Benzene.
Silica gel	Diethyl ether.
Calcium hydroxide	Chloroform.
Magnesium carbonate	Ethyl acetate.
Calcium phosphate	Acetone.
Calcium carbonate	Ethanol.
Sodium carbonate	Methanol.
Talc	Pyridine.
Inulin	Acetic acid.
Sucrose≈starch	Acetic acid.

TABLE 12. REPRESENTATIVE ION-EXCHANGE RESINS USED IN CHROMATOGRAPHY

Sulfonated polystyrene **Strong-acid cation exchanger**	**Aliphatic amine-type** **weak base anion exchangers**
AG 50W-x8	Amberlites IR-45 and IRA-67
Amberlite IR-120	Dowex 3-x4A
Dowex 50W-x8	Permutit E
Duolite 225	Permutit A 240A
Permutit RS	
Permutite C50D	
Carboxylic acid-type **Weak acid cation exchangers**	**Strong Base, anion exchangers**
Amberlite IRC-50	AG 2x8
Bio-Rex 70	Amberlite IRA-400
Chelex 100	Dowex 2-x8
Duolite 436	Duolite 113
Permutit C	Permutit ESB
Permutits H and H-70	Permutite 330D

TABLE 13. MODIFIED FIBROUS CELLULOSES FOR ION-EXCHANGE CHROMATOGRAPHY

Cation exchange	**Anion exchange**
CM cellulose (carboxymethyl)	DEAE cellulose (diethylaminoethyl)
CM 22, 23 cellulose	DE 22, 23 cellulose
P cellulose (phosphate)	PAB cellulose (*p*-aminobenzyl)
SE cellulose (sulfoethyl)	TEAE cellulose (triethylaminoethyl)
SM cellulose (sulfomethyl)	ECTEOLA cellulose

SE and SM are much stronger acids than CM, whereas P has two ionisable groups (pK 2-3, 6-7)*, one of which is stronger, the other weaker, than for CM* (3.5-4.5). For basic strengths, the sequence is: TEAE » DEAE (pK 8-95) > ECTEOLA (pK 5.5-7) > PAB. **Their exchange capacities lie in the range 0.3 to 1.0 mg equiv/g.**

TABLE 14. BEAD FORM ION-EXCHANGE PACKAGINGS FOR CHROMATOGRAPHY[1]

Cation exchange	Capacity (meq/g)	Anion exchange	Capacity (meq/g)
CM-Sephadex C-25, C-50.[2](weak acid)	4.5±0.5	DEAE-Sephadex A-25, A-50.[7] (weak base)	3.5±0.5
SP-Sephadex C-25, C-50.[3](strong acid)	2.3±0.3	QAE-Sephadex A-25, A-50.[8] (strong base)	3.0±0.4
CM-Sepharose CL-6B.[4]	0.12±0.02	DEAE-Sepharose CL-6B.[4]	0.13±0.02
		DEAE-Sephacel.[9]	1.4±0.1
Fractogel EMD,CO_2^- ($pK \sim 4.5$), SO_3^{2-} ($pK \sim <1$).[5]		Fractogel EMD, DMAE (pK ~9), DEAE (pK ~10.8), TMAE (pK >13).[5]	
CM-32 Cellulose.		DE-32 Cellulose.	
CM-52 Cellulose.[6]		DE-52 Cellulose	

[1]May be sterilised by autoclaving at pH 7 and below 120°. [2]Carboxymethyl. [3]Sulfopropyl. [4]Crosslinked agarose gel, no pre-cycling required, pH range 3-10. [5]Hydrophilic methacrylate polymer with very little volume change on change of pH (equivalent to *Toyopearl,* Sigma), available in superfine 650S, and medium 650M particle sizes. [6]Microgranular, pre-swollen, no pre-cycling required. [7]Diethylaminoethyl. [8]Diethyl(2-hydroxy-propyl)aminoethyl. [9]Bead form cellulose, pH range 2-12, no pre-cycling required. Sephadex and Sepharose are from GE Healthcare, Fractogel is from Merck and Cellulose is from Whatman.

TABLE 15 SELECTED CHIRAL COLUMNS FOR CHROMATOGRAPHY*

Column name	Chiral ligand	Attributes	Manufacture
CHIRA-chrom-1	*R*- or *S*- phenylglycine	High capacity	
	S-leucine	&	HICHROM
CHIRA-chrom-2	dinitrophenyl tartramide	efficiency	
CHIRAL-AGP	α 1-acid glycoprotein	Used in wide	
CHIRAL-CBH	cellobiohydrolase	pH range	CHROM TECH
CHIRAL-HAS	human serum albumin		
CHIRALCEL OD/OJ	cellulose derivative	Particular separations	
CHIRALPAK AD/AS/H	amylose derivative	versatile	
CHIRALPAK 1A	immobilised amylose	broad range	DIACEL
CHIRALPAK 1B	immobilised cellulose	broad range	
CROWNPAK	18-crown 6 type ether	for amino acids and primary amines	
CHIROSIL	(18-crown 6)$(CO_2H)_4$	for amino acids and primary amines	RStech

(Continued)

TABLE 15 (Continued) SELECTED CHIRAL COLUMNS FOR CHROMATOGRAPHY*

Column name	Chiral ligand	Attributes	Manufacture
CHIROBIOTIC R	Ristocetin A	Broad selectivity	
CHIROBIOTIC T	Teicoplanin	Broad selectivity	Astech 1
CHIROBIOTIC V	Vancomycin	Broad selectivity	
CYCLOBOND I	β-cyclodextrin	form chiral	Astech 1
CYCLOBOND II	γ-cyclodextrin	inclusion complexes	
KROMASIL DMB	Acetylated *N,N'*-diallyl	stable, high capacity	Eka Chemicals
KROMASIL TBB	*S*-tartardiamide	for large prep work	
NUCLEODEX β-OH	β-cyclodextrin	reverse phase work	
NUCLEODEX α-, β-	permethylated α-, β- and	reverse phase work	Macherey—
and γ-PM	γ-cyclodextrins	reverse phase work	Nagel
NUCLEOSIL Chiral-1	*S*-hydroxyproline-Cu^{2+} complex	ligand exchange, e.g. α-amino acids	
RESOLVOSIL BSA-7PX	bovine serum albumen	various applications	
ULTRON ES-OVM	ovomucoid protein	stable phase	Shinwa Chem
ULTRON ES-Pepsin	pepsin protein	stable phase	Industries
DACH-DNB	3,5-dinitrobenzoyl derivs	π-electron acceptor/	
ULMO	3,5-dinitrobenzoyl derivs	donor — widely used	
α-Burke 2	3,5-dinitrobenzoyl derivs	π-electron acceptor	
β-GEM 1	3,5-dinitrobenzoyl derivs	π-electron acceptor	
Leucine	3,5-dinitrobenzoyl derivs	π-electron acceptor	REGIS
Phenyglycine	β-lactamase chiral selector	π-electron acceptor	
PIRKLE-1J	*S*-naphthylleucine	π-electron donor	
Naphthylleucine	ligand exchange	good for underivatised	
DAVAKOV	ligand exchange	amino acids

TABLE 18. DRYING AGENTS FOR CLASSES OF COMPOUNDS

Class	Dried with
Acetals	K_2CO_3.
Acids (organic)	$CaSO_4$, $MgSO_4$, Na_2SO_4.
Acyl halides	$MgSO_4$, Na_2SO_4.
Alcohols	CaO, $CaSO_4$, $MgSO_4$, K_2CO_3, followed by Mg and I_2.
Aldehydes	$CaSO_4$, $MgSO_4$, Na_2SO_4.
Alkanes and alkenes	$MgSO_4$, $CaCl_2$, $CaSO_4$, H_2SO_4, P_2O_5.
Alkyl halides	$CaCl_2$, $CaSO_4$, $MgSO_4$, P_2O_5, Na_2SO_4, H_2SO_4.
Amines	BaO, CaO, KOH, NaOH, Na_2CO_3.
Aryl halides	$CaCl_2$, $CaSO_4$, $MgSO_4$, Na_2SO_4, P_2O_5.
Esters	$MgSO_4$, K_2CO_3, Na_2SO_4.
Ethers	$CaCl_2$, $CaSO_4$, $MgSO_4$, Na, $LiAlH_4$.
Heterocyclic bases	$MgSO_4$, K_2CO_3, KOH.
Hydrocarbons	$CaCl_2$, $CaSO_4$, $MgSO_4$, P_2O_5, Na (not for olefins).
Ketones	$CaSO_4$, $MgSO_4$, K_2CO_3, Na_2SO_4.
Mercaptans	$MgSO_4$, Na_2SO_4.
Nitro compounds and nitriles	$CaCl_2$, $MgSO_4$, Na_2SO_4.
Sulfides	$CaCl_2$, $CaSO_4$. **[See also Molecular Sieves in text above]**

TABLE 19. STATIC DRYING FOR SELECTED LIQUIDS (25°C)

Liquid	Water	Linde Type 4 A	Linde Type 5 A	Activated Alumina	Silicic Acid Gel
MeOH	Residual H_2O % Wt % absorbed	0.54 2.50	0.55 1.50	— —	0.60 —
EtOH	Residual H_2O % Wt % absorbed	0.25 7.00	0.25 6.80	0.45 1.50	0.68 —
1-Butylamine	Residual H_2O % Wt % absorbed	1.65 10.40	1.31 18.20	1.93 3.40	2.07 —
2-Ethyl-hexylamine	Residual H_2O % Wt % absorbed	0.25 15.10	0.08 21.10	0.43 6.10	0.53 1.70
Diethyl ether	Residual H_2O % Wt % absorbed	0.001 9.50	0.013 9.20	0.16 6.20	0.27 4.30
Amyl acetate	Residual H_2O % Wt % absorbed	0.002 9.30	— —	0.33 7.40	0.38 1.80

TABLE 20 FLUOROCHROMES*

	CAS registry No	λ_{ex} (nm)#	λ_{em} (nm)#	Applications
Acriflavin	[8048-52-0]	463	490	Stains many compounds
Allophycocyanin (APC)		604 (650)	650 (660)	Polypeptide with exceptional Fluorescence for cytometry
3-Aminocoumarin	[1635-31-0]	350	445	Forms fluorescent derivatives *via* reaction with the 3-NH_2 group
Auramine O (basic yellow 2)	[2465-27-2]	440	530	Fluorescent stain for bacteria and probe for certain enzymes, e.g. alcohol dehydrogenases
4-Bromomethyl-7-methoxycoumarin	[35231-44-8]	360 (340)	410 (421)	Forms fluorescent probes with various compds for TLC/HPLC
Chromomycin A_3	[7059-24-7]	445	575	Stains DNA
Ethidium bromide	[1239-45-8]	493	620	Stains DNA
Fluorescamine	[38183-12-9]			Reacts with various R-NH_2 to form fluorescent compds
Fluorescein	[2321-07-5]	490	514	Fluorescent nucleus for staining a Variety of compounds
Fluorescein-Isothiocyanate (FITC)	[3326-32-7]	492	518	Microsequencing of peptides & proteins, makes fluorescent Amino acids
Hoechst H 2495 (benzoxanthene yellow)	[72845-94-4]			Fluorochrome for various compds
Hoechst H33342 (bisBenzimide 3HCl)	[23491-52-3]	346	640	Intercalates DNA for cytometry and fluorescence microscopy
R-Phycoerythrin	[11016-17-4]	488	572	Forms fluorescent probes with proteins
PKH 2 and 72 (green)		490	504	A Protein Kinase polypeptide that links to cells causing fluorescence
PKH 26 (red)		557	567	Used for labeling cells (cf PKH 2 or 72)
Tetramethyl rhodamine Isothiocyanate (TRITC)	[95197-95-8]	529 (492)	596 (518)	Protein fluorochrome, used for immunofluorescence

** Of the many fluorochromes reported in this book only a very small selection is tabulated here. # These wavelengths may vary somewhat depending on the solvent used, and on the pH if measured in aqueous solutions.

TABLE 21. RESIDUAL SOLVENT SIGNALS OF COMMON NMR SOLVENTS
(Adapted from Gottieb et al. *J Org Chem* **62** 7512 *1997*, DOI: 10.1021/jo971176v; Fulmer et al. *Organometallics* **29**, 2176 *2010*, DOI: 10.1021/om100106e).

Solvents	**^{1}H NMR**	**^{13}C NMR**
Deuterated chloroform , $CDCl_3$	7.26	77.16
Deuterated dichloromethane CD_2Cl_2	5.32	53.84
Deuterated benzene, C_6D_6	7.16	128.06
Deuterated acetone, $(CD_3)_2CO$	2.05	29.84; 206.26
Deuterated dimethylsulfoxide, $(CD_3)_2SO$	2.50	35.52
Deuterated acetonitrile, CD_3CN	1.94	1.32; 118.26
Deuterated methanol, CD_3OD	3.31	49.00
Deuterated water, D_2O	4.79	-

Shaded region denotes residual undeuterated solvent. Multiplicities are singlet unless denoted otherwise (s=singlet, t=triplet, m=multiplet).
*The multiplicities of trace impurities maybe different for methanol and ethanol if coupling with the OH proton is observed.

TABLE 24. AQUEOUS BUFFERS

Approx. pH	Composition
0	2N sulfuric acid or N hydrochloric acid
1	0.1N hydrochloric acid or 0.18N sulfuric acid
2	**Either** 0.01N hydrochloric acid or 0.013N sulfuric acid **Or** 50 ml of 0.1M glycine (also 0.1M NaCl) + 50 ml of 0.1N hydrochloric acid
3	**Either** 20 ml of the 0.2M Na_2HPO_4 + 80 ml of 0.1M citric acid **Or** 50 ml of 0.1M glycine + 22.8 ml of 0.1N hydrochloric acid in 100 ml
4	**Either** 38.5 ml of 0.2M Na_2HPO_4 + 61.5 ml of 0.1M citric acid **Or** 18 ml of 0.2M NaOAc + 82 ml of 0.2M acetic acid
5	**Either** 70 ml of 0.2M NaOAc + 30 ml of 0.2M acetic acid **Or** 51.5 ml of 0.2M Na_2HPO_4 + 48.5 ml of 0.1M citric acid
6	63 ml of 0.2M Na_2HPO_4 + 37 ml of 0.1M citric acid
7	82 ml of M Na_2HPO_4 + 18 ml of 0.1M citric acid
8	**Either** 50 ml of 0.1M Tris buffer + 29 ml of 0.1N hydrochloric acid, in 100 ml **Or** 30 ml of 0.05M borax + 70 ml of 0.2M boric acid
9	80 ml of 0.05M borax + 20 ml of 0.2M boric acid
10	**Either** 25 ml of 0.05M borax + 43 ml of 0.1N NaOH, in 100 ml **Or** 50 ml of 0.1M glycine + 32 ml of 0.1N NaOH, in 100 ml
11	50 ml of 0.15M Na_2HPO_4 + 15 ml of 0.1N NaOH
12	50 mL of 0.15M Na_2HPO_4 + 75 ml of 0.1N NaOH
13	0.1N NaOH or KOH
14	N NaOH or KOH

These buffers are suitable for use in obtaining ultraviolet spectra. Alternatively, for a set of accurate buffers of low, but constant, ionic strength (I = 0.01) *covering a pH range 2.2 to 11.6 at 20°, see* Perrin *Aust J Chem* **16** 572 *1963,* DOI: 10.1071/CH9630572. 'In 100 ml' means that the solution is made up to 100 ml with pure water.

TABLE 24a. pKa OF SELECTED INORGANIC ACIDS AND BASES[§] in H_2O at 25°C.

Acids	pKa		Bases	pKa
Amidophosphoric	2.74, 8.30		Aluminium (Al^{3+})	5
Aminodisulfonic	8.50		Ammonia	9.25
Arsenic	11.2, 6.98		Ammonia (deuterated) [*]	9.76
Arsenious	9.18		Barium	13.36
Boric	9.23		Bismuth (Bi^{3+})	1.58
Carbonic	6.35, 10.33		Cadmium	9.10
Chlorous	1.94		Calcium	12.9
Cyanic (HCNO)	3.46		Chromium (Cr^{3+})	4
Diamidophosphoric	1.23, 4.94		Cobalt (Co^{2+})	9.85
Hydrazoic	4.72		Hydrazine[*] (NH_2NH_2)	-0.88, 8.11
Hydriodic	-9		Methylhydrazine[#†]	7.87
Hydrobromic	-8		Tetramethylhydrazine[#†]	6.30
Hydrchloric	-6.1		Phenylhydrazine[†]	5.27
Hydrocyanic	9.22		Hydroxylamine (NH_2OH)	5.69
Hydrofluoric	3.18		*O*-Methylhydroxylamine[††]	4.60
Hydrogen peroxide	11.65		*N,N*-DiMe-hydroxylamine[††]	5.20
Hydrogen sulfide[*]	7.05, 14.0		Trimethylhydroxylamine[††]	3.65
Hypophosphorous	1.23		Cyanamide ($H_2NC{\equiv}N$)*	-0.34, 10.27
Iodic	0.80		Phosphine	-14
Nitric	-1.44		Iron (Fe^{2+})	6.74
Nitrous[*]	3.20		Iron (Fe^{3+})	2.46
Perchloric	< 1.0		Lead (Pb^{2+})	8
Phosphoric	2.15, 7.20, 12.38		Lithium	13.82
			Magnesium	11.42
Phosphorous	1.43, 6.67		Mercury (Hg^{+})	5.0
Pyrophosphoric	1.53, 2.36, 6.60, 9.25		Mercury (Hg^{2+})	3.49
			Nickel	9.86
Silicic	9.77		Palladium (Pd^{2+})	1
Selenic acid	1.99		Potassium	16
Selenous acid	2.62, 8.32		Silver	>11
Sulfamic	0.99		Sodium	14.77
Sulfuric	-3, 1.96		Thallium (Tl^{+})	13.2
Deuterosulfuric	2.33		Thallium (Tl^{3+})	1.16
Sulfurous	1.89, 7.21		Tin (Sn^{2+})	1.70
Thiocyanic (HCNS)	-1.83		Zinc	8.96

[*]At 20°, [#]at 30°, [†] Not strictly inorganic but a derivative of hydrazine, and [††] Not strictly inorganic but a derivative of hydroxylamine.

The Ostwald coefficient (*l*)/L is for ml of gas in 1L of solution, and (*l*) is for ml of gas in 1ml of solution. Adapted from W.F. Linke, *A. Seidell's Solubilities of Inorganic and Metal-organic Compounds*, American Chemical Society, 1965.

TABLE 29. SOLUBILITIES OF HCl AND NH_3 AT 760mm (g/100g OF SOLUTION)

Gas	Temperature °C	MeOH	EtOH	Et_2O
Hydrogen Chloride*	-10	54.6	—	37.5 (-9.2°)
	0	51.3	45.4	35.6
	20	47.0 (18°)	41.0	24.9
	30	43.0	38.1	19.47
Ammonia	15	21.6 (27.6g/100g MeOH)	13.2 (9.2g/100ml soln)	—
	25	16.5 (19.8g/100g MeOH)	10.0 (6.0g/100ml soln)	—

* Saturated EtOH with HCl is ~ 5.7M at 25°C, i.e. 21.5g/100ml of solution.

TABLE 30. BOILING POINTS OF SOME USEFUL GASES AT 760 mm

Argon	-185.6°	Krypton	-152.3°
Carbon dioxide (sublimes)	-78.5°	Methane	-164.0°
		Neon	-246.0°
Carbon monoxide	-191.3°	Nitrogen	-209.9°
Ethane	-88.6°	Nitrous oxide	-88.5°
Helium	-268.6°	Nitric oxide	-195.8°
Hydrogen	-252.6°	Oxygen	-182.96°

TABLE 31. PREFIXES FOR QUANTITIES

Fractional	deci (d) = 10^{-1}	centi (c) = 10^{-2}	milli (m) = 10^{-3}	micro (μ) = 10^{-6}	nano (n) = 10^{-9}	pico (p) = 10^{-12}	femto (f) = 10^{-15}	atto (atto) = 10^{-18}
Multiple	deca (d) = 10^{1}	hecto (h) = 10^{2}	kilo (k) = 10^{3}	mega (M) = 10^{6}	giga (G) = 10^{9}	tera (T) = 10^{12}	penta (P) = 10^{15}	eka (E) = 10^{18}

BIBLIOGRAPHY

The following books and reviews provide fuller details of the topics indicated in this chapter. CHAPTER 2

CHEMICAL METHODS USED IN PURIFICATION

GENERAL REMARKS

Greater selectivity in purification can often be achieved by making use of differences in chemical properties between the substance to be purified and the contaminants. Unwanted metal ions may be removed by precipitation in the presence of a *collector* (see below). Sodium borohydride and other metal hydrides transform organic peroxides and carbonyl-containing impurities such as aldehydes and ketones in alcohols and ethers. Many classes of organic chemicals can be purified by conversion into suitable salts or derivatives, followed by regeneration. This chapter describes some relevant procedures.

REMOVAL OF TRACES OF METALS FROM REAGENTS

METAL IMPURITIES

The presence of metal contaminants in reagents may sometimes affect the chemical or biochemical outcomes of an experiment. In these cases, it is necessary to purify the reagents used. Metal (and other) impurities can be determined qualitatively and quantitatively by atomic absorption spectroscopy (AAA), x-ray photoelectron spectroscopy (XPS), various mass spectrometric methods and/or inductively coupled plasma mass spectrometry (ICP-MS) (see Chapter 1, Question of Purity) and the required purification procedures can be formulated. Metal impurities in organic compounds are usually in the form of ionic salts or complexes with organic compounds and very rarely in the form of free metal. If they are present in the latter form then they can be removed by crystallising the organic compound (whereby the insoluble metal can be removed by filtration), or by distillation in which case the metal remains behind with the residue in the distilling flask. If the impurities are in the ionic or complex forms, then extraction of the organic compound in a suitable organic solvent with aqueous acidic or alkaline solutions will reduce their concentration to acceptable levels.

When the metal impurities are present in inorganic compounds as in metals or metal salts, then advantage of the differences in chemical properties should be taken. Properties of the impurities like the solubility, the solubility product (product of the metal ion and the counter-ion concentrations), the stability constants of the metal complexes with organic complexing agents and their solubilities in organic solvents should be considered. *Alternatively*, the impurities can be masked by the addition of complexing agents which could lower the concentration of the metal ion impurities to such low levels that they would not interfere with the properties of main compound (see **complexation** below). Specific procedures and examples are provided below.

DISTILLATION

Reagents such as water, ammonia, hydrochloric acid, nitric acid, perchloric acid, and sulfuric acid can be purified *via* distillation (preferably under reduced pressure and particularly with perchloric acid) using an all-glass still. Isothermal distillation is convenient for ammonia: a beaker containing concentrated ammonia is placed alongside a beaker of distilled water for several days in an empty desiccator so that some of the ammonia distils over into the water. The redistilled ammonia should be kept in polyethylene or paraffin-waxed bottles. Hydrochloric acid can be purified in the same way. To ensure the absence of metal contaminants from some salts (e.g. ammonium acetate), it may be more expedient to synthesise the salts using distilled components rather than to attempt to purify the salts themselves.

Purification of Laboratory Chemicals.

SCAVENGER RESINS AND OTHER SUPPORTS

There is now available an extensive range of supported reactants for high throughput screening that use specific resins, silica, carbons etc, to clean up reactions prior to final purification in the laboratory. Some are specifically electrophilic resins, i.e. to derivatise specific types of compounds, e.g. aldehyde and isocyanate bound resins for removing unwanted hydrazines, aliphatic and aromatic amines; toluenesulfonyl chloride bound resins for removing OH and NH containing impurities. Nucleophilic scavenger resins such as diethylenetriamine bound resins scavenge acids, acid chlorides and anhydrides; sulfonamide bound resins react with acids, acid chlorides, aldehydes, isocyanates and chloroformate impurities have been used. [Varma et al. *Comb Chem High Throughput Screening* **11** 238 *2008*, DOI: 10.2174/138620708783877753.] Adsorbents such as Florisil, high purity silica coated with specific reagents, e.g. 2,4-dinitrophenylhydrazine, and various charcoals have been used in cartridges prior to purification through desired FPLC and HPLC columns. (cf Biotage, Supelco and Sigma-Aldrich catalogues.

USE OF ION-EXCHANGE RESINS

Application of ion-exchange columns has greatly facilitated the removal of heavy metal ions such as Cu^{2+}, Zn^{2+} and Pb^{2+} from aqueous solutions of many reagents. Thus, sodium salts and sodium hydroxide can be purified by passage through a column of a cation-exchange resin in its sodium form, prepared by washing the resin with 0.1M aqueous NaOH then washing with water until the pH of the effluent is ~7. Similarly, for acids, a resin in its H^+ form [prepared by washing the column with 0.1M aqueous mineral acid (HCl, H_2SO_4) followed by thorough washing with water until the effluent has pH ~7 is used]. In some cases, where metals form anionic complexes, they can be removed by passage through an anion-exchange resin. Iron in hydrochloric acid solution can be removed in this way.

Ion-exchange resins are also useful for demineralising biochemical preparations such as proteins. Removal of metal ions from protein solutions using polystyrene-based resins, however, may lead to protein denaturation. This difficulty may be avoided by using a weakly acidic cation exchanger such as Bio-Rex 70.

Heavy metal contamination of pH buffers can be removed by passage of the solutions through a Chelex X-100 column. For example when a solution of 0.02M HEPES [4-(2-hydroxyethyl)piperazine-1-ethanesulfonic acid] containing 0.2M KCl (1L, pH 7.5) alone or with *calmodulin*, is passed through a column of Chelex X-100 (~60g) in the K^+ form, the level of Ca^{2+} ions falls to less than 2×10^{-7} M as shown by atomic absorption spectroscopy. Such solutions should be stored in polyethylene containers that have been washed with boiling deionised water (5 minutes) and rinsed several times with deionised water. TES [*N*,*N*,*N'*,*N'*-Tetraethylsulfamide] and TRIS [Tris-(hydroxymethyl)aminomethane] have been similarly decontaminated from metal ions.

Water, with very low concentrations of ionic impurities (and approaching conductivity standards), is very readily obtained by percolation through alternate columns of cation- and anion- exchange resins, or through a mixed-bed resin, and many commercial devices are available for this purpose. For some applications, this method is unsatisfactory because the final deionised water may contain traces of organic material after passage through the columns. However, organic matter can be removed by using yet another special column in series for this purpose (see Water Purification Systems-Pure and Ultrapure in <www.millipore.com>).

PRECIPITATION

In removing traces of impurities by precipitation, it is necessary to include a material to act as a *collector* of the precipitated substance so as to facilitate its removal by filtration or decantation. The following are a few examples:

Removal of lead contaminants

Aqueous hydrofluoric acid can be freed from lead by adding 1ml of 10% strontium chloride per 100ml of acid, lead being co-precipitated as lead fluoride with the strontium fluoride. If the hydrofluoric acid is decanted from the precipitate and the process repeated, the final lead content in the acid is less than 0.003ppm. Similarly, lead can be precipitated from a nearly saturated sodium carbonate solution by adding 10% strontium chloride dropwise (1-2ml per 100ml) followed by filtration. (If the sodium carbonate is required as a solid, the solution can be evaporated to dryness in a platinum dish.) Removal of lead from potassium chloride uses precipitation as lead sulfide by bubbling H_2S, followed, after filtration, by evaporation and recrystallisation of the potassium chloride.

Removal of iron contaminants

Iron contaminants have been removed from potassium thiocyanate solutions by adding a slight excess of an

aluminium salt, then precipitating aluminum and iron as their hydroxides by adding a few drops of ammonia. Iron is also carried down on the hydrated manganese dioxide precipitate formed in cadmium chloride or cadmium sulfate solutions by adding 0.5% aqueous potassium permanganate (0.5ml / 100ml of solution), sufficient aqueous ammonia to give a slight precipitate, and 1ml of ethanol. The solution is heated to boiling to coagulate the precipitate, then filtered. Ferrous ion can be removed from copper solutions by adding some hydrogen peroxide to the solution to oxidise the iron, followed by precipitation of ferric hydroxide by adding a small amount of sodium hydroxide.

Removal of other metal contaminants

Traces of calcium can be removed from solutions of sodium salts by precipitation at pH 9.5-10 as the 8-hydroxyquinolinate. The excess 8-hydroxyquinoline acts as a *collector* and is extracted out with an organic solvent.

EXTRACTION

In some cases, a simple solvent extraction is sufficient to remove a particular impurity. For example, traces of gallium can be removed from titanous chloride in hydrochloric acid by extraction with diisopropyl ether. Similarly, ferric chloride can be removed from aluminium chloride solutions containing hydrochloric acid by extraction with diethyl ether. Usually, however, it is necessary to extract an undesired metal with an organic solvent in the presence of a suitable complexing agent such as dithizone (diphenylthiocarbazone) or sodium diethyl dithiocarbamate. When the former is used, weakly alkaline solutions of the substance containing the metal impurity are extracted with dithizone into chloroform (at about 25mg/L of chloroform) or carbon tetrachloride until the colour of some fresh dithizone solution remains unchanged after shaking. Dithizone complexes metals more strongly in weakly alkaline solutions. Excess dithizone in the aqueous medium is removed by extracting with the pure solvent (chloroform or carbon tetrachloride), the last traces of which, in turn, are removed by aeration. This method has been used to remove metal impurities from aqueous solutions of ammonium hydrogen citrate, potassium bromide, potassium cyanide, sodium acetate and sodium citrate. The advantage of dithizone for such a purpose lies in the wide range of metals with which it combines under these conditions. 8-Hydroxyquinoline (oxine) can also be used in this way. Sodium diethyl dithiocarbamate has been used to remove metals from aqueous hydroxylamine hydrochloride (made just alkaline to thymol blue by adding ammonia) from copper and other heavy metals by repeated extraction with chloroform until no more diethyl dithiocarbamate remained in the solution (which was then acidified to thymol blue by adding hydrochloric acid).

COMPLEXATION

Although not strictly a removal of an impurity, addition of a suitable complexing agent such as ethylenediaminetetraacetic acid often overcomes the undesirable effects of contaminating metal ions by reducing the concentrations of the free metal species to very low levels, i.e. *sequestering* metal ions by complexation. For a detailed discussion of this *masking*, see *Masking and Demasking of Chemical Reactions*, D.D.Perrin, Wiley-Interscience, New York, *1970*, ISBN 10: 0471680710 ISBN 13: 9780471680710.

USE OF METAL HYDRIDES

This group of reagents is commercially available in large quantities; some of its members-notably lithium aluminium hydride ($LiAlH_4$), calcium hydride (CaH_2), sodium borohydride ($NaBH_4$) and potassium borohydride (KBH_4) have found widespread use in the purification of chemicals.

LITHIUM ALUMINIUM HYDRIDE

This solid is stable at room temperature and is soluble in ether-type solvents. It reacts violently with water, liberating hydrogen, and is a powerful drying and reducing agent for organic compounds. It reduces aldehydes, ketones, esters, carboxylic acids, peroxides, acid anhydrides and acid chlorides to the corresponding alcohols. Similarly, amides, nitriles, aldimines and aliphatic nitro compounds yield amines, while aromatic nitro compounds are converted to azo compounds. For this reason it finds extensive application in purifying organic chemical substances by the removal of water and carbonyl containing impurities as well as peroxides formed by autoxidation. Reactions can generally be carried out at room temperature, or in refluxing diethyl ether, at

atmospheric pressure. *When drying organic liquids with this reagent it is important that the concentration of water in the liquid is below 0.1% - otherwise a violent reaction or* **EXPLOSION** *may occur. $LiAlH_4$ should be added cautiously to a cooled solution of organic liquid in a flask equipped with a reflux condenser.*

CALCIUM HYDRIDE

This powerful drying agent is suitable for use with hydrogen, argon, helium, nitrogen, hydrocarbons, chlorinated hydrocarbons, esters and higher alcohols.

SODIUM BOROHYDRIDE

This solid, which is stable in dry air up to 300°, is a less powerful reducing agent than lithium aluminium hydride, from which it differs also by being soluble in hydroxylic solvents and to a lesser extent in ether-type solvents. Sodium borohydride forms a dihydrate melting at 36-37°, and its aqueous solutions decompose slowly unless stabilised to above pH 9 by alkali. (For example, a useful sodium borohydride solution is one that is nearly saturated at 30-40° and containing 0.2% sodium hydroxide.) Its solubility in water is 25, 55 and 88g per 100ml of water at 0°, 25° and 60°, respectively. Boiling or acidification rapidly decomposes aqueous sodium borohydride solutions. The reagent, available either as a hygroscopic solid or as an aqueous sodium hydroxide solution, is useful as a water soluble reducing agent for aldehydes, ketones and organic peroxides. This explains its use for the removal of carbonyl-containing impurities and peroxides from alcohols, polyols, esters, polyesters, amino alcohols, olefins, chlorinated hydrocarbons, ethers, polyethers, amines (including aniline), polyamines and aliphatic sulfonates.

Purifications using sodium borohydride can be carried out conveniently using alkaline aqueous or methanolic solutions of sodium borohydride, allowing the reaction mixture to stand at room temperature for several hours. Other solvents that can be used with this reagent include isopropyl alcohol (without alkali), amines (including liquid ammonia, in which its solubility is 104g per 100g of ammonia at 25°, and ethylene diamine), diglyme, formamide, dimethylformamide and tetrahydrofurfuryl alcohol. *Alternatively*, the material to be purified can be percolated through a column of the borohydride. In the absence of water, sodium borohydride solutions in organic solvents such as dioxane or amines decompose only very slowly at room temperature. Treatment of ethers with sodium borohydride appears to inhibit peroxide formation.

POTASSIUM BOROHYDRIDE

Potassium borohydride is similar in properties and reactions to sodium borohydride, and can similarly be used as a reducing agent for removing aldehydes, ketones and organic peroxides. It is non-hygroscopic and can be used in water, ethanol, methanol or water-alcohol mixtures, provided some alkali is added to minimise decomposition, but it is somewhat *less soluble* than sodium borohydride in most solvents. For example, the solubility of potassium borohydride in water at 25° is 19g per 100ml of water, as compared to 55g of sodium borohydride.

PURIFICATION *via* DERIVATIVES

Relatively few derivatives of organic substances are suitable for use as aids to purification. This is because of the difficulty in regenerating the starting material. For this reason, we list below the common methods of preparation of derivatives that can be used in this way.

Whether or not any of these derivatives is likely to be satisfactory for use in any particular case will depend on the degree of difference in properties, such as solubility, volatility or melting point, between the starting material, its derivative and likely impurities, as well as on the ease with which the substance can be recovered. Purification *via* a derivative is likely to be of most use when the quantity of pure material that is required is not too large. Where large quantities (for example, more than 50g) are available, it is usually more economical to purify the material directly (for example, in distillations and recrystallisations).

The most generally useful purifications *via* derivatives are as follows:

ALCOHOLS

Aliphatic or aromatic alcohols are converted into solid esters. 4-Nitrobenzoates are examples of convenient esters to form because of their sharp melting points, and the ease with which they can be crystallised as well as the ease

with which the parent alcohol can be recovered. The *p*-nitrobenzoyl chloride used in the esterification is prepared freshly by refluxing dry *p*-nitrobenzoic acid with a 3 molar excess of thionyl chloride for 30 minutes on a steam bath (*in a fume cupboard*). The solution is cooled slightly and excess thionyl chloride is distilled off under vacuum, keeping the temperature below 40°. Dry toluene is added to the residue in the flask, then distilled off in a vacuum, the process being repeated two or three times to ensure complete removal of thionyl chloride, hydrogen chloride and sulfur dioxide. (This freshly prepared *p*-nitrobenzoyl chloride cannot be stored without decomposition; it should be used directly.) A solution of the acid chloride (1mol) in dry toluene or alcohol-free chloroform (distilled from P_2O_5 or by passage through an activated Al_2O_3 column) under a reflux condenser is cooled in an ice bath while the alcohol (1mol), with or without a solvent (preferably miscible with toluene or alcohol-free chloroform), is added dropwise to it. When addition is over and the reaction subsides, the mixture is refluxed for 30 minutes and the solvent is removed under reduced pressure. The solid ester is then recrystallised to constant melting point from toluene, acetone, low boiling point petroleum ether or mixtures of these, but not from alcohols (due to unwanted trans-esterifiction).

Hydrolysis of the ester is achieved by refluxing in aqueous N or 2N NaOH solution until the insoluble ester dissolves. The solution is then cooled, and the alcohol is extracted into a suitable solvent, e.g. ether, toluene or alcohol-free chloroform. The extract is dried ($CaSO_4$, $MgSO_4$) and distilled, then fractionally distilled if liquid or recrystallised if solid. (The *p*-nitrobenzoic acid can be recovered by acidification of the aqueous layer.) In most cases where the alcohol to be purified can be readily extracted from ethanol, the hydrolysis of the ester is best achieved with N or 2N ethanolic NaOH or 85% aqueous ethanolic N NaOH. The former is prepared by dissolving the necessary alkali in a minimum volume of water and diluting with absolute alcohol. The ethanolic solution is refluxed for one to two hours and hydrolysis is complete when an aliquot gives a clear solution on dilution with four or five times its volume of water. The bulk of the ethanol is distilled off and the residue is extracted as above. *Alternatively*, use can be made of ester formation with benzoic acid, toluic acid or 3,5-dinitrobenzoic acid, by the above method.

Other derivatives can be prepared by reaction of the alcohol with an acid anhydride. For example, phthalic or 3-nitrophthalic anhydride (1 mol) and the alcohol (1mol) are refluxed for half to one hour in a non-hydroxylic solvent, e.g. toluene or alcohol-free chloroform, and then cooled. The phthalate ester crystallises out, is precipitated by the addition of low boiling petroleum ether or is isolated by evaporation of the solvent. It is recrystallised from water, 50% aqueous ethanol, toluene or low boiling petroleum ether. Such an ester has a characteristic melting point and the alcohol can be recovered by acid or alkaline hydrolysis.

ALDEHYDES

The best derivative from which an aldehyde can be recovered readily is its *bisulfite addition compound*, the main disadvantage being the lack of a sharp melting point. The aldehyde (sometimes in ethanol) is shaken with a cold saturated solution of sodium bisulfite (evolution of heat) until no more solid adduct separates. The adduct is filtered off, washed with a little water, followed by alcohol. A better reagent to use is a freshly prepared saturated aqueous sodium bisulfite solution to which 75% ethanol is added to near-saturation. (Water may have to be added dropwise to render this solution clear.) With this reagent the aldehyde need not be dissolved separately in alcohol and the adduct is finally washed with alcohol. The aldehyde is recovered by dissolving the adduct in the least volume of water and adding an equivalent quantity of sodium carbonate (not sodium hydroxide) or concentrated hydrochloric acid to react with the bisulfite (SO_2 is liberated), followed by steam distillation or solvent extraction.

Other derivatives that can be prepared are the *Schiff bases* and semicarbazones. Condensation of the aldehyde with an equivalent of primary aromatic amine yields the Schiff base, for example aniline at 100° for 10-30 minutes. *Semicarbazones* are prepared by dissolving semicarbazide hydrochloride (*ca* 1g) and sodium acetate (*ca* 1.5g) in water (8-10ml) and adding the aldehyde or ketone (0.5-1g) with stirring. The semicarbazone crystallises out and is recrystallised from ethanol or aqueous ethanol. These are hydrolysed by steam distillation in the presence of oxalic acid or better by exchange with pyruvic acid [Hershberg *J Org Chem* **13** 542 *1948*, DOI: 10.1021/jo01162a011] [see also entry under Ketones].

AMINES

Salts

Amines can also be purified *via* their salts, e.g. hydrochlorides. A solution of the amine in dry toluene, diethyl ether, dichloromethane or chloroform is saturated with dry hydrogen chloride (generated by addition of concentrated sulfuric acid to dry sodium chloride, or to concentrated HCl followed by drying the gas through sulfuric acid, or the HCl gas is obtained from a hydrogen chloride cylinder) and the insoluble hydrochloride is

filtered off and dissolved in water. The solution is made alkaline and the amine is extracted, as above. Hydrochlorides can also be prepared by dissolving the amine in ethanolic HCl and adding diethyl ether. Where hydrochlorides are too hygroscopic or too soluble for satisfactory isolation, other salts, e.g. nitrate, sulfate, bisulfate or oxalate, can be used.

Double salts

The amine (1mol) is added to a solution of anhydrous zinc chloride (1mol) in concentrated HCl (42ml) in ethanol (200ml, or less depending on the solubility of the double salt). The solution is stirred for 1 hour and the precipitated salt is filtered off and recrystallised from ethanol. The free base is recovered by adding excess of 5-10N NaOH (to dissolve the zinc hydroxide that separates) and is steam distilled. Mercuric chloride (highly poisonous) in hot water can be used instead of zinc chloride and the salt is crystallised from 1% hydrochloric acid. Other double salts have been used, e.g. cuprous salts, but are not as convenient as the above salts.

Bis-(arylsulfonyl)imine salts

Bis-alkyl and aryl sulfonylimines [RSO_2NHSO_2R'], which are readily prepared, are acidic and form stable sodium or potassium salts that can be recrystallised. The bis-phenyl and bis-4-chlorophenyl derivatives form salts readily *via* their Na salts [**m** 314-316º (327-329º) and 278-280º (286-287º) respectively and crystallise as colourless needles from H_2O] with a large variety of amines, including some amino acids, basic drugs and natural bases, which can be readily recrystallised for characterisation and for purification. The *free* bases can be readily released on addition of alkali and isolated. [See 'Miscellaneous As, B, P, ….' section in Chapter 3, and Runge et al. *Chem Ber* **88** 533 *1955*, DOI: 10.1002/cber.19550880414; Runge et al. *Chem Ber* **86** 1571 *1953*, DOI: 10.1002/cber.19530861216; Runge & Pfeiffer *Chem Ber* **90** 1757 *1957*, DOI: 10.1002/cber.19570900910; Helferich & Grünert *Chem Ber* **73** 1131 *1940*, DOI: 10.1002/cber.19400731019.]

Picrates

The most versatile derivative from which the free base can be readily recovered is the picrate. This is very satisfactory for primary and secondary aliphatic amines and aromatic amines and is particularly so for heterocyclic bases. The amine, dissolved in water or alcohol, is treated with excess of a saturated solution of picric acid in water or alcohol, respectively, until separation of the picrate is complete. If separation does not occur, the solution is stirred vigorously and warmed for a few minutes, or diluted with a solvent in which the picrate is insoluble. Thus, solutions of the amine and picric acid in ethanol can be treated with petroleum ether to crystallise out the picrate salt. *Alternatively*, the amine can be dissolved in alcohol and aqueous picric acid added. The picrate is filtered off, washed with water or ethanol and recrystallised from boiling water, ethanol, methanol, aqueous ethanol, methanol or chloroform. The solubility of picric acid at ~20° in water and ethanol is about 1.4 and 6.23%

respectively.
It is not advisable to store large quantities of picrates for long periods, *particularly when they are dry due to their potential* **EXPLOSIVE** *nature*. Also this method is not advised when large quantities of amines (e.g. >25g) are to be purified. The free base should be recovered as soon as possible. The picrate is suspended in an excess of 2N aqueous NaOH and warmed a little. Because of the limited solubility of sodium picrate, excess hot water must be added. *Alternatively*, because of the greater solubility of lithium picrate, aqueous 10% lithium hydroxide solution can be used. The solution is cooled, the amine is extracted with a suitable solvent such as diethyl ether or toluene, washed with 5N NaOH until the alkaline solution remains colourless, then with water, and the extract is dried with anhydrous sodium carbonate. The solvent is distilled off and the amine is fractionally distilled (under reduced pressure if necessary) or recrystallised.
If the amines are required as their hydrochlorides, picrates can often be decomposed by suspending them in acetone and adding two equivalents of 10N HCl. The hydrochloride of the base is filtered off, leaving the picric acid in the acetone. Dowex No 1 anion-exchange resin in the chloride form is useful for changing solutions of the more soluble picrates (for example, of adenosine) into solutions of their hydrochlorides, from which sodium hydroxide precipitates the free base.

N-Acetyl derivatives

Purification as their *N*-acetyl derivatives is satisfactory for primary, and to a limited extent, secondary amines. Tertiary amines are not acetylated. The base is refluxed with slightly more than one equivalent of acetic anhydride for half to one hour, cooled and poured into ice-cold water. The insoluble derivative is filtered off, dried, and recrystallised from water, ethanol, aqueous ethanol or benzene (CAUTION **toxic**!). The derivative can be hydrolysed to the parent amine by refluxing with 70% sulfuric acid for a half to one hour. The solution is cooled, poured onto ice, and made alkaline. The amine is steam distilled or extracted as above. Alkaline hydrolysis is very slow.

N-Tosyl derivatives

Primary and secondary amines are converted into their tosyl derivatives by mixing equimolar amounts of amine and *p*-toluenesulfonyl chloride in dry pyridine (*ca* 5-10mols) and allowing to stand at room temperature overnight. The solution is poured into ice-water and the pH adjusted to 2 with HCl. The solid derivative is filtered off, washed with water, dried (vacuum desiccator) and recrystallised from an alcohol or aqueous alcohol solution to a sharp melting point. The derivative is decomposed by dissolving in liquid ammonia (*fume cupboard*) and adding sodium metal (in small pieces with stirring) until the blue colour persists for 10-15minutes. Ammonia is allowed to evaporate (*fume cupboard*), the residue treated with water and the solution checked that the pH is above 10. If the pH is below 10, then the solution has to be basified with 2N NaOH. The mixture is extracted with diethyl ether or toluene, the extract is dried (K_2CO_3), evaporated and the residual amine recrystallised if solid or distilled if liquid.

AROMATIC HYDROCARBONS

Adducts

Aromatic hydrocarbons can be purified as their picrates using the procedures described for amines. Instead of picric acid, 1,3,5-trinitrobenzene or 2,4,7-trinitrofluorenone can also be used. In all these cases, following recrystallisation, the hydrocarbon can be isolated either as described for amines or by passing a solution of the adduct through an activated alumina column and eluting with toluene or petroleum ether. The picric acid and nitro compounds are more strongly adsorbed on the column.

Sulfonation

Naphthalene, xylenes and alkyl benzenes can be purified by sulfonation with concentrated sulfuric acid and crystallisation of the sodium sulfonates. The hydrocarbon is distilled out of the mixture with superheated steam.

CARBOXYLIC ACIDS

4-Bromophenacyl esters

A solution of the sodium salt of the acid is prepared. If the salt is not available, the acid is dissolved in an equivalent of aqueous NaOH and the pH adjusted to 8-9 with this base. A solution of one equivalent of 4-bromophenacyl bromide (for a monobasic acid, two equivalents for a dibasic acid, etc) in ten times its volume of ethanol is then added. The mixture is heated to boiling, and, if necessary, enough ethanol is added to clarify the solution which is then refluxed for half an hour to three hours depending on the number of carboxylic groups that have to be esterified. (One hour is generally sufficient for monocarboxylic acids.) On cooling, the ester should crystallise out. If it does not, then the solution is heated to boiling, and enough water is added to produce a slight

turbidity. The solution is again cooled. The ester is collected, and recrystallised or fractionally distilled.
The ester is hydrolysed by refluxing for 1-2 hours with 1-5% of barium carbonate suspended in water or with aqueous sodium carbonate solution. The solution is cooled and extracted with diethyl ether, toluene or chloroform. It is then acidified and the acid is collected by filtration or extraction, and recrystallised or fractionally distilled. 4-Bromophenylphenacyl esters are used similarly.
p-Nitrobenzyl esters can be prepared in an analogous manner using the sodium salt of the acid and *p*-nitrobenzyl bromide. They are readily hydrolysed.

Alkyl esters

Of the alkyl esters, methyl esters are the most useful because of their rapid hydrolysis. The acid is refluxed with one or two equivalents of methanol in excess alcohol-free chloroform (or dichloromethane) containing about 0.1g of *p*-toluenesulfonic acid (as catalyst), using a Dean-Stark apparatus. (The water formed by the esterification is carried away into the trap.) When the theoretical amount of water is collected in the trap, esterification is complete. The chloroform solution in the flask is washed with 5% aqueous sodium carbonate solution, then water, and dried over anhydrous sodium sulfate or magnesium sulfate. The chloroform is distilled off and the ester is fractionally distilled through an efficient column, or recrystallised if it is a solid. The ester is hydrolysed by refluxing with 5-10% aqueous NaOH solution until the insoluble ester has completely dissolved. The aqueous solution is concentrated a little by distillation to remove almost all of the methanol. It is then cooled and acidified. The acid is either extracted with diethyl ether, toluene or chloroform, or filtered off and isolated as above. Other methods for preparing esters are available, e.g. addition of an ethereal solution of diazomethane (yellow in colour, poisonous, use a fume cupboard. CARE: Use diazomethane with extreme care as the reagent is POISONOUS and HIGHLY explosive; special precautions MUST be used; see *Fieser and Fieser's Reagents for Organic Synthesis* **1** pp191-195 *1967*, abbreviated to 'Fieser' in the text of following chapters) to the acid which dissolves as the acid is esterified, liberating N_2 and the yellow colour. The methyl ester so produced is obtained by evaporating the ethereal solution.

Salts (S-Arylisothiuronium)

The most useful salt derivatives for carboxylic, sulfonic and phosphorus acids are the isothiuronium salts. These are prepared by mixing almost saturated solutions containing the acid (carefully neutralised with N NaOH using phenolphthalein indicator) then adding two drops of N HCl and an equimolar amount of *S*-benzylisothiuronium chloride (Table 6), or its 4-chloro derivative (Table 7 and 8) in ethanol and filtering off the salt that crystallises out, and recrystallising to analytical purity (see Tables below). After recrystallisation from water, alcohol or aqueous alcohol the salt is decomposed by suspending or dissolving in 2N HCl and extracting the carboxylic acid from aqueous solution into diethyl ether, chloroform or toluene. *Alternatively*, the free acids can be obtained by passing a ~50% aqueous alcoholic solution through a Dowex 50W x8 resin previously washed with ~50% aqueous achohol, evaporating to a small volume and extraction into Et_2O (or similar solvent) from which the acid is isolated. [For preparations see 'Miscellaneous As, B, P, ….' in Chapter 3; Donleavy *J Am Chem Soc* **58** 1004 *1936*, DOI: 10.1021/ja01297a048; and for 4-chlorobenzylisothiuronium salts see Dewey and Sperry *J Am Chem Soc* **61** 3251 *1939*, DOI: 10.1021/ ja01267a005; Harvey & Jensen *J Org Chem* **28** 470 *1963*, DOI: 10.1021/ jo01037a047].

one week, the lower melting crystals remained unchanged, but the higher melting crystals now melted at the same temperature as the lower melting form. Both forms of crystals give the same derivatives with acids. In the case of phosphorus esters the thiuronium (complexes ?) are prepared differently, i.e. the phosphate ester in EtOH is refluxed for 24hrs with an ethanolic solution of EtSNa (from a mixture of Na and EtSH in EtOH), followed by addition of a saturated solution of an equivalent of S-4-chlorobenzylisothiuronium chloride. The precipitated NaCl is filtered off, the filtrate is evaporated to dryness and the residue is recrystallised from the appropriate solvent (see Table 8).

HYDROPEROXIDES

These can be converted to their sodium salts by precipitation below 30° with aqueous 25% NaOH. The salt is then decomposed by addition of solid (powdered) carbon dioxide and extracted with low-boiling petroleum ether. The solvent should be removed under reduced pressure below 20°. **The manipulation should be adequately shielded at all times to guard against EXPLOSIONS for the safety of the operator.**

KETONES

Bisulfite adduct

The adduct can be prepared and decomposed as described for aldehydes. *Alternatively*, because no Cannizzaro reaction is possible, it can also be decomposed with 0.5N NaOH.

Semicarbazones

A powdered mixture of semicarbazide hydrochloride (1mol) and anhydrous sodium acetate (1.3mol) is dissolved in water by gentle warming. A solution of the ketone (1mol) in the minimum volume of ethanol needed to dissolve it is then added. The mixture is warmed on a water bath until separation of the semicarbazone is complete. The solution is cooled, and the solid is filtered off. After washing with a little ethanol followed by water, it is recrystallised from ethanol or dilute aqueous ethanol. The derivative should have a characteristic melting point. The semicarbazone is decomposed by refluxing with excess of oxalic acid or with aqueous sodium carbonate solution. The ketone (which steam distils) is distilled off. It is extracted or separated from the distillate (after saturating with NaCl), dried with $CaSO_4$ or $MgSO_4$ and fractionally distilled using an efficient column (under vacuum if necessary). [See entry under Aldehydes.]

PHENOLS

The most satisfactory derivatives for phenols that are of low molecular weight or monohydric are the benzoate esters. (Their acetate esters are generally liquids or low-melting solids.) Acetates are more useful for high molecular weight and polyhydric phenols.

Benzoates

The phenol (1mol) in 5% aqueous NaOH is treated (while cooling) with benzoyl chloride (1mol) and the mixture is stirred in an ice bath until separation of the solid benzoyl derivative is complete. The derivative is filtered off, washed with alkali, then water, and dried (in a vacuum desiccator over NaOH). It is recrystallised from ethanol or dilute aqueous ethanol. The benzoylation can also be carried out in dry pyridine at low temperature (*ca* 0°) instead of in NaOH solution, finally pouring the mixture into water and collecting the solid as above. The ester is hydrolysed by refluxing in an alcohol (for example, ethanol, *n*-butanol) containing two or three equivalents of the alkoxide of the corresponding alcohol (for example, sodium ethoxide or sodium *n*-butoxide) and a few (*ca* 5-10) millilitres of water, for half an hour to three hours. When hydrolysis is complete, an aliquot will remain clear on dilution with four to five times its volume of water. Most of the solvent is distilled off. The residue is diluted with cold water and acidified, and the phenol is steam distilled. The latter is collected from the distillate, dried and either fractionally distilled or recrystallised. It can also be isolated by extraction from a slightly acidified (pH ~3) aqueous solution with diethyl ether.

Acetates

These can be prepared as for the benzoates using either acetic anhydride with 3N NaOH or acetyl chloride in pyridine. They are hydrolysed as described for the benzoates. This hydrolysis can also be carried out with aqueous 10% NaOH solution, completion of hydrolysis being indicated by the complete dissolution of the acetate in the aqueous alkaline solution. On steam distillation, acetic acid also distils off, but in these cases the phenols (see above) are invariably solids which can be filtered off and recrystallised.

PHOSPHATE AND PHOSPHONATE ESTERS

These can be converted to their uranyl nitrate addition compounds. The crude or partially purified ester is saturated with uranyl nitrate solution and the solid adduct is filtered off. It is recrystallised from *n*-hexane, toluene or ethanol. For the more soluble members crystallisation from hexane using low temperatures (-40°) has been successful. The adduct is decomposed by shaking with sodium carbonate solution and water, the solvent is steam distilled (if hexane or toluene is used) and the ester is collected by filtration. *Alternatively*, after decomposition, the organic layer is separated, dried with $CaCl_2$ or BaO, filtered, and fractionally distilled under high vacuum. See also characterisation and purification *via* their S-arylisothiuronium salts or complexes, Table 8.

MISCELLANEOUS

Impurities can sometimes be removed by conversion to derivatives under conditions where the major component does not react or reacts much more slowly. For example, normal (straight-chain) paraffins can be freed from unsaturated and branched-chain components by taking advantage of the greater reactivity of the latter with chlorosulfonic acid or bromine. Similarly, the preferential nitration of aromatic hydrocarbons can be used to remove e.g. benzene or toluene from cyclohexane by shaking for several hours with a mixture of concentrated nitric acid (25%), sulfuric acid (58%), and water (17%).

GENERAL METHODS FOR THE PURIFICATION OF CLASSES OF COMPOUNDS

Chapters 3-7 list a large number of individual compounds, with a brief statement of how each one may be purified. For substances that are not included in these chapters the following procedures may prove helpful.

PROCEDURES

If the laboratory worker does not know of a reference to the preparation of a commercially available substance, he/she may be able to make a reasonable guess at the synthetic methods used from published laboratory syntheses. In some cases brief syntheses are provided in this book. This information, in turn, can simplify the necessary purification steps by suggesting probable contaminants.

Physical methods of purification depend largely on the melting and boiling points of the materials. For gases and low-boiling liquids use is commonly made of the *freeze-pump-thaw* procedure. Gas chromatography is also useful, especially for low-boiling point liquids. Liquids are usually purified by refluxing with drying agents, acids or bases, reducing agents, charcoal, etc., followed by fractional distillation under reduced pressure. For solids, general methods include fractional freezing of the melted material, taking the middle fraction. Another procedure is sublimation of the solid under reduced pressure. The other commonly used method for purifying solids is by recrystallisation from a solution in a suitable solvent, by cooling with or without the prior addition of a solvent in which the solute is not very soluble (see Chapter 1).

The nature of the procedure will depend to a large extent on the quantity of purified material that is required. For example, for small quantities (50-250mg) of a pure volatile liquid, preparative gas chromatography is probably the best method. Two passes through a suitable column may well be sufficient. Similarly, for smaller amounts (100-500mg) of an organic solid, column chromatography is likely to be satisfactory, the eluate being collected as a number of separate fractions (*ca* 5-10ml) which are examined by FT-IR, NMR or UV spectroscopy, TLC or by some other appropriate analytical technique. (For information on suitable adsorbents and eluents the texts referred to in the bibliography at the end of Chapters 1 and 2 should be consulted.) Preparative thin layer chromatography or HPLC, FC and HPFC can also be used successfully for purifying up to 500mg of solid. The latter chromatographic techniques (see Chapter 1) are more and more commonly used procedures for the purification of small molecules as well as large molecules such as polypeptides and DNA.

Where larger quantities (upwards of 1g) are required, most of the impurities should be removed by preliminary treatments, such as solvent extraction, liquid-liquid partition, or conversion to a derivative (*vide supra*) which can be purified by crystallisation or fractional distillation before being converted to the starting material. The substance is then crystallised or distilled. If the final amounts must be in excess of 25g, preparation of a derivative is sometimes omitted because of the cost involved. In all of the above cases, purification is likely to be more laborious if the impurity is an isomer or a derivative with closely similar physical properties.

CRITERIA OF PURITY

Purification becomes meaningful only insofar as adequate tests of purity are applied: the higher the degree of purity that is sought, the more stringent these tests must be. For this, the experimenter has to resort, in the first place, to preliminary physical methods such as melting and boiling points, chromatographic and spectroscopic procedures which are described in detail in Chapter 1. If the material is an organic solid, its melting point should first be taken and compared with the recorded value. *Note that the melting points of most salts, organic or inorganic, are generally decomposition points and are not reliable criteria of purity.* As part of the preliminary examination, the sample might be examined by thin layer chromatography in several different solvent systems and in high enough concentrations to facilitate the detection of minor components. On the other hand, if the substance is a liquid, its boiling point should be measured. If, further, the boiling point of the liquid is too high, or it

decomposes on heating, then its purity should be assessed by high pressure liquid chromatography. Those liquids that are especially volatile can be studied very satisfactorily by gas chromatography, preferably using at least two different stationary and/or mobile phases. Spectroscopic methods, if facilities are available, such as atomic absorption spectroscopy (AAA), and inductively coupled plasma mass spectrometry (ICP-MS) are useful and sensitive methods for detecting metal impurities and the concentrations of metals and metal salts or complexes.
Application of these tests at successive steps will give a good indication of whether or not the purification is satisfactory and will also show when adequate purification has been achieved. Finally elemental analyses, e.g. of carbon, hydrogen, nitrogen, sulfur, metals etc., are very sensitive to impurities (other than with isomers), and are good criteria of purity.
There are certain requirements for purity of new compounds in most journals. This is especially so for samples which are shown to have biological activity. See instructions to authors for ACS journals especially in *J. Med. Chem* (see 'Guidelines for Authors' under *Purity Criteria of Tested Compounds* < http://pubs.acs.org/journal/jmcmar >.)

GENERAL PROCEDURES FOR THE PURIFICATION OF SOME CLASSES OF ORGANIC COMPOUNDS

In the general methods of purification described below, it is assumed that the impurities belong essentially to a class of compounds different from the one being purified. They are suggested for use in cases where substances are not listed in Chapters 3, 4 and the low-molecular-weight compounds in Chapter 6. In such cases, the experimenter is advised to employ them in conjunction with information given in these chapters for the purification of suitable analogues. Also, for a wider range of drying agents and the use of cartridges (e.g. Na_2SO_4 for removal of H_2O, or Celite for removal of tar), solvents for extraction and solvents for recrystallisation, the reader is referred to Chapter 1. A common method of purification of organic compounds is to convert them to a suitable derivative which is purified (with the assumption that the impurity does not form a similar derivative, or if it does its properties are different), and then regenerate the original compound and purify it further. Various derivatives are described for different classes of compounds below, but many more can be considered, and the reader is referred to texts on 'Protecting Groups' which describe ways of selectively protecting functional groups and facile means of deprotecting them, i.e. regenerating the unprotected group [P.J.Kocienski *Protecting Groups* Thieme International Publisher, *2005*, ISBN 9783131356031; J.R.Hanson *Protecting Groups in Organic Synthesis* Sheffield Academic Press, *1999*, ISBN 9781850759577, or J.Wiley & Sons, NY, *1999*, ISBN 980632045068]. See Chapter 6 for general purification procedures used for macromolecules.

ACETALS

These are generally diethyl or dimethyl acetal derivatives of aldehydes. They are more stable to alkali than to acids. Their common impurities are the corresponding alcohol, aldehyde and water. Drying with sodium wire removes alcohols and water, and polymerises aldehydes so that, after decantation, the acetal can be fractionally distilled. In cases where the use of sodium is too drastic, aldehydes can be removed by shaking with alkaline hydrogen peroxide solution and the acetal is dried with sodium carbonate or potassium carbonate. Residual water and alcohols (up to *n*-propyl) can be removed with Linde type 4A molecular sieves. The acetal is then filtered and fractionally distilled. Solid acetals (i.e. acetals of high-molecular-weight aldehydes) are generally low-melting and can be recrystallised from low-boiling petroleum ether, toluene or a mixture of both.

ACIDS

Carboxylic acids

Liquid carboxylic acids are first freed from neutral and basic impurities by dissolving them in aqueous alkali and extracting with diethyl ether. (The pH of the solution should be at least three units above the pK_a of the acid, see pK in Chapter 1). The aqueous phase is then acidified to a pH at least three units below the pK_a of the acid and again extracted with ether. It is quite unnecessary to add large excesses of mineral acid (e.g. HCl) to liberate the organic acid, as mineral acids dissolve appreciably in organic solvents such as diethyl ether. The extract is dried with magnesium sulfate or sodium sulfate and the ether is distilled off. The acid is fractionally distilled through an efficient column. It can be further purified by conversion to its methyl or ethyl ester (*vide supra*) which is then fractionally distilled. Hydrolysis yields the original acid which is again purified as above.
Acids that are solids can be purified in this way, except that distillation is replaced by repeated crystallisation

(preferable from at least two different solvents such as water, alcohol or aqueous alcohol, toluene, toluene with petroleum ether or acetic acid.) Water-insoluble acids can be partially purified by dissolution in N sodium hydroxide solution and precipitation with dilute mineral acid. If the acid is required to be free from sodium ions, then it is better to dissolve the acid in hot N ammonia, heat to *ca* 80°, adding slightly more than an equal volume of N formic acid and allowing to cool slowly for crystallisation. Any ammonia, formic acid or ammonium formate that adhere to the acid are removed when the acid is dried in a vacuum — these are volatile. Cartridges and columns are available (e.g. the Isolute SCX-2 made of polysulfonic acid bonded to silica as an ion exchange column developed by Biotage Inc <www.biotage.com>), particularly for the purification of acids using flash chromatography.
The separation and purification of naturally occurring fatty acids, based on distillation, salt solubility and low temperature crystallisation, are described by K.S.Markley (Ed.), *Fatty Acids*, 2nd Edn, part 3, Chap. 20, Interscience, New York, *1964*, see also N.Reavley *Essential Fatty Acids* Book Media Publ, *2002*, ISBN 9780958157643; G.Grati and K.Sato (Eds) *Crystallisation and Polymorphism of Fats and Fatty Acids* Marcel Dekker, *1988*, ISBN 9780824778750.
Aromatic carboxylic acids can be purified by conversion to their sodium salts, recrystallisation from hot water, and conversion to the free acids. See also characterisation and purification *via* their S-arylisothiuronium salts, Tables 6 and 7.

Sulfonic acids

The low solubility of sulfonic acids in organic solvents and their high solubility in water makes necessary a treatment different from that for carboxylic acids. Sulfonic acids are strong acids, they have the tendency to hydrate, and many of them contain water of crystallisation. The lower-melting and liquid acids can generally be purified with only slight decomposition by fractional distillation, preferably under reduced pressure. A common impurity is sulfuric acid, but this can be removed by recrystallisation from concentrated aqueous solutions. The wet acid can be dried by azeotropic removal of water with toluene, followed by distillation. The higher-melting acids, or acids that melt with decomposition, can be recrystallised from water or, occasionally, from ethanol. For a typical purification of aromatic sulfonic acids using their barium salts refer to benzenesulfonic acid in the 'Aromatic Compounds' section in Chapter 3. See also characterisation and purification *via* their S-arylisothiuronium salts, Tables 6 and 7.

Sulfinic acids

These acids are less stable, less soluble and less acidic than the corresponding sulfonic acids. The common impurities are the respective sulfonyl chlorides from which they have been prepared, and the thiolsulfonates (neutral) and sulfonic acids into which they decompose. The first two of these can be removed by solvent extraction from an alkaline solution of the acid. On acidification of an alkaline solution, the sulfinic acid crystallises out leaving the sulfonic acid behind. The lower molecular weight members are isolated as their metal (e.g. ferric) salts, but the higher members can be crystallised from water (made slightly acidic), or alcohol.

ACID CHLORIDES

The corresponding acid and hydrogen chloride are the most likely impurities. Usually these can be removed by efficient fractional distillation. Where acid chlorides are not readily hydrolysed (e.g. aryl sulfonyl chlorides) the compound can be freed from contaminants by dissolving in a suitable solvent such as alcohol-free chloroform, dry toluene or petroleum ether and shaking with dilute sodium bicarbonate solution. The organic phase is then washed with water, dried with anhydrous sodium sulfate or magnesium sulfate, and distilled or recrystallised. This procedure is *hazardous* with readily hydrolysable *carboxylic* acid chlorides such as acetyl chloride and benzoyl chloride. Solid acid chlorides should be thoroughly dried *in vacuo* over strong drying agents and are satisfactorily recrystallised from toluene, toluene-petroleum ether, petroleum ethers, alcohol-free chloroform/toluene, and, occasionally, from dry diethyl ether. Hydroxylic or basic solvents should be strictly avoided. *All operations should be carried out in a fume cupboard because of the* ***irritant*** *nature of these compounds which also attack the skin.*

ALCOHOLS

Monohydric alcohols

The common impurities in alcohols are aldehydes or ketones, and water. [*Ethanol* in Chapter 3 is typical.] Aldehydes and ketones can be removed by adding a small amount of sodium metal and refluxing for 2 hours, followed by distillation. Water can be removed in a similar way but it is preferable to use magnesium metal instead of sodium because it forms a more insoluble hydroxide, thereby shifting the equilibrium more completely from metal alkoxide to metal hydroxide. The magnesium should be activated with iodine (or a small amount of methyl iodide), and the water content should be low, otherwise the magnesium will be deactivated. If the amount of water is large, it should be removed by azeotropic distillation (see below), or by drying over anhydrous $MgSO_4$ (not $CaCl_2$ which combines with alcohols). Acidic materials can be removed by treatment with anhydrous Na_2CO_3, followed by a suitable drying agent, such as calcium hydride, and fractional distillation, using gas chromatography to establish the purity of the product [Ballinger & Long, *J Am Chem Soc* **82** 795 *1960*, DOI: 10.1021/ja01489a008]. *Alternatively*, the alcohol can be refluxed with freshly ignited CaO for 4 hours and then fractionally distilled [McCurdy & Laidler, *Can J Chem* **41** 1867 *1963*, DOI: 10.1139/v63-274].
With higher-boiling alcohols it is advantageous to add some freshly prepared magnesium ethoxide solution (only slightly more than required to remove the water), followed by fractional distillation. *Alternatively*, in such cases, water can be removed by azeotropic distillation with toluene. Higher-melting alcohols can be purified by crystallisation from methanol or ethanol, toluene/petroleum ether or petroleum ether. Sublimation in vacuum, molecular distillation and gas and liquid chromatographic methods are also useful means of purification. For purification *via* derivatives, *vide supra*.

Polyhydric alcohols

These alcohols are more soluble in water than are monohydric alcohols. Liquids can be freed from water by shaking with type 4A Linde molecular sieves and can safely be distilled only under high vacuum. Carbohydrate alcohols can be crystallised from concentrated aqueous solutions or, preferably, from mixed solvents such as ethanol/petroleum ether or dimethyl formamide/toluene. Crystallisation usually requires seeding and is extremely slow. Further purification can be effected by conversion to the acetyl or benzoyl derivatives which are much less soluble in water and which can readily be recrystallised, e.g. from ethanol. Hydrolysis of the acetyl derivatives, followed by removal of acetic or benzoic acid and metal ions by ion-exchange chromatography, gives the purified material. On no account should solutions of carbohydrates be concentrated above 40º because of darkening and formation of *caramel*. Ion exchange, charcoal or cellulose column chromatography has been used for the purification and separation of carbohydrates.

ALDEHYDES

Common impurities found in aldehydes are the corresponding alcohols, aldols and water from self-condensation, and the corresponding acids formed by autoxidation. Acids can be removed by shaking with aqueous 10% sodium bicarbonate solution. The organic liquid is then washed with water. It is dried with anhydrous sodium sulfate or magnesium sulfate and then fractionally distilled. Water soluble aldehydes must be dissolved in a suitable solvent such as diethyl ether before being washed in this way. Further purification can be effected *via* the bisulfite derivative (see above) or the Schiff base formed with aniline or benzidine. Solid aldehydes can be dissolved in diethyl ether and purified as above. *Alternatively*, they can be steam distilled, then sublimed and crystallised from toluene or petroleum ether.

AMIDES

Amides are stable compounds. The lower-melting members (such as acetamide) can be readily purified by fractional distillation. Most amides are solids which have low solubilities in water. They can be recrystallised from large quantities of water, ethanol, ethanol/ether, aqueous ethanol, chloroform/toluene, chloroform or acetic acid. The likely impurities are the parent acids or the alkyl esters from which they have been made. The former can be removed by thorough washing with aqueous ammonia followed by recrystallisation, whereas elimination of the latter is by trituration or recrystallisation from an organic solvent. Amides can be freed from solvent or water by drying below their melting points. These purifications can also be used for sulfonamides and acid hydrazides.

AMINES

The common impurities found in amines are nitro compounds (if prepared by reduction), the corresponding halides (if prepared from them) and the corresponding carbamate salts. Amines are dissolved in aqueous acid, the

pH of the solution being at least three units below the pK_a value of the base to ensure almost complete formation of the cation. They are extracted with diethyl ether to remove neutral impurities and to decompose the carbamate salts. The solution is then made strongly alkaline and the amines that separate are extracted into a suitable solvent (ether or toluene) or steam distilled. The latter process removes coloured impurities. Note that chloroform cannot be used as a solvent for primary amines because, in the presence of alkali, poisonous carbylamines (isocyanides) are formed. However, chloroform is a useful solvent for the extraction of heterocyclic bases. In this case it has the added advantage that while the extract is being freed from the chloroform solvent most of the moisture is removed with the solvent.

Alternatively, the amine may be dissolved in a suitable solvent (e.g. toluene), and dry HCl gas is passed through the solution to precipitate the amine hydrochloride. This is purified by recrystallisation from a suitable solvent mixture (e.g. ethanol/diethyl ether). The free amine can be regenerated by adding sodium hydroxide and isolated as above. Cartridges and columns are available (e.g. KP-NH silica column with slightly nitrogenous alkaline chemistry developed by Biotage Inc (<www.biotage.com>) for the purification of amines using flash chromatography.

Liquid amines can be further purified *via* their acetyl or benzoyl derivatives (*vide supra*). Solid amines can be recrystallised from water, alcohol, toluene or toluene-petroleum ether. *Care should be taken in handling large quantities of amines because their vapours are* ***harmful (possibly carcinogenic)*** *and they are readily absorbed through the skin.*

AMINO ACIDS

Because of their zwitterionic nature, amino acids are generally soluble in water. Their solubility in organic solvents rises as the fat-soluble portion of the molecule increases. The likeliest impurities are traces of salts, heavy metal ions, proteins and other amino acids. Purification of these is usually easy, by recrystallisation from water or ethanol/water mixtures. The amino acid is dissolved in the boiling solvent, decolorised if necessary by boiling with 1g of acid-washed charcoal/100g amino acid, then filtered hot, chilled, and set aside for several hours to crystallise. The crystals are filtered off, washed with ethanol, then ether, and dried.

Amino acids have high melting or decomposition points and are best examined for purity by paper or thin layer chromatography. The spots are developed with ninhydrin. Customary methods for the purification of small quantities of amino acids obtained from natural sources, i.e. 1-5g, are ion-exchange chromatography (see Chapter 1). For general treatment of amino acids see Greenstein and Winitz [*The Amino Acids*, Vols 1-3, J.Wiley & Sons, New York 1961] and individual amino acids in Chapters 3 and 6.

A useful source of details such as likely impurities, stability and tests for homogeneity of amino acids is *Specifications and Criteria for Biochemical Compounds*, 3rd edn, National Academy of Sciences, USA, 1972.

ANHYDRIDES

The corresponding acids, resulting from hydrolysis, are the most likely impurities. Distillation from phosphorus pentoxide, followed by fractional distillation, is usually satisfactory. With high boiling or solid anhydrides, another method involves boiling under reflux for 0.5-1 hours with acetic anhydride, followed by fractional distillation. Acetic acid distils first, then acetic anhydride and finally the desired anhydride. Where the anhydride is a solid, removal of acetic acid and acetic anhydride at atmospheric pressure is followed by heating under vacuum. The solid anhydride is then either crystallised as for acid chlorides or (in some cases) sublimed in a vacuum. A preliminary purification when large quantities of acid are present in a solid anhydride (such as phthalic anhydride) is by preferential solvent extraction of the (usually) more soluble anhydride from the acid (e.g. with $CHCl_3$ in the case of phthalic anhydride). *All operations with liquid anhydrides should be carried out in a fume cupboard because of their* **LACHRYMATORY** *properties. Almost all anhydrides attack skin.*

CAROTENOIDS

These usually are decomposed by light, air and solvents, so that degradation products are probable impurities. Chromatography and adsorption spectra permit the ready detection of coloured impurities, and separations are possible using solvent distribution, chromatography or crystallisation. Thus, in partition between immiscible solvents, xanthophyll remains in 90% methanol while carotenes pass into the petroleum ether phase. For small amounts of material, thin-layer or paper chromatography may be used, while column chromatography is suitable for larger amounts. Colourless impurities may be detected by IR, NMR or mass spectrometry. The more common separation procedures are described by P. Karrer and E. Jucker in *Carotenoids*, E.A. Braude (translator), Elsevier, NY, *1950*. Purity can be checked by chromatography (on thin-layer plates, Kieselguhr, paper or columns), by UV

or NMR procedures. See 'Carotenoids' in Chapter 6.

ESTERS

The most common impurities are the corresponding acid and hydroxy compound (i.e. alcohol or phenol), and water. A liquid ester from a carboxylic acid is washed with 2N sodium carbonate or sodium hydroxide to remove acid material, then shaken with calcium chloride to remove ethyl or methyl alcohols (if it is a methyl or ethyl ester). It is dried with potassium carbonate or magnesium sulfate, and distilled. Fractional distillation then removes residual traces of hydroxy compounds. This method does not apply to esters of inorganic acids (e.g. dimethyl sulfate) which are more readily hydrolysed in aqueous solution when heat is generated in the neutralisation of the excess acid. In such cases, several fractional distillations, preferably under vacuum, are usually sufficient.

Solid esters are easily crystallisable materials. It is important to note that esters of alcohols must be recrystallised either from non-hydroxylic solvents (e.g. toluene) or from the alcohol from which the ester is derived. Thus methyl esters should be crystallised from methanol or methanol/toluene, but not from ethanol, *n*-butanol or other alcohols, in order to avoid alcohol exchange and contamination of the ester with a second ester. Useful solvents for crystallisation are the corresponding alcohols or aqueous alcohols, toluene, toluene/petroleum ether, and chloroform (ethanol-free)/toluene. Esters of carboxylic acids derived from phenols are more difficult to hydrolyse and exchange, hence any alcoholic solvent can be used freely. Sulfonic acid esters of phenols are even more resistant to hydrolysis: they can safely be crystallised not only from the above solvents but also from acetic acid, aqueous acetic acid or boiling *n*-butanol. Note that sulfonic esters of lower alcohols, e.g. methanol, are good alkylating agents.

Fully esterified phosphoric acid and phosphonic acids differ only in detail from the above mentioned esters. Their major contaminants are alcohols or phenols, phosphoric or phosphonic acids (from hydrolysis), and (occasionally) basic material, such as pyridine, which is used in their preparation. Water-insoluble esters are washed thoroughly and successively with dilute acid (e.g. 0.2N sulfuric acid), water, 0.2N sodium hydroxide and water. After drying with calcium chloride they are fractionally distilled. Water-soluble esters should first be dissolved in a suitable organic solvent and, in the washing process, water should be replaced by saturated aqueous sodium chloride. Some esters (e.g. phosphate and phosphonate esters) can be further purified through their uranyl adducts (*vide supra*). Traces of water or hydroxy compounds can be removed by percolation through, or shaking with, activated alumina (about 100g/L of liquid solution), followed by filtration and fractional distillation in a vacuum. For high molecular weight esters (which cannot be distilled without some decomposition) it is advisable to carry out distillation at as low a pressure as possible. Solid esters can be crystallised from toluene or petroleum ether. Alcohols can be used for recrystallising solid phosphoric or phosphonic esters of phenols.

ETHERS

The purification of diethyl ether (see Chapter 3) is typical of liquid ethers. The most common contaminants are the alcohols or hydroxy compounds from which the ethers are prepared, their oxidation products (e.g. aldehydes), peroxides and water. Dialkyl ethers form peroxides much more readily than other ethers, e.g. ethyl phenyl ethers, on standing in air. Peroxides, aldehydes and alcohols can be removed by shaking with alkaline potassium permanganate solution for several hours, followed by washing with water, concentrated sulfuric acid [CARE], then water. After drying with calcium chloride, the ether is distilled. It is then dried with sodium or with lithium aluminium hydride, redistilled and given a final fractional distillation. The drying process is repeated if necessary. *Alternatively*, methods for removing peroxides include leaving the ether to stand in contact with iron filings or copper powder, shaking with a solution of ferrous sulfate acidified with N sulfuric acid, shaking with a copper-zinc couple, passage through a column of activated alumina, and refluxing with phenothiazine. Cerium(III) hydroxide has also been used.

A simple test for ether peroxides is to add 10ml of the ether to a stoppered cylinder containing 1ml of freshly prepared 10% solution of potassium iodide containing a drop of starch indicator. No colour should develop during one minute if free from peroxides. *Alternatively*, a 1% solution of ferrous ammonium sulfate, 0.1M in sulfuric acid and 0.01M in potassium thiocyanate should not increase appreciably in red colour when shaken with two volumes of the ether. Merck-Chemicals supply peroxide test kits (Perex Test) which use a colorimetric method with test strips which can be used to estimate the amount of hydrogen peroxide, from as low a concentration as 0.2mg/L to as high as1000mg/L. They are very convenient as they can give an indication of the concentration of peroxide rapidly <see http://www.merck-chemicals.com>. As a safety precaution against **EXPLOSION** in case purification from peroxides has been insufficiently thorough, at least a quarter of the total volume of liquid ether should remain in the distilling flask when the distillation is discontinued, as the peroxides are generally

higher boiling than the corresponding ethers. To minimize peroxide formation, ethers should be stored in dark bottles and, if they are liquids, they should be left in contact with type 4A Linde molecular sieves, in a cold place, over sodium amalgam. The rate of formation of peroxides depends on storage conditions and is accelerated by metal impurities, heat, light, air and moisture. Always be vigilant and test for peroxides. The formation of peroxides is inhibited in the presence of diphenylamine, di-*tert*-butylphenol, or other antioxidants which can be used as stabilisers.
Ethers that are solids (e.g. phenyl ethers) can be steam distilled from an alkaline solution which will hold back any phenolic impurity. After the distillate is made alkaline with sodium carbonate, the insoluble ether is collected either by extraction (e.g. with chloroform, diethyl ether or toluene) or by filtration. It is then crystallised from alcohols, alcohol/petroleum ether, petroleum ether, toluene or mixtures of these solvents, sublimed in a vacuum and recrystallised if necessary.

HALIDES

Aliphatic halides are likely to be contaminated with halogen acids and the alcohols from which they have been prepared, whereas in aromatic halides the impurities are usually aromatic hydrocarbons, amines or phenols. In both groups the halogen is less reactive than it is in acid halides. Purification is by shaking with concentrated hydrochloric acid, followed by washing successively with water, 5% sodium carbonate or bicarbonate, and water. After drying with calcium chloride, the halide is distilled and then fractionally distilled using an efficient column. For a solid halide the above purification is carried out by dissolving it in a suitable solvent such as toluene. Solid halides can also be purified by chromatography using an alumina column and eluting with toluene or petroleum ether. They can be crystallised from toluene, petroleum ethers, toluene/petroleum ether or toluene/chloroform/ petroleum ether. Care should be taken when handling organic halogen compounds because of their HIGH **TOXICITY**. It should be noted that methyl iodide is a cancer suspect.
Liquid aliphatic halides are obtained alcohol-free by distillation from phosphorus pentoxide. They are stored in dark bottles to prevent oxidation and, in some cases, the formation of phosgene.
A general method for purifying *chlorohydrocarbons* uses repeated shaking with concentrated sulfuric acid [CARE] until no further colour develops in the acid, then washing with water followed by a solution of sodium bicarbonate, then with water again. After drying with calcium chloride, the chlorohydrocarbon is fractionally redistilled to constant boiling point or recrystallised.

HYDROCARBONS

Gaseous hydrocarbons are best freed from water and gaseous impurities by passage through suitable adsorbents and (if olefinic material is to be removed) oxidants such as alkaline potassium permanganate solution, followed by fractional cooling (see Chapter 1 for cooling baths) and fractional distillation at low temperature. To effect these purifications and also to store the gaseous sample, a vacuum line is necessary.
Impurities in hydrocarbons can be characterised and evaluated by gas chromatography and mass spectrometry. The total amount of impurities present can be estimated from the thermometric freezing curve.
Liquid aliphatic hydrocarbons are freed from aromatic impurities by shaking with concentrated sulfuric acid [CARE] whereby the aromatic compounds are sulfonated. Shaking is carried out until the sulfuric acid layer remains colourless for several hours. The hydrocarbon is then freed from the sulfuric acid and the sulfonic acids by separating the two phases and washing the organic layer successively with water, 2N sodium hydroxide, and water. It is dried with $CaCl_2$ or Na_2SO_4, and then distilled. The distillate is dried with sodium wire, P_2O_5, or metallic hydrides, or passage through a dry silica gel column, or preferably, and more safely, with molecular sieves (see Chapter 1) before being finally fractionally distilled through an efficient column. If the hydrocarbon is contaminated with olefinic impurities, shaking with aqueous alkaline permanganate is necessary prior to the above purification. Alicyclic and paraffinic hydrocarbons can be freed from water, non-hydrocarbon and aromatic impurities by passage through a silica gel column before the final fractional distillation. This may also remove isomers. (For the use of chromatographic methods to separate mixtures of aromatic, paraffinic and alicyclic hydrocarbons see references in the bibliography in Chapter 1 under *Liquid and Flash Chromatography, Gas Chromatography and High Performance Liquid Chromatography*). Another method of removing branched-chain and unsaturated hydrocarbons from straight-chain hydrocarbons depends on the much faster reaction of the former with chlorosulfonic acid.
Isomeric materials which have closely similar physical properties can be serious contaminants in hydrocarbons. With aromatic hydrocarbons, e.g. xylenes and alkyl benzenes, advantage is taken of differences in ease of sulfonation. If the required compound is sulfonated more readily, the sulfonic acid is isolated, crystallised (e.g. from water), and decomposed by passing superheated steam through the flask containing the acid. The sulfonic

acid undergoes hydrolysis, and the liberated hydrocarbon distils with the steam. It is separated from the distillate, dried, distilled and then fractionally distilled. For small quantities (10-100mg), vapour phase chromatography is the most satisfactory method for obtaining a pure sample (for column materials for packings see Chapter 1). Azeotropic distillation with methanol or 2-ethoxyethanol (cellosolve) has been used to obtain highly purified saturated hydrocarbons and aromatic hydrocarbons such as xylenes and isopropylbenzenes. Carbonyl-containing impurities can be removed from hydrocarbons (and other oxygen-lacking solvents such as $CHCl_3$ and CCl_4) by passage through a column of Celite 545 (100g) mixed with concentrated sulfuric acid (60ml). After first adding some solvent and about 10g of granular Na_2SO_4, the column is packed with the mixture and a final 7-8cm of Na_2SO_4 is added at the top [Hornstein & Crowe, *Anal Chem* **34** 1037 *1962*, DOI: 10.1021/ac60188a051]. *Alternatively*, Celite impregnated with 2,4-dinitrophenylhydrazine can be used.
With solid hydrocarbons such as naphthalene and polycyclic hydrocarbons, preliminary purification by sublimation in vacuum (or high vacuum if the substance is high melting) is followed by zone refining and finally by chromatography (e.g. on alumina) using low-boiling liquid hydrocarbon eluents. These solids can be recrystallised from alcohols, alcohol/petroleum ether or from liquid hydrocarbons (e.g. toluene) and dried below their melting points. Aromatic hydrocarbons that have been purified by zone melting include anthracene, biphenyl, fluoranthrene, naphthalene, perylene, phenanthrene, pyrene and terphenyl, among others. Some polycyclic hydrocarbons, e.g. benzopyrene, are CARCINOGENIC.
Olefinic hydrocarbons have a very strong tendency to polymerise, and commercially available materials are generally stabilised, e.g. with hydroquinone. When distilling compounds such as vinylpyridine or styrene, the stabiliser remains behind and the purified olefinic material is more prone to polymerisation. The most common impurities are higher-boiling dimeric or polymeric compounds. Vacuum distillation in a nitrogen atmosphere not only separates monomeric from polymeric materials but in some cases also depolymerises the impurities. The distillation flask should be charged with a polymerisation inhibitor, and the purified material should be used immediately or stored in the dark and mixed with a small amount of stabiliser (e.g. 0.1% of hydroquinone or di-*tert*-butylcatechol). It is also advisable to add to the flask a small amount (*ca* 5-10% by volume of liquid in the flask) of a ground mixture of Kieselguhr and NaCl which will provide nuclei for facilitating boiling and finally for cleaning the flask from insoluble polymeric residue (due to the presence of the water soluble NaCl in the residue).

IMIDES

Imides (e.g. phthalimide) can be purified by conversion to their potassium salts by reaction in ethanol with ethanolic potassium hydroxide. The imides are regenerated when the salts are hydrolysed with water or dilute acid. Like amides, imides readily crystallise from alcohols and, in some cases (e.g. quinolinic imide), from glacial acetic acid.

IMINO COMPOUNDS

These substances contain the -C=NH group and, because they are strong, unstable bases, they are kept as their more stable salts, such as the hydrochlorides. (The free base usually hydrolyses to the corresponding oxo compound and ammonia.) Like amine hydrochlorides, the salts are purified by solution in alcohol containing a few drops of hydrochloric acid. After treatment with charcoal, and filtering, dry diethyl ether (or petroleum ether if ethanol is used) is added until crystallisation sets in. The salts are dried and kept in a vacuum desiccator.

KETONES

Ketones are more stable to oxidation than aldehydes and can be purified from oxidisable impurities by refluxing with potassium permanganate until the colour persists, followed by shaking with sodium carbonate (to remove acidic impurities) and distilling. Traces of water can be removed with type 4A Linde molecular sieves. Ketones which are solids can be purified by crystallisation from alcohol, toluene, or petroleum ether, and are usually sufficiently volatile for sublimation in vacuum. Ketones can be further purified *via* their bisulfite, semicarbazone or oxime derivatives (*vide supra*). The bisulfite addition compounds are formed only by aldehydes and methyl ketones but they are readily hydrolysed in dilute acid or alkali.

MACROMOLECULES See Chapter 6.

NITRILES

All purifications should be carried out in an efficient fume cupboard because of the **TOXIC** *nature of these compounds*. Nitriles are usually prepared either by reacting the corresponding halide or diazonium salts with a cyanide salt or by dehydrating an amide. Hence, possible contaminants are the respective halides or alcohols (from hydrolysis), phenolic compounds, amines or amides. Small quantities of phenols can be removed by chromatography on alumina. More commonly, purification of liquid nitriles or solutions of solid nitriles in a solvent such as diethyl ether is by shaking with dilute aqueous sodium hydroxide, followed by washing successively with water, dilute acid and water. After drying with sodium sulfate, the solvent is distilled off. Liquid nitriles are best distilled from a small amount of P_2O_5 which, besides removing water, dehydrates any amide impurity to the nitrile. About one-fifth of the nitrile should remain in the distilling flask at the end of the distillation (*the residue may contain some inorganic cyanide*). This purification also removes alcohols and phenols. Solid nitriles can be recrystallised from ethanol, toluene or petroleum ether, or a mixture of these solvents. They can also be sublimed under vacuum. Preliminary purification by steam distillation is usually possible. Strong alkali or heating with dilute acids may lead to hydrolysis of the nitrile and should be avoided. They have a characteristic band in the IR spectrum at ν_{max} ~2200 cm^{-1}.

NITRO COMPOUNDS

Aliphatic nitro compounds are generally acidic. They are freed from alcohols or alkyl halides by standing for a day with concentrated sulfuric acid, then washed with water, dried with magnesium sulfate followed by calcium sulfate and distilled. The principal impurities are isomeric or homologous nitro compounds. In cases where the nitro compound was originally prepared by vapour phase nitration of the aliphatic hydrocarbon, fractional distillation should separate the nitro compound from the corresponding hydrocarbon. Fractional crystallisation is more effective than fractional distillation if the melting point of the compound is not too low.

The impurities present in aromatic nitro compounds depend on the aromatic portion of the molecule. Thus, benzene, phenols or anilines are probable impurities in nitrobenzene, nitrophenols and nitroanilines, respectively. Purification should be carried out accordingly. Isomeric compounds are likely to remain as impurities after the preliminary purifications to remove basic and acidic contaminants. For example, *o*-nitrophenol may be found in samples of *p*-nitrophenol. Usually, the *o*-nitro compounds are more steam volatile than the *p*-nitro isomers and can be separated in this way. Polynitro impurities in mononitro compounds can be readily removed because of their relatively lower solubilities in solvents. With acidic or basic nitro compounds that cannot be separated in the above manner, advantage may be taken of their differences in pK values (see Chapter 1). The compounds can thus be purified by preliminary extractions with several sets of aqueous buffers of known pH (see for example Table 24, Chapter 1) from a solution of the substance in a suitable solvent such as diethyl ether. This method is more satisfactory and less laborious the larger the difference between the pK value of the impurity and the desired compound. Heterocyclic nitro compounds require similar treatment to the nitroanilines. Neutral nitro compounds can be steam distilled.

NUCLEIC ACIDS See Chapter 6.

PHENOLS

Because phenols are weak acids, they can be freed from neutral impurities by dissolution in aqueous N sodium hydroxide (cf pK) and extraction with a solvent such as diethyl ether, or by steam distillation to remove the non-acidic material. The phenol is recovered by acidification of the aqueous phase with 2N sulfuric acid, and either extracted with ether or steam distilled. In the second case the phenol is extracted from the steam distillate after saturating it with sodium chloride (salting out). A solvent is necessary when large quantities of liquid phenols are purified. The phenol is fractionated by distillation under reduced pressure, preferably in an atmosphere of nitrogen to minimise oxidation. Solid phenols can be crystallised from toluene, petroleum ether or a mixture of these solvents, and can be sublimed under vacuum. Purification can also be effected by fractional crystallisation or zone refining. For further purification of phenols *via* their acetyl or benzoyl derivatives *vide supra*.

POLYPEPTIDES AND PROTEINS See Chapter 6.

QUINONES

These are neutral compounds which are usually coloured. They can be separated from acidic or basic impurities

by extraction of their solutions in organic solvents with aqueous basic or acidic solutions, respectively. Their colour is a useful property in their purification by chromatography through an alumina column with, e.g. toluene, as eluent. They are volatile enough for vacuum sublimation, although with high-melting quinones a very high vacuum is necessary. *p*-Quinones are stable compounds and can be recrystallised from water, ethanol, aqueous ethanol, toluene, petroleum ether or glacial acetic acid. *o*-Quinones, on the other hand, are readily oxidised. They should be handled in an inert atmosphere, preferably in the absence of light.

SALTS

With metal ions

Water-soluble salts are best purified by preparing a concentrated aqueous solution to which, after decolorising with charcoal and filtering, ethanol or acetone is added so that the salts crystallise. They are collected, washed with aqueous ethanol or aqueous acetone, and dried. In some cases, water-soluble salts can be recrystallised satisfactorily from alcohols. With very water-soluble salts, pure crystals are best obtained by dissolving them in water and allowing the solution to evaporate slowly in a desiccator over a suitable desiccant in a cold room. When crystals are formed they are removed, e.g. by centrifugation, washed with a little ice-cold water and dried in a vacuum. Water-insoluble salts are purified by Soxhlet extraction, first with organic solvents and then with water, to remove soluble contaminants. The purified salt is recovered from the thimble.

With organic cations

Organic salts (e.g. trimethylammonium benzoate) are usually purified by recrystallisation from polar solvents (e.g. water, ethanol or dimethyl formamide). If the salt is too soluble in a polar solvent, its concentrated solution should be treated dropwise with a miscible non-polar, or less polar, solvent (see Tables 6 and 7, Chapter 1) until crystallisation begins and cooled.

With sodium alkane sulfonates

These are purified from sulfites by boiling with aqueous HBr. They are purified from sulfates by adding $BaBr_2$. Sodium alkane disulfonates are finally precipitated by addition of MeOH [Pethybridge & Taba *JCS Faraday Trans 1* **78** 1331 *1982*, DOI: 10.1039/F19827801331].

SULFUR COMPOUNDS

Disulfides

These can be purified by extracting acidic and basic impurities with dilute aqueous base or acid, respectively. However, they are somewhat sensitive to strong alkali which slowly cleaves the disulfide bond. The lower-melting members can be fractionally distilled under vacuum. The high members can be recrystallised from alcohol, toluene or glacial acetic acid.

Sulfones

Sulfones are neutral and very stable compounds that can be distilled without decomposition. They are freed from acidic and basic impurities in the same way as disulfides. The low-molecular-weight members are quite soluble in water, but the higher members can be recrystallised from water, ethanol, aqueous ethanol or glacial acetic acid.

Sulfonic acids

These are strong acids whose solubilities in water varies. They can be recrystallised from water, sometimes form hydrates and can be characterised and purified *via* their S-arylisothiuronium salts, see Tables 6 and 7, and above.

Sulfoxides

These are odourless, rather unstable compounds because they oxidise to sulfones, and should be distilled under vacuum in an inert atmosphere. They are generally water-soluble but can be extracted from aqueous solution with a solvent such as diethyl ether.

Thioethers (sulfides)

Thioethers are neutral stable compounds that can be freed from acidic and basic impurities as described for disulfides and are more stable than disulfides in alkaline solutions. They can be recrystallised from organic solvents and distilled without decomposition. They have sulfurous odours.

Thiols

Thiols, or mercaptans, are stronger acids than the corresponding aliphatic hydroxy or phenolic compounds, but can be purified in a similar manner. However, care must be exercised in handling thiols to avoid their oxidation to disulfides. For this reason, purification is best carried out in an inert atmosphere in the absence of oxidising agents. Similarly, thiols should be stored out of contact with air. They can be distilled without change, and the higher-melting thiols (which are usually more stable) can be crystallised, e.g. from water or dilute alcohol. They oxidise readily in alkaline solution but can be separated from the disulfide which is insoluble in this medium.
They should be stored in the dark below 0°. *All operations with thiols should be carried out in an efficient fume cupboard because of their very unpleasant odour and their* **TOXICITY**.

Thiolsulfonates (disulfoxides)

Thiolsulfonates are neutral and are somewhat light-sensitive compounds. Their most common impurities are sulfonyl chlorides (neutral) or the sulfinic acid or disulfide from which they are usually derived. The first can be removed by partial freezing or crystallisation, the second by shaking with dilute alkali, and the third by recrystallisation because of the higher solubility of the disulfide in solvents. Thiolsulfonates decompose slowly in dilute, or rapidly in strong, alkali to form disulfides and sulfonic acids. Thiolsulfonates also decompose on distillation but they can be steam distilled. The solid members can be recrystallised from water, alcohols or glacial acetic acid.

PURIFICATION *via* FLUOROCHROMES

If the purification procedure is proving difficult then by tagging the desired molecule in a mixture with a fluorochrome (see Table 20, Chapter 1) can provide a means of following the substance through the purification process. The fluorochrome should have a group which can react with the desired compound, and it should be possible to remove the fluorochromic group after purification. Such groups are present for example in fluorescein-isothiocyanate (FITC), where the SCN group can react with an RNH_2 compound to form fluorescent thioureas; e.g. 4-bromomethyl-7-methoxycoumarin, which can react with R-OH or R-COONa compounds to form fluorescent ether or ester links with the desired compound; or 3-aminocoumarin, which reacts through its NH_2 group to form fluorescent amides. The fluorescent products can then be readily identified by their fluorescence, separated from impurities, and it should be possible to recover the purified compound after chemically separating it from the fluorescent tag. Such procedures can also be used as analytical tools for detecting specific substances (see *fluorescence spectra* in Chapter 1 and Table 20).

ADVANCES IN CHEMICAL TECHNIQUES USED IN PURIFICATION

Chemical techniques used in purification mainly involve conversion of compounds to be purified into derivatives, e.g. nitrobenzoyl derivatives (where covalent bonds have been formed), into complexes or adducts such as phenanthrene picrate, or into a salt, e.g. aniline bis-4-chlorobenzoylimide salt which can be purified by recrystallisation or some other means. The purified compounds are then recovered by cleaving the covalent bond in the derivatives, by removal of picric acid, e.g. by passage through alumina, or by basifying the salts and subsequently isolating the *free* bases. These procedures can increase the purity of compounds considerably. There are still continuing efforts in devising new ways to derivatise compounds, particularly for selecting desired functional groups in such a manner that selective removal of the derivatising group can be achieved in high yield. This has been very successful for synthesising most elaborate structures. However, with all the previous work and current improvements, [see P. G. M. Wuts, T. W. Greene, *Greene's Protective Groups in Organic Synthesis*, 4th Edition, J.Wiley & Sons Inc, *2006*. DOI: 10.1002/0470053488; Print ISBN: 9780471697541, Online ISBN: 9780470053485 and <synarchive.com>], the present armoury of protecting and derivatising groups limit the use of chemical methods for the purification of compounds to small scale work. That is because ***atom economy*** is not possible on large scale purification due to the necessary wasteful jettisoning or recycling of unwanted products. Medium to large scale purification necessitates the use of physical techniques (see Chapter 1), and a large number have been developed and are continually being improved. The strength of chemical techniques lies in the analytical information that can be derived which not only conveniently provides information of what, and how much, impurities are present but also can help to suggest the best procedures to use for purification.
For advances in *Laboratory on a Chip* and *microfluidics* and their potential use in purification, analyses and chemical syntheses see 'ADVANCES IN PHYSICAL METHODS USED IN PURIFICATION' in Chapter 1.

BIBLIOGRAPHY

CHAPTER 3

PURIFICATION OF ORGANIC CHEMICALS

INTRODUCTION

The general principles, techniques and methods of purification in Chapters 1 and 2 are applicable to this chapter. Most organic liquids and a number of solids can readily be purified by fractional distillation, usually at atmospheric pressure. Sometimes, particularly with high boiling or sensitive liquids, or when in doubt about stability, distillation or fractionation under as low a pressure as possible should be carried out. To save space, the present chapter omits many substances for which the published purification methods involve simple distillation. Where boiling points are given, purification by distillation is another means of removing impurities. Literature references, and in particular *Beilstein* references, are included for most entries which refer the reader directly or indirectly to the original sources. Substances are listed alphabetically in each section, usually with some criteria of purity, giving brief details of how they can be purified. Also noted are the empirical formulae, molecular weights (to the first decimal place), melting points and/or boiling points together with the respective densities and refractive indexes for liquids, and specific optical rotations for chiral compounds. All temperatures are in degrees ***centigrade*** unless stated otherwise. When temperatures and/or wavelengths are not given for the last three named properties, then they should be assumed to be 20°C and the average of the wavelengths of the sodium D lines respectively; and most densities are relative to water at 4°C. When pressure is stated as **atm** it means that it is not mentioned specifically in the literature, but is assumed to be 760mm of Hg or 101.325 kPa.
Ionisation constants of ionisable compounds are given as **pK** values (published in the literature) and refer to the **pKa** values at room temperature (~ 15°C to 25°C) when not specified. Values at other temperatures are given as superscripts, e.g. $\mathbf{pK^{30}}$ for 30°C. Estimated values are entered as $\mathbf{pK_{Est}}$ (see Chapter 1).

Rapid purification procedures are included for commonly used solvents and reagents which make them suitable for general use in synthetic chemistry. Commercially available polymer supported reagents are indicated with **§** under the appropriate reagent.

Abbreviations of titles of periodicals are defined as in the Chemical Abstracts Service Source Index (CASSI) but without punctuation. References to Fieser & Fieser's *Reagents for Organic Synthesis* are shortened to Fieser throughout, e.g. Fieser **2** 254, **11** 88, etc. Other abbreviations are self evident.

As a good general rule, all low boiling (<100°) organic liquids should be treated as highly flammable and toxic (because they can be inhaled in large quantities) and the necessary precautions should be taken (see Safety precautions associated with the purification of laboratory chemicals in Chapter 1).

Benzene has been used as a solvent successfully and extensively in the past for reactions and purification but is now considered a **very dangerous and CARCINOGENIC substance**. It should be used with extreme care. We emphasise that alternative solvents (e.g. toluene, toluene-petroleum ether, or a petroleum ether to name a few) should be used first. However, if no other solvent system can be found, then all operations involving benzene (and storage) should be performed in an efficiently running fumehood, and precautions taken to avoid inhalation and contact with skin and eyes. An asterisk has been inserted in the text, e.g. $^{*}C_6H_6$ or *benzene, to remind the user that special precautions should be adopted.

This chapter consists of four sections *viz*: **Aliphatic Compounds, Alicyclic Compounds, Aromatic Compounds, Heterocyclic Compounds** and **Miscellaneous As, B, P, Si, S, Se, and Te Compounds.**

Purification of Laboratory Chemicals.
http://dx.doi.org/10.1016/B978-0-12-805457-4.50003-3,

ALIPHATIC COMPOUNDS

Acetal (acetaldehyde diethylacetal) *[105-57-7]* **$C_6H_{14}O_2$, M 118.2, b 103.7-104°, d_4^{20} 0.831, n_D^{25} 1.38054, n^{25} 1.3682.** Dry acetal over Na to remove alcohols and H_2O, and to polymerise aldehydes, then fractionally distil. Or, treat it with alkaline H_2O_2 at 40-45° to remove aldehydes, then saturate with NaCl, separate, dry with K_2CO_3 and distil from Na [Vogel *J Chem Soc* 616 *1948*, DOI: 10.1039/JR9480000616]. [*Beilstein* **1** IV 3103.]

Acetaldehyde *[75-07-0]* **C_2H_4O, M 44.1, b 20.2°/atm, d_4^{20} 0.788, n_D^{25} 1.33113, pK^{25} 13.57 (hydrate).** Acetaldehyde is usually purified by fractional distillation in a glass helices-packed column under dry N_2, discarding the first portion of distillate. Or, it is shaken for 30 minutes with $NaHCO_3$, dried with $CaSO_4$ and fractionally distilled at 760mm through a 70cm Vigreux column. The middle fraction is collected and further purified by standing for 2 hours at 0° with a small amount of hydroquinone (free radical inhibitor), followed by distillation [Longfield & Walters *J Am Chem Soc* **77** 810 *1955*, DOI: 10.1021/ja01608a094]. [*Beilstein* **1** IV 3094.]

Acetaldehyde dimethyl acetal (1,1-dimethoxyethane) *[534-15-6]* **$C_4H_{10}O_2$, M 90.1, b 63-65°/atm, d_4^{20} 0.852, n_D^{25} 1.36678.** Distil the dimethyl acetal through a fractionating column and the fraction boiling at 63.8°/751mm is collected. It forms an azeotrope with MeOH. *Alternatively*, purify it as for *acetal* above. It has been purified by GLC. [*Beilstein* **1** IV 3103.]

Acetamide *[60-35-5]* **C_2H_5NO, M 59.1, m 81°, pK_1^{25} -1.4, pK_2^{25} +0.37.** Acetamide is crystallised by dissolving in hot MeOH (0.8ml/g), diluting with Et_2O and allowing to stand [Wagner *J Chem Edu* **7** 1135 *1930*, DOI: 10.1021/ed007p1135]. Alternate crystallisation solvents are acetone, *benzene, chloroform, dioxane, methyl acetate or *benzene/ethyl acetate mixtures (3:1 and 1:1). It has also been recrystallised from hot water after treating with HCl-washed activated charcoal (which had been repeatedly washed with water until free from chloride ions), then crystallised again from hot 50% aqueous EtOH and finally twice from hot 95% EtOH [Christoffers & Kegeles *J Am Chem Soc* **85** 2562 *1963*, DOI: 10.1021/ja00900a005]. Finally it is dried in a vacuum desiccator over P_2O_5. Acetamide is also purified by distillation (**b 221-223°/atm**) or by sublimation *in vacuo*. It has also been purified by two recrystallisations from cyclohexane containing 5% (v/v) of *benzene. Needle-like crystals separate and are filtered, washed with a small volume of distilled H_2O and dried with a flow of dry N_2. [Slebocka-Tilk et al. *J Am Chem Soc* **109** *4620 1987*, DOI: 10.1021/ja00249a027; *Beilstein* **2** H 175, **2** I 80, **2** II 177, **2** III 384, **2** IV 399.]

Acetamidine hydrochloride *[124-42-5]* **$C_2H_7ClN_2$, M 94.5, m 164-166°, 165-170°(dec), 174°, pK^{25} 12.40.** The hydrochloride can be recrystallised from small volumes of EtOH. *Alternatively*, it is dissolved in EtOH, filtered, Et_2O is added; filter the crystalline salt off under N_2 and dry it in a vacuum desiccator over H_2SO_4. The salt is deliquescent and should be stored in a tightly stoppered container. Its solubility in H_2O is 10% at room temperature and it is soluble in Me_2CO. The *free base* reacts strongly alkaline in H_2O. It has λ_{max} 224nm (ε 4000) in H_2O. The ***picrate*** has **m 252°** (sintering at ~245°). [Dox *Org Synth* Coll Vol **I** 5 *1941*, DOI: 10.15227/orgsyn.008.0001; Davies & Parsons *Chem Ind (London)* 628 *1958*, Barnes et al. *J Am Chem Soc* **62** 1281 *1940*, DOI: 10.1021/ja01862a086, give **m** 177-178°; *Beilstein* **2** H 185, **2** I 85, **2** II 183, **2** III 416, **2** IV 428.]

***N*-(2-Acetamido)-2-aminoethanesulfonic acid (ACES)** *[7365-82-4]* **$C_4H_{10}N_2O_4S$, M 182.2, m > 220°(dec), pK_{Est} ~1.5, pK_2 6.9.** Recrystallise ACES from hot aqueous EtOH. [Perrin & Dempsey *Buffers for pH and Metal Ion Control* Chapman & Hall, London *1974*, ISBN 0412117002; *Beilstein* **4** III 1707.]

***N*-(2-Acetamido)iminodiacetic acid (ADA)** *[26239-55-4]* **$C_6H_{10}N_2O_5$, M 190.2, m 219°(dec), pK_1 ~2.3, pK_2 6.6.** Dissolve ADA in water, add one equivalent of NaOH solution (to final pH of 8-9), then acidify with HCl to precipitate the free acid. This is filtered off, washed with water and dried *in vacuo*. [*Beilstein* **4** IV 2441.]

Acetamidomethanol *[625-51-4]* **$C_3H_7NO_2$, M 89.1, m 47-50°, 54-56°, 55°.** Recrystallise it from freshly

distilled Me_2CO, wash the crystals with dry Et_2O and dry them in a vacuum desiccator over P_2O_5. R_F 0.4 on paper chromatography with $CHCl_3$/EtOH (2:8) as solvent and developed with ammoniacal $AgNO_3$. It also crystallises in needles from EtOAc containing a few drops of Me_2CO. It is *hygroscopic* and should be stored under dry conditions. [Bachmann et al. *J Am Chem Soc* **73** 2775 *1951*, DOI: 10.1021/ja01150a101; Walter et al. *Chem Ber* **99** 3204 *1966*, DOI: 10.1002/cber.19660991019; Einhorn & Ladisch *Justus Liebigs Ann Chem* **343** 265 *1905*, DOI: 10.1002/jlac.19053430207; *Beilstein* **2** IV 405.]

Acetic acid (glacial) *[64-19-7]* **$C_2H_4O_2$, M 60.1, m 16.6°, b 118°/atm, d $_4^{20}$ 1.049, n $_D^{25}$ 1.37171, n^{25} 1.36995, pK^{25} 4.76.** Usual impurities are traces of acetaldehyde and other oxidisable substances and water. Glacial acetic acid is very *hygroscopic*. The presence of 0.1% water lowers its **m** by 0.2°. Purify it by adding some acetic anhydride to react with water present, heat it for 1 hour to just below boiling in the presence of 2g CrO_3 per 100ml and then fractionally distil it [Orton & Bradfield *J Chem Soc* 983 *1927*, DOI: 10.1039/JR9270000983]. Instead of CrO_3, use 2-5% (w/w) of $KMnO_4$, and boil under reflux for 2-6 hours. Traces of water have been removed by refluxing with tetraacetyl diborate (prepared by warming 1 part of boric acid with 5 parts (w/w) of acetic anhydride at 60°, cooling, and filtering off, followed by distillation [Eichelberger & La Mer *J Am Chem Soc* **55** 3633 *1933*, DOI: 10.1021/ja01336a023].
Refluxing with acetic anhydride in the presence of 0.2g % of 2-naphthalenesulfonic acid as catalyst has also been used [Orton & Bradfield *J Chem Soc* 983 *1927*, DOI: 10.1039/JR9270000983]. Other suitable drying agents include anhydrous $CuSO_4$ and chromium triacetate: P_2O_5 converts some acetic acid to the anhydride. Azeotropic removal of water by distillation with thiophene-free *benzene or with butyl acetate has been used [Birdwhistell & Griswold *J Am Chem Soc* **77** 873 *1955*, DOI: 10.1021/ja01609a016]. An alternative purification uses fractional freezing. [*Beilstein* **2** H 96, **2** IV 94.] **Rapid procedure:** Add 5% acetic anhydride, and 2% of CrO_3. Reflux and fractionally distil.

Acetic anhydride *[108-24-7]* **$C_4H_6O_3$, M 102.1, b 138°/atm, d $_4^{20}$ 1.082, n $_D^{25}$ 1.3904.** Adequate purification can usually be achieved by fractional distillation through an efficient column. Acetic acid can be removed by prior refluxing with CaC_2 or with coarse Mg filings at 80-90° for 5 days, or by distillation from a large excess of quinoline (1% AcOH in quinoline) at 75mm pressure. Acetic anhydride can also be dried by standing with Na wire for up to a week, removing the Na and distilling it under vacuum. (Na reacts vigorously with acetic anhydride at 65-70°). Dippy & Evans [*J Org Chem* **15** 451 *1950*, DOI: 10.1021/jo01149a001] let the anhydride (500g) stand over P_2O_5 (50g) for 3 hours, then decanted it and stood it over ignited K_2CO_3 for a further 3 hours. The supernatant liquid was distilled and the fraction **b** 136-138° was further dried with P_2O_5 for 12 hours, followed by shaking with ignited K_2CO_3, before two further distillations through a five-section Young and Thomas fractionating column. The final material distilled at 137.8-138.0°/atm. It can also be purified by azeotropic distillation with toluene: the azeotrope boils at 100.6°. After removal of the remaining toluene, the anhydride is distilled [sample had a specific conductivity of 5 x 10^{-9} $ohm^{-1}cm^{-1}$]. [*Beilstein* **2** H 96, **2** I 39, **2** II 91, **2** III 134, **2** IV 94.] **Rapid procedure:** Shake with P_2O_5, separate, shake with dry K_2CO_3 and fractionally distil. ***Acetic hydrazide*** *[1068-57-1]* **$C_2H_6N_2O$, M 74.1, m 67°, b 127°/18mm,** crystallises as needles from EtOH. It reduces $NH_3/AgNO_3$. [*Beilstein* **2** H 191, **2** IV 435.]

Acetoacetamide *[5977-14-0]* **$C_4H_7NO_2$, M 101.1, m 54-55°, 54-56°**. Recrystallise the amide from $CHCl_3$, or Me_2CO/petroleum ether. It also crystallises from pyridine with 4mols of solvent. It is slightly soluble in H_2O, EtOH and AcOH but is insoluble in Et_2O. The ***phenylhydrazone*** has **m 128°**. [Kato *Chem Pharm Bull Jpn* **15** 921 923 *1967*, DOI: org/10.1248/cpb.15.921; Claisen & Meyer *Chem Ber* **35** 583 *1902*, DOI: 10.1002/cber.19020350190; *Beilstein* **3** H 659, **3** I 231, **3** III 1204, **3** IV 1545.]

Acetone *[67-64-1]* **C_3H_6O, M 58.1, b 56.2°/atm, d $_4^{20}$ 0.791, n $_D^{25}$ 1.35880, pK $_1^{25}$ -6.1 (basic, monoprotonated), pK $_2^{25}$ 20.0 (acidic)** The commercial preparation of acetone by catalytic dehydrogenation of isopropyl alcohol gives relatively pure material. Analytical reagent quality generally contains less than 1% of organic impurities but may have up to about 1% of H_2O. Dry acetone is appreciably *hygroscopic*. The main organic impurity in acetone is mesityl oxide, formed by aldol condensation. It can be dried with anhydrous $CaSO_4$, K_2CO_3 or type 4A Linde molecular sieves, and then distilled. Silica gel and alumina, or mildly acidic or basic desiccants cause acetone to undergo the aldol condensation, so that its water content is increased by pass-

age through these reagents. This also occurs to some extent when P_2O_5 or sodium amalgam is used. Anhydrous $MgSO_4$ is an inefficient drying agent, and $CaCl_2$ forms an addition compound. Drierite (anhydrous $CaSO_4$) offers minimum acid and base catalysis for aldol formation and is the recommended drying agent for this solvent [Riddick & Bunger *Organic Solvents* Wiley-Interscience, NY, 3rd edn, *1970*]. Acetone can be shaken with Drierite (25g/L) for several hours before it is decanted and distilled from fresh Drierite (10g/L) through an efficient column, maintaining atmospheric contact through a Drierite drying tube.
The equilibrium water content is about 10^{-2}M. Anhydrous $Mg(ClO_4)_2$ **should not be used as drying agent as there is a high risk of EXPLOSION with acetone vapour.**
Organic impurities have been removed from acetone by adding 4g of $AgNO_3$ in 30ml of water to 1L of acetone, followed by 10ml of M NaOH, shaking for 10 minutes, filtering, drying with anhydrous $CaSO_4$ and distilling [Hawley et al. *Analyst (London)* **58** 333 *1933*, DOI: 10.1039/AN9335800333]. *Alternatively*, successive small portions of $KMnO_4$ have been added to acetone at reflux, until the violet colour persists, followed by drying and distilling. Refluxing with chromium trioxide (CrO_3) has also been used. Methanol has been removed from acetone by azeotropic distillation (at 35°) with methyl bromide, and treatment with acetyl chloride.
Small amounts of acetone can be purified as the NaI addition compound, by dissolving 100g of finely powdered NaI in 400g of boiling acetone, then cooling in ice and salt to -8°. Crystals of NaI.3Me_2CO are filtered off and, on warming in a flask, acetone distils off readily. [This method is more convenient than the one using the bisulfite addition compound.] It has also been purified by gas chromatography on a 20% free fatty acid phthalate (on Chromosorb P) column at 100°.
For efficiency of desiccants in drying acetone see Burfield and Smithers [*J Org Chem* **43** 3966 *1978*, DOI: 10.1021/jo00414a038]. The water content of acetone can be determined by a modified Karl Fischer titration [Koupparis & Malmstadt *Anal Chem* **54** 1914 *1982*, DOI: 10.1021/ac00248a072]. [*Beilstein* **1** IV 3180.]
Rapid procedure: Dry over anhydrous $CaSO_4$ and distil. ***Acetoxime (acetone oxime)*** *[127-06-0]* **C_3H_7NO, M 73.1, m 63°, b 135°/760mm, d_4^{20} 0.901, pK^{40} 0.99,** crystallises from petroleum ether (b 40-60°) and can be sublimed. [*Beilstein* **1** H 649, **1** IV 3202.] ***Acetone semicarbazone*** *[110-20-3]* **$C_4H_{10}N_3O$, M 115.1, m 187°, pK^{25} 1.33,** crystallises from water or from aqueous EtOH. [*Beilstein* **3** H 101, **3** I 48, **3** II 81, **3** III 189, **3** IV 179.]

Acetone cyanohydrin *[75-86-5]* **C_4H_7NO, M 85.1, b 48°/2.5mm, 68-70°/11mm, 78-82°/15mm, d_4^{20} 0.93.** Dry the cyanohydrin with Na_2SO_4, and distil it as rapidly as possible under vacuum to avoid decomposition. Discard fractions boiling below 78-82°/15mm. Store it in the dark. **USE AN EFFICIENT FUME HOOD as HCN (POISONOUS) released is always present.** [Cox & Stormont *Org Synth* Coll Vol **2** 7 *1940*, DOI: 10.15227/orgsyn.015.0001; *Beilstein* **3** H 316, **3** IV 785.]

Acetonedicarboxylic acid (3-oxoglutaric acid) *[542-05-2]* **$C_5H_6O_5$, M 146.1, m 138°(dec), pK^{25} 3.10.** Crystallise it from ethyl acetate and store it over P_2O_5. It decarboxylates in hot water. [*Beilstein* **3** IV 1816.]

Acetonitrile (methyl cyanide) *[75-05-8]* **C_2H_3N, M 41.1, b 81.6°/atm, d^{25} 0.77683, n_D^{20} 1.3441, n^{25} 1.34163.** Commercial acetonitrile is a by-product of the reaction of propylene and ammonia to acrylonitrile. The following procedure that significantly reduces the levels of acrylonitrile, allyl alcohol, acetone, and *benzene was used by Kiesele [*Anal Chem* **52** 2230 *1988*, DOI: 10.1021/ac50063a062]. Methanol (300ml) is added to 3L of acetonitrile fractionated at high reflux ratio until the boiling temperature rises from 64° to 80°, and the distillate becomes optically clear down to λ = 240nm. Add sodium hydride (1g) free from paraffin, to the liquid, reflux for 10 minutes, and then distil rapidly until about 100ml of residue remains. Immediately pass the distillate through a column of acidic alumina, discarding the first 150ml of percolate. Add 5g of CaH_2 and distil the first 50ml at a high reflux ratio. Discard this fraction, and collect the following main fraction. The best way of detecting impurities is by gas chromatography.
Usual contaminants in commercial acetonitrile include H_2O, acetamide, NH_4OAc and NH_3. Anhydrous $CaSO_4$ and $CaCl_2$ are inefficient drying agents. Preliminary treatment of acetonitrile with cold, saturated aqueous KOH is undesirable because of base-catalysed hydrolysis and the introduction of water. Drying by shaking with silica gel or Linde 4A molecular sieves removes most of the water in acetonitrile. Subsequent stirring with CaH_2 until no further hydrogen is evolved leaves only traces of water and removes acetic acid. The acetonitrile is then fractionally distilled at high reflux, taking precaution to exclude moisture by refluxing over CaH_2 [Coetzee *Pure Appl Chem* **13** 427 *1966*, DOI: org.virtual.anu.edu.au/10.1351/pac196613030427]. *Alternatively*, 0.5-1% (w/v)

P_2O_5 is often added to the distilling flask to remove most of the remaining water. Excess P_2O_5 should be avoided because it leads to the formation of an orange polymer. Traces of P_2O_5 can be removed by distilling from anhydrous K_2CO_3.
Kolthoff, Bruckenstein and Chantooni [*J Am Chem Soc* **83** 3927 *1961*, DOI: 10.1021/ja01480a001] removed acetic acid from 3L of acetonitrile by shaking for 24 hours with 200g of freshly activated alumina (which had been reactivated by heating at 250° for 4 hours). The decanted solvent was again shaken with activated alumina, followed by five batches of 100-150g of anhydrous $CaCl_2$. (Water content of the solvent was then less than 0.2%.) It was shaken for 1 hour with 10g of P_2O_5, twice; and distilled in a 1m x 2cm column, packed with stainless steel wool and protected from moisture by $CaCl_2$ tubes. The middle fraction had a water content from 0.7 to 2mM. Traces of unsaturated nitriles can be removed by initially refluxing with a small amount of aqueous KOH (1ml of 1% solution per L). Acetonitrile can be dried by azeotropic distillation with dichloromethane, *benzene or trichloroethylene. Isonitrile impurities can be removed by treatment with concentrated HCl until the odour of isonitrile has gone, followed by drying with K_2CO_3 and distilling.
Acetonitrile is refluxed with, and distilled from alkaline $KMnO_4$ and $KHSO_4$, followed by fractional distillation from CaH_2. (This is better than fractionation from molecular sieves or passage through a type H activated alumina column, or refluxing with KBH_4 for 24 hours and fractional distillation) [Bell et al. *JCS Faraday Trans* **73** 315 *1977*, DOI: 10.1039/F19777300315; Moore et al. *J Am Chem Soc* **108** 2257 *1986*, DOI: 10.1021/ja00269a022].
Material suitable for polarography is obtained by refluxing over anhydrous $AlCl_3$ (15g/L) for 1 hour, distilling, refluxing over Li_2CO_3 (10g/L) for 1 hour and redistilling. It is then refluxed over CaH_2 (2g/L) for 1 hour and fractionally distilled, retaining the middle portion. The product is not suitable for UV spectroscopy use. A better purification procedure uses refluxing over anhydrous $AlCl_3$ (15g/L) for 1 hour, distilling, refluxing over alkaline $KMnO_4$ (10g $KMnO_4$, 10g Li_2CO_3/L) for 15 minutes, and distilling. A further reflux for 1 hour over $KHSO_4$ (15g/L), then distillation, is followed by refluxing over CaH_2 (2g/L) for 1 hour, and fractional distillation. The product is protected from atmospheric moisture and stored under nitrogen [Walter & Ramalay *Anal Chem* **45** 165 *1973*, DOI: 10.1021/ac60323a041]. Purification of 'General Purity Reagent' for this purpose is not usually satisfactory because very large losses occur at the $KMnO_4/LiCO_3$ step. For electrochemical work involving high oxidation fluorides, further reflux over P_2O_5 (1g/ml for 0.5 hours) and distilling (discarding 3% of first and last fractions) and repeating this step is necessary. The distillate is kept over molecular sieves *in vacuo* after degassing, for 24 hours and distilling in a vacuum onto freshly activated 3A molecular sieves. The MeCN should have absorption at 200nm of <0.05 (H_2O reference) and UV cutoff at *ca* 175nm. Also the working potential range of purified $Et_4N^+ BF_4^-$ (0.1mol.dcm^{-3} in the MeCN) should be +3.0 to -2.7V *vs* Ag^+/Ag^o. If these criteria are not realised then further impurities can be removed by treatment with activated neutral alumina (60 mesh) *in vacuo* before final molecular sieves treatment [Winfield *J Fluorine Chem* **25** 91 *1984*, DOI: 10.1016/S0022-1139(00)81199-9].
Acetonitrile has been distilled from $AgNO_3$, collecting the middle fraction over freshly activated Al_2O_3. After standing for two days, the liquid is distilled from the activated Al_2O_3. The specific conductivity should be 0.8-1.0 x 10^{-8} mhos [Harkness & Daggett *Can J Chem* **43** 1215 *1965*, DOI: 10.1139/v65-158]. *Acetonitrile ^{14}C* is best purified by gas chromatography, is water free, and distils at 81°/atm. [*Beilstein* **2** H 183, **2** IV 419.]
Rapid procedure: Dry over anhydrous K_2CO_3 for 24 hours, followed by further drying for 24 hours over 3A molecular sieves or boric anhydride, followed by distillation. *Alternatively*, stir over P_2O_5 (5% w/v) for 24 hours then distil. However, this last method is not suitable for reactions with very acid sensitive compounds.

Acetonylacetone (2,5-hexanedione) *[110-13-4]* **$C_6H_{10}O_2$, M 114.2, m -9°, b 76-78°/13mm, 88°/25mm, 137°/150mm, 188°/atm, d_4^{20} 0.9440, n_D^{20} 1.423, pK^{25} 18.7.** Purify it by dissolving in Et_2O, stiring with K_2CO_3 (a quarter of the weight of dione), filtering, drying over anhydrous Na_2SO_4 (**not $CaCl_2$**), filtering again, evaporating the filtrate and distilling it in a vacuum. Then redistil through a 30cm Vigreux column (oil bath temperature 150°). It is miscible with H_2O and EtOH. The ***dioxime*** has **m 137°** (plates from *C_6H_6), the ***monooxime*** has **b 130°/11mm**, and the ***2,4-dinitrophenylhydrazone*** has **m 210-212°** (red needles from EtOH). It forms complexes with many metals. [Werner et al. *Chem Ber* **22** 2097 *1989*, DOI: 10.1002/cber.19891221109; for enol content see Gero *J Org Chem* **19** 1960 *1954*, DOI: 10.1021/jo01377a013; *Beilstein* **1** IV 3688.]

Acetoxyacetone (acetonyl acetate, acetol acetone) *[592-20-1]* **$C_5H_8O_3$, M 116.1, b 65°/11mm, 73-75°/17mm, 174-176°/atm, d_4^{20} 1.0757, n_D^{20} 1.4141.** Distil it in a vacuum, then redistil it at atmospheric press-

ure. It is miscible with H_2O, but is slowly decomposed by it. Store it in a dry atmosphere. The ***2,4-dinitrophenylhydrazone*** has **m 115-115.5°** (from $CHCl_3$/hexane). [Perkin Jr *J Chem Soc* **59** 786 *1891*, DOI: 10.1039/CT8915900786; Reich & Samuels *J Org Chem* **21** 68 *1956*, DOI: 10.1021/jo01377a013; Nef *Justus Liebigs Ann Chem* **335** 247 *1904*, DOI: 10.1002/jlac.19043350302; *Beilstein* **2** IV 297.]

1-Acetoxy-1,3-butadiene (1,3-butadienyl acetate) ***cis-trans*** mixture *[1515-76-0]* **$C_6H_8O_2$, M 112.1, b 42-43°/16mm, 51-52°/20mm, 60-61°/40mm, d_4^{20} 0.9466, n_D^{20} 1.4622.** The commercial sample is stabilised with 0.1% of *p-tert*-butylcatechol. If the material contains crotonaldehyde (by IR, used in its synthesis), it should be dissolved in Et_2O, shaken with 40% aqueous sodium bisulfite, then 5% aqueous Na_2CO_3, water, dried (Na_2SO_4) and distilled several times in a vacuum through a Widmer [*Helv Chim Acta* **7** 59 *1924*, DOI: 10.1002/hlca.19240070107] or Vigreux column [Wichterle & Hudlicky *Coll Czech Chem Commun* **12** 564 *1947*, DOI: 10.1135/cccc19470564; Hagemeyer & Hull *Ind Eng Chem* **41** 2920 *1949*, DOI: 10.1021/ie50480a063]. [*Beilstein* **2** III 295.]

1-Acetoxy-2-butoxyethane (2-butyloxyethyl acetate) *[112-07-2]* **$C_8H_{16}O_3$, M 160.2, b 61-62°/0.2mm, 75-76°/12mm, 185.5°/740mm, 188-192°/atm, d_4^{20} 0.9425, n_D^{20} 1.4121.** Shake the ester with anhydrous Na_2CO_3, filter and distil it in a vacuum. Redistillation can then be carried out at atmospheric pressure. [Dunbar & Bolstad *J Org Chem* **21** 1041 *1956*, DOI: 10.1021/jo01115a613; *Beilstein* **2** IV 215.]

2-Acetoxyethanol (2-hydroxyethyl acetate) *[542-59-6]* **$C_4H_8O_3$, M 104.1, b 61°/1mm, 79-81°/12mm, 187°/761mm, d_4^{20} 1.108, n_D^{20} 1.42.** Dry the ester over K_2CO_3 (**not $CaCl_2$**), and distil it. [Davis & Ross *J Chem Soc* 3056 1950, DOI: 10.1039/JR9500003056; rate of hydrolysis: Davis & Ross *J Chem Soc* 2706 *1951*, DOI: 10.1039/JR9510002706; *Beilstein* **2** H 141, **2** I 66, **2** II 154, **2** III 303, **2** IV 214.]

1-Acetoxy-2-ethoxyethane *[111-15-9]* **$C_6H_{12}O_3$, M 132.2, b 30°/3mm, 49-50°/12mm, 156-159°, d_4^{20} 0.97, n_D^{20} 1.406.** Shake the ethoxy-ethane with anhydrous Na_2CO_3, filter and distil it in a vacuum. Redistillation can then be carried out at atmospheric pressure. [Dunbar & Bolstad *J Org Chem* **21** 1041 *1956*, DOI: 10.1021/jo01115a613; *Beilstein* **2** IV 214.]

1-Acetoxy-2-methoxyethane *[110-49-6]* **$C_5H_{10}O_3$, M 118.1, b 30°/6mm, 40-41°/12mm, 140-144°/760mm, d_4^{20} 1.009, n_D^{20} 1.4011.** Shake the methoxy-ethane with anhydrous Na_2CO_3, filter and distil it in a vacuum. Redistillation can be then be carried out at atmospheric pressure. [Dunbar & Bolstad *J Org Chem* **21** 1041 *1956*, DOI: 10.1021/jo015a61311; *Beilstein* **2** IV 214.]

***S*-(-)-2-Acetoxypropionyl chloride** *[36394-75-9]* **$C_5H_7ClO_3$, M 150.6, b 51-53°/11mm, d_4^{20} 1.19, n_D^{20} 1.423, $[\alpha]_D^{27}$ -33, (c 4, $CHCl_3$), $[\alpha]_{546}^{20}$ -38 (c 4, $CHCl_3$).** It is moisture sensitive and is hydrolysed to the corresponding acid. Check the IR spectrum. If the OH band above 3000cm $^{-1}$ is too large and broad then the mixture should be refluxed with pure acetyl chloride for 1 hour, evaporated and distilled under reduced pressure. [Doolittle & Heath *J Org Chem* **49** 5041 1984, DOI: 10.1021/jo01115a613; *Beilstein* **3** II 189.]

***S*-Acetoxysuccinic anhydride** *[59025-03-5]* **$C_6H_6O_5$, M 158.1, m 58° (*RS* 81.5-82.5°, 86-87°), $[\alpha]_D^{20}$ -26.0 (c 19, Me_2CO), $[\alpha]_D^{20}$ -28.4 (c 13, Ac_2O).** Recrystallise it from Ac_2O and dry it in a vacuum over KOH, or by washing it with dry Et_2O due to its deliquescent nature. [Jones *J Chem Soc* 788 *1933,* DOI: 10.1039/JR9330000788; Henrot et al. *Synth Commun* **16** 183 *1986*, DOI: 10.1080/00397918608057706; Shiuey et al. *J Org Chem* **53** 1040 *1988*, DOI: 10.1021/jo00240a021; *RS*: Cohen et al. *J Am Chem Soc* **88** 5306 *1966*, DOI: 10.1021/ja00974a051]

Acetylacetone (2,4-pentanedione, acac) *[123-54-6]* **$C_5H_8O_3$, M 100.1, m -23°, 45°/30mm, b 140.4°/atm, $d^{30.2}$ 0.9630, $n^{18.5}$ 1.45178, pK_1^{25} -5.0 (enol), -6.6 (keto), pK_2^{25} 8.95.** Small amounts of acetic acid are removed by shaking with small portions of 2N NaOH until the aqueous phase remains faintly alkaline. The sample, after washing with water, is dried with anhydrous Na_2SO_4, and distilled through a modified Vigreux column [Cartledge *J Am Chem Soc* **73** 4416 *1951,* DOI: 10.1021/ja01153a112]. An additional purification step is fractional crystallisation from the melt. *Alternatively*, there is less loss of acetylacetone if it is dissolved in four volumes of *benzene and the solution is shaken three times with an equal volume of distilled water (to extr-

act acetic acid): the *benzene is then removed by distillation at 43-53°/20-30mm through a helices-packed column. It is then refluxed over P_2O_5 (10g/L) and fractionally distilled under reduced pressure. The distillate (sp conductivity 4 x 10^{-8} $ohm^{-1}cm^{-1}$) is suitable for polarography [Fujinaga & Lee *Talanta* **24** 395 *1977* DOI: 10.1016/0039-9140(77)80028-3]. To recover used acetylacetone, metal ions are stripped from the solution at pH 1 (using 100ml 0.1M H_2SO_4/L of acetylacetone). The acetylacetone is then washed with (1:10) ammonia solution (100ml/L) and with distilled water (100ml/L, twice), then treated as above. It complexes with Al, Be, Ca, Cd, Ce , Cu, Fe^{2+}, Fe^{3+}, Mn, Mg, Ni, Pb and Zn. [*Beilstein* **1** H 777, **1** I 401, **1** II 831, **1** III 3113, **1** IV 3662.]

Acetyl bromide *[506-96-7]* **C_2H_3BrO, M 123.0, b 76-77°/atm, d_4^{20} 1.65.** Boil acetyl bromide with PBr_3/Ac_2O for 1 hour, then distil the latter off and redistil it. Store it dry and in the dark. [Burton & Degering *J Am Chem Soc* **62** 227 *1940*, DOI: 10.1021/ja01858a502; *Beilstein* **2** IV 398.] **LACHRYMATORY.**

2-Acetylbutyrolactone *[517-23-7]* **$C_6H_8O_3$, M 128.1, b 105°/5mm, 120-123°/11mm, 142-143°/30mm, d_4^{20} 1.1846, n_D^{20} 1.459.** Purify the lactone by distillation, which will convert any free acid to the lactone. *Alternatively*, dissolve it in Et_2O, wash well with 0.5N HCl, dry the organic layer and distil it. Its solubility in H_2O is 20% v/v. The ***2,4-dinitrophenylhydrazone*** forms orange needles from MeOH, **m 146°**. The lactone hydrolyses in mineral acid to 2-acetyl-4-hydroxybutyric acid which can be converted to the ***di-n-propylamine salt*** with **m 68-70°**. The lactone is a **SKIN IRRITANT**. [Willman & Schinz *Helv Chim Acta* **35** 2401 *1952*, DOI: 10.1002/hlca.19520350728; *Beilstein* **17/11** V 16.]

Acetyl chloride *[75-36-5]* **C_2H_3ClO, M 78.5, b 52°/atm, d_4^{20} 1.1051, n_D^{20} 1.38976.** Reflux acetyl chloride with PCl_5 for several hours to remove traces of acetic acid, then distil it. Redistil it from one-tenth its volume of dimethylaniline or quinoline to remove free HCl. A.R. quality is freed from HCl by pumping it for 1 hour at -78° and distilling it into a trap at -196°. [*Beilstein* **2** IV 395.] **LACHRYMATORY.**

Acetylene *[74-86-2]* **C_2H_2, M 26.0, m -80.8°, b -84°/atm, pK^{25} ~25.** If very impure, acetylene should be purified by successive passage through spiral wash bottles containing, in this order, saturated aqueous $NaHSO_4$, H_2O, 0.2M iodine in aqueous KI (two bottles), sodium thiosulfate solution (two bottles), alkaline sodium hydrosulfite with sodium anthraquinone-2-sulfonate as indicator (two bottles), and 10% aqueous KOH solution (two bottles). The gas is then passed through a Dry-Ice trap and two drying tubes, the first containing $CaCl_2$, and the second, Dehydrite [$Mg(ClO_4)_2$] [Conn et al. *J Am Chem Soc* **61** 1868 *1939*, DOI: 10.1021/ja01876a066]. Acetone vapour can be removed from acetylene by passage through H_2O, then concentrated H_2SO_4, or by passage through two gas traps at -65° and -80°, concentrated H_2SO_4 and a soda lime tower, a tower of 1-mesh Al_2O_3 then through H_2SO_4 [Reichert & Nieuwland *Org Synth* Coll Vol **I** 229 *1941*, DOI: 10.15227/orgsyn.004.0023; Wiley *Org Synth* Coll Vol **3** 853 *1955*, DOI: 10.15227/orgsyn.028.0094; Skattebol et al. *Org Synth* Coll Vol **4** 792 *1963* DOI: 10.15227/orgsyn.039.0056]. Sometimes it contains acetone and air. These can be removed by a series of bulb-to-bulb distillations, e.g. a train consisting of a concentrated H_2SO_4 trap and a cold EtOH trap (-73°), or passage through H_2O and H_2SO_4, then over KOH and $CaCl_2$. [See Brandsma *Preparative Acetylenic Chemistry,* 1st Edn Elsevier *1971* p15, for pK, ISBN 0444409475, 2nd Edn Elsevier *1988*, ISBN 0444429603, and below for sodium acetylide.] It is also available commercially as 10ppm in helium, and several concentrations in N_2 for instrument calibration. [*Beilstein* **1** IV 939.]
Sodium acetylide *[1066-26-8]* **M 48.0**, is prepared by dissolving Na (23g) in liquid NH_3 (1L) and bubbling acetylene until the blue color is discharged (*ca* 30 minutes) and evaporated to dryness [Saunders *Org Synth* Coll Vol **3** 416 *1955*, DOI: 10.15227/orgsyn.029.0047], and is available commercially as a suspension in xylene/light mineral oil. [See entry in 'Metal-organic Compounds', Chapter 4.]

Acetylenedicarboxamide (Aquamycin, Cellocidin) *[543-21-5]* **$C_4H_4N_2O_2$, M 112.1, m 216-218°(dec), 219-221°(dec).** Acetylenedicarboxamide crystallises from MeOH and H_2O [**m 190-192°(dec)** as ***hemihydrate***]. When prepared from the ester + NH_3 it has **m 213°(dec)**. Also a melting point of **290-292°(dec)** has been reported. [Saggimo *J Org Chem* **22** 1171 *1957*, DOI: 10.1021/jo01361a009; Kharash et al. *J Org Chem* **10** 386 *1945*, DOI: 10.1021/jo01181a002; Blomquist & Winslow *J Org Chem* **10** 149 *1945*, DOI: 10.1021/jo01178a010; *Beilstein* **2** I 317, **2** III 1995, **2** IV 2295.]

Acetylenedicarboxylic acid (butynedioic acid) *[142-45-0]* **$C_4H_2O_4$, M 114.1, m 179°(anhydrous), pK_1^{19} 1.04, pK_2^{19} 2.50.** The acid is soluble in Et_2O and crystallises from Et_2O/petroleum ether (**m 183-183.5°**), or H_2O as the *dihydrate* which dehydrates in a desiccator over concentrated H_2SO_4 in a vacuum. The *dipicrate* crystallises from aqueous ether. For the mono K salt see entry in 'Metal-organic Compounds', Chapter 4. [Abbott et al. *Org Synth* Coll Vol **2** 10 *1943*, DOI: 10.15227/orgsyn.018.0003; Huntress et al. *Org Synth* Coll Vol **4** 329 *1963*, DOI: 10.15227/orgsyn.032.0055; *Beilstein* **2** H 801, **2** I 317, **2** II 670, **2** III 1991, **2** IV 2290.]

N*-Acetylethylenediamine** *[1001-53-2]* **$C_4H_{10}N_2O$, M 102.1, m 50-51°, 51°, b 128°/3mm, 125-130°/5mm, 133-139°/27mm, pK^{25} 9.28.** The acetyl-diamine has been fractionated under reduced pressure and fraction **b** 125-130°/5mm was re-fractionated, fraction **b 132-135°/4mm** was collected and it solidified. It is a low melting *hygroscopic* solid which can be recrystallised from dioxane/Et_2O. It is soluble in H_2O, Et_2O and *C_6H_6. The ***p-toluenesulfonate salt can be recrystallised from EtOH/EtOAc (1:8), has **m 125-126°**, but the free base cannot be recovered from it by basifying and extracting with CH_2Cl_2. The ***picrate*** has **m 175°** (from EtOH) [Aspinall *J Am Chem Soc* **63** 852 *1941*, DOI: 10.1021/ja01848a060; Hall *J Am Chem Soc* **78** 2570 *1956*, DOI: 10.1021/ja01592a066]. [*Beilstein* **4** IV 1193.]

Acetyl fluoride *[557-99-3]* **C_2H_3FO, M 62.0, b 20.5°/760mm, d_4^{20} 1.032.** Purify acetyl fluoride by fractional distillation. It attacks glass and is sold in steel cylinders. [*Beilstein* **2** H 172, **2** I 79, **2** II 175, **2** III 385, **2** IV 393.] **TOXIC and LACHRYMATORY.**

Acetyl iodide *[507-02-8]* **C_2H_3IO, M 170.0, b 39.5-40°/64mm, 108°/760mm.** Purify it by fractional distillation. Store it in the dark. [*Beilstein* **2** II 177, **2** III 393, **2** IV 399.] **TOXIC and LACHRYMATORY.**

3-(S-Acetylmercapto)isobutyric acid *[RS 33325-40-5]* **$C_6H_{10}O_3S$, M 162.2, m 40-40.5°, b *ca* 120°/1.25mm, pK_{Est} ~4.0.** Distil the acid under high vacuum and recrystallise it from *C_6H_6. [Fredga & Mastersson *Chem Abstr* **38** 3616 *1944*.]

Acetyl methanesulfonate *[5539-53-7]* **$C_3H_6O_4S$, M 138.1, b <120°/<0.01mm.** The main impurity is methanesulfonic acid. Reflux it with redistilled acetyl chloride for 6-10 hours, i.e. until no further HCl is absorbed in a trap, and exclude moisture. Distil off excess of AcCl and carefully distil it below 0.001mm with the bath temperature below 120° to give the anhydride as a pale yellow oil which solidifies below 0°. Below ~130° it gives the disulfonic anhydride, and above ~130° polymers are formed. It is used for cleaving ethers [Preparation, IR, NMR: Mazur & Karger *J Org Chem* **36** 528, 532 *1971*, DOI: 10.1021/jo00803a009; DOI: 10.1021/jo00803a010]. [*Beilstein* **2** H 166, **2** III 349.]

3-(Acetylthio)propionic acid *[41345-70-4]* **$C_5H_8O_3S$, M 148.2, m 48-52°, 52-54°, b 127-128°/3mm, pK_{Est} ~4.2.** Purify the propionic acid by distillation in a vacuum. It has λ_{max} at 231nm (ε 4200). It is a potential enzyme inhibitor [Noda et al. *J Am Chem Soc* **75** 913 *1953*, DOI: 10.1021/ja01100a041; Clegg et al. *J Am Chem Soc* **121** 5319 *1999*, DOI: 10.1021/ja9901011; Larsson et al. *Angew Chem Int Ed* **43** 3716 *2004*, DOI: 10.1002/anie.200454165]. [*Beilstein* **3** III 551, **3** IV 731.]

***N*-Acetylthiourea** *[591-08-2]* **$C_3H_6ON_2S$ M 118.2, m 164-165°, 166-168°**. Recrystallise the thiourea from AcOH; the solid is washed with Et_2O and dried in air, then at 100°. [Zahradnik *Coll Czech Chem Commun* **24** 3678 *1959*, DOI:10.1135/cccc19593678; *Beilstein* **3** IV 354.]

cis*-Aconitic acid (1,2,3-propenetriscarboxylic acid)** *[585-84-2]* **$C_6H_6O_6$, M 174.1, m 126-129°(dec).** Crystallise the *cis*-acid from water by cooling (solubility is 1g in 2ml of water at 25°). Dry it in a vacuum desiccator. [*Beilstein* **2** IV 2405.] ***trans-Aconitic acid *[4023-65-8]* **$C_6H_6O_6$, M 174.1, m 195°(dec), m 198-199°(dec), 204-205°(dec), pK_1^{25} 2.81, pK_2^{25} 4.46,** is purified dissolving it in AcOH (77g/150ml), filtering and cooling. The acid separates (55g) as colourless needles. A further quantity (10g) can be obtained by reducing the volume of the filtrate. The acid is dried in air then in a vacuum desiccator over NaOH. The acid can be recrystallised from $Me_2CO/CHCl_3$. The highest melting point is obtained with the very dry acid, and **m 209°** was obtained on a Dennis bar [Dennis & Shalton *J Am Chem Soc* **52** 3128 *1930*, DOI: 10.1021/ja01371a013; Bruce *Org Synth* Coll Vol **2** 12 *1943*, DOI: 10.15227/orgsyn.017.0001]. [*Beilstein* **2** IV 2405.]

cis*-Aconitic anhydride** *[6318-55-4]* **$C_6H_4O_5$, M 156.1, m 75°, 76-78°, 78-78.5°.** Reflux it in xylene (7.5 parts) for 1 hour, then evaporate and recrystallise the residue from *C_6H_6. *Alternatively*, reflux it in Ac_2O, evaporate and recrystallise from *C_6H_6. It is sensitive to moisture, store dry. [IR: Groth & Dahlén *Acta Chem Scand* ***21 291 *1967*, DOI: 10.3891/acta.chem.scand.21-0291; Malachowski & Maslowski *Chem Ber* **61** 2521 *1928*, DOI: 10.1002/cber.19280611119; NMR: Gawron & Mahajan *Biochemistry* **5** 2335 *1966*, DOI: 10.1021/bi00871a023.] [*Beilstein* **18/8** V 530.]

Acrolein (acraldehyde, 2-propenal) *[107-02-8]* **C_3H_4O, M 56.1, fp -86.95°, b 25°/100mm, 52.69°/760mm (dt/dp 0.0355°/mm, d_4^{20} 0.839, n^{25} 1.3992**. Purify acrolein by fractional distillation, under nitrogen, drying with anhydrous $CaSO_4$ and then re-distilling under vacuum. Blacet, Young and Roof [*J Am Chem Soc* **59** 608 *1937*, DOI: 10.1021/ja01283a004] distilled it under nitrogen through a 90cm column packed with glass rings. To avoid formation of diacryl, the vapour is passed through an ice-cooled condenser into a receiver cooled in an ice-salt mixture and containing 0.5g catechol. The acrolein is then distilled twice from anhydrous $CuSO_4$ at low pressure, catechol being placed in the distilling flask and the receiver to avoid polymerisation. [*Alternatively*, hydroquinone (1% of the final solution) can be used.] **Respiratory irritant, work in an efficient fume cupboard.** [*Beilstein* **1** IV 3435.] ***Acrolein semicarbazone*** *[6055-71-6]* **$C_4H_8N_3O$, M 114.1, m 171°**, crystallises from water in needles. [Auwers & Heineke *Justus Liebigs Ann Chem* **458** 186 *1927*, DOI: 10.1002/jlac.1927458011; *Beilstein* **1** II 785.]

Acrolein diacetyl acetal (1,1-diacetoxy-2-propene). *[869-29-4]* **$C_7H_{10}O_4$, M 158.2, b 75°/10mm, 184°/atm, d_4^{20} 1.08, n_D^{20} 1.4203.** Check the NMR spectrum. If it is not satisfactory, then add Ac_2O and a drop of concentrated H_2SO_4 and heat at 50° for 10 minutes. Then add anhydrous NaOAc (*ca* 3g/100g of liquid) and fractionate. Note that it forms an azeotrope with H_2O, so do not add H_2O at any time. It is a **highly flammable and TOXIC** liquid; use protective gloves. [Smith et al. *J Am Chem Soc* **73** 5282 *1951*, DOI: 10.1021/ja01155a080; *Beilstein* **2** H 154, **2** I 72, **2** III 356, **2** IV 291.]

Acrolein diethyl acetal (3,3-diethoxy-1-propene or 1,1-diethoxy2-propene) *[3054-95-3]* **$C_7H_{14}O_2$, M 130.2, b 120-125°/atm, n_D^{20} 1.398-1.407**. Add Na_2CO_3 (*ca* 3.5%) and distil it using an efficient column, or better use a spinning band column. [Witzemann et al. *Org Synth* Coll Vol **2** 17 *1943*, DOI: 10.15227/orgsyn.011.0001, *Beilstein* **1** H 727, **1** I 378, **1** III 2960, **1** IV 3437.]

Acrolein dimethyl acetal (1,1-dimethoxy-2-propene) *[6044-68-4]* **$C_5H_{10}O_2$, M 102.1, b 87.5-88°/750mm, 89-90°/760mm, d_4^{20} 0.86, n_D^{20} 1.3962.** Fractionally distil it (after adding 0.5g of hydroquinone) under reduced pressure through an all glass column (40cm x 2.5 cm) packed with glass helices and provided with a heated jacket and a total reflux variable take-off head. Stainless steel Lessing rings (1/8 x 1/8 in) or gauze have also been used as packing. It is a **highly flammable and TOXIC** liquid; keep away from the skin. [Hall & Stern *J Chem Soc* 2657 *1955*, DOI: 10.1039/JR9550002657; *Beilstein* **1** IV 3437.]

Acrylamide *[79-06-1]* **C_3H_5NO, M 71.1, m 84°, b 125°/25mm**. Crystallise acrylamide from acetone, chloroform, ethyl acetate, methanol or *benzene/chloroform mixture, then vacuum dry, and store it in the dark under a vacuum. Recrystallise it from $CHCl_3$ by dissolving 200g in 1L, heating to boiling and filtering without suction in a warmed funnel through Whatman 541 filter paper; allowing to cool to room temperature and keeping at -15° overnight. The crystals are collected with suction in a cooled funnel and washed with 300ml of cold MeOH. The crystals are air-dried in a warm oven. [Dawson et al. *Data for Biochemical Research*, Oxford Press *1986* p. 449, *Beilstein* **2** IV 1471.]
CAUTION: *Acrylamide is extremely* **TOXIC (neurotoxic),** *and precautions must be taken to avoid skin contact or inhalation. Use gloves and handle in a well-ventilated fume cupboard.*

Acrylic acid *[79-10-7]* **$C_3H_4O_2$, M 72.1, m 13°, b 30°/3mm, 70°/50mm, d_4^{20} 1.051, pK^{25} 4.25.** It can be purified by steam distillation, or vacuum distillation through a column packed with copper gauze to inhibit polymerisation. (This treatment also removes inhibitors, such as methylene blue, that may be present.) Azeotropic distillation of the water with *benzene converts aqueous acrylic acid to the anhydrous material. [*Beilstein* **2** H 397, **2** I 186, **2** II 383, **2** III 1215, **2** IV 1455.]

Acrylonitrile *[107-13-1]* **C_3H_3N, M 53.1, b 78°/atm, d_4^{20} 0.806, n^{25} 1.3886**. Wash acrylonitrile with dilute H_2SO_4 or dilute H_3PO_4, then with dilute Na_2CO_3 and water. Dry it with Na_2SO_4, $CaCl_2$ or (better) by shaking with molecular sieves. Fractionally distil it under N_2. It can be stabilised by adding 10ppm *tert*-butyl catechol. Immediately before use, the stabiliser can be removed by passage through a column of activated alumina (or by washing with 1% NaOH solution if traces of water are permissible in the final material), followed by distillation. *Alternatively*, shake it with 10% (w/v) NaOH to extract inhibitor, and then wash it in turn with 10% H_2SO_4, 20% Na_2CO_3 and distilled water. Dry for 24 hours over $CaCl_2$ and fractionally distil under N_2 collecting fraction boiling at 75.0-75.5°/734mm). Store it with 10ppm *tert*-butyl catechol. Acrylonitrile is distilled off when required. [Burton et al. *JCS Faraday Trans 1* **75** 1050 *1979*, DOI: 10.1039/F19797501050; *Beilstein* 2 IV 1473.]

Acryloyl chloride (acrylyl chloride) *[814-68-6]* **C_3H_3ClO, M 90.5, b 72-74°/740mm, 74°/760mm, d_4^{20} 1.1127, n_D^{20} 1.4337.** Distil acryloyl chloride rapidly through an efficient 25cm column after adding 0.5g of hydroquinone/200g of chloride, and then re-distil it carefully at atmospheric pressure preferably in a stream of dry N_2. [Stempel et al. *J Am Chem Soc* **72** 2299 *1950*, DOI: 10.1021/ja01161a527; *Beilstein* **2** IV 1471.] **The liquid is an irritant and is TOXIC.**

Adipic acid *[124-04-9]* **$C_6H_{10}O_4$, M 146.1, m 154-154.5°, b 159.5°/0.1mm, 191°/5mm, 205.5°/10mm, 222.5°/20mm, 337.5°/760mm, pK_1^{20} 4.42, pK_2^{20} 5.41; pK_1^{25} 4.44, pK_2^{25} 5.45; pK_1^{40} 4.54, pK_2^{40} 5.59.** For use as a volumetric standard, adipic acid is crystallised once from hot water with the addition of a little animal charcoal, dried at 120° for 2 hours, then recrystallised from acetone and again dried at 120° for 2 hours. Other purification procedures include crystallisation from ethyl acetate and from acetone/petroleum ether, fusion, followed by filtration and crystallisation from the melt, and preliminary distillation under vacuum. [*Beilstein* **2** H 649, **2** I 277, **2** II 572, **2** III 1705, **2** IV 1956.] ***Diethyl adipate*** *[141-28-6]* **M 202.3, m -20°** to **-19°, b 111°/5mm, 125°/10mm, 133°/15mm, 251°/atm, d^{25} 1.0034, n_D^{20} 1.42776**, is prepared in the usual way by boiling the acid and excess EtOH in the presence of a catalytic amount of H_2SO_4 and distilled. [*Beilstein* **2** H 652, 2 I 277, **2** II 574, **2** III 1721, **2** IV 1960.]

Adiponitrile (1,4-dicyanobutane) *[111-69-3]* **$C_6H_8N_2$, M 108.14, m 2.4°, b 123°/0.5mm, 153°/6mm, 175°/26mm, 184°/30mm, 295°/atm, d_4^{20} 0.9396, n_D^{20} 1.4371.** Reflux adiponitrile over P_2O_5 and $POCl_3$, and fractionally distil it, then fractionate it through an efficient column. **The liquid is TOXIC and is an IRRITANT.** [Braun & Rudolph *Chem Ber* **67** 1762 *1934*, DOI: 10.1002/cber.19340671020; Reppe et al. *Justus Liebigs Ann Chem* **596** 127 *1955*, DOI: 10.1002/jlac.19555960108; Gagnon et al. *Can J Chem* **34** 1662 *1956*, DOI:10.1139/v56-214; Copley et al. *J Am Chem Soc* **62** 227 *1940*, DOI: 10.1021/ja01858a503; *Beilstein* **2** IV 1947.]

Agaricic acid [1-(*n*-hexadecyl)citric acid] *[666-99-9]* **$C_{22}H_{40}O_7$, M 416.6, m 142°(dec), $[\alpha]_D$ -9.8 (in NaOH), $pK_{Est(1)}$ ~2.7, $pK_{Est(2)}$ ~4.2, $pK_{Est(3)}$ ~5.5.** Crystallise the acid from EtOH. The ***trihydrazide*** has **m 170°(dec)** (from EtOH). [Brandänge et al. *Acta Chem Scand B* **31** 307 *1977*, DOI: 10.3891/acta.chem.scand.31b-0307; *Beilstein* **3** I 186, **3** II 372, **3** III 1109, **3** IV 1284.]

Agmatine sulfate [5-guanidinopent-1-ylamine sulfate] *[2482-00-0]* **$C_5H_{16}N_4O_4S$, M 228.3, m 231°, $pK_{Est(1)}$ ~9.1, $pK_{Est(2)}$ ~13.0.** Crystallise the salt from aqueous MeOH. The ***free base*** has *[306-60-5]* **$C_5H_{14}N_4$, M 130.2, m 101.5-103°**, the ***gold chloride hydrochloride*** crystallises from H_2O with **m 223°(dec)**, and the ***picrate*** has **m 236-238°**. [Kossel *Z Physiol Chem* **66** 257 *1910*, DOI: 10.1515/bchm2.1910.66.3.257; Raasch et al. for 'Biological significance of agmatine, an endogenous ligand at imidazoline binding sites' see: *Br J Pharmacol* **133** 755 *2001*, DOI: 10.1038/sj.bjp.0704153; *Beilstein* **4** I 420, **4** II 703, **4** III 575, **4** IV 1291.]

Aldol (3-hydroxybutanal) *[107-89-1]* **$C_4H_8O_2$, M 88.1, b 80-81°/20mm, d^{16} 1.109.** An ethereal solution of aldol is washed with a saturated aqueous solution of $NaHCO_3$, then with water. The non-aqueous layer is dried with anhydrous $CaCl_2$ and distilled immediately before use. The fraction, **b 80-81°/20mm**, is collected as a thick liquid which decomposes at 85°/atm. It is a sedative and a hypnotic, but is used in perfumery. [Mason et al. *J Am Chem Soc* **76** 2255 *1954*, DOI: 10.1021/ja01637a069]. [*Beilstein* **1** H 824, **1** I 419, **1** II 868, **1** III 3195, **1** IV 3984.]

Aleuritic acid [*RS-erythro*-9,10,16-trihydroxyhexadecanoic acid] *[533-87-9]* **$C_{16}H_{32}O_5$, M 304.4, m 100-101°, pK Est ~4.9.** Crystallise this *RS*-acid from aqueous EtOH. It is soluble in MeOH, and forms a less soluble crystalline sodium salt. The ***methyl ester*** **m 72-73°**, **b 235°/0.2mm**, is best prepared by reaction with diazomethane and forms fine feathery needles; it is soluble in MeOH, EtOH, $CHCl_3$, Me_2CO, slightly soluble in *C_6H_6 and insoluble in petroleum ether. The ***ethyl ester*** *[6003-09-4]* **m 59°**, crystallises in needles from EtOH. The ***hydrazide*** *[6003-10-7]* crystallises from EtOH and has **m 139-140°**. The *RS-acid* has been isolated from Shellac although it has two asymmetric carbon atoms, and possibly contains the *RS-erythro* or *RS-cis form* [Gidvani *J Chem Soc* 305 *1944*, DOI: 10.1039/JR9440000305]. Stereoisomers have been synthesised [Hunsdiecker *Chem Ber* **76** 142 *1943*, DOI: 10.1002/cber.19430760120; Hunsdiecker *Chem Ber* **77** 185 *1944*, DOI: 10.1002/cber.19440770308]. [*Beilstein* **3** III 901.]

***n*-Alkylammonium chloride n=2,4,6**. Recrystallise them from EtOH or an EtOH/Et_2O mixture. [Hashimoto & Thomas *J Am Chem Soc* **107** 4655 *1985,* DOI: 10.1021/ja00302a010; Chu & Thomas *J Am Chem Soc* **108** 6270 *1986*, DOI: 10.1021/ja00280a026.]

***n*-Alkyltrimethylammonium bromide n=10,12,16**. Recrystallise them from an EtOH/Et_2O mixture. [Hashimoto & Thomas *J Am Chem Soc* **107** 4655 *1985,* DOI: 10.1021/ja00302a010.]

Allene (propadiene) *[463-49-0]* **C_3H_4, M 40.1, m -146°, b -32°/atm.** Freeze allene in liquid nitrogen, evacuate, then thaw out. This cycle is repeated several times, then the allene is frozen in a methylcyclohexane/liquid nitrogen bath and pumped for some time. It has also been purified by HPLC. [Cripps & Kiefer *Org Synth* **42** 12 *1962*, DOI: 10.15227/orgsyn.042.0012; *Beilstein* **1** IV 966.]

***neo*-Allocimene (allocimene B, *tc*-2,6-dimethyl-2,4,6-octatriene)** *[7216-56-0; cis/trans mixture 673-84-7; trans/trans 3016-19-1]* **$C_{10}H_{16}$, M 136.2, b 80°/13mm, 196-198°/atm, d_4^{20} 0.8161, n_D^{20} 1.5437.** Fractionally distil allocimene through an efficient column and repeatedly distil it at 15mm through a long column of glass helices, with a final distillation from sodium under nitrogen. It should be stabilised with *ca* 0.1% of hydroquinone. Its UV has λ_{max} nm(ε $M^{-1}cm^{-1}$) at 290 (32 500), 279 (41 900) and 278 (42,870). [Alder et al. *Justus Liebigs Ann Chem* **609** 1 *1957*, DOI: 10.1002/jlac.19576090102; O'Connor & Goldblatt *Anal Chem* **26** 1726 *1954*, DOI: 10.1021/ac60095a014; *Beilstein* **1** IV 1106.]

Allyl acetate *[591-87-7]* **$C_5H_8O_2$, M 100.1, b 103°/atm, d_4^{20} 0.928, n_D^{17} 1.4004, n_D^{20} 1.4040.** The ester is freed from peroxides by standing with crystalline ferrous ammonium sulfate, then washed with 5% $NaHCO_3$, followed by saturated $CaCl_2$ solution. Dry it with Na_2SO_4 and fractionally distil it in an all-glass apparatus. **FLAMMABLE LIQUID.** [*Beilstein* **2** H 136, **2** IV 180.]

Allylacetic acid (pent-4-enoic acid) *[591-80-0]* **$C_5H_8O_2$, M 100.1, m -22.5°, b 83-84°/12mm, 90°/15mm, 187-189°/~760mm, d_4^{20} 0.9877, n_D^{20} 1.4280, pK^{25} 4.68.** Distil the acid through an efficient column (allyl alcohol has **b** 95-97°). It is characterised as the **S-*benzylisothiouronium salt*** **m 155-158°** (from 96% EtOH, or aqueous EtOH) [Friediger & Pedersen *Acta Chem Scand* **9** 1425 *1955*, DOI: 10.3891/acta.chem.scand.09-1425], and the ***4-bromophenacyl ester*** has **m 59.5-60.5°** (from 90% EtOH). Its solubility at 18° in solvents is: pyridine (57%), AcOH (7.3%), MeOH (5.4%), Me_2CO (3.2%), MeOAc (2.8%), EtOH (5.4%), H_2O (1.8%), PrOH (1.6%), isoPrOH (0.27%). [Brown & Berkowski *J Am Chem Soc* **74** 1894 *1952*, DOI: 10.1021/ja01128a007; *Beilstein* **2** IV 1542.]

Allyl alcohol *[107-18-6]* **C_3H_6O, M 58.1, b 98°/atm, d_4^{20} 0.857, n_D^{20} 1.4134.** It can be dried with K_2CO_3 or $CaSO_4$, or by azeotropic distillation with *benzene followed by distillation under nitrogen. It is difficult to obtain it free of peroxide. It has also been refluxed with magnesium and fractionally distilled [Kamm & Marvel *Org Synth* Coll Vol **1** 42 *1941*, DOI: 10.15227/orgsyn.001.0015]. [*Beilstein* **1** IV 2079.]

Allylamine *[107-11-9]* **C_3H_7N, M 57.1, b 52.9°/atm, d_4^{20} 0.761, n_D^{20} 1.42051, pK^{25} 9.49.** Purify allylamine by fractional distillation from calcium chloride. It is a strong base and should be stored under N_2. It causes sneezing and tears. [*Beilstein* **4** IV 1057.]

Allyl bromide *[106-95-6]* **C_3H_5Br, M 121, b 70°/atm, d_4^{20} 1.398, n_D^{20} 1.46924.** Wash the bromide with $NaHCO_3$ solution then distilled water, dry ($CaCl_2$ or $MgSO_4$), and fractionally distil. Protect it from strong light. [*Beilstein* **1** IV 754.] **LACHRYMATORY, HIGHLY TOXIC and FLAMMABLE.**

Allyl butyl ether *[3739-64-8]* **$C_7H_{14}O$, M 114.2, b 64-65°/120mm, 117.8-118°/763mm, d_4^{20} 1.4057, n_D^{20} 0.7829.** Check the IR for the presence of OH str vibrations near ~ 3000cm^{-1}; if so then wash it well with H_2O, dry it with $CaCl_2$ and distil it through a good fractionating column. **The liquid is an irritant.** [Watanabe et al. *J Org Chem* **23** 1666 *1958*, DOI: 10.1021/jo01105a021; Schueler & Hanna *J Am Chem Soc* **73** 3528 *1951*, DOI: 10.1021/ja01151a532; *Beilstein* **1** IV 2084.]

Allyl chloride *[107-05-1]* **C_3H_5Cl, M 76.5, b 45.1°/atm, d_4^{20} 0.939, n_D^{20} 1.4130.** Likely impurities include 2-chloropropene, propyl chloride, *iso*-propyl chloride, 3,3-dichloropropane, 1,2-dichloropropane and 1,3-dichloropropane. Purify it by washing with concentrated HCl, then with Na_2CO_3 solution, dry it with $CaCl_2$, and distil it through an efficient column [Oae & Vanderwerf *J Am Chem Soc* **75** 2724 *1953,* DOI: 10.1021/ja01107a052]. [*Beilstein* **1** IV 738.] **LACHRYMATORY, TOXIC.**

Allyl chloroformate *[2937-50-0]* **$C_4H_5ClO_2$, M 120.5, b 56°/97mm, 109-110°/atm, d_4^{20} 1.14, n_D^{20} 1.4223.** Wash the chloroformate several times with cold H_2O to remove alcohol and HCl and dry it over $CaCl_2$. It is **important** to dry well before distilling *in vacuo*. Note that the receiver should be cooled in ice to avoid loss of distillate into the trap and vacuum pump. The liquid is **highly TOXIC and flammable.** [Fierz-David & Müller *J Chem Soc* **125** 26 *1924*, DOI: 10.1039/JR9330000788; Strain et al. *J Am Chem Soc* **72** 1254 *1950*, DOI: 10.1021/ja01159a052; *Beilstein* **3** IV 29.]

Allyl cyanide (3-butene nitrile) *[109-75-1]* **C_3H_5N, M 67.1, b -19.6°/1.0mm, 2.9°/5mm, 14.1°/5mm, 26.6°/20mm, 48.8°/60mm, 60.2°/100mm, 98°/400mm, 119°/760mm, d_4^{20} 0.8341, n_D^{20} 1.406.** The nitrile should be redistilled at atmospheric pressure, then distilled under a vacuum to remove the final traces of HCN from the residue. Note that the residue from the first distillation may be difficult to remove from the flask and should be treated with concentrated HNO_3 then H_2O and finally hot EtOH **(CARE)**. Allyl cyanide has an onion-like odour and is stable to heat. It forms a complex with $AlCl_3$ (2:2) **m** 41°, and (3:2) **m** 120°. **All operations should be done in an efficient fume hood as the liquid is flammable, may contain cyanide and is HIGHLY TOXIC.** [Supniewski et al. *Org Synth* Coll Vol **I** 46 *1941*, DOI: 10.15227/orgsyn.008.0004; *Beilstein* **2** IV 1491.]

Allyl disulfide (diallyl disulfide) *[2179-57-9]* **$C_6H_{10}S_2$, M 146.3, b 58-59°/5mm, 79-81°/20mm, 138-139°/atm, d_4^{20} 1.01, n_D^{20} 1.541.** Purify the disulfide by fractional distillation until the molar refractivity is in uniformly good agreement with the calculated value [Small et al. *J Am Chem Soc* **69** 1710 *1947*, DOI: 10.1021/ja01199a040]. It has also been purified by gas chromatography [retention times: Carson & Wong *J Org Chem* **24** 175 *1959*, DOI: 10.1021/jo01084a007; UV: Koch *J Chem Soc* 394 *1949*, DOI: 10.1039/JR9490000394]. It is present in garlic. [*Beilstein* **1** IV 2098.]

Allyl iodide (3-iodopropene) *[556-56-9]* **C_3H_5I, M 167.98, b 103°/760mm, d^{12} 1.848.** Purify allyl iodide in a dark room by washing with aqueous Na_2SO_3 to remove free iodine, then dry with $MgSO_4$ and distil at 43°/90 mm or at atmospheric pressure to give a very pale yellow liquid. (This material, dissolved in hexane, can be stored in a light-protected tight container at -5° for up to three months before free iodine can be detected, by its colour in the solution.) Store it away from light. [Sibbett & Noyes *J Am Chem Soc* **75** 761 *1953*, DOI: 10.1021/ja01100a001; *Beilstein* **1** H 202, **1** I 84, **1** II 172, **1** III 714, **1** IV 761.]

Allylisocyanate *[1476-23-9]* **C_4H_5NO, M 83.1, b 84°/atm, 87-89°/atm, d_4^{20} 0.94, n_D^{20} 1.417.** Purify it as for allylisothiocyanate below and it is **TOXIC**. [*Beilstein* **4** IV 1081.]

Allylisothiocyanate *[57-06-7]* **C_4H_5NS, M 99.2, m -80°, b 84-85°/80mm, 150°/760mm, 151°/atm, d_4^{20} 1.017, n_D^{20} 1.5268.** Fractionate the isothiocyanate using an efficient column, preferably in a vacuum. It is a yellow **pungent, irritating and a TOXIC (suspected CARCINOGEN) liquid.** Store it in a sealed tube under N_2. The ***N'-benzylthiourea*** derivative has **m 94.5°** (from aqueous EtOH) [Weller et al. *J Am Chem Soc* **74** 1104 *1952*,

DOI: 10.1021/ja01124a531]. [*Beilstein* **4** IV 1081.]

***N*-Allylthiourea (thiosinamine)** *[109-57-9]* **$C_4H_8N_2S$, M 116.2, m 70-73°, 78°.** Recrystallise it from H_2O. It is soluble in 30 parts of cold H_2O, and is soluble in EtOH but insoluble in $*C_6H_6$. It has also been recrystallised from acetone, EtOH or ethyl acetate, after decolorising with charcoal. The white crystals have a bitter taste with a slight garlic odour and are **TOXIC**. An unstable crystalline form is obtained by recrystallising from the melt. [McCrone et al. *Anal Chem* **21** 421 *1949*, DOI: 10.1021/ac60027a600; *Beilstein* **4** IV 1072.]

***N*-Allylurea** *[557-11-9]* **$C_4H_8N_2O$, M 100.1, m 85°.** It can be recrystallised from EtOH, EtOH/ether, EtOH/chloroform or EtOH/toluene. [*Beilstein* **4** IV 1070.]

Aminoacetaldehyde dimethyl acetal (2,2-dimethoxyethylamine) *[22483-09-6]* **$C_4H_{11}NO_2$, M 105.1, m <-78°, b 139.5°/768mm, 137-139°/atm, d_4^{20} 0.9676 n_D^{20} 1.4144.** Dry the acetal over KOH pellets and distil it through a 30cm vacuum jacketed Vigreux column. [Lawson *J Am Chem Soc* **75** 3398 *1953*, DOI: 10.1021/ja01110a029; Erickson et al. *J Am Chem Soc* **77** 6640 *1955*, DOI: 10.1021/ja01629a074; *Beilstein* **4** IV 1918.]

Aminoacetonitrile bisulfate *[151-63-3]* **$C_2H_4N_2 . H_2SO_4$, M 154.15, m 125°(dec), pK^{25} 5.34 (NH_2).** Recrystallise the hydrogen sulfate (1:1) from EtOH/Et_2O (hygroscopic leaflets). The ***Sulfate* (2:1)** [5466-22-8] crystallises as flat prisms from H_2O/EtOH with **m 166°(dec)**. [Stephen *J Chem Soc* 871 *1931*, DOI: 10.1039/JR9310000871; Anslow & King *J Chem Soc* 2463 *1929*, DOI: 10.1039/JR9290002463; *Beilstein* **4** III 1120.]

Aminoacetonitrile hydrochloride *[6011-14-9]* **$C_2H_4N_2 . HCl$, M 92.5, m 166-167°, 172-174°, pK^{25} 5.24 (NH_2).** The salt recrystallises from dilute EtOH as *hygroscopic* leaflets. It is best to crystallise it from absolute EtOH/Et_2O (1:1) and then recrystallise it from absolute EtOH. The melting point recorded ranges from 144° to 174°. The ***free base*** has **b 58°/15mm** with partial decomposition. [Mange *J Am Chem Soc* **56** 2197 *1934*, DOI: 10.1021/ja01325a063; Goldberg & Kelly *J Chem Soc* 1369 *1947*, DOI: 10.1039/JR9470001369; *Beilstein* **4** H 344, **4** I 468, **4** II 783, **4** III 1120, **4** IV 2363.]

2-Amino-1-butanol *[RS(±) 96-20-8, R(-) 5856-63-3, S(+) 5856-62-2]* **$C_4H_{11}NO$, M 89.1, m ~ -2°, b 78-80°/10mm and 179-183°/atm for (±), 172-174°/atm for (+) or (-), pK^0 10.353, pK^{20} 9.672, pK^{60} 8.555.** They are purified by shaking with solid NaOH, filtering and distilling through a short column. The ***oxalate salt*** of the racemate has **m 176°**. They are strong bases and should be stored under N_2 in the absence of CO_2. The *enantiomers* have $[\alpha]_D^{20}$ +12.5 and -12.5 (c 2, EtOH). [Johnson & Degering *J Org Chem* **08** 7 *1943*, DOI: 10.1021/jo01189a002; Nagao et al. *J Org Chem* **51** 2391 *1986*, DOI: 10.1021/jo00362a047; Santaniello et al. *JCS Perkin Trans 1* 919 *1985*, DOI: 10.1039/P19850000919; *Beilstein* **4** H 291, **4** IV 1705.]

2-Aminoethanol (ethanolamine) *[141-43-5]* **C_2H_7NO, M 61.1, f 10.5°, b 72-73°/12mm, 171.1°/760mm, d_4^{20} 1.012, n_D^{20} 1.14539, pK^{25} 9.51.** It decomposes slightly when distilled at atmospheric pressure, with the formation of conducting impurities. Fractional distillation at about 12mm pressure is most satisfactory. After distillation, 2-aminoethanol is further purified by repeated washing with ether and crystallising from EtOH (at low temperature). After fractional distillation in the absence of CO_2, it is twice crystallised by cooling, followed again by distillation. It is *hygroscopic*, and absorbs CO_2 from the atmosphere. [Reitmeier et al. *J Am Chem Soc* **62** 1943 *1940*, DOI: 10.1021/ja01865a009.] It can be dried by azeotropic distillation with dry *benzene. [*Beilstein* **4** IV 1406.] ***2-Aminoethanol hydrochloride*** *[2002-24-6]* **$C_2H_7NO . HCl$, M 97.6, m 75-77°,** is recrystallised from EtOH. It is deliquescent; store it dry. [*Beilstein* **4** IV1406.] ***2-Aminoethyl hydrogen sulfate (sulfuric acid mono-2-aminoethyl ester)*** *[926-39-6]* **$C_2H_7NO_4S$, M 141.1, m 285-287° (chars at 275°),** crystallises from water, or is dissolved in water and EtOH is added. Wash this with Et_2O and dry it *in vacuo*. [*Beilstein* **4** III 1414.]

S-(2-Aminoethyl)isothiouronium bromide hydrobromide *[56-10-0]* **$C_3H_9N_3S . 2HBr$, M 281.0, m 194-195°**. Crystallise the salt from absolute EtOH/ethyl acetate or MeOH. Store dry as it is *hygroscopic* in a humid atmosphere. It is a radioprotective agent. When refluxed in EtOH for 16 hours or H_2O for 30 minutes, it decom-

poses to ***2-amino-4(5H)-thiazoline hydrobromide*** which on recrystallisation from isoPrOH/EtOAc has **m 175-176°** [Doherty et al. *J Am Chem Soc* **79** 5667 *1957*, DOI: 10.1021/ja01578a022].

(2-Aminoethyl)trimethylammonium chloride hydrochloride (chloramine chloride hydrochloride) *[3399-67-5]* **$C_5H_{15}N_2Cl$. HCl, M 175.1, m 268°(dec).** Crystallise the hydrochloride from EtOH. The material is very soluble in H_2O. [*Beilstein* **4** II 690.]

Aminomalononitrile toluene-4-sulfonate *[5098-14-6]* **C_3HN_2. $CH_3C_6H_5SO_4H$, M 253.3, m 168-170°, 172°(dec), pK_{Est} ~ 1.3.** It forms colourless crystals on recrystallisation from MeCN (1.8g in 100mL) using activated charcoal. Wash the crystals with dry Et_2O and dry them at 25°/1mm. Recovery is ~80%. [Ferris et al. *Org Synth* Coll Vol **5** 32 *1973*, DOI: 10.15227/orgsyn.048.0001.]

(±)-2-Amino-4-methylhexane (Forthane, 1,3-dimethylpentylamine) *[105-41-9]* **$C_7H_{17}N$, M 115.2, b 131-133°/atm, 130-135°/atm, 135-136°/atm, d_4^{20} 0.760, n_D^{15} 1.4160, n_D^{24} 1.4160, pK^{25} 10.54.** This strong base is obtained by catalytic hydrogenation of 4-methylhexan-2-one oxime (57g) in EtOH (50ml) with Raney Ni (6g) in a bomb at 75-80° and 1000psi of H_2, cool, filter off the catalyst, acidify with HCl, and evaporate to dryness. Basify the residue with aqueous NaOH, extract it with Et_2O, dry the extract ($MgSO_4$), filter, evaporate, and distil to give the base in 75-80% yield. It forms a ***sulfate salt*** **m 215-220°(dec)**, and it readily forms a *carbonate salt*, hence it should be stored in the absence of CO_2. It is physiologically active as an opium *pressor* and is adrenergic. [Rohrmann & Shonle *J Am Chem Soc* **66** 1516 *1944*, DOI: 10.1021/ja01237a032; Chiang *J Clin Chem Soc* **18** 65 *1951*, USP to E. Lilly 2350318 (1943) *Chem Abstr* **39** 1510 *1945*, USP 2386273 (1943) *Chem Abstr* **40** 598 *1946*, *Beilstein* **4** III 378, **4** IV 747.]

2-Amino-2-methyl-1,3-propanediol *[115-69-5]* **$C_4H_{11}NO_2$, M 105.1, m 111°, b 151-152°/10mm, pK^{25} 8.80.** Crystallise the diol three times from MeOH, dry in a stream of dry N_2 at room temperature, then in a vacuum oven at 55°. Store it over $CaCl_2$ [Hetzer & Bates *J Phys Chem* **66** 308 *1962*, DOI: 10.1021/j100808a027]. [*Beilstein* **4** IV 1881.]

2-Amino-2-methyl-1-propanol (β-aminoisobutanol) *[124-68-5]* **$C_4H_{11}NO_2$, M 89.1, m 24°, 31°, b 67°/10mm, 164-166°/760mm, d_4^{20} 0.935, n_D^{20} 1.45, pK^{25} 9.71.** Purify it by distilling and fractional freezing. Store away from CO_2. The ***hydrochloride*** [3207-12-3] has **m 204°-206°**. [*Beilstein* **4** III 783, **4** IV 1740.]

***n*-Amyl acetate (*n*-pentyl acetate)** *[628-63-7]* **$C_7H_{14}O_2$, M 130.2, b 149.2°/atm, d_4^{20} 0.876, n_D^{20} 1.40228.** Shake the ester with saturated $NaHCO_3$ solution until neutral, washed it with water, dry with $MgSO_4$ and distil it. The ester has also been purified by repeated fractional distillation through an efficient column or spinning band column. [Mumford & Phillips *J Chem Soc* 75 *1950*, DOI: 10.1039/JR9500000075; ^{1}H NMR: Crawford & Foster *Can J Phys* **34** 653 *1956*, DOI 10.1139/p56-074; *Beilstein* **2** IV 152.]

***n*-Amyl alcohol (1-pentanol)** *[71-41-0]* **$C_5H_{12}O$, M 88.2, b 138.1°/atm, d^{15} 0.818, n_D^{20} 1.4100.** Dry 1-pentanol with anhydrous K_2CO_3 or $CaSO_4$, filter and fractionally distil it. It has also been treated with 1-2% of sodium and heated at reflux for 15 hours to remove water and chlorides. Traces of water can be removed from the near-dry alcohol by refluxing it with a small amount of sodium in the presence of 2-3% *n*-amyl phthalate or succinate followed by distillation (see *ethanol*). Small amounts of amyl alcohol have been purified by esterifying with *p*-hydroxybenzoic acid, recrystallising the ester from CS_2, saponifying with ethanolic-KOH, drying with $CaSO_4$ and fractionally distilling [Olivier *Recl Trav Chim Pays-Bas* **55** 1027 *1936*, DOI: 10.1002/recl.19360551207]. [*Beilstein* **1** IV 1640.]

***tert*-Amyl alcohol (2-methyl-2-butanol)** *[75-85-4]* **$C_5H_{12}O$, M 88.2, m -12°, b 102.3°/atm, d^{15} 0.8135, n_D^{20} 1.4058.** Reflux it with K_2CO_3, CaH_2, CaO or sodium, then fractionally distil. The near-dry alcohol is further dried by refluxing with Mg activated with iodine, as described for *ethanol*. Further purification is possible using fractional crystallisation and zone refining at <-10° or preparative gas chromatography. [*Beilstein* **1** IV 1668.]

***n*-Amylamine [1-aminopentane]** *[110-58-7]* **$C_5H_{13}N$, M 87.2, b 105°/atm, d_4^{20} 0.752, pK^{25} 10.63.** Dry it by prolonged shaking with NaOH pellets, then distilling. Store it in a CO_2-free atmosphere. [*Beilstein* **4** IV 674.]

***n*-Amyl bromide (*n*-pentylbromide)** *[110-53-2]* **$C_5H_{11}Br$, M 151.1, b 129.7°/atm, d_4^{20} 1.218, n_D^{20} 1.445.** Wash the bromide with conc H_2SO_4, then water, 10% Na_2CO_3 solution, again with water, dry with $CaCl_2$ or K_2CO_3, and fractionally distil it just before use. [*Beilstein* **1** IV 312.]

***n*-Amyl chloride (1-chloropentane)** *[543-59-9]* **$C_5H_{11}Cl$, M 106.6, b 107.8°/atm, d_4^{20} 0.882, n_D^{20} 1.41177.** Purify as for *sec*-amyl chloride below. [*Beilstein* **1** IV 309.]

***sec*-Amyl chloride (1-chloro-2-methylbutane)** *[616-13-7]* **$C_5H_{11}Cl$, M 106.6, b 52.2°/150mm, 96-97° (100°)/760mm, d_4^{20} 0.886, n_D^{20} 1.412.** Purify the chloride by stirring vigorously with 95% H_2SO_4, replacing the acid when it becomes coloured, until the layer remains colourless after 12 hours stirring. The amyl chloride is then washed with saturated Na_2CO_3 solution, then distilled water, and dried with anhydrous $MgSO_4$, followed by filtration, and distillation through a 10-in Vigreux column. *Alternatively*, a stream of oxygen containing 5% ozone is passed through the amyl chloride for three times as long as it takes to cause the first coloration of starch iodide paper by the exit gas. The liquid is washed with $NaHCO_3$ solution to hydrolyse the ozonides and remove organic acids prior to drying and fractional distillation [Chien & Willard *J Am Chem Soc* **75** 6160 *1953,* DOI: 10.1021/ja01120a016. The *S*(+)-*enantiomer* [40560-29-0] has **b 50-51°/140mm, 100°/760, mm**, n_4^{20} 1.404 $[\alpha]_D^{20}$ +1.64 (neat) [Brown et al. *J Am Chem Soc* **62** 3435 *1940*, DOI: 10.1021/ja01869a040]. [*Beilstein* **1** H 134, **1** I 46, **1** III 356, **1** IV 326.]

***tert*-Amyl chloride (2-chloro-2-methylbutane)** *[594-36-5]* **$C_5H_{11}Cl$, M 106.6, b 86°/atm, d_4^{20} 0.866.** Methods of purification commonly used for other alkyl chlorides lead to decomposition. Unsaturated contaminants are removed by chlorination with a small amount of chlorine in bright light, followed by distillation [Chien & Willard *J Am Chem Soc* **75** 6160 *1953*, DOI: 10.1021/ja01120a016]. [*Beilstein* **1** H 134, **1** I 46, **1** II 100, **1** III 357, **1** IV 324.]

Amylene (β-*iso*-amylene, 2-methyl-2-butene) *[513-35-9]* **C_5H_{10}, M 70.1, b 37-38°/760mm, d_4^{20} 0.663, n_D^{20} 1.387.** Distil amylene and collect the distillate at low temperature. It has also been distilled from sodium. **FLAMMABLE.** It is available in steel cylinders and has a short shelf life. [*Beilstein* **1** H 211, **1** I 87, **1** II 187, **1** III 788, **1** IV 820.]

Amyl ether (dipentyl ether) *[693-65-2]* **$C_{10}H_{22}O$, M 158.3, b 186.8°/atm, d_4^{20} 0.785, n_D^{20} 1.41195.** Repeatedly reflux amyl ether over sodium and distil it. [*Beilstein* **1** IV 1643.]

Arachidic (eicosanoic C_{20}) acid *[506-30-9]* **$C_{20}H_{40}O_2$, M 312.5, m 77°, pK_{Est} ~5.0.** Crystallise the C_{20} acid from absolute EtOH. [*Beilstein* **2** IV 1276.] **Arachidic alcohol (1-eicosanol C_{20})** *[629-96-9]* **$C_{20}H_{42}O$, M 298.6, m 65.5° (71°), b 200°/3mm.** Crystallise the C_{20} alcohol from *benzene or *benzene/petroleum ether. [*Beilstein* **1** IV 1900.]

Azelaic acid (1,9-nonanedioic acid, heptane-1,7-dicarboxylic acid) *[123-99-9]* **$C_9H_{16}O_4$, M 188.2, m 105-106°, b 225°/10mm, 256°/50mm, pK_1^{25} 4.53, pK_2^{25} 5.33.** Recrystallise it from H_2O (charcoal) or thiophene-free *benzene. The acid can be dried by azeotropic distillation with toluene, the residual toluene solution is then cooled and filtered, and the precipitate is dried in a vacuum oven. It has been purified by zone refining or by sublimation onto a cold finger at 10^{-3}torr. It distils above 360° with partial formation of the anhydride. The ***dimethyl ester*** [1732-10-1] **$C_{11}H_{20}O_4$, M 216.3**, has **m –3.9°** and **b 140°/8mm**, 156°/20mm, d^{25} 1.007g/ml, n_D^{20} 1,435. [Hill & McEwen *Org Synth* Coll Vol **2** 53 *1943*, DOI: 10.15227/orgsyn.013.0004; *Beilstein* **2** IV 2055.]

2,2'-Azobis(isobutyronitrile) [α,α'-bis-azo-(2-methylpropionitrile), AIBN] *[78-67-1]* **$C_8H_{12}N_4$, M 164.2, m 102.1-103.2°, 103°, 103-104°.** Crystallise the nitrile from Et_2O, Me_2CO, $CHCl_3$, aqueous EtOH or MeOH. It has also been crystallised from absolute EtOH below 40° in subdued light. Dry it under vacuum at room temperature over P_2O_5 and store it under vacuum in the dark at <-10° until required. Also crystallise it from $CHCl_3$ solution by addition of petroleum ether (b <40°). It is a ***radical inhibitor***. [Askham et al. *J Am Chem Soc* **107** 7423 *1985*, DOI: 10.1021/ja00311a034; Ennis et al. *JCS Dalton Trans* 2485 *1986*, DOI: 10.1039/DT9860002485; Inoue & Anson *J Phys Chem* **91** 1519 *1987*, DOI: 10.1021/j100290a046; Tanner et al. *J Org Chem* **52** 2142 *1987*, DOI: 10.1021/jo00387a005.] It is prepared by the oxidation of *N,N'-bis(isobutyro-nitrile)*

hydrazine by addition of the solid hydrazine (4.15g, 0.025mole) to a solution of HNO_3 (100%, 6.5g, 0.1mol) and Ac_2O (30ml) (0.1mole) which are previously mixed at -30°. As the temperature rises to -20° the solid begins to dissolve and the colour of the solution turns to green, and dissolution is complete at ~5°. After stirring at 25° for 0.5 hours, the solution is poured onto cracked ice and H_2O (100ml), the product separates out, is filtered off, and washed free from acid with H_2O. The solid (m 95-100°) is dried *in vacuo,* recrystallised from 50% EtOH and from Et_2O to give pure *AIBN* (2.5g, 60%), m 105°. [Picard & Boivin *Can J Chem* **29** 223 *1951*, DOI:10.1139/v51-027.] *Alternatively*, the *hydrazine* (0.989g, 6mmol) is added to a solution of AcOH (40ml) and conc H_2SO_4 (3ml) at ~0°, followed by addition of $NaMnO_2.3H_2O$ (1.8g) in H_2O (25ml). MnO_2 separates, excess $NaMnO_2$ and MnO_2 are reduced with aq sodium bisulfite and the mixture is poured into H_2O. AIBN separates, is filtered off, washed with H_2O, dried *in vacuo* and recrystallised as above to give pure *azo compound* (0.61g, 63%). [Overberger & Lebovitz *J Am Chem Soc* **76** 2722 *1954*, DOI: 10.1021/ja01639a039; Overberger et al. *J Am Chem Soc* **71** 2661 *1949*, DOI: 10.1021/ ja01176a018.] [*Beilstein* **4** I 566, **4** III 1750, **4** IV 3377.]

Azomethane (dimethyldiimide) *[503-28-6]* **$C_2H_6N_2$, M 58.1, m -78°, b 1.5°/atm, d_0^{15} 0.981, n_D^{19} 1.3933.** Purify azomethane by distillation in a vacuum line and store it in the dark at -80°. It is soluble in EtOH, Et_2O and EtOAc. It can be **EXPLOSIVE.** [*Beilstein* **4** H 562, **4** I 566, **4** II 966, **4** III 1747, **4** IV 3366.]

Batyl alcohol (***rac*-3-[1-octadecyloxy]-1,2-propanediol)** *[544-62-7]* **$C_{21}H_{44}O_3$, M 344.6, m 71-71.5°.** Batyl alcohol crystallises from aqueous Me_2CO, EtOH or petroleum ether (b 40-60°). [Taguchi & Armarego *Med Res Rev* **18** 43 *1998*, DOI: 10.1002/(SICI)1098-1128(199801); *Beilstein* **1** IV 2758.] Natural ***S*(+)-alcohol** has **m 71-72°** (from dry Me_2CO), and **$[\alpha]_D^{25}$ +1.54, $[\alpha]_{365}^{25}$ +3.9 (c 6.7 $CHCl_3$)**, and *isopropylidene derivative* has **m 34-36°** and **$[\alpha]_D^{40}$ -11.15 (melt)**. [Baer & Fischer *J Biol Chem* **140** 397 *1941*, http://www. jbc.org/ content/140/2/397.citation; Taguchi et al. *Pteridines* **6** 45 *1995*, DOI: 10.1515/pteridines.1995.6.2.45.]

Behenoyl chloride (docosanoyl chloride) *[21132-76-3]* **$C_{22}H_{43}ClO$, M 359.0, m 40°.** If the IR shows OH bands, then it should be dissolved in oxalyl chloride in *C_6H_6 solution and warmed at 35° for 24 hours in the absence of moisture, evaporated and distilled in a vacuum of 10^{-5}mm. It is soluble in *C_6H_6 and Et_2O. It is moisture sensitive. **LACHRYMATORY**. [Francis et al. *J Chem Soc* 999 *1937*, DOI: 10.1039/ JR9370000999; Levene & Taylor *J Biol Chem* **59** 905 *1924*, http://www.jbc.org/content/59/3/ 905; *Beilstein* **2** III 1076.]

Biacetyl (butan-2,3-dione) *[431-03-8]* **$C_4H_6O_2$, M 86.1, b 88°/atm, d_4^{20} 0.981, $n^{18.5}$ 1.3933.** Dry biacetyl over anhydrous $CaSO_4$, $CaCl_2$ or $MgSO_4$, then distil it in a vacuum under nitrogen, taking the middle fraction and storing it at Dry-Ice temperature in the dark (to prevent polymerisation). [*Beilstein* **1** IV 3644.]

Biguanide *[56-03-1]* **$C_2H_7O_5$, M 101.1, m 130° pK_1^{25} 3.1, pK_2^{25} 12.8 (11.52).** Crystallise biguanide from EtOH. It gives a red Cu derivative, and it forms salts with many metals. The ***monohydrochloride*** has **m 235°** [38664-03-8] and the ***dihydrochloride*** forms plates with **m 248°** (**213-214°**, also reported) [25836-74-2]. [*Beilstein* **3** H 93, **3** I 44, **3** II 76, **3** III 171, **3** IV 162.]

Bis-acrylamide (*N,N*'-methylene bisacrylamide) *[110-26-9]* **$C_7H_{10}N_2O_2$, M 154.2, m >300°.** Recrystallise the amide from MeOH (100g dissolved in 500ml boiling MeOH) and filter without suction in a warmed funnel. Allow to stand at room temperature and then at -15° overnight. The crystals are collected with suction in a cooled funnel and washed with cold MeOH. The crystals are air-dried in a warm oven. [*Beilstein* **2** IV 1472.] **VERY TOXIC (neurotoxic).**

Bis(β-chloroethyl)amine hydrochloride *[821-48-7]* **$C_4H_9Cl_2N$. HCl, M 178.5, m 214-215°, 216-217°, pK_{Est} ~5.8 (free base).** Crystallise the salt from Me_2CO or MeOH/Et_2O. The ***picrate*** has **m 112-113°** (from EtOH or Me_2CO). [Mann *J Chem Soc* 461 *1934*, DOI: 10.1039/JR9340000461; Ward *J Am Chem Soc* **57** 914 *1935*, DOI: 10.1021/ja01308a041; *Beilstein* **4** III 238.]

Bis(β-chloroethyl) ether *[111-44-4]* **$C_4H_8Cl_2O$, M 143.0, b 94°/33mm, 178.8°, d_4^{20} 1.220, n_D^{20} 1.45750.** Wash the ether with conc H_2SO_4, then Na_2CO_3 solution, dry with anhydrous Na_2CO_3, and finally pass it through a 50cm column of activated alumina before distillation. *Alternatively*, wash it with 10% ferrous sulfate solution

to remove peroxides, then H_2O, dry with $CaSO_4$, and distil it in a vacuum. Add 0.2% of catechol to stabilise it. [*Beilstein* **1** IV 1375, Kamm & Waldo *J Am Chem Soc* **43** 2223 *1921*, DOI: 10.1021/ja01443a013.] **VERY TOXIC**.

2,2'-Bis[di-(carboxymethyl)-amino]diethyl ether, (EEDTA, $HOOCCH_2)_2NCH_2CH_2OCH_2CH_2N(CH_2COOH)_2$ *[923-73-9]* **$C_{12}H_{20}N_2O_9$, M 336.3, pK_1^{20} 1.8, pK_2^{20} 2.76, pK_3^{20} 8.84, K_4^{20} 9.47.** Crystallise it from EtOH or aqueous EtOH. *Alternatively*, boil in MeOH, filter hot and cool. The tetra-acid is collected, recystallised from H_2O, and the solid is collected and dried over P_2O_5 at 90°/0.01mm. [Schwarzenbach et al. *Helv Chim Acta* **40** 1886 *1957*, DOI: 10.1002/hlca.19570400640.] It complexes with Ca^{2+}, Ba^{2+}, Sr^{2+}, Mg^{2+}, Ag^+, Hg^{2+}, Cd^{2+} and Nd^{3+}. [*Beilstein* **4** II 37, **4** IV 2433.]

Bis(2-ethylhexyl) sebacate ['dioctyl' sebacate, di(2-ethylhexyl) 1,8-octanedicarboxylate] *[122-62-3]* **$C_{26}H_{50}O_4$, M 426.7, b 212°/1mm, d_4^{25} 1.914, n_D^{20} 1.4496.** If it is acidic due to hydrolysis (effervesces with $NaHCO_3$), then purify by dissolving in Et_2O, shaking with aqueous Na_2CO_3, dry (Na_2SO_4), filter, evaporate and distil the residue at a high vacuum. Note that ***2-ethylhexan-1-ol*** has **b 184-185°/760mm** with estimated **b ~40-50°/1mm** (see Figure 1, and Table 2A, Chapter 1) and will distil at a much lower temperature than the ester. Otherwise it should be distilled through a short column under high vacuum and the higher boiling fraction is redistilled. This vacuum pump oil can be prepared by esterifying decanedioic acid with 2-ethylhexanoic acid by Fischer-Speier's method (Fischer & Speier *Chem Ber* **28** 1145 1895, DOI: 10.1002/cber.189502801248], whereby dry HCl gas is bubbled through the alcohol until its weight is increased by ~10%, the acid is added, the mixture is heated at 100° until esterification is complete (~2-3 hours), and purified as above. [Bruno USPat 2628249 *1953*, GBPat 747260 *1956*, *Beilstein* **2** IV 2803.]

***N,N*-Bis(2-hydroxyethyl)-2-aminoethanesulfonic acid (BES)** *[10191-18-1]* **M 213.3, m 150-155°, pK^{25} 7.17.** Crystallise BES from aqueous EtOH. [*Beilstein* **4** IV 3290.]

Bis(2-hydroxyethyl)amino-tris-(hydroxymethyl)methane (BIS-TRIS) *[6976-37-0]* **$C_8H_{19}NO_5$, M 209.2, m 89°, 104°, pK^{20} 6.46.** Crystallise BIS-TRIS from hot 1-butanol and dry it in a vacuum at 25°.

Bis(2-hydroxypropyl) ether [dipropylene glycol, 4-oxaheptane-2,6-diol, 1,1'-oxybis(propan-2-ol)] *[110-98-5, 25265-71-8 non-specific]* **$C_6H_{14}O_3$, M 134.2, m 45-46.5°, 46-48°, b 113-114°/10mm, 222.2°/760mm, 229-232°/atm, d_4^{60} 0.9878, n_D^{60} 1.4284.** Fractionally distil the diol preferably at low pressure, using a packed column and taking precautions to avoid absorption of water. It has also been purified by crystallisation from ether at Dry Ice temperatures which gives a white solid. There are apparently two forms (*meso* and *d,l* ?) [see Summerbell et al. *J Org Chem* **27** 4433 *1961*, DOI: 10.1021/jo01059a075]. The ***bis-p*-nitrobenzoate** has **m 150-151°**, (**146-148°**) and the ***bis*-triphenylmethyl ether** has **m 145-146°** [Sexton & Britton *J Am Chem Soc* **75** 4357 *1953,* DOI: 10.1021/ja01113a525; *Beilstein* **1** II 537, **1** III 2149, **1** IV 2473.]

Bis(3-hydroxypropyl) ether [4-oxaheptane-1,7-diol, 3,3'-oxybis(propan-1-ol)] *[2396-61-4, 25265-71-8 non-specific]* **$C_6H_{14}O_3$, M 134.2, b 92-102°/0.01mm, d_4^{25} 1.023, n_D^{20} 1.441.** Fractionally distil the diol under 15mm pressure, using a packed column and taking precautions to avoid absorption of water. Four isomers are obtained from the condensation of 2 molecules of propylene oxide which have to be separated by fractional distillation [Sexton & Britton *J Am Chem Soc* **75** 4357 *1953*, DOI: 10.1021/ja01113a525, see Summerbell et al. *J Org Chem* **27** 4433 *1961*, DOI: 10.1021/jo01059a075]. However, a clean product was obtained in 23% yield, by reduction of *diethyl 3-oxaheptanoate* with $LiAlH_4$ in Et_2O under N_2 and distilling under high vacuum. Its ^1H NMR (in $CDCl_3$/TMS, 60MHz) has δ 1.81 (2 x 2H, quint), 3.55 (2 x 2 H, t) and 3.70 (2 x 2 H, t); MS *m/z* 134. The *mono- and bis- tosylates* are oils. [Samat et et al. *JCS Perkin Trans 1* 1717 *1985*, DOI: 10.1039/JR9550002657.] [*Beilstein* **1** III 542, **1** IV 2496.] The ***bis*-phenylurethane** has **m 104-105°**(from EtOH). The ***Di(propylene glycol) dibenzoate*** *[27138-31-4]* **$C_{20}H_{22}O_4$, M 326.4,** is purified by redistillation at **232°/5mm, d_4^{25} 1.12, n_D^{20} 1.528** [*Beilstein* **9** II 108].

Bis(2-mercaptoethyl)sulfone (BMS) *[145626-87-5]* **$C_4H_{10}O_2S_3$, M 186.3, m 57-58°, pK_1^{25} 7.9, pK_2^{25} 9.0**. BMS recrystallises from hexane as white fluffy crystals. Large amounts are best recrystallised from de-oxygenated H_2O (charcoal). It is a good alternative reducing agent to dithiothreitol. Its IR (film) has

ν_{max} at 2995, 2657, 1306, 1248, 1124 and 729 cm^{-1}. The synthetic intermediate ***thioacetate*** has **m** 82-83° (white crystals from CCl_4). The ***disulfide*** is purified by flash chromatography on SiO_2 and elution with 50% EtOAc/hexane, recrystallised from hexane, and has **m 137-139°**. [Lamoureux & Whitesides *J Org Chem* **58** 633 *1993*, DOI: 10.1021/jo00055a015; *Beilstein* **1** IV 2455.]

Bis(trichloromethyl) carbonate (triphosgene) *[32315-10-9]* **$C_3Cl_6O_3$, M 296.8, m 79-83°, 81-83°, b 203-206°(slight dec).** It is a good solid substitute for phosgene (using a third mol per mol). Crystallise it from petroleum ether (b 60-80°), wash it with anhydrous cold Et_2O, de-gas it at 200mm then dry at 0.1mm (over H_2SO_4). It has IR with ν_{max} at 900 and 1900 cm^{-1}. It is a **lachrymator**, is **TOXIC**, and should be handled with gloves and in an efficient fume hood. [Hales et al. *J Chem Soc* 618 *1957*, DOI: 10.1039/JR9570000618; Eckert & Forster, **26** 894 *1987*, DOI: 10.1002/anie.198708941; *Aldrichimica Acta* **21** 47 *1988*, *Beilstein* **3** H 17, **3** I 8, **3** II 16, **3** III 36, **3** IV 33.]

Bistrifluoroacetamide (BTFA) *[407-24-9]* **$C_4HF_6NO_2$, M 209.1, m 85°, b 135-136°/744mm, 141°/760mm.** A major impurity is trifluoroacetamide. Add trifluoroacetic anhydride to BTFA, reflux for 2 hours and fractionate using a Vigreux column at atmospheric pressure. [Donike *J Chromatogr* **78** 273 *1973*, Donike *J Chromatogr* **103** 91 *1975*, DOI 10.1016/S0021-9673(00)83805-4; *Beilstein* **2** IV 471.]

Biuret (allophanic acid amide, carbamoylurea) *[108-19-0]* **$C_2H_5N_3O_2$, M 103.1, sinters at 218° and chars at 270°, pK_1^{25} -0.88, pK_2^{25} >4.** Crystallise biuret from EtOH. [*Beilstein* **3** IV 141.]

***N*-Bromoacetamide** *[79-15-2]* **C_2H_4BrNO, M 138.0, m 102-105°, 107-109°, 108°(anhydrous).** A possible contaminant is CH_3CONBr_2. Recrystallise it from $CHCl_3$/hexane (1:1, seed if necessary) or water and dry over $CaCl_2$. It is a brominating agent. [Oliveto & Gerold *Org Synth* Coll Vol **4** 104 *1963*, DOI: 10.15227/orgsyn.031.0017.] *Alternatively*, dissolve it in the minimum volume of warm H_2O (60°), then cool in an ice bath, collect the crystals and dry them in an anhydrous atmosphere, dissolve in Et_2O, chill and evaporate till crystallisation occurs. Dry the crystals *in vacuo* at 25°, then at 45° (**m 108°**). Crystallise from $CHCl_3$ (**m 103°**). Estimate the available Br iodometrically [Buckles et al. *J Org Chem* **23** 483 *1958*, DOI: 10.1021/jo01097a605]. [*Beilstein* **2** H 181, **2** I 82, **2** II 180, **2** III 406, **2** IV 417.]

Bromoacetic acid *[79-08-3]* **$C_2H_3BrO_2$, M 138.9, m 50°, b 118°/15mm, 208°/760mm, d^{25} 1.93, pK^{25} 2.92.** Crystallise bromoacetic acid from petroleum ether (b 40-60°). A diethyl ether solution of it is passed through an alumina column, and the ether is evaporated at room temperature under vacuum. It is best obtained by distillation from a Claisen flask (immersed in an oil bath) fitted with an insulated Vigreux column and the fraction **b 108-110°/30mm** is collected. It is light and moisture sensitive. [Natelson & Gottfried *Org Synth* Coll Vol **3** 381 *1955*, DOI: 10.15227/orgsyn.023.0037; *Beilstein* **2** IV 526.] **LACHRYMATORY and is a skin IRRITANT**.

Bromoacetone *[598-31-2]* **C_3H_5BrO, M 137.0, b 31.5°/8mm, 63.5-64°/50mm, 137°/atm, d^{23} 1.643.** Stand bromoacetone over anhydrous $CaCO_3$, filter, distil it under low vacuum, and store it with $CaCO_3$ in the dark at 0°. [Levene *Org Synth* Coll Vol **2** 88 *1943*, DOI: 10.15227/orgsyn.010.0012.] **Violently LACHRYMATORY and skin IRRITANT.**

2-Bromobutane *[78-76-2]* **C_4H_9Br, M 137.0, b 91.2°/atm, d_4^{20} 1.255, n_D^{20} 1.4367, n^{25} 1.4341.** Wash 2-bromobutane with concentrated HCl, water, 10% aqueous $NaHSO_3$, and then water. Dry it with $CaCl_2$, Na_2SO_4 or anhydrous K_2CO_3, and fractionally distil it through a 1m glass helices packed column. [*Beilstein* **1** IV 261.]

Bromoform *[75-25-2]* **$CHBr_3$, M 252.7, m 8.1°, 55-56°/35mm, 149.6°/760mm, d^{15} 2.9038, d^{30} 2.86460, n^{15} 1.60053, n_D^{20} 1.5988.** The storage and stability of bromoform and chloroform are similar. Ethanol, added as a stabiliser, is removed by washing with H_2O or with saturated $CaCl_2$ solution, and the $CHBr_3$, after drying with $CaCl_2$ or K_2CO_3, is fractionally distilled. Prior to distillation, $CHBr_3$ has also been washed with concentrated H_2SO_4 until the acid layer is no longer coloured, then dilute NaOH or $NaHCO_3$, and H_2O. A further purification step is fractional crystallisation by partial freezing. [*Beilstein* **1** IV 82.]

(±)-2-Bromohexadecanoic acid (2-bromopalmitic acid) *[18263-25-7]* **$C_{16}H_{31}BrO_2$, M 335.3, m 51-53°, 52.3-52.5°, 53°, pK_{Est} ~3.2.** Recrystallise the acid from petroleum ether (b 60-80°, charcoal) and finally from EtOH. The ***ethyl ester*** has **b 177-178°/2mm**, d_{28}^{28} 1.0484, n_D^{20} 1.4560. [IR: Sweet & Estes *J Org Chem* **21** 1426 *1956*, DOI: 10.1021/jo01118a026; *Beilstein* **2** IV 1184.]

(±)2-Bromohexanoic acid (α-bromocaproic acid) *[616-05-7]* **$C_6H_{11}BrO_2$, M 195.1, b 118-125°/8mm, 148-153°/30mm, 240°/atm, d_4^{20} 1.37g/ml, n_D^{20} 1.472, pK_{Est} ~3.1.** It can be synthesised as described by Clarke & Taylor [*Org Synth* **4** 9 *1925*, and *Org Synth* Coll Vol **I** 115 *1941*, DOI: 10.15227/orgsyn.004.0009] and finally purified by distillation in a vacuum. It is soluble in EtOH and Et_2O. Optical Resolution *via* the strychnine salt, [Levene et al. *J Biol Chem* **75** 337 *1927*, http://www.jbc.org/content/75/1/337.citation.full.ht ml; Levene & Mardashew *J Biol Chem* **117** 707 *1937*, http://www.jbc.org/content/117/2/707.citation.full.h tml] and final distillation at 106-107°/4mm or 129-130°/14mm gives the **(-)-bromo acid** with **$[\alpha]_D^{20}$ -27.0 (in Et_2O),** and the **(+)-bromo acid** with **b 86-89°/0.35mm** and **$[\alpha]_D^{25}$ +5.6 (neat).** [*Beilstein* **2** II 287, **2** III 736, **2** IV 938.] The **(±)-*ethyl ester* $C_8H_{15}BrO_2$,** is a liquid with an aniseed odour and **b 95-96°/9mm, 148-153°/30mm, 120-122°/41mm, 206-210°/atm, d_4^{25} 1.2210, n_D^{20} 1.4456.**

6-Bromohexanoic acid (6-bromocaproic acid) *[4224-70-8]* **$C_6H_{11}BrO_2$, M 195.1, m 32-33°, 35°, 34-36°, b 129-130°/5mm.** It has been prepared by the oxidation of 6-bromohexanol with concentrated HNO_3 (sp. gr. 1.42, 1 hour for addition at 25-30°, stir at ~25° for 4 hours then at 100° for 45 minutes) [Degering & Boatright *J Am Chem Soc* **72** 5137 *1950*, DOI: 10.1021/ja01167a091]. It is made more conveniently by oxidation of cyclohexanone (174 g) with Caro's acid (using a mixture prepared from 919g of potassium persulfate for 10-15 minutes as in Barger et al. *J Chem Soc* 718 *1937*, DOI: 10.1039/JR9570000618), and the crude lactone (200g) that is formed is treated with a cooled mixture of 48% HBr (1L) and concentrated H_2SO_4 (240ml). After standing at ~25° for 2 hours, then for 4 hours at 100°, the mixture is cooled, poured into H_2O, the organic layer is separated, the aqueous layer is saturated with $(NH_4)_2SO_4$, and is extracted with Et_2O. The combined organic layers and extracts are washed with saturated $(NH_4)_2SO_4$, dried (Mg_2SO_4), evaporated and distilled in a vacuum. [See Brown & Partridge *J Am Chem Soc* **66** 839 *1944*, DOI: 10.1021/ja01233a503 ; Degering & Boatright *J Am Chem Soc* **72** 5137 *1950*, DOI: 10.1021/ja01167a091]. [*Beilstein* **2** II 287, **2** III 737, **2** IV 940.] When the acid is refluxed with $SOCl_2$ in the absence of moisture until all the HCl and SO_2 have evolved, then evaporated, and the residue is distilled in a vacuum, it provides **6-bromohexanoyl chloride** *[22809-37-6]* **M 213.5, b 130°/20mm, d^{25} 1.395, n_D^{20} 1.486** as an almost colourless oil which is typically reactive and corrosive like most acid chlorides. [Osbond *J Chem Soc* 3464 *1951*, DOI: 10.1039/JR9510003464]. ***6-Bromohexanamide*** has **m 107-108°**, and the ***anilide*** has **m 84°**. [*Beilstein* **2** IV 940.]

1-Butanesulfonyl chloride *[2386-60-9]* **$C_4H_9ClO_2S$, M 156.6, b 75-76°/7mm, 98°/13mm, 100-103°/27-28mm, d_4^{20} 1.2078, n_D^{20} 1.4559**. It has a pungent odour and is **LACHRYMATORY.** If IR shows OH bands,

then dissolve in Et_2O, wash with cold saturated aqueous $NaHCO_3$ (care since CO_2 will be generated) then H_2O, dry it over solid Na_2SO_4, filter, evaporate and distil the residue twice. Characterise it by shaking a solution in Et_2O or $*C_6H_6$ with aqueous NH_3, collect the solid ***1-butanesulfonamide*** with **m 48°** after recrystallisation from $CHCl_3$, CCl_4 or Et_2O/petroleum ether. [Douglass & Johnson *J Am Chem Soc* **60** 1486 *1938*, DOI: 10.1021/ja01273a063; Lee & Dougherty *J Org Chem* **5** 81 *1940*, DOI: 10.1021/jo01208a001; *Beilstein* **4** IV 45.]

1-Butanethiol *[109-79-5]* **$C_4H_{10}S$, M 90.2, b 98.4°/atm, d^{25} 0.837, n_D^{20} 1.443, n^{25} 1.440, pK_{Est} ~11.3.** Dry the thiol with $CaSO_4$ or Na_2SO_4, then reflux it over magnesium, or dry with, and distil it from CaO, under nitrogen [Roberts & Friend *J Am Chem Soc* **108** 7204 *1986*, DOI: 10.1021/ja01273a063]. It has been separated from hydrocarbons by extractive distillation with aniline.
Dissolve it also in 20% NaOH, extract with a small amount of $*C_6H_6$, then steam distil it until the distillate is clear. The distillate is then cooled and acidified slightly with 15% H_2SO_4. The thiol is distilled out, dried with $CaSO_4$ or $CaCl_2$, and fractionally distilled under N_2 [Mathias & Filho *J Phys Chem* **62** 1427 *1958* , DOI: 10.1021/j150569a018]. It has also been purified by precipitation as the lead mercaptide from alcoholic solution, then regeneration by addition of dilute HCl to the residue followed by steam distillation. *All operations should be carried out in a fume cupboard due to the* **TOXICITY** *and obnoxious odour of the thiol*. [*Beilstein* **1** IV 1555.]

2-Butanethiol *[513-53-1]* **$C_4H_{10}S$, M 90.2, b 37.4°/134mm, d^{25} 0.846, n^{25} 1.4338, pK_{Est} ~11.4.** Purify it as for 1-butanethiol above. [*Beilstein* **1** IV 1584.]

***n*-Butanol** *[71-36-3]* **$C_4H_{10}O$, M 74.1, b 117.7°/760mm, d^{25} 0.80572, n_D^{20} 1.39922, n^{15} 1.40118.** Dry it with $MgSO_4$, CaO, K_2CO_3, or solid NaOH, followed by refluxing with, and distilling from, small amounts of calcium, magnesium activated with iodine, or aluminium amalgam. It can also be dried with molecular sieves (4A), or by refluxing with *n*-butyl phthalate or succinate. (For method, see *Ethanol*.) *n*-Butanol can also be dried by efficient fractional distillation, water passing over in the first fraction as a binary azeotrope (contains about 37% water). An ultraviolet-transparent distillate has been obtained by drying with magnesium and distilling from sulfanilic acid. To remove bases, aldehydes and ketones, the alcohol is washed with dilute H_2SO_4, then $NaHSO_4$ solution; esters are removed by boiling for 1.5 hours with 10% NaOH.
It has also been purified by adding $NaBH_4$ (2g) to butanol (1.5L), under gentle bubbling of argon, and a reflux condenser for 1 day at 50°. Then add freshly cut sodium (2g, washed with butanol) and refluxed for 1 day. Distil, and collect the middle fraction [Jou & Freeman *J Phys Chem* **81** 909 *1977*, DOI: 10.1021/j100524a021]. [*Beilstein* **1** IV 1506.]

2-Butanone (methyl ethyl ketone, MEK) *[78-93-0]* **C_4H_8O, M 72.1, b 79.6°/atm, d_4^{20} 0.853, n_D^{20} 1.37850, n^{25} 1.37612, pK^{25} -7.2 (aqueous H_2SO_4).** In general, purification methods are the same as for acetone. Aldehydes can be removed by refluxing with $KMnO_4$ + CaO, until the Schiff aldehyde test is negative, prior to distillation. Shaking with saturated K_2CO_3, or passing through a small column of activated alumina, removes cyclic impurities. The ketone can be dried by careful distillation (an azeotrope containing 11% water boils at 73.4°), or over $CaSO_4$, P_2O_5, Na_2SO_4, or K_2CO_3, followed by fractional distillation. Purification as the bisulfite addition compound is achieved by shaking with excess saturated Na_2SO_3, cooled to 0°, filtering off the precipitate, washing with a little ethyl ether and drying in air; this is followed by decomposition with a slight excess of Na_2CO_3 solution and steam distillation, the distillate being saturated with K_2CO_3 so that the ketone can be separated, dried with K_2CO_3, filtered, and distilled. Purification as the *NaI addition compound* (**m** 73-74°) is more convenient. (For details, see *Acetone*.) Small quantities of 2-butanone can be purified by conversion to the semicarbazone, recrystallisation to constant melting point, drying it under vacuum over $CaCl_2$ and paraffin wax, refluxing for 30 minutes with excess oxalic acid, followed by steam distillation, salting out, drying and distilling [Cowan et al. *J Chem Soc* 171 *1940*, DOI: 10.1039/JR9400000171]. [*Beilstein* **1** IV 3243.]

1-Butene *[106-98-9]* **C_4H_8, M 56.1, m -185°, b -81°/10mm, -6.3°/atm, $d^{-6.47}$ 0.6255.** Present in petroleum oils and coal gas. The gas is dried with CaH_2 and purified by gas chromatography. *Alternatively*, the gas (from Linde Air Products Company, USA) is cooled with liquid nitrogen, evacuated until about one tenth of the sample has evaporated, distilled into a second receiver and the last tenth is discarded. This operation is repeated seven times. During the first three cycles decreasingly small amounts of a white solid are observed when the sample is

cooled, but they disappear by the fourth cycle. This butane was used for the studies of vapour pressure, orthobaric liquid density and critical constants. [Calingaert *J Am Chem Soc* **45** 130 *1923*, DOI: 10.1021/ja01654a019; Coffin & Maas *J Am Chem Soc* **50** 1427 *1928*, DOI: 10.1021/ja01392a028; Beattie & Marple *J Am Chem Soc* **72** 1449 *1950*, DOI: 10.1021/ja01160a006.] [*Beilstein* **1** H 205, **1** II 176, **1** III 728, **1** IV 765.] **HIGHLY FLAMMABLE GAS.**

***cis*-2-Butene** *[590-18-1]* **C_4H_8, M 56.1, b 2.95-3.05°/746mm.** The gas is dried with CaH_2 and purified by gas chromatography. [*Beilstein* **1** H 205, **1** II 176, **1** III 728, **1** IV 778.] **HIGHLY FLAMMABLE.** ***trans*-2-Butene** *[624-64-6]* **b 0.3-0.4°/744mm**, is also a gas which is purified as the *cis*-isomer. [*Beilstein* **1** H 205, **1** II 176, **1** III 730, **1** IV 781.] **HIGHLY FLAMMABLE.**

2-Butene-1,4-dicarboxylic acid (*trans*-3-hexenedioic acid, *trans*-ß-hydromuconic acid) *[4436-74-2]* **$C_4H_8O_4$, M 144.1, m 194-197°, 195-196°, $pK_{Est(1)}$ ~4.2, $pK_{Est(2)}$ ~5.00.** Crystallise the acid from boiling water, then dry it at 50-60° in a vacuum oven. [*Beilstein* **2** IV 2237.]

2-Butoxyethanol (butyl cellosolve) *[111-76-2]* **$C_6H_{14}O_2$, M 118.2, b 171°/745mm, d_4^{20} 0.903, n_D^{20} 1.4191.** Peroxides can be removed by refluxing with anhydrous $SnCl_2$ or by passage under slight pressure through a column of activated alumina. Dry with anhydrous K_2CO_3 and $CaSO_4$, filter and distil, or reflux with, and distil from NaOH. [*Beilstein* **1** IV 2380.]

***n*-Butyl acetate** *[123-86-4]* **$C_6H_{12}O_2$, M 116.2, b 126.1°/atm, d_4^{20} 0.882, n_D^{20} 1.394.** Distil, reflux with successive portions of $KMnO_4$ until the colour persists, dry with anhydrous $CaSO_4$, filter and redistil. [*Beilstein* **2** IV 143.]

***tert*-Butyl acetate** *[540-88-5]* **$C_6H_{12}O_2$, M 116.2, b 97-98°/atm, d_4^{20} 0.866, n_D^{20} 1.387.** Wash the ester with 5% Na_2CO_3 solution, then saturated aqueous $CaCl_2$, dry with $CaSO_4$ and distil it. [McCloskey et al. *Org Synth* Coll Vol **4** 261 *1963,* DOI: 10.15227/orgsyn.034.0026; Mangia et al. *Org Prep Proc Int* **18** 13 *1986*, DOI:10.1080/00304948609356822; *Beilstein* **2** IV 151.]

***tert*-Butyl acetoacetate** *[1694-31-1]* **$C_8H_{14}O_3$, M 158.2, b 71°/10mm, 85°/20mm, d_4^{20} 0.954, n_D^{20} 1.42.** Distil it under reduced pressure through a short column. [Lawesson et al. *Org Synth* Coll Vol **5** 155 *1973*, DOI: 10.15227/orgsyn.042.0028; *Beilstein* **3** IV 1536.] **HARMFUL VAPOUR.**

***tert*-Butylacetyl chloride** *[7065-46-5]* **$C_6H_{11}ClO$, M 134.6, b 68-71°/100mm, 81°/180mm, 128-132°/atm, d_4^{20} 0.964, n_D^{20} 1.423.** Distil it under vacuum. If IR shows OH group, then treat with thionyl chloride or oxalyl chloride at *ca* 50° for 30 minutes, evaporate and fractionate the residue using a short column. Strongly **LACHRYMATORY**, use a good fume hood. [Berliner & Berliner *J Am Chem Soc* **72** 222 *1950*, DOI: 10.1021/ja01157a063; Traynham & Battiste *J Org Chem* **22** 1551 *1957*, DOI: 10.1021/jo01363a004; *Beilstein* **2** IV 956.]

Butyl acrylate *[141-32-2]* **$C_7H_{12}O_2$, M 128.2, b 59°/25mm, d_4^{20} 0.894, n^{12} 1.4254.** Wash it repeatedly with aqueous NaOH to remove inhibitors such as hydroquinone, then with distilled water. Dry with $CaCl_2$. Fractionally distil under reduced pressure in an all-glass apparatus. The middle fraction is sealed under N_2 and stored at 0° in the dark until required or with a stabiliser [Mallik & Das *J Am Chem Soc* **82** 4269 *1960*, DOI: 10.1021/ja01501a038]. [*Beilstein* **2** IV 1463.]

***tert*-Butyl acrylate** *[1663-39-4]* **$C_7H_{12}O_2$, M 128.2, b 30.0-30.8°/26mm, 61-63°/15mm, 117-120°/760mm, d^{25} 0.875, n_D^{20} 1.410.** Purify the ester by fractional distillation. If it contains acid (OH bands in the IR), then dissolve it in Et_2O, wash it with aqueous $NaHCO_3$, dry the organic layer (Na_2SO_4), filter it and distil it under reduced pressure. Stabilise it by adding hydroquinone monomethyl ether (~0.05%). It forms a crystalline *tert*-butyl acrylate polymer which is soluble in organic solvents [Garrett et al. *J Am Chem Soc* **81** 1007 *1959*, DOI: 10.1021/ja01513a064]. [*Beilstein* **2** IV 1465.] For other alkyl acrylates see Rehberg *Org Synth* Coll Vol **3** 146 *1955*, DOI: 10.15227/orgsyn.026.0018.

(±)-*sec*-Butyl alcohol (± 2-butanol) *[78-92-2; 15892-23-6]* **$C_4H_{10}O$, M 74.1, b 99.4°/atm, d_4^{20} 0.808.** Purification methods are the same as for *n*-Butanol. These include drying with K_2CO_3 or $CaSO_4$, followed by filtration and fractional distillation, refluxing with CaO, distillation, then refluxing with magnesium and redistillation, and refluxing with, then distilling from CaH_2. Calcium carbide has also been used as a drying agent. The anhydrous alcohol is obtained by refluxing with *sec*-butyl phthalate or succinate. (For method see *Ethanol*.) Small amounts of alcohol can be purified *via* conversion to the alkyl hydrogen phthalate and recrystallisation [Hargreaves *J Chem Soc* 3674, 3679(note page) *1956*, DOI: 10.1039/JR9560003674]. For purification of optical isomers, see Timmermans and Martin [*J Chim Phys. Phys-Chim Biol* **25** 411 *1928*]. [*Beilstein* **2** III 1566.]

***tert*-Butyl alcohol** *[75-65-0]* **$C_4H_{10}O$, M 74.1, m 23-25°, 25.7°, b 28.3°/60mm, 43.3°/123.8mm, 61.8°/315mm, 72.5°/507mm, 82.45°/760mm, d_4^{20} 0.7858, n_D^{20} 1.3878.** It is synthesised commercially by the hydration of 2-methylpropene in dilute H_2SO_4. Dry it with CaO, K_2CO_3, $CaSO_4$ or $MgSO_4$, filter and fractionally distil it. Dry further by refluxing with, and distilling from, either magnesium activated with iodine, or small amounts of calcium, sodium or potassium, under nitrogen. Passage through a column of type 4A molecular sieves is another effective method of drying; as well as refluxing with *tert*-butyl phthalate or succinate. (For method see *Ethanol*.) Other methods include refluxing with excess aluminium *tert*-butylate, or standing over CaH_2, and distilling as needed. Further purification is achieved by fractional crystallisation by partial freezing, taking care to exclude moisture. *tert*-Butyl alcohol samples containing much water can be dried by adding *benzene, so that the water distils off as a tertiary azeotrope, **b** 67.3°. Traces of isobutylene have been removed from dry *tert*-butyl alcohol by bubbling dry pre-purified nitrogen through for several hours at 40-50° before using. It forms azeotropic mixtures with a large number of compounds. It has also been purified by distillation from CaH_2 onto Linde 4A molecular sieves which had been activated at 350° for 24 hours [Jaeger et al. *J Am Chem Soc* **101** 717 *1979*, DOI: 10.1021/ja00497a039]. [*Beilstein* **1** IV 1609.]
Rapid purification: Dry *tert*-butanol over CaH_2 (5% w/v), distil and store it over 3A molecular sieves.

***n*-Butylamine** *[109-73-9]* **$C_4H_{11}N$, M 73.1, b 77.8°/atm, d_4^{20} 0.740, n_D^{20} 1.4009, n^{25} 1.399, pK^{25} 10.66.** Dry *n*-butylamine with solid KOH, K_2CO_3, $LiAlH_4$, CaH_2 or $MgSO_4$, then reflux it with, and fractionally distil it from P_2O_5, CaH_2, CaO or BaO. Further purification is by precipitation as the ***hydrochloride*, m 213-213.5°**, from ethereal solution by bubbling HCl gas into it. This is re-precipitated three times from EtOH by adding ether, followed by liberation of the free amine using excess strong mineral base. The amine is extracted into ether, which is separated, dried with solid KOH, the ether is removed by evaporation and then the amine is distilled. It is stored in a desiccator over solid NaOH [Bunnett & Davis *J Am Chem Soc* **82** 665 *1960*, DOI: 10.1021/ja01488a043; Lycan et al. *Org Synth* Coll Vol **2** 318 *1943*, DOI: 10.15227/orgsyn.011.0058]. [*Beilstein* **4** IV 540.] **SKIN IRRITANT.**

R*-(-)-*sec*-Butylamine** *[13250-12-9]* **$C_4H_{11}N$, M 73.1, b 61-63°/atm, 62.5°/atm, d_4^{20} 0.731, n_D^{20} 1.393, $[\alpha]_D^{20}$ -7.5 (neat), pK^{25} 10.56.** Dry it over solid NaOH overnight and fractionate it through a short helices packed column. The **L-*hydrogen tartrate salt has **m 139-140°** (from H_2O), the *1H_2O* has **m 96°** $[\alpha]_D^{21}$ +18.1 (c 11, H_2O), the ***hydrochloride*** has **m 152°** $[\alpha]_D^{21}$ -1.1 (c 13, H_2O) and the ***benzoyl*** derivative crystallises from EtOH as needles with **m 97°**, $[\alpha]_D^{21}$ -34.9 (c 11, H_2O). [Bruck et al. *J Chem Soc* 921 *1956*, DOI: 10.1039/JR9560000921; Kjaer & Hansen *Acta Chem Scand* **11** 898 *1957*, DOI: 10.3891/acta.chem.scand.11-0898.] [*Beilstein* **4** H 161, **4** I 372, **4** III 308, **4** IV 617.] The ***S*-(+)-*enantiomer*** has the same properties except for the optical rotation which has the opposite sign.

***tert*-Butylamine** *[75-64-9]* **$C_4H_{11}N$, M 73.1, b 42°/atm, d_4^{20} 0.696, pK^{25} 10.68.** Dry it with KOH or $LiAlH_4$, and/or distil it from CaH_2 or BaO. [*Beilstein* **4** IV 657.] ***tert*-Butylammonium bromide** *[60469-70-7]* **$C_4H_{11}N$. HBr, M 154.1, m >250°(dec)**, is recrystallised several times from absolute EtOH and thoroughly dried at 105° *in vacuo*. **Toxic vapours.** [*Beilstein* **4** IV 657.]

***n*-Butyl bromide** *[109-65-9]* **C_4H_9Br, M 137.0, b 101-102°/atm, d^{25} 1.2678, n_D^{20} 1.4399, n^{25} 1.4374.** Wash the bromide with concentrated H_2SO_4, water, 10% Na_2CO_3 and again with water. Dry it over $CaCl_2$, $CaSO_4$ or K_2CO_3, and distil it. Redistil it after drying with P_2O_5, or pass it through two columns containing 5:1 silica gel/Celite mixture and store it with freshly activated alumina. [*Beilstein* **1** IV 258.]

***tert*-Butyl bromoacetate** *[5292-43-3]* **$C_6H_{11}BrO_2$, M 195.1, b 52°/10mm, 74-76°/25mm, d_4^{20} 1.324, n_D^{25} 1.4162.** Dissolve the ester in Et_2O, wash it well with ice cold 10% aqueous K_2CO_3, dry it over $CaCl_2$, filter and evaporate the Et_2O, then fractionate it through a Vigreux column in a vacuum. **LACHRYMATORY.** [Abramovitch et al. *J Am Chem Soc* **64** 2272 *1942*, DOI: 10.1021/ja01262a01; Abramovitch & Hauser *J Am Chem Soc* **65** 986 *1943*, DOI: 10.1021/ja01245a501; *Beilstein* **2** III 482.]

***tert*-Butyl carbazate** *[870-46-2]* **$C_5H_{12}NO_2$, M 132.2, m 41-42°, b 64°/0.01mm, 55-57°/0.4mm.** Distil it in a Claisen flask with a water or oil bath at *ca* 80°. After a couple of drops have distilled, the carbazate is collected as an oil which solidifies to a snow white solid. It can be crystallised with 90% recovery from a 1:1 mixture of petroleum ether (b 30-60°) and petroleum ether (b 60-70°). [Carpino et al. *Org Synth* Coll Vol **5** 166 *1973*, DOI: 10.15227/orgsyn.044.0020; *Beilstein* **3** IV 175.]

***n*-Butyl chloride** *[109-69-3]* **C_4H_9Cl, M 92.6, b 78°/atm, d_4^{20} 0.886, n_D^{25} 1.4021.** Shake it repeatedly with concentrated H_2SO_4 (until no further colour develops in the acid layer), then wash it with water, aqueous $NaHCO_3$ or Na_2CO_3, and more water. Dry it with $CaCl_2$, or $MgSO_4$ (then with P_2O_5 if desired), decant and fractionally distil it. *Alternatively*, a stream of oxygen continuing *ca* three times as long as is necessary to obtain the first coloration of starch iodide paper by the exit gas. After washing with $NaHCO_3$ solution to hydrolyse ozonides and to remove the resulting organic acid, the liquid is dried and distilled [Chien & Willard *J Am Chem Soc* **75** 6160 *1953*, DOI: 10.1021/ja01120a016]. [*Beilstein* **1** IV 246.]

***tert*-Butyl chloride** *[507-20-0]* **C_4H_9Cl, M 92.6, f -24.6°, b 50.4°/atm, d_4^{20} 0.851, n_D^{25} 1.38564.** Purification methods commonly used for other alkyl halides lead to decomposition. Some impurities can be removed by photochlorination with a small amount of chlorine prior to use. The liquid is washed with ice water, dried with $CaCl_2$ or $CaCl_2$ + CaO and fractionally distilled. It has been further purified by repeated fractional crystallisation by partial freezing. [*Beilstein* **1** IV 288.]

***tert*-Butyl chloroacetate** *[107-59-5]* **$C_6H_{11}ClO_2$, M 150.6, b 48-49°/11mm, 60.2°/15mm, 155°/atm (dec), d_4^{25} 1.4204, n_D^{20} 1.4259.** Check the NMR spectrum; if satisfactory then distil in a vacuum; if not then dissolve in Et_2O, wash with H_2O, 10% H_2SO_4 until the acid extract does not become cloudy when made alkaline with NaOH. Wash the organic layer again with H_2O, then saturated aqueous $NaHCO_3$, dry over Na_2SO_4, evaporate and fractionate it through a carborundum-packed column or a 6-inch Widmer column (*see tert-butyl ethyl malonate for precautions to avoid decomposition during distillation*). [Johnson et al. *J Am Chem Soc* **75** 4995 *1953*, DOI: 10.1021/ja01116a033; Baker *Org Synth* Coll Vol **3** 141 *1944*, DOI: 10.15227/orgsyn.024.0018; *Beilstein* **2** III 444.]

***tert*-Butyl cyanide (trimethylacetonitrile, pivalonitrile)** *[630-18-2]* **C_5H_9N, M 83.1, m 16-18°, b 104-106°/atm, d_4^{20} 0.765.** Purify it by a two-stage vacuum distillation and de-gas by the freeze-pump-thaw technique. Store it under vacuum at 0°. **TOXIC,** use an efficient fume hood. [*Beilstein* **2** IV 875.]

***tert*-Butyl cyanoacetate** *[1116-98-9]* **$C_7H_{11}NO_2$, M 141.2, b 40-42°/0.1mm, 54-56°/0.3mm, 90°/10mm, 107-108°/23mm, d_4^{20} 0.989, n_D^{20} 1.4198**. The IR spectrum of a film should have bands at 1742 (ester CO) and 2273 (C≡N), but no band at *ca* 3500 broad (OH) cm^{-1}. If it does not have the last-named band, then fractionally distil; otherwise dissolve in Et_2O, wash with saturated aqueous $NaHCO_3$, dry over K_2CO_3, evaporate Et_2O, and distil the residue under a vacuum (*see tert-butyl ethyl malonate for precautions to avoid decomposition during distillation*). [Beech & Piggott *J Chem Soc* 423 *1955*, DOI: 10.1039/JR9550000423; Dahn & Hauth *Helv Chim Acta* **42** 1214 *1959*, DOI: 10.1002/hlca.19590420416; *Beilstein* **2** I 255.]

***tert*-Butyl diazoacetate** *[3505950-8]* **$C_6H_{10}N_2O_2$, M 142.2, b 51-53°/12mm, d_4^{25} 1.026, n_D^{20} 1.443.** It is a poisonous orange-yellow liquid which is explosive, and the necessary precautions should be strictly adhered to (i.e. efficient fume cupboard, and face and body protection; see reference below). Check the purity by TLC on Merck Kieselgel F_{254} or Eastman Kodak Silica Gel without indicator using $CHCl_3$ as eluent (R_F 0.72). If the ester is suspect, then dissolve it in Et_2O, wash it with brine, H_2O, dry the organic layer (Na_2SO_4), and filter. Remove most of the Et_2O at 30°/water pump vacuum (rotovap), the remaing ether during distillation under lower pressure (<12mm), and the residual oil then distils as a coloured liquid using a water bath at ~50° (no higher) as

heat source. [Regitz et al. *Org Synth* Coll Vol **5** 179 *1972*, DOI: 10.15227/orgsyn.048.0036.]

***n*-Butyl disulfide** *[629-45-8]* **$C_8H_{18}S_2$, M 178.4, b 110-113°/15mm, d_4^{20} 0.938, n^{22} 1.494.** Shake it with lead peroxide, filter and distil it in a vacuum under N_2. [*Beilstein* **1** IV 1560.]

***n*-Butyl ether (di-*n*-butyl ether)** *[142-96-1]* **$C_8H_{18}O$, M 130.2, b 52-53°/26mm, 142.0°/760mm, d_4^{20} 0.764, n_D^{20} 1.39925, n^{25} 1.39685, pK^{25} -5.40 (aqueous H_2SO_4).** Peroxides (detected by the liberation of iodine from weakly acid HCl solutions of 2% KI) can be removed by shaking 1L of ether with 5-10ml of a solution comprising of ferrous sulfate (6.0g) in concentrated H_2SO_4 (6ml) and water (110ml), with aqueous Na_2SO_3, or with acidified NaI, water, then aqueous $Na_2S_2O_3$. After washing with dilute NaOH, KOH, or Na_2CO_3, then water, the ether is dried with $CaCl_2$ and distilled. It can be further dried by distillation from CaH_2 or Na (after drying with P_2O_5), and stored in the dark with Na or NaH. The ether can also be purified by treating with CS_2 and NaOH, expelling the excess sulfide by heating. The ether is then washed with water, dried with NaOH and distilled [Kusama & Koike *J Chem Soc Jpn, Pure Chem Sect* **72** 229 *1951*]. Other purification procedures include passage through an activated alumina column to remove peroxides, or through a column of silica gel, and distillation after adding about 3% (v/v) of a 1M solution of MeMgI in *n*-butyl ether. [*Beilstein* **1** IV 1520.]

***n*-Butyl ethyl ether** *[628-81-9]* **$C_6H_{14}O$, M 102.2, b 92.7°/atm, d_4^{20} 0.751, n_D^{20} 1.38175, n^{25} 1.3800.** Purify by drying with $CaSO_4$, by passage through a column of activated alumina (to remove peroxides), followed by prolonged refluxing with Na and then fractional distillation. [*Beilstein* **4** IV 1518.]

***tert*-Butyl ethyl ether** *[637-92-3]* **$C_6H_{14}O$, M 102.2, b 71-72°/atm, d_4^{20} 0.741.** Dry the ether with $CaSO_4$, pass it through an alumina column, and fractionally distil it. [*Beilstein* **1** IV 1618.]

***tert*-Butyl ethyl malonate** *[32864-38-3]* **$C_9H_{16}O_4$, M 188.2, b 83-85°/8mm, 93-95°/17mm, 107-109°/24mm, d_4^{25} 0.994, n_D^{24} 1.4150.** A likely impurity is monoethyl malonate; check IR for OH bands at 3330 br cm^{-1}. To *ca* 50g of ester add ice cold NaOH (50g in 200ml of H_2O and 200g of ice). Swirl a few times (filter off ice if necessary), place it in a separating funnel and extract with Et_2O (2 x 75ml). Dry the extract ($MgSO_4$) (since traces of acid decompose the *t*-Bu group of the ester, the distillation flask has to be washed first with aqueous NaOH, rinsed with H_2O and allowed to dry). Addition of some K_2CO_3 or MgO before distilling is recommended to inhibit decomposition. Distil it under reduced pressure through a 10cm Vigreux column. *Decomposition is evidenced by severe foaming due to autocatalytic decomposition and cannot be prevented from accelerating except by stopping the distillation and rewashing the distillation flask with alkali again*. [Breslow et al. *J Am Chem Soc* **66** 1286 *1944*, DOI: 10.1021/ja01236a022; Hauser et al. *J Am Chem Soc* **64** 2714 *1942*, DOI: 10.1021/ja01263a054; Strube *Org Synth* Coll Vol **4** 417 *1963*, DOI: 10.15227/orgsyn.037.0034; *Beilstein* **2** IV 1884.]

***n*-Butyl formate** *[592-84-7]* **$C_5H_{10}O_2$, M 102.1, b 106.6°/atm, d_4^{20} 0.891, n_D^{20} 1.3890.** Wash the formate with saturated $NaHCO_3$ solution in the presence of saturated NaCl, until no further reaction occurs, then with saturated NaCl solution, dry ($MgSO_4$), filter and fractionally distil the filtrate. [*Beilstein* **2** IV 28.]

Butyl glycolate *[7397-62-8]* **$C_6H_{12}O_3$, M 132.2, b 191-192°/755mm, 187-190°/atm, d_4^{20} 1.019, n_D^{20} 1.4263.** Dissolve the ester in $CHCl_3$ (EtOH-free), wash with 5% $KHCO_3$ until effervescence ceases (if free acid is present), dry over $CaCl_2$, filter, evaporate and distil through a short column. [Bøhme & Opfer *Z Anal Chem* **139** 255 *1953*, Filachione et al. *J Am Chem Soc* **73** 5265 *1951*, DOI: 10.1021/ja01155a075; *Beilstein* **3** IV 589.]

***tert*-Butyl hydroperoxide (TBHP)** *[75-91-2]* **$C_4H_{10}O_2$, M 90.1, f 5.4°, m 0.5-2.0°, b 38°/18mm, d_4^{20} 0.900, n_D^{20} 1.4013, pK^{20} 12.8.** *Care should be taken when handling this peroxide because of the possibility of* **EXPLOSION. It explodes when heated over an open flame. Work in an efficient fume cupboard, behind a thick plastic transparent shield, and with eye protection.** Alcoholic and volatile impurities can be removed by prolonged refluxing at 40° under reduced pressure, or by steam distillation. For example, Bartlett, Benzing and Pincock [*J Am Chem Soc* **82** 1762 *1960*, DOI: 10.1021/ja01492a055] refluxed at 30mm pressure in an apparatus for azeotropic liquid separation until the two phases no longer separated, and then distilled at 41°/23mm. Pure material is stored under N_2, in the dark at 0°. Crude commercial material has been added to

25% NaOH below 30°, and the crystals of the sodium salt have been collected, washed twice with *benzene and dissolved in distilled water. After the pH of the solution is adjusted to 7.5 by adding solid CO_2, the peroxide is extracted into petroleum ether, from which, after drying with K_2CO_3, TBHP is recovered by distilling off the solvent under reduced pressure at room temperature [O'Brien et al. *J Am Chem Soc* **79** 6238 *1957*, DOI: 10.1021/ja01580a034]. **The temperatures should be kept below 75°**. It has also been distilled through a helices packed column (*ca* 15 plates) and the material with **b 34-35°/20mm** is collected. Similarly, a solution in petroleum ether has been extracted with cold aqueous NaOH, and the hydroperoxide has been regenerated by adding at 0°, $KHSO_4$ to a pH not higher than 4.5, then extracted into diethyl ether, dried with $MgSO_4$, filtered and the ether evaporated in a rotary evaporator under reduced pressure at as low a temperature as possible [Milas & Djokic *J Am Chem Soc* **84** 3098 *1962*, DOI: 10.1021/ja00875a012].
A 3M solution of TBHP in CH_2Cl_2 is prepared by swirling of commercial TBHP (85ml, 0.61mol, 70% TBHP-30% H_2O, **d** 0.935 *ca* 7.2mmol/ml) with of CH_2Cl_2 (140ml) in a separating funnel. The milky mixture is allowed to stand until the phases separate (*ca* 30 minutes). The organic (lower) layer (*ca* 200ml) containing 0.60mole of TBHP is separated from the aqueous layer (*ca* 21ml) and used without further drying. TBHP is assayed by iodometric titration. With 90% grade TBHP (w/w, d 0.90, *ca* 9.0mmole/ml) no separation of layers occurs, i.e. when TBHP (66.67ml, 0.60mole) is added to CH_2Cl_2 (140ml) the resulting solution (*ca* 200ml) should be clear. [Walling & Buckler *J Am Chem Soc* **77** 6032 *1955*, DOI: 10.1021/ja01627a069; Rogers & Campbell *J Am Chem Soc* **74** 4742 *1952*, DOI: 10.1021/ja01139a004; Akashi et al. *J Org Chem* **43** 2063 *1978* DOI: 10.1021/jo00404a052 state the quality of available grades, handling and compatibility for reactions, *Beilstein* **1** IV 1616.]

***n*-Butyl iodide (1-iodobutane)** *[542-69-8]* **C_4H_9I, M 184.0, b 130.4°/atm, d_4^{20} 1.616, n^{25} 1.44967.** Dry the iodide with $MgSO_4$ or P_2O_5, fractionally distil it through a column packed with glass helices, taking the middle fraction and storing over calcium or mercury in the dark. *Alternatively*, purify it by prior passage through activated alumina or by shaking with concentrated H_2SO_4 then washing with Na_2SO_3 solution. It has also been treated carefully with sodium to remove free HI and H_2O, before distilling through a column containing copper turnings at the top. Another purification procedure consisted of treatment with bromine, followed by extraction of free halogen with $Na_2S_2O_3$, washing with H_2O, drying and fractionally distilling. [*Beilstein* **1** IV 271.]

***tert*-Butyl iodide** *[558-17-8]* **C_4H_9I, M 184.0, m -38°, b 98.1°/760mm, 100°(dec)/atm, d_4^{20} 1.544, d^{25} 1.622g/cm^3, n_D^{20} 1.502.** Vacuum distillation has been used to obtain a distillate which remained colourless for several weeks at -5°. More extensive treatment has been used by Boggs, Thompson & Crain [*J Phys Chem* **61** 1625 *1957*, DOI: 10.1021/j150558a013] who washed it with aqueous $NaHSO_3$ solution to remove free iodine, dried this for 1 hour over Na_2SO_3 at 0°, and purified it by four or five successive partial freezings of the liquid to obtain colourless material, and was stored at -78° with Ag wool. [For resonance Raman spectra see Phillips et al. *J Phys Chem* **95** 9085 *1991*, DOI: 10.1021/j100176a014; for steric hindrance see Marcellin & Brooks *J Am Chem Soc* **97** 1710 *1975*, DOI: 10.1021/ja00840a015; *Beilstein* **1** IV 300.]

***tert*-Butyl isocyanate** *[1609-86-5]* **C_5H_9NO, M 99.1, m 10.5-11.5°, b 30.5-32°/10mm, 64°/52mm, d_{25}^{25} 0.9079, n_D^{25} 1.470.** It is **LACHRYMATORY** and **TOXIC**, and should have IR with ν_{max} at 2251 (C≡N) cm^{-1} but no OH bands. The NMR should have one band at 1.37 ppm from TMS. Purify it by fractional distillation under reduced pressure. [Stowell et al. *J Org Chem* **36** 3056 *1971*, DOI: 10.1021/jo00819a039; Curtius *J Prakt Chem* **125** 152 *1930*, *Beilstein* **4** IV 669.]

***tert*-Butyl isocyanide** *[7188-38-7]* **C_5H_9N, M 83.1, b 91-92°/730mm, 90°/758mm, d_4^{20} 0.735.** Dissolve it in petroleum ether (b 40-60°), wash it with H_2O, dry (Na_2SO_4), filter, remove petroleum ether under slight vacuum, and distil it using a vacuum-jacketed Vigreux column at atmospheric pressure, its IR has a band at ν_{max} 2134 cm^{-1}. [Ugi & Meyr *Chem Ber* **93** 239 *1960*, DOI: 10.1002/cber.19600930136; *Beilstein* **4** IV 661.] It has **toxic vapours**.

Carbon Black *[1333-86-4]* **C, M 12.0, d 1.887/ml, bulk d 0.056g/ml, surface area >200m²/g, av pore diameter 64Å.** Leach the carbon for 24 hours with 1:1 HCl to remove oil contamination, then wash it repeatedly with distilled water. Dry it in air, and elute for one day each with *benzene and acetone. Again dry it in air at room temperature, then heat it in a vacuum for 24 hours at 600° to remove adsorbed gases. [Tamamushi & Tamaki *Trans Faraday Soc* **55** 1007 *1959*, DOI: 10.1039/TF9595501007.]

Carbon tetrabromide *[558-13-4]* **CBr_4, M 331.6, m 92.5°.** Reactive bromide is removed from CBr_4 by reflux ing with dilute aqueous Na_2CO_3, then steam distilling, crystallising from EtOH, and drying in the dark under vacuum. [Sharpe & Walker *J Chem Soc* 157 *1962*, DOI: 10.1039/JR9620000157.] It can be sublimed at 70° and low pressure. **It must not be dried with sodium.** [*Beilstein* **1** IV 85.]

Carbon tetrachloride *[56-23-5]* **CCl_4, M 153.8, b 76.8°/atm, d^{25} 1.5842.** For many purposes, careful fractional distillation gives adequate purification. Carbon disulfide, if present, can be removed by shaking vigorously for several hours with saturated KOH, separating, and washing with water: this treatment is repeated. The CCl_4 is shaken with concentrated H_2SO_4 until there is no further coloration, then washed with water, dried with $CaCl_2$ or $MgSO_4$ and distilled (from P_2O_5 if desired). **It must not be dried with sodium.** An initial refluxing with mercury for 2 hours removes sulfides. Other purification steps include passage of dry CCl_4 through activated alumina, and distillation from $KMnO_4$. Carbonyl containing impurities can be removed by percolation through a Celite column impregnated with 2,4-dinitrophenylhydrazine (DNPH), H_3PO_4 and water. (Prepared by dissolving 0.5g DNPH in 6ml of 85% H_3PO_4 by grinding together, then mixing with 4ml of distilled water and 10g Celite.) [Schwartz & Parks *Anal Chem* **33** 1396 *1961*, DOI: 10.1021/ac60178a036]. Photochlorination of CCl_4 has also been used: CCl_4 to which a small amount of chlorine has been added is illuminated in a glass bottle (e.g. for 24 hours with a 200W tungsten lamp near it), and, after washing out the excess chlorine with 0.02M Na_2SO_3, the CCl_4 is washed with distilled water and distilled from P_2O_5. It can be dried by passing through 4A molecular sieves and distilled. Another purification procedure is to wash CCl_4 with aqueous NaOH, then repeatedly with water and N_2 gas is bubbled through the liquid for several hours. After drying over $CaCl_2$ it is percolated through silica gel and distilled under dry N_2 before use [Klassen & Ross *J Phys Chem* **91** 3668 *1987*, DOI: 10.1021/j100297a041]. [*Beilstein* **1** IV 56.]
Rapid purification: Distil, discarding the first 10% of distillate or until the distillate is clear. The distilled CCl_4 is then stored over 5A molecular sieves.

Carbon tetrafluoride *[75-73-0]* **CF_4, M 88.0, b -15°/atm.** Purify CF_4 by repeated passage over activated charcoal at solid-CO_2 temperatures. Traces of air are removed by evacuating while alternately freezing and melting. *Alternatively*, liquefy CF_4 by cooling in liquid air and then fractionally distil it under vacuum. (The chief impurity originally present is probably CF_3Cl). Use brass equipment. It is non-flammable, but is TOXIC. [Priest *Inorg Synth* **3** 178 *1950*, Kwasnik in *Handbook of Preparative Inorganic Chemistry (Ed. Brauer)* Academic Press Vol **I** p 203 *1963*, *Beilstein* **1** H 59, **1** I 8, **1** II 11, **1** III 35, **1** IV 26.]

Carbon tetraiodide *[507-25-5]* **CI_4, M 519.6, m 168°(dec), [171°(dec)].** Sublime CI_4 *in vacuo*. It hydrolyses in hot EtOH or MeOH, and in H_2O it decomposes slowly into CHI_3 and I_2, but is soluble and stable in $CHCl_3$ and $*C_6H_6$. [McArthur & Simons *Inorg Synth* **3** 37 *1950*, *Beilstein* **1** H 74, **1** IV 98.]

Cetyl acetate (hexadecyl acetate) *[629-70-9]* **$C_{18}H_{36}O_2$, M 284.5, m 18.3°, b 158°/2mm, 204°/18mm, d_4^{20} 0.861.** Distil the ester in a vacuum twice, then recrystallise it several times from diethyl ether/MeOH. [*Beilstein* **2** H 136, **2** II 146, **2** III 265, **2** IV 171.]

Cetyl alcohol (1-hexadecanol) *[36653-82-4]* **$C_{16}H_{34}O$, M 242.5, m 49.3°.** Crystallise the alcohol from aqueous EtOH or from cyclohexane. *Alternatively*, purify it by zone refining. The purity can be checked by gas

chromatography. [*Beilstein* **1** H 429, **1** I 219, **1** II 466, **1** III 1815, **1** IV 1876.]

Cetylamide *[629-54-9]* **$C_{16}H_{34}NO$, M 255.4, m 104-104.5°, 106-107°, b 235-236°/12mm.** Crystallise the amide from thiophene-free *benzene and dry it under vacuum over P_2O_5. It is slightly soluble in EtOH, Me_2CO, $CHCl_3$ and toluene but insoluble in H_2O. [*Beilstein* **2** H 374, **2** II 341, **2** III 975, **2** IV 1182.]

Cetylamine (HDA, 1-hexadecylamine) *[143-27-1]* **$C_{16}H_{35}N$, M 241.5, m 48°, b 162-165°/5.2mm, pK^{25} 10.60.** Crystallise the base from thiophene-free *benzene and dry under vacuum over P_2O_5. Store away from CO_2 [*Beilstein* **4** IV 818.] ***Cetylammonium chloride*** *[1602-97-7]* **$C_{16}H_{35}N$. HCl, M 278.0, m 178°**, crystallises from MeOH. [*Beilstein* **4** IV 818.]

Cetyl bromide (1-bromohexadecane) *[112-82-3]* **$C_{16}H_{33}Br$, M 305.4, m 15°, 16-18°, b 144.8°/1mm, 171.5-172°/5mm, 190°/11mm, 193-196°/14mm, d^{25} 0.999, n_D^{20} 1.461.** It is prepared by boiling hexadecan-1-ol with 48% aqueous HBr and 25% H_2SO_4 for several hours, distilling and purifying by shaking the bromide with H_2SO_4, washing with H_2O, drying with K_2CO_3 and fractionally distilling it *in vacuo*. [Bezzi & Lanza *Gazzetta* **80** 180 *1950*, Vogel *J Chem Soc* **146** 636 *1943*, DOI: 10.1039/JR9430000636; Heston et al. *J Am Chem Soc* **72** 2071 *1950*, DOI: 10.1021/ja01161a054; *Beilstein* **1** H 17, **1** I 68, **1** II 138, **1** III 559, **1** IV 542.]

Cetyl ether (dihexadecyl ether) *[4113-12-6]* **$C_{32}H_{66}O$, M 466.9, m 53-56°, 54°, 55°, b 503.8°/760mm** Distil the ether in under high vacuum, then crystallise it several times from MeOH/*benzene. [Gooch *Encyclopedic Dictionary of Polymers* Springer NY, p 209 *2011*, DOI: 10.1007/978-1-4419-6247-8_3544, Online ISBN: 978-1-4419-6247-8; *Beilstein* **1** H 430, **1** II 467, **1** III 1820, **1** IV 1878.]

Cetyltrimethylammonium bromide (cetrimonium bromide, CTAB) *[57-09-0]* **$C_{19}H_{42}N$. Br, M 364.5, m 227-235°(dec).** Crystallise it from EtOH, EtOH/*benzene or from wet acetone after extracting twice with petroleum ether or dry Et_2O. Shake it with anhydrous Et_2O, filter and dissolve it in a little hot MeOH. After cooling in the refrigerator, the precipitate is filtered off at room temperature and re-dissolved in MeOH. Anhydrous Et_2O is added and, after warming to obtain a clear solution, it is cooled and the crystalline material is collected and dried *in vacuo*. Dry in a vacuum oven at 60° before use. [Dearden & Wooley *J Phys Chem* **91** 2404 *1987*, DOI: 10.1021/j100293a040; Hakemi et al. *J Am Chem Soc* **91** 120 *1987*, DOI: 10.1021/j100285a028; *Beilstein* **4** IV 819.]

Cetyltrimethylammonium chloride *[112-02-7]* **$C_{19}H_{42}N$. Cl, M 320.0.** Crystallise the chloride from acetone/ether mixture, EtOH/ether, or from MeOH. [Moss et al. *J Am Chem Soc* **109** 4363 *1987*, DOI: 10.1021/ja00248a038; *Beilstein* **4** IV 819.]

Charcoal *[7440-44-0]* **C, M 12.0, m ~3550°.** Charcoal (50g) is added to 1L of 6M HCl and boiled for 45 minutes. The supernatant is discarded, and the charcoal is boiled with two more lots of HCl, then with distilled water until the supernatant no longer gives a test for chloride ion. The charcoal (now phosphate-free) is filtered onto a sintered-glass funnel and dried in air at 120° for 24 hours. [Lippin et al. *J Am Chem Soc* **76** 2871 *1954*, DOI: 10.1021/ja01640a004.] The purification can be carried out using a Soxhlet extractor (without cartridge), allowing longer extraction times. Treatment with concentrated H_2SO_4 instead of HCl has been used to remove reducing substances.

Chimyl alcohol (1-*O*-*n*-hexadecylglycerol) *[(+) 506-03-6, 10550-58-0 (chimyl alcohol)]* **$C_{19}H_{40}O_3$, M 316.5, m 64°.** It is soluble in hexane, $CHCl_3$, Me_2CO and is crystallised from hexane and dried *in vacuo*. The natural ***S*(+)-alcohol** (from the testes of boars or bulls) crystallises from Et_2O/hexane, and has **m 64° (m 62.5-63.5°)** and $[\alpha]_D^{20}$ +3.0 (c 1.16, $CHCl_3$); $[\alpha]_D^{20}$ +2.5 ±0.5 (c 1.0, $CHCl_3$) was also reported. The ***di-phenylurethane*** crystallises from petroleum ether as colourless plates with **m 97.5-98.5°**. The ***di-p-nitrobenzoate*** has **m 52°** and $[\alpha]_D^{20}$ -29.2 (c 8.2, 1,1,2,2-tetrachloroethane). [Baer & Fischer *J Biol Chem* **140** 397 *1941*, http://www.jbc.org/content/140/2/397; Prelog et al. *Helv Chim Acta* **27** 674 *1944*, DOI: 10.1002/ hlca.19440270186; Taguchi et al. *Pteridines* **6** 45 *1995*, DOI: 10.1515/pteridines.1995.6.2.45; *Beilstein* **1** III 2322.]

Chloral (trichloroacetaldehyde) *[75-87-6, 302-17-0 (hydrate)]* **C_2HCl_3O (anhydr), $C_2H_3Cl_3O_2$ (hydrate),**

M 147.4 (anhydrous), 165.4 (hydrate), b 26°/35mm, 98°/760mm. pK^{25} 10.04. Distil chloral, then dry it by distilling through a heated column of $CaSO_4$. It readily forms a ***hydrate*** **m 57°**, an ***alcoholate*** **m 47.5°** [515-83-3] and an ***ammonia adduct*** **m 72-74°** [507-47-1]. It is a sedative and a hypnotic. [*Beilstein* **1** H 616, **1** I 328, **1** II 467, **1** III 2663, **1** IV 3142 for anhydr, **1** IV 3143 for hydrate.]

Chloralacetone chloroform (2,2,2-trichloro-1-[2,2,2-trichloro-1,1-dimethylethoxy]ethanol) *[512-47-0]* **M 324.9, m 65°.** Crystallise it from *benzene. It sublimes on careful heating and hydrolyses in cold H_2SO_4 to chloral acetone and chloroform. [*Beilstein* **1** H 622.]

Chloroacetaldehyde dimethyl acetal *[97-97-2]* **$C_4H_9ClO_2$, M 124.6, m -34.4°, b 64°/23mm, 71-72°/35mm, d $_4^{20}$ 1.0172, n $_D^{20}$ 1.4175.** Purify the acetal by fractional distillation, preferably in a vacuum. [Melhotra *J Indian Chem Soc* **36** 4405 *1959*, *Beilstein* **1** IV 3134.]

Chloroacetic acid *[79-11-8]* **$C_2H_3ClO_2$, M 94.5, m 62.8°, b 189°, pK^{25} 2.87.** Crystallise the acid from $CHCl_3$, CCl_4, *benzene or water. Dry it over P_2O_5 or concentrated H_2SO_4 in a vacuum desiccator. Further purification is by distillation from $MgSO_4$, and by fractional crystallisation from the melt. Store it under vacuum or under dry N_2. [Bernasconi et al. *J Am Chem Soc* **107** 3621 *1985*, DOI: 10.1021/ja00298a035; *Beilstein* **2** IV 474.] **α-*Chloroacetamide*** *[79-07-2]* **C_2H_4ClNO, M 93.5, m 121°, b 224-225°/743mm**, is recrystallised from acetone and dried under vacuum over P_2O_5. [*Beilstein* **2** IV 490.]

Chloroacetic anhydride *[541-88-8]* **$C_4H_4Cl_2O_3$, M 171.0, m 46°, b 122-123°/20mm, 203°/760mm, d $_4^{20}$ 1.5494.** Crystallise it from *benzene, and distil it preferably under a vacuum. [Eglinton et al. *J Chem Soc* 1860 *1954*, DOI: 10.1039/JR9540001860; *Beilstein* **2** IV 487.] **IRRITANT, keep away from eyes and skin.**

Chloroacetone *[78-95-5]* **C_3H_5ClO, M 92.5, b 61°/50mm, 119°/763mm, d $_4^{20}$ 1.15.** Dissolve it in water and shake it repeatedly with small amounts of diethyl ether which extracts, preferentially, 1,1-dichloroacetone present as an impurity. The chloroacetone is then extracted from the aqueous phase using a large volume of diethyl ether, and distil at slightly reduced pressure. It is dried with $CaCl_2$ and stored at Dry-ice temperature. *Alternatively*, it is kept over $CaSO_4$ for several hours, distilled and stored over $CaSO_4$. It is steam volatile. The ***2,4-dinitrophenylhydrazone*** forms yellow needles from EtOH with **m 120°** or **124°**. [*Beilstein* **1** IV 3215.] **LACHRYMATOR with toxic vapour.**

Chloroacetonitrile *[107-14-2]* **C_2H_2ClN, M 75.5, b 125°/atm.** Reflux it with P_2O_5 for one day, then distil it through a helices-packed column. Also purified by gas chromatography. [*Beilstein* **2** IV 492.] **LACHRYMATORY AND HIGHLY TOXIC.**

2-Chlorobutane *[78-86-4]* **C_4H_9Br, M 92.6, b 68.5°/atm, d $_4^{20}$ 0.873, n^{25} 1.3945.** Purify it in the same way as *n*-butyl chloride. [*Beilstein* **1** IV 248.]

***N*-Chlorocarbonyl isocyanate** *[27738-96-1]* **C_2ClNO_2, M 105.5, m -68°, b 63.6°/atm, d $_4^{20}$ 1.310.** Fractionally distil it at 760mm using a 40cm column. **TOXIC** *vapour, use a good fume hood*. Store it dry, its IR (film) has ν_{max} at 2260 (NCO), 1818 (CO) and 1420 (NCO sym) cm^{-1}. [Jäckh & Sundermeyer *Chem Ber* **106** 1752 *1973*, DOI: 10.1002/cber.19731060609.]

2-Chloroethanol (ethylene chlorohydrin) *[107-07-3]* **C_2H_5ClO, M 80.5, b 51.0°/31mm, 128.6°/760mm, d $_4^{20}$ 1.201, n^{15} 1.444.** Dry it with, then distil it from, $CaSO_4$ in the presence of a little Na_2CO_3 to remove traces of acid. [*Beilstein* **1** IV 1372.]

2-Chloroethyl bromide (1-bromo-2-chloroethane) *[107-04-0]* **C_2H_4BrCl, M 143.4, b 106-108°/atm, d $_4^{20}$ 1.723, n $_D^{20}$ 1.490.** Wash it with concentrated H_2SO_4, water, 10% Na_2CO_3 solution, and again with water, then dry with $CaCl_2$ and fractionally distil before use. [*Beilstein* **1** H 89, **1** I 28, **1** II 61, **1** III 179, **1** IV 155.]

2-Chloroethyl chloroformate *[627-11-2]* **$C_3H_4Cl_2O_2$, M 143.0, b 52-54°/12mm, 153°/760mm, d $_4^{18}$ 1.3760, n $_D^{20}$ 1.446.** Purify it by fractional distillation, preferably in a vacuum, and store it in a dry atmosphere. [Jones *J*

Chem Soc 2735 *1957*, DOI: 10.1039/JR9570002735; *Beilstein* **3** IV 24.]

2-Chloroethyl vinyl ether *[110-75-8]* **C_4H_7ClO, M 106.6, b 109°/760mm, d_4^{20} 1.048, n_D^{20} 1.437.** Wash the ether repeatedly with equal volumes of water made slightly alkaline with KOH, dry with sodium, and distil it under a vacuum. Stabilise it with ~0.01% of triethanolamine. [*Beilstein* **1** IV 2051.] **TOXIC**.

Chlorofluoroacetonitrile (ClFCHCN) *[± 92484-61-2 and 359-05-7]* **C_2HClFN, M 93.4, b 66°/atm, d_4^{20} 1.267, n_D^{25} 1.3627.** It is prepared from ethyl chlorofluoroacetate (see below) by conversion to the ***amide*** (0.5mol, **b 72-77°/1mm**) which is added slowly to P_2O_5 (0.25mol), and the nitrile (3.5g) is distilled off at 50-70°/atm and redistilled (30g, 66°/atm). It is slowly hydrolysed by H_2O but rapidly by aqueous alkali. [Young & Tarrant *J Am Chem Soc* **71** 2432 *1949*, DOI: 10.1021/ja01175a055; *Beilstein* **2** III 454]. Theoretical studies of the molecular dynamics of the enantiomers {(+)- [85196-70-9] and (-)- [85196-71-0]} have been made although they had not been separated [Roselli et al. *J Mol Liq* **29** 1 *1984*, DOI:10.1016/0167-7322(84)80031-8; Evans *Phys Rev* A **30** 2062 *1984*, DOI: org/10.1103/PhysRevA.30.2062; Craig & Elsum *Chem Phys* **73** 349 *1982*, DOI:10.1016/0301-0104(82)85174-4]. Samarium (II) iodide [32248-43-4] promotes the reaction of chlorofluoroacetonitrile with aldehydes to form cyanofluorohydrins in the presence of HMPA [Asano et al. *Synthesis* 1309 *2007*, DOI: 10.1055/s-2007-966006].

Chloroform *[67-66-3]* **$CHCl_3$, M 119.4, b 61.2°/atm, d^{15} 1.49845, d^{10} 1.47060, n^{15} 1.44858.** It reacts slowly with oxygen, or oxidising agents, when exposed to air and light, giving, mainly, phosgene, Cl_2 and HCl. Commercial $CHCl_3$ is usually stabilised with up to 1% of EtOH or of dimethylaminoazobenzene. Simplest purifications involve washing with water to remove the EtOH, drying with K_2CO_3 or $CaCl_2$, refluxing with P_2O_5, $CaCl_2$, $CaSO_4$ or Na_2SO_4, and distilling. **It must not be dried with sodium.** The distilled $CHCl_3$ should be stored in the dark to avoid photochemical formation of phosgene. In an alternative purification, $CHCl_3$ (500ml) was shaken (mechanically) with several small portions of 12% H_2SO_4 for 1 hour, washed thoroughly with water, saturated $NaHCO_3$, washed again with water, and dried over $CaCl_2$ or K_2CO_3 (100g) for 1 hour before filtering and distilling. After further drying for a short time over P_2O_5, the $CHCl_3$ was redistilled and stored over Drierite in the dark [Reynolds & Evans *J Am Chem Soc* **60** 2559 *1938,* DOI: 10.1021/ja01277a080]. EtOH can be removed from $CHCl_3$ by passage through a column of activated alumina, or through a column of silica gel 4-ft long by 1.75-in diameter at a flow rate of 3ml/minute. (The alumina column, which can hold about 8% of its weight of EtOH, is regenerated by air drying and then heating at 600° for 6 hours. It is pre-purified by washing with $CHCl_3$, then EtOH, leaving in concentrated H_2SO_4 for about 8 hours, washing with water until the washings are neutral, then air drying, followed by activation at 600° for 6 hours. Just before use it is reheated for 2 hour at 154°.) [McLaughlin et al. *Anal Chem* **30** 1517 *1958*, DOI: 10.1021/ac60141a021.]
Carbonyl-containing impurities can be removed from $CHCl_3$ by percolation through a Celite column impregnated with 2,4-dinitrophenylhydrazine (DNPH), phosphoric acid and water. (Prepared by dissolving 0.5g DNPH in 6ml of 85% H_3PO_4 by grinding together, then mixing with 4ml of distilled water and 10g of Celite.) [Schwartz & Parks *Anal Chem* **33** 1396 *1961*, DOI: 10.1021/ac60178a036]. Chloroform can be dried by distillation from powdered type 4A Linde molecular sieves. For use as a solvent in IR spectroscopy, chloroform is washed with water (to remove EtOH), then dried for several hours over anhydrous $CaCl_2$ and fractionally distilled. This treatment removes material absorbing near 1600 cm^{-1}. (Percolation through activated alumina increases this absorbing impurity). [Goodspeed & Millson *Chem Ind (London)* 1594 *1967*, *Beilstein* **1** IV 42.]
Rapid purification: Pass through a column of basic alumina (Grade I, 10g/ml of $CHCl_3$), and either dry by standing over 4A molecular sieves, or *alternatively*, distil from P_2O_5 (3% w/v). Store away from light (to avoid formation of phosgene which is tested by shaking with NH_3 forming solid urea) and use as soon as possible.

Chloromethyl methyl ether (MOMCl) *[107-30-2]* **C_2H_5ClO, M 80.5, b 55-57°/atm, d_4^{20} 1.060, n_D^{20} 1.396.** If suspect (check IR), shake it with saturated aqueous $CaCl_2$ solution, dry over $CaCl_2$ and fractionally distil taking the middle fraction. *Alternatively*, it can be prepared afresh. While working in a fume cupboard, a rapid stream of HCl gas ([7647-73-6] from a cylinder, or generated from concentrated H_2SO_4 on NaCl) is bubbled through a solution of MeOH (438ml, 10.9moles) and technical formalin (900ml, 252g, 8.4moles, [50-00-0]) which is cooled with running water. After 2 hours two layers are formed, but HCl flow is continued for 2 to 3 hours further until saturation. The MOMCl layer is separated, the aqueous phase is saturated with $CaCl_2$, and the additional MOMCl that is salted out is combined with the first lot, dried over $CaCl_2$, filtered and fractionally

distilled at atmospheric pressure. The fraction that distils at 55-60° is redistilled to give pure MOMCl (586-600g, 86-89%). [Marvel & Porter *Org Synth* Coll Vol **I** 377 *1941*, DOI: 10.15227/orgsyn.009.0058; *Beilstein* **1** H 580, **1** I 304, **1** II 645, **1** III 2587, **1** IV 3046.] **VERY TOXIC VAPOUR** and **CARCINOGENIC**.

1-Chloro-2-nitroethane *[625-47-8]* **$C_2H_4ClNO_2$, M 109.5, b 37-38°/20mm, 55°/60mm, 127.5°/atm, n_D^{20} 1.4224, n^{25} 1.4235.** Dissolve it in alkali, extract with ether (discard), then the aqueous phase is acidified with hydroxylamine hydrochloride, and the nitro compound is collected and fractionally distilled under reduced pressure. [Pearson & Dillon *J Am Chem Soc* **75** 2439 *1953*, DOI: 10.1021/ja01106a048; *Beilstein* **1** H 101, **1** III 202, **1** IV 173.]

Chloropicrin (trichloronitromethane) *[76-06-2]* **CCl_3NO_2, M 164.5, m -69°, b 112°/atm.** Dry it over $MgSO_4$ and fractionally distil. A ***fumigant***, soil insecticide and also used as a war gas. [Jackson *Chem Rev* **14** 251 *1934*, Wilhelm **US** pat 3106588 *1963*, *Beilstein* **1** IV 106.] **EXTREMELY NEUROTOXIC, use appropriate precautions.**

RS*-2-Chloropropionic acid** *[598-78-7]* **$C_3H_5ClO_2$, M 108.5, b 98°/3mm, d_4^{20} 1.182, n_D^{20} 1.453 pK^{25} 2.89.** Dry it over P_2O_5 and fractionally distil it under vacuum. [*Beilstein* **2** IV 745.] ***S*-(-)-*2*-Chloropropionic acid** *[29617-66-1]* **$C_3H_5ClO_2$, M 108.5, b 77°/10mm, 80.7°/10mm, 185-188°/atm, d_4^{25} 1.2485, n_D^{25} 1.436, $[\alpha]_D^{25}$ -14.6 (neat)**, is purified by fractionating twice through a 115cm Podbielniak column (calculated 50 theoretical plates at atmospheric pressure) using a take-off ratio of 1:5. The ***acid chloride is prepared by dissolving the acid in $SOCl_2$, adding a few drops of PCl_3, refluxing and then distilling through a 30cm column, **b 53°/100mm**, $[\alpha]_D^{25}$ -4.6 (neat), d_4^{25} 1.2689, n_D^{25} 1.4368. [Fu et al. *J Am Chem Soc* **76** 6054 *1954*, DOI: 10.1021/ja01652a057; *Beilstein* **2** IV 745.]

3-Chloropropionic acid *[107-94-8]* **$C_3H_5ClO_2$, M 108.5, m 41°, pK^{25} 4.08.** Crystallise the acid from petroleum ether or *benzene. [*Beilstein* **2** IV 748.] ***3-Chloropropyl bromide* (1-bromo-3-chloropropane)** *[109-70-6]* **C_3H_6BrCl, M 157.5, b 142-145°, n^{25} 1.4732**, is washed with concentrated H_2SO_4, water, 10% Na_2CO_3 solution, water again and then dried with $CaCl_2$ and fractionally distilled just before use [Akagi et al. *J Am Chem Soc* **78** 4034 *1956*, DOI: 10.1021/ja01597a046]. [*Beilstein* **1** H 109, **1** IV 212.]

2-Chloro-1,1,1-triethoxyethane *[51076-95-0]* **$C_8H_{17}ClO_3$, M 196.7, b 75-80°/5mm, 91°/25mm, 147°/atm, d_4^{25} 1.024, n_D^{20} 1.422.** Distil the chloroethane in a vacuum; but if it is discoloured or suspect, then it is better to prepare it anew. To $(EtO)_3CH$ (ethyl orthoformate see [122-51-0]) in CCl_4 add a slight excess of *N*-chlorosuccinimide and heat to 60° while exposing to a sun lamp. An exothermic reaction occurs during 30 minutes; filter off the succinimide formed, evaporate and distil the residue *in vacuo*. [McElvain & Nelson *J Am Chem Soc* **64** 1825 *1942*, DOI: 10.1021/ja01260a024; Mylari et al. *Synth Commun* **19** 2921 *1989*, DOI:10.1080/00397918908052683; Ueno et al. *J Med Chem* **34** 2468 *1991*, DOI: 10.1021/jm00112a023; *Beilstein* **2** III 442, **2** IV 482.]

2-Chlorotriethylamine hydrochloride (2-chloro-*N*,*N*-diethylethylamine hydrochloride) *[869-24-9]* **$C_6H_{14}ClN$. HCl, M 172.1, m 208-210°, pK_{Est} ~8.6 (free base).** Crystallise the salt from absolute MeOH (to remove highly coloured impurities). [*Beilstein* **4** III 240.]

Chlorotrifluoroethylene (CTFE) *[79-38-9]* **C_2F_3Cl, M 116.5, m -158°, b -26 to -24°/atm (-28.4°/atm).** Scrub it with 10% KOH solution, then 10% H_2SO_4 solution to remove inhibitors, dry and pass it through silica gel. It is stabilised with ~1% tributylamine. Use brass equipment. [*Beilstein* **1** III 646.] **TOXIC GAS.**

Chlorotrifluoromethane *[75-72-9]* **CF_3Cl, M 104.5, m -180°, b -81.5°/atm.** Main impurities are CO_2, O_2, and N_2. The CO_2 is removed by passage through saturated aqueous KOH, followed by concentrated H_2SO_4. The O_2 is removed using a tower packed with activated copper on Kieselguhr at 200°, and the gas is dried over P_2O_5. [Miller & Smyth *J Am Chem Soc* **79** 20 *1957*, DOI: 10.1021/ja01558a004; *Beilstein* **1** III 42, **1** IV 34.] **VERY TOXIC GAS.**

Citraconic acid (methylmaleic acid) *[498-23-7]* **$C_5H_6O_4$, M 130.1, m 91°, pK_1^{25} 2.2, pK_2^{25} 5.60 (cis).** Steam

distil, and recrystallise it from EtOH/ligroin. [*Beilstein* **2** H 768, **2** I 309, **2** II 652, **2** III 1938, **2** IV 2230.] ***Citraconic anhydride*** **(methylmaleic anhydride)** *[616-02-4]* **$C_5H_4O_3$, M 112.1, m 8-9°, b 109°/30mm, 132°/74mm, 213°/760mm, d_4^{20} 1.245, n_D^{20} 1.472**, is possibly contaminated with the acid formed by hydrolysis. If the IR has OH bands, then reflux it with Ac_2O for 30 minutes, evaporate, and distil the residue in a vacuum; otherwise distil in a vacuum. Store it in a dry atmosphere. [Vaughan & Andersen *J Am Chem Soc* **77** 6702 *1955*, DOI: 10.1021/ja01629a122; Vaughan & Andersen *J Org Chem* **21** 673 *1956*, DOI: 10.1021/jo01112a023; *Beilstein* **17** H 440, **17** I 234, **17** II 448, **17** III/IV 5912, **17/11** V 65.]

Citric acid (H_2O) *[5949-29-1 (monohydrate); 77-92-9 (anhydrous)]* **$C_6H_8O_7$. H_2O, $C_6H_8O_7$, M 210.1 (hydrate), 292.1 (anhydrous), m 156-157°, 153° (anhyd), pK_1^{25} 2.96, pK_2^{25} 4.38, pK_3^{25} 5.68.** Crystallise it from hot H_2O solution (w/w solubility is 54% at 10°, 71% at 50° and 84% at 100°). The ***monohydrate*** (softens at ~75° and melts at ~100°) dehydrates in air or when heated gently above 40°. The ***triethylester*** (*[77-93-0]* **$C_{12}H_{20}O_7$, M 276.3, b 127°/1mm, 294°/atm, d_4^{20} 1.137, n_D^{20} 1.4420**) is a bitter tasting oil. [*Beilstein* **3** H 556 and 568, **3** IV 1272.]

Crotonaldehyde (2-butenal) *[123-73-9, trans]* **C_4H_6O, M 70.1, b 104-105°/atm, d_4^{20} 0.851, n_D^{20} 1.437.** Fractionally distil it under N_2, through a short Vigreux column. Stabilise it with 0.01% of 2,6-di-tert-butyl-*p*-cresol and store it in sealed ampoules. [*Beilstein* **1** IV 3447.]

***trans*-Crotonic acid (*trans*-2-butenoic acid)** *[107-93-7]* **$C_4H_6O_2$, M 86.1, m 72-72.5°, pK_1^{25} -6.17 (aqueous H_2SO_4), pK_2^{18} 4.71.** Distil the acid under reduced pressure and/or recrystallise it from petroleum ether (b 60-80°) or water, or by partial freezing of the melt. [*Beilstein* **2** IV 1498.]

***E*- and *Z*-Crotonitrile (mixture)** *[4786-20-3]* **C_4H_5N, M 67.1, b 120-121°/atm, d_4^{20} 1.091, n_D^{20} 1.4595.** Separate the mixture by preparative GLC on a column using 5% FFAP on Chromosorb G. [Lewis et al. *J Am Chem Soc* **108** 2818 *1986*, DOI: 10.1021/ja00271a006; *Beilstein* **2** IV 1507.]

***trans*-Crotonoyl chloride** *[625-35-4]* **C_4H_5ClO, M 104.5, b 42-45°/20mm, 124-125°/760mm, d_4^{20} 1.080, n_D^{20} 1.4570.** If the IR of a film has no OH bands, then fractionally distil it, taking the middle fraction and redistilling it. If OH bands are present then add excess of oxalyl chloride, reflux for 3 hours, then distil off the reagent and fractionally distil the crotonoyl chloride as before. Stabilise the distillate with 160ppm of hydroquinone. The

amide forms needles **m 158°** from aqueous ammonia, and the ***anilide*** also forms needles from H_2O, but with **m 115-118°**. [*Beilstein* **2** H 411, **2** I 188, **2** II 392, **2** III 1265, **2** IV 1506.]

Crotyl bromide *[29576-14-5 trans, 591-97-9 cis/trans]* **C_4H_7Br, M 135.0, b 103-105°/740mm, n^{25} 1.4792.** Dry the bromide with $MgSO_4/CaCO_3$ mixture and fractionally distil it through an all-glass Todd column. [*Beilstein* **1** IV 789.]

Cyanoacetic acid *[372-09-8]* **$C_3H_3NO_2$, M 85.1, m 70.9-71.1°, pK^{25} 2.47.** Recrystallise the acid to constant melting point from *benzene/acetone (2:3), and dry it over silica gel. [*Beilstein* **2** H 583, **2** I 253, **2** II 530, **2** III 1626, **2** IV 1888.] ***Cyanoacetamide*** *[107-91-5]* **$C_3H_4N_2O$, M 84.1, m 119.4°**, is crystallised from MeOH/dioxane (6:4), then water and dried over P_2O_5 under vacuum. [*Beilstein* **2** IV 1891.] ***Cyanoacetic acid hydrazide*** *[140-87-4]* **$C_3H_5N_3O$, M 99.1, m 114.5-115°**, crystallises from EtOH. The ***hydrochloride*** has **m 178-180°** and the ***benzylidene derivative*** has **m 178°**. It is converted to *3-oxo-5-iminopyrazolidine* in hot 40% aqueous NaOH. [*Beilstein* **2** H 591, **2** I 256, **2** III 1636.] **IRRITANT.**

Cyanoguanidine (dicyandiamide) *[461-58-5]* **$C_2H_4N_4$, M 84.1, m 209.5°, pK^{25} -0.4.** Recrystallise cyanoguanidine from water or EtOH. [*Beilstein* **3** IV 160.]

***n*-Decane** *[124-18-5]* **$C_{10}H_{22}$, M 142.3, m –29.7°, b 57.6°/10mm, 174.1°, d_4^{20} 0.7300, n_D^{20} 1.4102, n^{25} 1.40967.** It can be purified by shaking with concentrated H_2SO_4, washing with water, aqueous $NaHCO_3$, and more water, then drying with $MgSO_4$, refluxing with Na and distilling. Also purify through a column of silica gel or alumina. It has been purified by azeotropic distillation with 2-butoxyethanol, the alcohol being washed out of the distillate using water, the decane is next dried and redistilled. It can be stored with NaH. Further purification can be achieved by preparative gas chromatography on a column packed with 30% SE-30 (General Electric methyl-silicone rubber) on 42/60 Chromosorb P at 150° and 40psig, using helium carrier gas [Chu *J Chem Phys* **41** 226 *1964*, DOI: org.virtual.anu.edu.au/10.1063/1.1725626]. It is soluble in EtOH and Et_2O. [*Beilstein* **1** IV 484.]

Decan-1,10-diol *[112-47-0]* **$C_{10}H_{22}O$, M 174.3, m 72.5-74°.** Crystallise the diol from dry ethylene dichloride. [*Beilstein* **1** IV 2613.]

***n*-Decanol (*n*-decyl alcohol)** *[112-30-1]* **$C_{10}H_{22}O_2$, M 158.3, f 6.0°, b 109°/8mm, 231°/atm, d_4^{20} 0.823, n_D^{20} 1.434.** Fractionally distil *n*-decanol in an all-glass unit at 10mm pressure (**b 110°**), then crystallise by partial freezing. Also purify by preparative GLC, and passage through alumina before use. [*Beilstein* **1** IV 1815.]

***n*-Decyl bromide (1-bromodecane)** *[112-29-8]* **$C_{10}H_{21}Br$, M 221.2, b 117-118°/15.5mm, d_4^{20} 1.066.** Shake the it with H_2SO_4, wash with H_2O, dry with K_2CO_3, and fractionally distil it. [*Beilstein* **1** IV 470.]

Decyltrimethylammonium bromide *[2082-84-0]* **$C_{13}H_{30}BrN$, M 280.3, m 239-242°.** Crystallise the salt from 50% (v/v) EtOH/Et_2O, or from acetone and wash with ether. Dry it under vacuum at 60°. Also recrystallise it from EtOH and dry it over silica gel. [McDowwell & Kraus *J Am Chem Soc* **73** 2170 *1952*, DOI: 10.1021/ja01149a074; Dearden & Wooley *J Phys Chem* **91** 2404 *1987*, DOI: 10.1021/j100293a040; *Beilstein* **4** IV 784.]

Diacetamide *[625-77-4]* **$C_4H_7NO_2$, M 101.1, m 75.5-76.5°, b 222-223°/atm.** Purify the amide by recrystallisation from MeOH [Arnett & Harrelson *J Am Chem Soc* **109** 809 *1987*, DOI: 10.1021/ja00237a028]. It forms complexes with Mn^{2+}, Fe^{2+}, Co^{2+}, Ni^{2+}, Cu^{2+}, and Zn^{2+} perchlorates. [*Beilstein* **2** H 181.]

(+)-Di-*O*-acetyl-L-tartaric anhydride [(*R,R*)-2,3-diacetoxysuccinic anhydride] *[6283-74-5]* **$C_8H_8O_7$, M 216.2, m 129-132°, 133-134°, 135°, 137.5°, $[\alpha]_D^{20}$ +97.2 (c 0.5, dry $CHCl_3$), $[\alpha]_D^{20}$ +60 (c 6, Me_2CO).** If the IR is good, i.e. no OH bands, then keep it in a vacuum desiccator overnight (over P_2O_5/paraffin) before use. If OH bands are present then reflux 4g in Ac_2O (12.6ml) containing a few drops of concentrated H_2SO_4 for 10 minutes (use a relatively large flask), pour onto ice, collect the crystals, wash with dry *C_6H_6 (2 x 2ml), stir with 17ml of

cold Et_2O, filter and dry in it a vacuum desiccator as above, or store it in dark evacuated ampoules under N_2 in small aliquots. It is not very stable in air, the melting point of the crystals drop one degree in the first four days then remains constant (132-134°). If placed in a stoppered bottle, it becomes gummy and the **m** falls 100° in three days. Recrystallisation leads to decomposition. If good quality anhydride is required it, should be prepared freshly from tartaric acid. It sublimes in a CO_2 atmosphere. [Shriner & Furrow *Org Synth* Coll Vol **4** 242 *1963*, DOI: 10.15227/orgsyn.035.0049; Bell *Aust J Chem* **34** 671 *1981*, DOI:10.1071/CH9810671; *Beilstein* **18** III/IV 2296.]

Diallyl amine (*N*-2-propenyl-2-propen-1-amine) *[124-02-7]* **$C_6H_{11}N$, M 97.2, b 107-111°/760mm, 112°/760mm, d_4^{20} 0.789, n_D^{20} 1.440, pK^{20} 9.42.** Keep the amine over KOH pellets overnight, decant and distil it from a few pellets of KOH at atmospheric pressure (**b** 108-111°), then fractionate through a Vigreux column. [Vliet *J Am Chem Soc* **46** 1307 *1924*, DOI: 10.1021/ja01670a026; Vliet *Org Synth* Coll Vol **1** 201 *1941*, DOI: 10.15227/orgsyn.005.0043]. It is a strong base, store under N_2 away from CO_2. The ***hydrochloride*** has **m 164-165°** (from Me_2CO/EtOH). [Butler & Angelo *J Am Chem Soc* **79** 3128 *1957*, DOI: 10.1021/ja01569a037.]

The ***dihydrochloride*** has **m 273-274°**. [Naegeli & Lendorff *Helv Chim Acta* **15** 55 *1932*, DOI: 10.1002/hlca.19320150109; *Beilstein* **4** III 612.]

1,5-Diaminopentane (Cadaverine) *[462-94-2]* **$C_5H_{14}N_2$, M 102.2, m 14-16°, b 78-80°/12mm, 101-103°/35mm, 178-180°/750mm, d_4^{20} 0.869, n_D^{20} 1.458, pK $_1^{20}$ 10.02, pK $_2^{20}$ 10.96.** Purify the base by distillation, after standing over KOH pellets (at room temperature, i.e. liquid form). It is a strong base, store under N_2 away from CO_2. Its ***dihydrochloride*** has **m 275°** (sublimes in a vacuum), and its ***tetraphenyl boronate*** has **m 164°**. [Schwarzenbach et al. *Helv Chim Acta* **35** 2333 *1952*, DOI: 10.1002/hlca.19520350719; *Beilstein* **4** IV 1310.]

1,3-Diaminopropane dihydrochloride *[10517-44-9]* **$C_3H_{10}N_2$, 2HCl, M 147.1, m 243°, pK $_1^{25}$ 8.29, pK $_2^{25}$ 10.30.** Crystallise the salt from EtOH/H_2O. [*Beilstein* **4** IV 1258 free base.]

1,3-Diaminopropan-2-ol *[616-29-5]* **$C_3H_{10}N_2O$, M 90.1, m 38-40°, pK $_1^{25}$ 7.94, pK $_2^{25}$ 9.57.** Dissolve it in an equal amount of water, shake it with charcoal and distil it at **68°/0.1mm**. The distillate solidifies. It is too viscous to be distilled through a packed column. [*Beilstein* **4** IV 1694.]

1,11-Diamino-3,6,9-trioxaundecane [2,2'-oxybis(ethylenoxy)bisethylamine] *[929-75-9]* **$C_8H_{20}N_2O_3$, M 192.3, b 115°/0-2mm, 138-153°/1mm, 145-150°/2mm, 135°/3mm, n_D^{20} 1.440.** Distil the diamine *in vacuo*, but if it is suspect then dissolve it in EtOH add 6N HCl boil for 1 hour, evaporate to dryness, and dry the residue in a vacuum. The solid di-hydrochloride residue is treated with 4N NaOH to release the free base which is extra-

cted into CH_2Cl_2, the extract is dried over K_2CO_3, filtered, evaporated and then distilled in a vacuum. It is a hydrophilic linker in dendrimer formation or biotinylation. It shoule be a strong base, store under N_2 away from CO_2. [Zhang et al. *J Am Chem Soc* **123** 8914 *2001*, DOI: 10.1021/ja0041369; Yinglin et al. *Synth Commun* **21** 79 *1991*, DOI:10.1080/ 00397919108020793; Bogatiskii et al. *J Org Chem USSR* (English Transl) **16** 1124 *1980*, McReynolds et al. *Bioorg Med Chem* **10** 625 *2002*, DOI:10.1016/S0968-0896(01)00325-X.]

Diazomethane [H_2CN_2] *[334-88-3]* **$C_2H_2N_2$, M 42.0, m –145°, b –23°/atm.** Diazomethane is produced when *N*-methyl-*N*-nitroso-amides, e.g. *N*-methyl-*N*-nitrosourea, *N,N'*-dimethyl-*N,N'*-dinitrosooxamide, *bis*-(*N*-methyl-*N*-nitroso)terephthalamide or *p*-toluenesulfonyl-*N*-methyl-*N*-nitrosoamide (Diazald), are treated with strong solutions of NaOH or KOH. [Fieser **1** 191, **2** 102.] It has been commonly prepared from Diazald as it is commercially available, although *N*-methyl-*N*-nitrosourea, which is readily prepared and stored below 5° [Arndt *Org Synth* Coll Vol **2** 461 *1943*, DOI: 10.15227/orgsyn.015.0048] is also frequently used. *Diazomethane is a sweet smelling, highly irritating yellow gas which is TOXIC when inhaled, causing severe irritation, pulmonary oedema, asthma, chest pains, headaches, weakness as well as producing hypersensitivity reactions and skin irritation. It is a carcinogen. Diazomethane and its precursors should be handled in an efficient fume cupboard; and because of its potentially explosive nature experiments should be carried out behind a safety screen with face and eye protection.*
Preparation: A distilling flask (100ml) containing KOH (5g) in H_2O (8ml) and diluted with 95% EtOH (25ml) is heated to ~65° using a water bath, and a solution of Diazald (21.4g, see [80-11-5]) in Et_2O (130ml) is added through a dropping funnel in ~25 minutes while the ether which is yellow in colour due to the diazomethane distils off, and the distillate is collected in a receivers immersed in ice. When addition of Diazald is complete, a further volume of Et_2O (20ml) is added dropwise and distillation is continued until the Et_2O distillate is colourless. The yield of diazomethane in the distillate is ~3g. [*Note* that if 95% EtOH is not added to the KOH solution no diazomethane is formed since the base does not dissolve into the Et_2O.] Do **NOT** redistil this ethereal solution as an explosion may result, particularly from the smaller volume left in the flask. [For alcohol-free diazomethane distillate, the distilling flask should contain diethyleneglycol monomethyl ether (35ml), Et_2O (10ml) and KOH (6g) in H_2O (10ml) to which is added the ethereal Diazald as before]. [deBoer & Backer *Org Synth* Coll Vol **6** 943 *1963*, DOI: 10.15227/orgsyn.034.0096; *Recl Trav Chim Pays-Bas* **73** 229 *1954*, DOI: 10.1002/recl.19540730308.] By using ^{13}C, ^{14}C and/or ^{2}H or ^{3}H methyl labeled Diazald (some of these are also commercially available) appropriately labeled diazomethane can be prepared. The amount of diazomethane is determined by adding a measured volume of 0.2N pure benzoic acid in ether to an aliquot of the ethereal diazomethane solution which will discharge the yellow colour, meaning that all the diazomethane has been consumed. Water is added to this mixture and the excess of benzoic acid is then titrated with 0.1N aqueous NaOH. (See the safer Me_3SiCHN_2 [18107-18-1] in 'Miscellaneous As, B, P…' section in this chapter.)
For most purposes it is not necessary to distil the diazomethane in ether. In such cases it is better to use *N*-methyl-*N*-nitrosourea because the unwanted products of the reaction are soluble in water. To a mixture of 50% aqueous KOH (60ml) and pure Et_2O (200ml) at 0° to 5° is added solid nitrosomethylurea (20g) with shaking or stirring. The ethereal layer becomes deep yellow and is decanted or siphoned off; or separated if in a separating funnel. The aqueous layer can be extracted with Et_2O to get a further amount of diazomethane. The ethereal solutions can be dried over KOH pellets and can be used directly or kept at ~0° for 2-3 days. [Arndt *Org Synth* Coll Vol **2** 165 *1943*, DOI: 10.15227/orgsyn.015.003] Diazomethane is a very powerful methylating agent and, in so doing the yellow colour disappears and N_2 bubbles off. It is a versatile reagent in organic synthesis [Black *Aldrichim Acta* **16** 2 *1983*.]

Di-*O*-benzoyl-(*R* and *S*)-tartaric acid (H_2O) *[R-(+) 17026-42-5, S-(–) 2743-38-6 (anhydrous), 62708-56-9 (hydrate)]* **$C_{18}H_{14}O_8$. Dry it in a vacuum desiccator over KOH/H_2SO_4 (yield 16.4g) as ***monohydrate***, **m 88-89°**. It crystallises from xylene as the ***anhydrous acid***, **m 173° (150-153°)**. It ***does not*** crystallise from $*C_6H_6$, toluene, $*C_6H_6$/petroleum ether (forms oil), or $CHCl_3$/petroleum ether. [Acs et al. *Tetrahedron* **41** 2465 *1985*, DOI: 10.1016/S0040-4020(01)96641-4; *R*(+) *Beilstein* **9** IV 557, *S*(-) *Beilstein* **9** III 870.] Zetzsche & Hubacher [*Helv Chim Acta* **9** 291 *1926*; DOI: 10.1002/hlca.19260090134] obtained the 2*R*,3*R*(+)-tartaric (L) acid by hydrolysis of the anhydride with dilute NH_3 followed by acidification with HCl.

***trans*-1,4-Dibromobut-2-ene** *[821-06-7]* **$C_4H_6Br_2$, M 213.9, m 54°, b 85°/10mm, 205°/atm,.** Crystallise the dibromide from ligroin and/or distil it in a vacuum. [*Beilstein* **1** IV 79.]

Dibromodichloromethane *[594-18-3]* **CBr_2Cl_2, M 242.7, m 21.8°, b 66°/81mm, d_4^{20} 2.433, n_D^{25} 1.5499.** Crystallise CBr_2Cl_2, repeatedly from its melt, after washing with aqueous $Na_2S_2O_3$ and drying with BaO. *Alternatively*, distil it in a vacuum. Store away from light. [*Beilstein* **1** H 68, **1** III 88, **1** IV 82.]

1,2-Dibromoethane (ethylene dibromide, EDB) *[106-93-4]* **$C_2H_4Br_2$, M 187.9, f 10.0°, b 29.1°/10mm, 131.7°/760mm, d 2.179, n^{15} 1.54160.** Wash the dibromide with concentrated HCl or H_2SO_4, then water, aqueous $NaHCO_3$ or Na_2CO_3, more water, and dry it with $CaCl_2$. Fractionally distil it. *Alternatively*, keep in daylight with excess bromine for 2 hours, then extract with aqueous Na_2SO_3, wash with water, dry with $CaCl_2$, filter and distil. It can also be purified by fractional crystallisation by partial freezing. Store it in the dark. [*Beilstein* **1** H 90, **1** I 28, **1** II 61, **1** III 182, **1** IV 158.]

Dibromomaleic acid *[608-37-7]* **$C_4H_2Br_2O_4$, M 273.9, m 123.5°, 125°(dec), pK_1^{25} 1.45, pK_2^{25} 4.62.** It has been recrystallised from Et_2O or $Et_2O/CHCl_3$. It is soluble in AcOH, also slightly soluble in water, but insoluble in $*C_6H_6$ and $CHCl_3$. [Salmony & Simonis *Chem Ber* **38** 2583 *1905*, DOI: 10.1002/cber.19050380329; Ruggli *Helv Chim Acta* **3** 559 *1920*, DOI: 10.1002/hlca.19200030152; *Beilstein* **3** IV 2224.]

1,3-Dibromopropane *[109-64-8]* **$C_3H_6Br_2$, M 201.9, f -34.4°, b 63-63.5°/26mm, 76-77°/40mm, 90°/80mm, 165°/atm, d_4^{20} 1.977, n_D^{20} 1.522.** Wash the dibromide with dilute aqueous Na_2CO_3, then water. Dry and fractionally distil it under reduced pressure. [*Beilstein* **1** IV 216.]

***meso*-2,3-Dibromosuccinic acid** *[608-36-6]* **$C_4H_4Br_2O_4$, M 275.9, m 288-290°(sealed tube, dec), pK_1^{20} 1.56, pK_2^{20} 2.71.** Crystallise the acid from distilled water, keeping the temperature below 70°. [*Beilstein* **2** IV 1930.]

1,2-Dibromotetrafluoroethane *[124-73-2]* **$C_2Br_2F_4$, M 259.8, b 47.3°/760mm.** Wash it with water, then with weak alkali. Dry with $CaCl_2$ or H_2SO_4 and distil it. [Locke et al. *J Am Chem Soc* **56** 1726 *1934*, DOI: 10.1021/ja01323a023.] Also purify it by gas chromatography on a silicone DC-200 column. [Hazeldine *J Chem Soc* 4259 *1952*, DOI: 10.1039/JR9520004259; *Beilstein* **1** III 189.]

Di-*n*-butylamine *[111-92-2]* **$C_8H_{19}N$, M 129.3, m -62°, b 159°, d_4^{20} 0.761, n_D^{20} 1.41766, pK^{25} 11.25.** Dry this strong base with $LiAlH_4$, CaH_2 or KOH pellets, filter and distil it from BaO or CaH_2. [*Beilstein* **4** IV 550.]

Di-*tert*-butylazodicarboxylate *[870-50-8]* **$C_{10}H_{18}N_2O_4$, M 230.3, m 89-92°, 90-92°.** The *tert*-butyl ester has the advantage over the ethyl ester (below) in being a solid and more acid labile. It crystallises from ligroin and is best purified by covering the dry solid (22g) with petroleum ether (b 30-60°, 35-40 ml) heating to boiling and adding ligroin (b 60-90°) until the solid dissolves. On cooling, large lemon yellow crystals of the ester separate (~ 20g), **m 90.7-92°**. Evaporation of the filtrate gives a further crop of crystals [Carpino & Crowley *Org Synth* **44** 18 *1964*]. This reagent is useful in the Mitsunobu reaction [Mitsunobu *Synthesis* 1 *1981*, DOI: 10.1055/s-1981-29317; Gennari et al. *J Am Chem Soc* **108** 6394 *1986*, DOI: 10.1021/ja00280a049; Hughes *Org React* **42** 335 *1992*, Dodge et al. *Org Synth* **73** 110 *1996*, DOI: 10.15227/orgsyn.073.0110; Hughes *Org Prep Proc Int* **28** 127 *1996*, DOI:10.1080/00304949609356516; Ferguson et al. *J Am Chem Soc* **128** 4576 *2006*, DOI: 10.1021/ja058746q; see also **DEAD** and **DIAD** below].

Dibutylcarbitol (di[ethyleneglycol]-dibutyl ether, bis[2-butoxethyl]-ether *[112-73-2]* **$C_{12}H_{26}O_2$, M 218.3, b 125-130°/0.1mm, 256°/atm, d_4^{20} 0.883, n_D^{20} 1.424.** Dibutylcarbitol is freed from peroxides by slow passage through a column of activated alumina. The eluate is then shaken with Na_2CO_3 (to remove any remaining acidic impurities), washed with water, and stored with $CaCl_2$ in a dark bottle [Tuck *J Chem Soc* 3202 *1957*, DOI: 10.1039/JR9570003202]. [*Beilstein* **1** IV 2395.]

Di-*tert*-butyl dicarbonate (di-*tert*-butyl pyrocarbonate, Boc anhydride) *[24424-99-5]* **$C_{10}H_{18}O_5$, M 218.3, m 23° (21-22°), b 55-56°/0.15mm, 62-65°/0.4mm, d_4^{20} 0.950, n_D^{20} 1.409.** Melt the ester by heating at ~35°, and distil it in a vacuum. If the IR and NMR (ν_{max} 1810m and 1765 cm^{-1}, δ in CCl_4 1.50 singlet) suggest that it

is very impure, then wash it with an equal volume of H_2O containing citric acid to make the aqueous layer slightly acidic, collect the organic layer, dry it over anhydrous $MgSO_4$ and distil it in a vacuum. Store it away from moisture at ~ 4°. If some moisture enters the container pressure may develop since it hydrolyses to *tert*-BuOH and CO_2. It is also available commercially as a 1.0 M solution in THF. It is **FLAMMABLE.** [Pope et al. *Org Synth* **57** 45 *1977*, DOI: 10.15227/orgsyn.057.0045; Keller et al. *Org Synth* **63** 160 *1985*, DOI: 10.15227/orgsyn.063.0160.] It is a useful reagent for easy introduction of the *N*-Boc protecting group in amines [Iwanowicz et al. *Synth Commun* **23** 1443 *1993*, DOI:10.1080/00397919308011234], amino acids, peptides and proteins [Keller et al. *Org Synth* **63** 160 *1985*, DOI: 10.15227/orgsyn.063.0160], amides [Flynn et al. *J Org Chem* **48** 2424 *1983*, DOI: 10.1021/jo00162a028; Grehn et al. *Angew Chem Int Ed* **24** 510 *1985*, DOI: 10.1002/anie.198505101], and *N*-Boc-ylation of sensitive compounds in non-aqueous media [Kemp & Carey *J Org Chem* **54** 3640 *1989*, DOI: 10.1021/jo00276a026]. Boc protection of alcohols has been achieved *via* Lewis acid catalysis [Bartoli et al. *Synlett* 2104 *2006*, DOI: 10.1055/s-2006-949609], and Boc reacted with 4-carboxyphenylhydrazine to form the *N,N,N'*-tris-Boc protected acid which was converted to 4-Fmoc(9-fluorenylmethoxycarbonyl ester)phenyl-hydrazine which is used as a chromophoric reagent to quantify aldehydes attached to a solid-phase since the hydrazine NH_2 group forms a coloured Schiff's base with the aldehyde [Shannon & Barany *J Org Chem* **69** 4586 *2004*, DOI: 10.1021/jo049830b]. [See the many volumes of Fieser *Reagents for Organic Synthesis*, J Wiley & Sons, for more applications.]

1,2-Dichloro-1,2-difluoroethane *[431-06-1]* **$C_2H_2Cl_2F_2$, M 134.9, b 59°/atm, n_D^{20} 1.376.** Purify it by fractional distillation [Hazeldine *J Chem Soc* 4259 *1952*, DOI: 10.1039/JR9520004259]. For purification of a diastereoisomeric mixture, with resolution into *meso* and *rac* forms, see Machulla and Stoecklin [*J Phys Chem* **78** 658 *1974*, DOI: 10.1021/j100600a002].

Dichlorodifluoromethane (Freon 12) *[75-71-8]* **CCl_2F_2, M 120.9, m -158°, b -29.8°/atm, 42.5°/10atm.** Pass the gas through saturated aqueous KOH then concentrated H_2SO_4, and a tower packed with activated copper on Kielselguhr at 200° to remove CO_2 and O_2. A trap cooled to -29° removes a trace of high boiling material. It is a non-flammable propellant and refrigerant.

1,1-Dichloroethane (ethylidene dichloride) *[75-34-3]* **$C_2H_4Cl_2$, M 99.0, b 57.3°/atm, d^{15} 1.18350, d_4^{20} 1.177, n^{15} 1.41975.** Shake it with concentrated H_2SO_4 or aqueous $KMnO_4$, then wash it with water, saturated aqueous $NaHCO_3$, again with water, dry with K_2CO_3 and distil it from CaH_2 or $CaSO_4$. Store it over silica gel. [*Beilstein* **1** IV 130.]

1,2-Dichloroethane *[107-06-2]* **$C_2H_4Cl_2$, M 99.0, m -35°, b 83.4°/atm, d_4^{20} 1.256, n^{15} 1.44759.** It is usually prepared by chlorinating ethylene, so that likely impurities include higher chloro derivatives and other chloro compounds depending on the impurities originally present in the ethylene. It forms azeotropes with water, MeOH, EtOH, trichloroethylene, CCl_4 and isopropanol. Its azeotrope with water (containing 8.9% water, has **b** 77°) can be used to remove gross amounts of water prior to final drying. As a preliminary purification step, it can be steam distilled, and the lower layer is treated as below.
Shake it with concentrated H_2SO_4 (to remove alcohol added as an oxidation inhibitor), wash with water, then dilute KOH or aqueous Na_2CO_3 and again with water. After an initial drying with $CaCl_2$, $MgSO_4$ or by distillation, it is refluxed with P_2O_5, $CaSO_4$ or CaH_2 and fractionally redistilled. Carbonyl-containing impurities can be removed as described for chloroform. [*Beilstein* **1** IV 131.]

1,2-Dichloroethylene *[cis + trans 540-59-0]* **$C_2H_2Cl_2$, M 96.9, b 60° (*cis*), d_4^{20} 1.284, b 48°/atm (*trans*), d_4^{20} 1.257.** Shake it successively with concentrated H_2SO_4, water, aqueous $NaHCO_3$ and water. Dry it with $MgSO_4$ and fractionally distil it through an efficient column to separate the *cis*- and *trans*-isomers. [*Beilstein* **1** IV 707-709.] ***cis*-1,2-Dichloroethylene (*cis*-acetylene dichloride)** *[156-59-2]* **$C_2H_2Cl_2$, M 96.9, m -80°, b 60.4°/atm, d_4^{20} 1.2830, n^{15} 1.44903, n_D^{20} 1.4495**, is purified by careful fractional distillation, followed by passage through neutral activated alumina. Also by shaking with mercury, drying with K_2CO_3 and distilling from $CaSO_4$. Stabilise with 0.02% of 2,6-di-*tert*-butyl-*p*-cresol. [*Beilstein* **1** IV 707.] ***trans*-1,2-Dichloroethylene (*trans*-acetylene dichloride)** *[156-60-5]* **$C_2H_2Cl_2$, M 96.9, m -50°, b 47.7°, n^{15} 1.45189, d_4^{20} 1.2551, n_D^{20} 1.4462**, is dried with $MgSO_4$, and fractionally distilled under CO_2. Fractional crystallisation at low temperatures has also been used. [*Beilstein* **1** IV 709.]

2,3-Dichloromaleic anhydride *[1122-17-4]* **$C_4Cl_2O_3$, M 167.0, m 105-115°, 120°, 121-121.5°.** Purify the anhydride by sublimation *in vacuo* [Katakis et al. *JCS Dalton Trans* 1491 *1986*, DOI: 10.1039/DT9860001491]. It has also been purified by Soxhlet extraction with hexane, recrystallisation from $CHCl_3$ and by sublimation. [MS, Relles *J Org Chem* **37** 3630 *1972*, DOI: 10.1021/jo00796a015]. [*Beilstein* **17/11** V 63.]

Dichloromethane (methylene dichloride) *[75-09-2]* **CH_2Cl_2, M 84.9, m -97°, b 40.0°/atm, d_4^{20} 1.325, n_D^{20} 1.42456, n^{25} 1.4201.** Shake it with portions of concentrated H_2SO_4 until the acid layer is colourless, then wash with water, aqueous 5% Na_2CO_3, $NaHCO_3$ or NaOH, then water again. Pre-dry it with $CaCl_2$, and distil it from

$CaSO_4$, CaH_2 or P_2O_5. Store it away from bright light in a brown bottle with Linde type 4A molecular sieves, in an atmosphere of dry N_2. Other purification steps include washing with aqueous $Na_2S_2O_3$, passage through a column of silica gel, and removal of carbonyl-containing impurities as described under **Chloroform**. It has also been purified by treatment with basic alumina, distillation, and is stored over molecular sieves under nitrogen [Puchot et al. *J Am Chem Soc* **108** 2353 *1986*, DOI: 10.1021/ja00269a036]. Dichloromethane from Japanese sources contained MeOH as stabiliser which is not removed by distillation. It can, however, be removed by standing over activated 3A Molecular Sieves (note that 4A Sieves cause the development of pressure in bottles), passed through activated Al_2O_3 and distilled [Gao et al. *J Am Chem Soc* **109** 5765 *1987*, DOI: 10.1021/ja00253a032]. It has been fractionated through a platinum spinning band column, degassed, and distilled onto degassed molecular sieves Linde 4A (heated under high vacuum at over 450° until the pressure readings reached the low values of 10^{-6} mm, ~1-2 hours). Stabilise it with 0.02% of 2,6-di-*tert*-butyl-*p*-cresol [Kosower & Mohammad *J Am Chem Soc* **93** 2713 *1971*, DOI: 10.1021/ja00740a022]. [*Beilstein* **1** IV 35.] **Rapid purification:** Reflux over CaH_2 (5% w/v) and distil it. Store it over 3A molecular sieves.

1,2-Dichloropropane (propylene dichloride) *[78-87-5]* **$C_3H_6Cl_2$, M 113°, m -110°, b 95.9-96.2°/atm, d_4^{20} 1.158, n_D^{20} 1.439.** Distil the propane from CaH_2. It has a limited shelf life. [*Beilstein* **1** IV 195.]

2,2-Dichloropropane (isopropylidene dichloride) *[594-20-7]* **$C_3H_6Cl_2$, M 113.0, m -35°, b 69.3°/atm, d_4^{20} 1.090, n_D^{20} 1.415.** Wash it with aqueous Na_2CO_3 solution, then distilled water, dry it over $CaCl_2$ and fractionally distil it. [*Beilstein* **1** IV 196.]

Di-*n*-decylamine *[1120-49-6]* **$C_{20}H_{43}N$, M 297.6, m 34°, b 153°/1mm, 359°/760mm, pK_{Est} ~11.0.** Dissolve the amine in *benzene and precipitate it as its bisulfate salt by shaking with 4M H_2SO_4. Filter, wash with *benzene, separate by centrifugation. The free base is obtained by treating with NaOH [McDowell & Allen *J Phys Chem* **65** 1358 *1961*, DOI: 10.1021/j100826a020], and is a strong base; store away from CO_2. [*Beilstein* **4** IV 780.]

Didodecylamine *[3007-31-6]* **$C_{24}H_{51}N$, M 353.7, m 51.8°, b 263-265°/27mm, d_4^{25} 0.806, pK^{25} 11.00.** Crystallise the amine from EtOH/*C_6H_6 under N_2, and store away from CO_2. It provides two crystalline forms: an α-form with **m** 44.4° and a β-form with **m** 51.8°. The ***hydrochloride*** has **m 207-208° dec** (from isoProOH), the ***hydroiodide*** has **m 23.8-234° dec** (sealed capillary), and the *nitrate* has **m 125.4-125.2° dec** (sealed capillary) when crystallised from MeOH/Me_2CO. [Hoerr et al. *J Am Chem Soc* **65** 328 1943, DOI: 10.1021/ja01243a008; Hoerr & Harwood *J Org Chem* **16** 779 *1951*, DOI: 10.1021/jo01145a020; *Beilstein* **4** IV 801.]

Didodecyldimethylammonium bromide *[3282-73-3]* **$C_{26}H_{56}BrN$, M 462.6, m 157-162°.** Recrystallise the salt from acetone, acetone/ether mixture, then from ethyl acetate, wash with ether and dry it in a vacuum oven at 60° [Chen et al. *J Phys Chem* **88** 1631 *1984*, DOI: 10.1021/j150652a038; Rupert et al. *J Am Chem Soc* **107** 2628 *1985*, DOI: 10.1021/ja00295a012; Rupert et al. *J Am Chem Soc* **108** 3920 *1986*, DOI: 10.1021/ja00274a011; Allen et al. *J Phys Chem* **91** 2320 *1987*, DOI: 10.1021/j100293a022]. [*Beilstein* **4** IV 801.]

Diethanolamine (2,2'-iminodiethanol) *[111-42-2]* **$C_4H_{11}NO_2$, M 105.1, m 28°, b 154-155°/10mm, 270°/760mm, pK^{25} 8.88.** Fractionally distil the amine twice, then fractionally crystallise it from its melt. Its solubility in H_2O is 10% at 20°. It absorbs CO_2 and H_2O from the atmosphere. [Perrin & Dempsey *Buffers for pH and Metal Ion Control* Chapman & Hall, London *1974*, *Beilstein* **4** H 283, **4** II 729, **4** III 689, **4** IV 1514.]

***N,N*-Diethylacetamide** *[685-91-6]* **$C_6H_{13}NO$, M 115.2, b 86-88°/atm, d_4^{20} 0.994, n_D^{20} 1.474.** Dissolve the amide in cyclohexane, shake with anhydrous BaO and then filter. The procedure is repeated three times, and the cyclohexane is distilled off at atmospheric pressure. The crude amide is also fractionally distilled three times from anhydrous BaO. [*Beilstein* **4** III 349.]

Diethyl acetamidomalonate *[1068-90-2]* **$C_9H_{15}NO_5$, M 217.2, m 96°, b 185°/10mm.** Crystallise the ester from *benzene/petroleum ether. [*Beilstein* **4** III 2993.]

Diethyl acetylenedicarboxylate *[762-21-0]* **$C_8H_{10}O_4$, M 170.2, b 60-62°/0.3mm, 107-110°/11mm, 118-120°/**

20mm, d_4^{20} 1.0735, n_D^{20} 1.4428. Dissolve the ester in *C_6H_6, wash it with $NaHCO_3$, H_2O, dry over Na_2SO_4, filter, evaporate and distil it in a vacuum [IR: Walton & Hughes *J Am Chem Soc* **79** 3985 *1957*, DOI: 10.1021/ja01572a008; Truce & Kruse *J Am Chem Soc* **81** 5372 *1959*, DOI: 10.1021/ja01529a030]. [*Beilstein* **2** H 803.]

Diethylamine *[109-89-7]* **$C_4H_{11}N$, M 73.1, m -50°, b 55.5°/atm, d_4^{20} 0.707, n_D^{20} 1.38637, pK^{15} 11.38.** Dry diethylamine with $LiAlH_4$ or KOH pellets. Reflux it with, and distil it from, BaO or KOH. Convert it to the *p*-toluenesulfonamide and crystallise it to constant melting point from dry petroleum ether (b 90-120°), then hydrolyse it with HCl; excess NaOH is added, and the amine is passed through a column of activated alumina. Redistil the amine and dry it with activated alumina before use [Swift *J Am Chem Soc* **64** 115 *1942,* DOI: 10.1021/ja01253a030]. [*Beilstein* **4** III 313.] § A polystyrene diethylaminomethyl supported version is commercially available. ***Diethylamine hydrochloride*** *[660-68-4]* **$C_4H_{11}N$. HCl, M 109.6, m 223.5°, 226-229°**, is recrystallised from absolute EtOH. Also recrystallise it from dichloroethane/MeOH. *Hygroscopic*. [*Beilstein* **4** III 113.]

Diethyl azodicarboxylate (DEAD) *[1972-28-7]* **$C_6H_{10}N_2O_4$, M 174.2, b 104.5°/12mm, 211-213°/atm, d_4^{20} 1.110, n_D^{20} 1.420.** Dissolve DEAD in toluene, wash it with 10% $NaHCO_3$ till neutral (may require several washes if too much hydrolysis had occurred: check IR for OH bands), then wash it with H_2O (2x), dry it over Na_2SO_4, filter, evaporate the toluene and distil it through a short Vigreux column at as high a vacuum as possible. The main portion boils at 107-111°/15mm. *Since it is likely to explode, use an oil bath for heating the still and all operations should be carried out behind an adequate shield with head protection*. [Rabjohn *Org Synth* Coll Vol **3** 375 *1955*, DOI: 10.15227/orgsyn.028.0058; see Kauer *Org Synth* Coll Vol **4** 411 *1963*, DOI: 10.15227/orgsyn.000.0007]. [*Beilstein* **3** III 233.] It is commercially available as a 40% solution in toluene. This reagent is useful in the Mitsunobu reaction [Mitsunobu DOI: 10.1055/s-1981-29317; 1 *1981*, Fürstner & Thiel *J Org Chem* **65** 1738 *2000*, DOI: 10.1021/jo991611g; Gennari et al. *J Am Chem Soc* **108** 6394 *1986*, DOI: 10.1021/ja00280a049; Hughes *Org React* **42** 335 *1992*, Dodge et al. *Org Synth* **73** 110 *1996*, DOI: 10.15227/orgsyn.073.0110; Hughes *Org Prep Proc Int* **28** 127 *1996*, DOI:10.1080/00304949609356516; Ferguson et al. *J Am Chem Soc* **128** 4576 *2006*, DOI: 10.1021/ja058746q, see also di-*tert*-butyl azodicarboxylate above and **DIAD** below].
§ A polystyrene supported DEAD version is commercially available with a loading of ~1.2mmol/g.

Diethyl bromomalonate *[685-87-0]* **$C_7H_{11}BrO_2$, M 239.1, b 116-118°/10mm, 122-123°/20mm, d_4^{20} 1.420, n_D^{20} 1.4507.** Purify the ester by fractional distillation in a vacuum. Its IR (film) has ν_{max} 1800 and 1700cm^{-1} [Abramovitch *Can J Chem* **37** 1146 *1959*, DOI: 10.1139/v59-169; Bretschneider & Karpitschka *Monatsh Chem* **84** 1091 *1953*, DOI:10.1007/BF00904132]. [*Beilstein* **2** IV 1904.]

Diethyl *tert*-butylmalonate *[759-24-0]* **$C_{11}H_{20}O_4$, M 216.3, b 40-42°/0.03, 102-104°/11mm, 109.5-110.5°/17mm, 205-210°/760mm, d_4^{20} 0.980, n_D^{20} 1.425.** Dissolve it in Et_2O, wash with aqueous $NaHCO_3$, H_2O, dry ($MgSO_4$), filter, evaporate and distil the residue. Identify by hydrolysis to the acid and determine the neutralisation equivalent (theor: 80.0). The ***acid*** has **m 155-157°** effervescence [Hauser et al. *J Am Chem Soc* **64** 2714 *1942*, DOI: 10.1021/ja01263a054; Bush & Beauchamp *J Am Chem Soc* **75** 2949 *1953,* DOI: 10.1021/ja01108a048]. [*Beilstein* **2** IV 2027.]

Diethyl carbonate *[105-58-8]* **$C_5H_{10}O_3$, M 118.1, m -43°, b 124-125°/atm, 126.8°/atm, d_4^{20} 0.975, n^{25} 1.38287.** Wash the ester (100ml) with an aqueous 10% Na_2CO_3 (20ml) solution, saturated $CaCl_2$ (20ml), then water (30ml). After drying by standing over solid $CaCl_2$ for 1 hour (note that prolonged contact should be avoided because slow combination with $CaCl_2$ occurs), it should be fractionally distilled. Also dry it over $MgSO_4$ and distil it. [*Beilstein* **3** H 5, **3** I 4, **3** II 4, **3** III 5, **3** IV 5.]

Diethyl disulfide *[110-81-6]* **$C_4H_{10}S_2$, M 122.3, b 86.2°/87mm, 154-155°/atm, d_4^{20} 0.993, n_D^{20} 1.506.** Dry the disulfide over silica gel or $MgSO_4$ and distil it under reduced pressure (optionally from $CaCl_2$). [*Beilstein* **1** H 347, **1** I 173, **1** II 345, **1** III 1377, **1** IV 1379.]

Diethylene glycol *[111-46-6]* **$C_4H_{10}O_3$, M 106.1, f -10.5°, b 244.3°/atm, d_4^{20} 1.118, n^{15} 1.4490, n_D^{20} 1.4475.**

Fractionally distil it in a vacuum (**b 133°/14mm**, 2.5cm x 1.3m heli-grid column), then recrystallise it by partial freezing. [Feldman et al. *J Am Chem Soc* **73** 4341 *1951*, DOI: 10.1021/ja01153a091; *Beilstein* **1** III 2090, **1** IV 2390.] ***Diethylene glycol ditosylate*** *[7460-82-4]* **$C_{18}H_{22}O_7S_2$, M 414.5, m 86-87°, 87-88°, 88-89°**, is purified by recrystallisation from Me_2CO and dried in a vacuum. [*Beilstein* **11** III 225.]

Diethylene glycol diethyl ether *[112-36-7]* **$C_8H_{18}O_3$, M 162.2, b 76°/32mm, 85-86°/10mm, 188.2-188.3°/751mm, d_4^{20} 0.910, n_D^{20} 1.412.** Dry the ether with $MgSO_4$, then CaH_2 or $LiAlH_4$, under N_2. If sodium is used, the ether should be redistilled alone to remove any products which may be formed by the action of sodium on the ether. As a preliminary purification, the crude ether (2L) can be refluxed for 12 hours with 25ml of concentrated HCl in 200ml of water, under reduced pressure, with slow passage of N_2 to remove aldehydes and other volatile substances. After cooling, add sufficient solid KOH pellets (slowly and with shaking until no more dissolves) to give two liquid phases. The upper of these is decanted, dried with fresh KOH pellets, decanted, then refluxed over, and distilled from sodium. It can be passed through (alkaline) alumina prior to purification. [*Beilstein* **1** IV 2394.]

Diethylene glycol mono-*n*-butyl ether (butyl carbitol) *[112-34-5]* **$C_8H_{18}O_3$, M 162.2, b 69-70°/0.3mm, 230.5°/760mm, d_4^{20} 0.967, n_D^{20} 1.4286.** Dry the ether with anhydrous K_2CO_3 or $CaSO_4$, filter and fractionally distil it. Peroxides can be removed by refluxing with stannous chloride or a mixture of $FeSO_4$ and $KHSO_4$ (or, less completely, by filtration under slight pressure through a column of activated alumina). [*Beilstein* **1** IV 2394.]

Diethylene glycol monoethyl ether (carbitol) *[111-90-0]* **$C_6H_{14}O_3$, M 134.2, b 201.9°/atm, d_4^{20} 0.999, n_D^{20} 1.4273, n^{25} 1.4254.** Ethylene glycol can be removed by extracting 250g in 750ml of *benzene with 5ml portions of water, allowing for phase separation, until successive aqueous portions show the same volume increase. Dry, and free from peroxides, as described for diethylene glycol mono-*n*-butyl ether. [*Beilstein* **1** IV 2393.]

Diethylene glycol monomethyl ether *[111-77-3]* **$C_5H_{13}O_3$, M 120.2, m -70°, b 194°/atm, d_4^{20} 1.010, n_D^{20} 1.423.** Purify it as for diethylene glycol mono-*n*-butyl ether. [*Beilstein* **1** IV 2392.]

Diethylenetriaminepenta-acetic acid (DTPA, DEPTAPAC) *[67-43-6]* **$C_{14}H_{23}N_3O_{10}$, M 393.4, m 219-220°, pK_1^{25} 1.79, pK_2^{25} 2.56, pK_3^{25} 4.42, pK_4^{25} 8.76, pK_5^{25} 10.42.** Crystallise DTPA from water. Dry it under vacuum or at 110°. [Bielski & Thomas *J Am Chem Soc* **109** 7761 *1987*, DOI: 10.1021/ja00259a026; NMR: Wenzel et al. *Anal Chem* **54** 615 *1982*, DOI: 10.1021/ac00241a004; *Beilstein* **4** IV 2454.]

Diethyl ether (ethyl ether) *[60-29-7]* **$C_4H_{10}O$, M 74.1, m -116°, b 34.6°/760mm, d_4^{20} 0.714, n^{15} 1.3555, n_D^{20} 1.35272.** Usual impurities are water, EtOH, diethyl peroxide (which is explosive when concentrated), and aldehydes. Peroxides [detected by liberation of iodine from weakly acid (HCl) solutions of KI, or by the blue colour in the ether layer when 1mg of $Na_2Cr_2O_7$ and 1 drop of dilute H_2SO_4 in 1ml of water is shaken with 10ml of ether] can be removed in several different ways. The simplest method is to pass dry ether through a column of activated alumina (80g Al_2O_3/700ml of ether). More commonly, 1L of ether is shaken repeatedly with 5-10ml of a solution comprising 6.0g of ferrous sulfate and 6ml of concentrated H_2SO_4 in 110ml of water. Aqueous 10% Na_2SO_3 or stannous chloride can also be used. The ether is then washed with water, dried for 24 hours with $CaCl_2$, filtered and dried further by adding sodium wire until it remains bright. The ether is stored in a dark cool place, until distilled from sodium before use. Peroxides can also be removed by wetting the ether with a little water, then adding excess $LiAlH_4$ or CaH_2 and leaving to stand for several hours. (This also dried the ether.) Werner [*Analyst* **58** 333 *1933*, DOI: 10.1039/AN9335800333] removed peroxides and aldehydes by adding 8g $AgNO_3$ in 60ml of water to 1L of ether, then 100ml of 4% NaOH and shaking for 6 minutes. Fierz-David [*Chimia* **1** 246 *1947*] shook 1L of ether with 10g of a zinc-copper couple. (This reagent is prepared by suspending zinc dust in 50ml of hot water, adding 5ml of 2M HCl and decanting after 20 seconds, washing twice with water, covering with 50ml of water and 5ml of 5% cuprous sulfate with swirling. The liquid is decanted and discarded, and the residue is washed three times with 20ml of ethanol and twice with 20ml of diethyl ether). Aldehydes can be removed from diethyl ether by distillation from hydrazine hydrogen sulfate, phenylhydrazine or thiosemicarbazide. Peroxides and oxidisable impurities have also been removed by shaking with strongly alkaline saturated-$KMnO_4$ (with which the ether was left to stand in contact for 24 hours), followed by washing with water, concentrated H_2SO_4, water again, drying ($CaCl_2$), and distillation from sodium, or Na containing

benzophenone to form the ketyl. Other purification procedures include distillation from sodium triphenylmethide or butyl magnesium bromide, and drying with solid NaOH or P_2O_5. [*Beilstein* **1** IV 1314.]
Rapid purification: Same as for 1,4-dioxane.

Diethyl ethoxymethylene malonate *[87-13-8]* **$C_{10}H_{16}O_5$, M 216.2, b 014°/0.2mm, 109°/0.5mm, 279-283°/atm, d_4^{20} 1.079, n_D^{20} 1.4623.** Likely impurity is diethyl diethoxymethylene malonate which is difficult to separate from diethyl ethoxymethylene malonate by distillation, and it is necessary to follow the course of the distillation by the change in refractive index instead of boiling point. After a low boiling fraction is collected, there is obtained an intermediate fraction (n_D^{20} 1.414—1.458), the size of which depends on the amount of the diethoxymethylene compound. This fraction is fractionated through a 5inch Vigreux column at low pressure, and avoiding interruption in heating. Fraction **b 108-110°/0.25mm** is *ca* 10° higher than the submitters' fraction (b 97.2°/0.25mm, n_D^{20} 1.4612—1.4623) [Parham & Reed *Org Synth* Coll Vol **3** 395 *1955*, DOI: 10.15227/orgsyn.028.0060; Fuson et al. *J Org Chem* **11** 194 *1946*, DOI: 10.1021/jo01172a014; Duffin & Kendal *J Chem Soc* 893 *1948* DOI: 10.1039/JR9480000890]. [*Beilstein* **3** IV 1192.]

N,N'*-Dimethylethylenediamine [1,2-bis(methylamino)ethane]** *[110-70-3]* **$C_4H_{12}N_2$, M 88.2, b 110-112°/750mm, 119°/760mm, d_4^{20} 0.819, n_D^{20} 1.431, (pK[25] 7.01 and 9.88).** This strong base has been prepared in various ways including hydrolysis of *N,N'-di(benzylsulfonyl)-N,N'-dimethylethylenediamine* (**m 217-219°**, from AcOH) and concentrated HCl (120-130°) [Johnson & Bailey *J Am Chem Soc* **38** 2135 *1916*, DOI: 10.1021/ja02267a024], the reaction of 1,2-dibromoethane with 21-33% aqueous $MeNH_2$ in EtOH (reflux for 2 hours, 50% yield) [Kermack & Wight *J Chem Soc* 1421 *1935*, DOI: 10.1039/JR9350001421; Woodburn & O'Gee *J Org Chem* **17** 1235 *1952*, DOI: 10.1021/jo50009a008], hydrolysis of *N,N'-di(p-toluenesulfonyl)-N,N'-dimethylethylenediamine* (1mol, **m 164°**, from AcOH) with H_2SO_4 (8.2mol) and H_2O (9mol) at 140-145°/7 hours [Boon *J Chem Soc* 307 *1947*, DOI: 10.1039/JR9470000307], LAH reduction in THF of *3-benzenesulfonyloxy-5,6-dihydrouracil* (**m 175-176°**, from iso-PrOH) and isolated as the ***dibenzoyl derivative (41%, **m 177-178°**, from $*C_6H_6$) [Bauer *J Am Chem Soc* **78** 1945 *1956*, DOI: 10.1021/ja01590a049], and by catalytic hydrogenation of *N-benzyl-N,N'-dimethylethylenediamine* (**b 73-74°/0.1mm**) with 10% Pd/C [Jucker & Rissi *Helv Chim Acta* **45** 2383 *1962*, DOI: 10.1002/hlca.19620450710]. General isolation and purification procedures involve steam distillation of the product diamine, acidifying the distillate with HCl, evaporating to dryness, treating the residual salt with 10% excess of cold 32% aqueous NaOH, collecting the organic layer (**care**: very caustic solution), drying it over solid KOH, and distilling from it. Final distillation of the dry base over Na has been reported (see also [107-15-3]). The diamine is a strong base and readily absorbs CO_2 and H_2O from the atmosphere—store it in a dark stoppered bottle, wax the stopper if it should be stored for long periods. The ***dihydrochloride*** [5752-40-9] has **m 235-236°(dec)**, and the ***picrate*** has **m 160°** (from EtOH and Me_2CO in rectangular plates). It forms complexes with Cu, Ni, and Pt among other metals. Its FT-IR (neat) has ν_{max} at 3285.5, 2788.2, 1447.2, 1346.5, 1251.0, 1106.5, 1040.5, 876.9 and 763.7 cm^{-1}. [For pK and metal complexes see Gustafson & Martell *J Am Chem Soc* **81** 525 *1959*, DOI: 10.1021/ja01512a005; *Beilstein* **4** H 250, **4** I 415, **4** II 689, **4** III 512, **4** IV 1171.]

***N,N*-Diethylformamide** *[617-84-5]* **$C_5H_{11}NO$, M 101.2, b 29°/0.5mm, 61-63°/10mm, 178.3-178.5°/760mm, d_4^{20} 0.906, n_D^{25} 1.4313.** Distil it under reduced pressure, then at atmospheric pressure [Winteler et al. *Helv Chim Acta* **37** 2370 *1954*, DOI: 10.1002/hlca.19540370752; NMR: Hoffmann *Z Anal Chem* **170** 177 *1959*]. [*Beilstein* **4** IV 346.]

Diethyl fumarate *[623-91-6]* **$C_{10}H_{16}O_5$, M 172.2, m 1-2°, b 218°/atm, d 1.052, n 1.441.** Wash the fumarate with aqueous 5% Na_2CO_3, then with saturated $CaCl_2$ solution, dry with $CaCl_2$ and distil it. [*Beilstein* **2** IV 2207.] Note that **dimethyl fumarate** *[624-49-7]* **M 144.1, m 102°, b 192-193°/atm** is a higher melting solid. [*Beilstein* **2** IV 2205.]

***N,N*-Diethyl-1,1,2,3,3,3-hexafluoropropylamine (Ishikawa's Reagent, perfluoropropyldiethylamine, PPDA)** *[309-88-6]* **$C_7H_{11}F_6N$, M 223.2, b 56-57°/58mm d_4^{25} 1.230, n_D^{20} 1.3460.** When this reagent is prepared from diethylamine (11g, 0.15mol) in dry Et_2O (30ml) in a glass pressure bomb cooled to -70° (sealed bomb) is allowed to rise to ~25°, and stirred at this temperature overnight, the reaction is complete. Crystalline $Et_2NH.HF$ is removed by fitration, the solvent (Et_2O) is evaporated, and the residual oil is distilled in a vacuum

to give a liquid (23.7g, ~72%) which boils at **56-57°/58mm**. This liquid is shown, by its ^{19}F NMR signal intensities, to be a 3:1 mixture of PPDA and exclusively (*E*)-*N,N*-**d**iethyl-**p**entafluoro-**p**ropenyl**a**mine (*trans*-dppa) with respectively δ_F [PPDA] at -3.0 (1-CF_3), 6.0 (3-CF_A), 11.0 (3-CF_B), 131.0 (2-CF), and δ_F [*trans*-dppa] at -12.0 (1- CF_3, $^{1,3}J$ = 14Hz, $^{1,4}J$ = 23.5Hz), 41.0 (3-CF, $^{1,4}J$ = 23.5Hz, $^{1,3}J_{trans}$ = 117Hz), 122 (2-CF, $^{1,3}J$ = 14Hz, $^{1,3}J_{trans}$ = 117Hz) upfield from external CF_3CO_2H with 3:1 relative intensities. The mixture is easy to handle, and is stable on storage at room temperature without discolouration or loss of activity for at least 6 months. It reacts with a variety of CHOH groups to form the respective CHF derivatives, with carboxylic acids to form the acid fluorides [Takaoka, Iwakiri and Ishikawa *Bull Chem Soc Jpn* **52** 3377 *1979*, DOI: org/10.1246/bcsj.52.3377; Watanabe, Fujita, Ushi and Kitazume *J Fluorine Chem* **31** 247 *1986*, DOI:10.1016/S0022-1139(00)81428-1; Watanabe, Fujita, Sakamoto, Kuramochi and Kitazume *J Fluorine Chem* **36** 361 *1987* DOI:10.1016/S0022-1139(00)82078-3], and allylic alcohols to form α-fluoro-α-(trifluoromethyl)-γ,δ-unsaturated amide precursors [Ogu, Akazome and Ogura *Tetrahedron Lett* **39** 305 *1998*, DOI:10.1016/S0040-4039(97)10548-2]. The crude 3:1 reaction product has been used satisfactorily without distillation. The presence of 33% of *trans*-dppa is not a drawback because HF is liberated in the reaction of PPDA with OH, and the HF that is liberated adds on to the olefinic *trans*-dppa to give PPDA; so that as long as there is at least equal amounts of these two compounds the mixture behaves as if it were completely made up of DDPA.
When the above synthesis is carried out at ~5-10° while *F*-propene is bubbled through (completely absorbed within 2 hours), then stirred at ~25° overnight, an oil is obtained (89% yield) with **51-53°/58mm** which is a 1:1 mixture (by ^{19}F NMR) of PPDA and *trans*-dppa. If *n*-Bu_2NH, or piperidine, replace Et_2NH in the reaction at -70° in sealed bombs, (*n*-Bu)$_2$N-CF_2CHFCF_3 and (*E*)-(*n*-Bu)$_2$N-CF=$CFCF_3$ (**55-57°/5mm**, 2:1, 78% yield) or C_5H_{10}N-CF_2CHFCF_3 only (**49-50°/7mm**, 80% yield) respectively are obtained [Takaoka, Iwakiri and Ishikawa *Bull Chem Soc Jpn* **11** 3377 *1979*, DOI: org/10.1246/bcsj.52.3377]. For use in fluorination see Koch et al. [*Synlett* 693 *2004*, DOI:10.1055/s-2004-817771] and Ogu et al. [*Tetrahedron Lett* **39** 305 *1998*, DOI: 10.1016/S0040-4039(97)10548-2]. [*Beilstein* **4** IV 353.]

Diethyl ketone (3-pentanone) *[96-22-0]* **$C_5H_{10}O$, M 86.1, m -42°, b 102°/751mm, 102.1°/atm, d $^{20}_4$ 0.8099, n $^{20}_D$ 1.392.** The ketone is dried with anhydrous $CaSO_4$ or $CuSO_4$, and distil from P_2O_5 under N_2 or under reduced pressure. Further purification is by conversion to the semicarbazone (recrystallise to constant **m 139°**, from EtOH) which, after drying *in vacuo* over $CaCl_2$ and paraffin wax, is refluxed for 30 minutes with excess oxalic acid, then steam distilled and salted out with K_2CO_3. Dry it with Na_2SO_4 and distil it [Cowan et al. *J Chem Soc* 171 *1940*, DOI: 10.1039/JR9400000171]. [*Beilstein* **1** IV 3279.]

Diethyl malonate *[105-53-3]* **$C_7H_{12}O_4$, M 160.2, m -51-52°, b 92°/22mm, 198-199°/760mm, d $^{20}_4$ 1.056, d^{25} 1.0507, n $^{20}_D$ 1.413.** If too impure (IR, NMR) the ester (250g) is heated on a steam bath for 36 hours with absolute EtOH (125ml) and conc H_2SO_4 (75ml), then fractionally distilled under reduced pressure. Otherwise fractionally distil it under reduced pressure and collect the steady boiling middle fraction. [*Beilstein* **2** IV 1881.]

Diethylnitrosamine (*N*-nitrosodiethylamine) *[55-18-5]* **$C_4H_{10}N_2O$, M 102.1, b 172-173.5°/atm, 177°/atm, d $^{20}_4$ 0.95, n $^{20}_D$ 1.437.** Dry it over anhydrous K_2CO_3 and distil it at atmospheric pressure which removes any Et_2NH. See purification of dimethylnitrosamine below, and preparation in A.I. Vogel *Practical Organic Chemistry* Textbooks. [*Beilstein* **4** IV 3386.] **Carcinogen**.

2,2-Diethyl-1,3-propanediol *[115-76-4]* **$C_7H_{16}O_2$, M 132.2, m 61.4-61.8°, b 130-133°/16mm, n $^{20}_D$ 1.4574.** Crystallise the diol from petroleum ether (b 65-70°). **IRRITANT.** [McKusick *J Am Chem. Soc* **70** 1982 *1948*, DOI: 10.1021/ja01185a602; *Beilstein* **1** III 2217, **1** IV 2589.]

Diethyl pyrocarbonate (DEP) *[1609-47-8]* **$C_6H_{10}O_5$, M 162.1, b 38-40°/12mm, 160-163°/atm, d $^{20}_4$1.119, n $^{20}_D$ 1.398.** Dissolve the ester in Et_2O, wash it with dilute HCl, H_2O, dry over Na_2SO_4, filter, evaporate and distil the residue first *in vacuo* then at atmospheric pressure. It is soluble in alcohols, esters, ketones and hydrocarbon solvents. A 50% w/w solution is usually prepared for general use. **Treat with great CAUTION as DEP irritates the eyes, mucous membranes and skin.** [Boehm & Mehta *Chem Ber* **71** 1797 *1938*, DOI: 10.1002/cber.19380710904; Thoma & Rinke *Justus Liebigs Ann Chem* **624** 30 *1959*, DOI: 10.1002/jlac.19596240104; *Beilstein* **3** IV 18.]

Diethyl succinate *[123-25-1]* **$C_8H_{14}O_4$, M 174.2, m -20°, b 105°/15mm, 218°/atm, d_4^{20} 1.047, n_D^{20} 1.4199.** Dry the succinate with $MgSO_4$, and distil it at 15mm pressure. [*Beilstein* **2** IV 1914.]

Diethyl sulfate *[64-67-5]* **$C_4H_{10}O_4S$, M 154.2, m -24°, b 96°/15mm, 118°/40mm, d_4^{20} 1.177, n_D^{20} 1.399.** Wash the ester with aqueous 3% Na_2CO_3 (to remove acidic material), then distilled water, dry ($CaCl_2$), filter and distil it in a vacuum. *It is an* ***ethylating agent*** *and blisters the skin*. [*Beilstein* **1** IV 1236.]

Diethyl sulfide *[352-93-2]* **$C_4H_{10}S$, M 90.2, m -100°, b 0°/15mm, 90.1°/760mm, d_4^{20} 0.837, n_D^{20} 1.443.** Wash the sulfide with aqueous 5% NaOH, then water, dry with $CaCl_2$ and distil it from sodium. It can also be dried with $MgSO_4$ or silica gel. *Alternative* purification is *via* the Hg(II) chloride complex [$(Et)_2S.2HgCl_2$] (see dimethyl sulfide). [*Beilstein* **1** IV 1394.]

Diethyl (-)-D- (from the non-natural) *[13811-71-7]* **and (+)-L- (from the natural acid)** *[89-91-2]* **tartrate $C_8H_{14}O_6$, M 206.2, m 17°, b 80°/0.5mm, 162°/19mm, 278-282°/atm, d_4^{20} 1.204, n_D^{20} 1.4476, $[\alpha]_D^{20}$ (+) and (+) 26.5 (c 1, H_2O) and (-) and (+) 8.5 (neat), $[\alpha]_{546}^{20}$ (+) and (+) 30 (c 1, H_2O).** Distil the esters under high vacuum and store them under vacuum or in an inert atmosphere in a desiccator in round bottomed flasks equiped with a vacuum stopcock. They have also been distilled by Kügelrohr distillation and/or by 'wiped-film' molecular distillation. They are slightly soluble in H_2O but miscible with EtOH and Et_2O. [Gao et al. *J Am Chem Soc* **109** 5765 *1987*, DOI: 10.1021/ja00253a032; IR: Pristera *Anal Chem* **25** 844 *1953*, DOI: 10.1021/ac60078a002; *Beilstein* **3** III 1025 for D-(-), **3** IV 1232 for L(+).]

***sym*-Diethylthiourea** *[105-55-5]* **$C_5H_{12}N_2S$, M 132.2, m 76-77°, 77-79°.** Crystallise it from *benzene. [*Beilstein* **4** H 118, **4** I 355, **4** II 610, **4** III 220, **4** IV 375.]

Difluoroacetic acid *[381-73-7]* **$C_2H_2F_2O_2$, M 96.0, m -0.35°, b 67-70°/20mm, 134°/760mm, d_4^{20} 1.530, n_D^{20} 1.3428, pK^{25} 1.28.** Purify the acid by distilling over P_2O_5. The ***acid chloride*** is a fuming liquid **b 25°/atm**, the ***amide*** has **b 108.6°/35mm**, **m 52°** (from *C_6H_6), and the ***anilide*** has **b 90°/1mm, 114°/5mm,** and **m 58°** [Henne & Pelley *J Am Chem Soc* **74** 1426 *1952*, DOI: 10.1021/ja01126a019; Coffman et al. *J Org Chem* **14** 747 *1949*, DOI: 10.1021/jo01157a005; NMR: Meyer et al. *J Am Chem Soc* **75** 4567 *1953*, DOI: 10.1021/ja01114a053; pK: Wegscheider *Z Phys Chem* **69** 614 *1909*]. [*Beilstein* **2** IV 455.] It is a strong acid see pKa.

Diglycolic acid (2-oxapentane-1,5-dioic acid) *[110-99-6]* **$C_6H_6O_5$, M 134.1, m 148° (monohydrate), pK_1^{25} 2.97, pK_2^{25} 4.37.** Crystallise diglycolic acid from water. [*Beilstein* **3** IV 577.]

Diglyme [bis(2-methoxyethyl) ether, diethylene glycol dimethyl ether] *[111-96-6]* **$C_6H_{14}O_3$, M 134.2, m -64°, b 62°/17mm, 75°/35mm, 160°/760mm, d_4^{20} 0.917, n_D^{20} 1.4087.** Dry diglyme with NaOH pellets or CaH_2, then reflux with, and distil it (under reduced pressure) from Na, CaH_2, $LiAlH_4$, $NaBH_4$ or NaH. These operations are carried out under N_2. The amine-like odour of diglyme has been removed by shaking with a weakly acidic ion-exchange resin (Amberlite IR-120) before drying and distilling. Addition of 0.01% $NaBH_4$ to the distillate inhibits peroxidation. Purify it also as for dioxane. It has been passed through a 12-in column of molecular sieves to remove water and peroxides. [*Beilstein* **1** IV 2393.]

Dihydroxyfumaric (1,2-dihydroxybut-1-ene-1,2-dioic acid dihydrate, dihydroxymaleic acid) *[133-38-0, 20688-70-4 dihydrate]* **$C_4H_4O_6$, 2 H_2O, M 184.1, m 155°(dec), pK_1^{25} 1.57, pK_2^{25} 3.36.** The acid has been prepared from tartaric acid by oxidation with $H_2O_2/FeSO_4$ at low temperatures (<0°). Traces of metals cause the acid to deteriorate rapidly particularly if it is in the hydrated form. Recrystallisation is a way to reduce traces of heavy metals. The acid (100 g) is dissolved in absolute MeOH (400 mL) at room temperature and filtered (using a further 50 mL of MeOH for transferring and washing). Water (450 mL) is added with stirring whereby white hydrated dihydroxyfumaric acid separates. After 15 minutes the acid is filtered off, washed with several 25 mL portions of 50% aqueous MeOH and allowed to dry in air. It is dehydrated over P_2O_5 in a vacuum desiccator at 0.1mm pressure to constant weight (70-78 g). The dihydrate undergoes a slow change in air becoming yellow and sticky, and develops an odour resembling that of commercial sodium pyruvate. The anhydrous acid is stable in a desiccator at room temperature for at least 6 months even with repeated opening of the desiccator. It appears to keep indefinitely if sealed up with P_2O_5. [The acid has UV with λ_{max} at 292nm (ε 9100) in H_2O, and λ_{max} at

308nm (ε 7900) in Et_2O)]. Almost complete removal of heavy metals reduces spontaneous decarboxylation and oxidation in aqueous solution.
The acid forms a labile insoluble dimercury salt which can be used for its estimation [Schmalfuss & Barthmeyer *Hoppe-Seyler's Z physiol Chem* **160** 106 *1926*]. The *anhydrous acid* melts at ~**141°**. [Hartree *Biochemical Preparations* **3** 56 *1953*, Powers et al. *Biochemical Preparations* **4** 56 *1955*, Fox *J Org Chem* **12** 535 *1947*, DOI: 10.1021/jo01168a007; *Beilstein* **3** I 186, **3** II 346, **3** III 1045, **3** IV 1975.]

1,2-Diiodoethane *[624-73-7]* **$C_2H_4I_2$, M 281.9, m 81-84°, d ^{25} 2.134g/cm^3.** Dissolve it in ether, wash it with saturated aqueous $Na_2S_2O_3$, dry it over $MgSO_4$, and evaporate the ether *in vacuo* then distil it. Store it in the dark. [Molander et al. *J Am Chem Soc* **109** 453 *1987*, DOI: 10.1021/ja00236a025]. [*Beilstein* **1** IV 169.]

Diiodomethane (methylene diiodide) *[75-11-6]* **CH_2I_2, M 267.8, m 6.1°, b 66-70°/11-12mm, d $^{20}_4$ 3.325.** Fractionally distil it under reduced pressure, then fractionally crystallise it by partial freezing, and stabilise it with silver wool if necessary. It has also been purified by drying over $CaCl_2$ and fractionally distilling from Cu powder. Store it in the dark. [*Beilstein* **1** IV 97.]

Diisopropanolamine *[110-97-4]* **$C_6H_{15}NO_2$, M 133.2, m 41-44°, d $^{20}_4$ 1.004, pK$_{Est}$ ~10.7.** Crystallise the amine repeatedly from dry diethyl ether. It is a strong base, store away from CO_2 and H_2O. [*Beilstein* **4** III 761.]

Diisopropylamine *[108-18-9]* **$C_6H_{15}N$, M 101.2, m -61°, b 83.5°/760mm, d $^{20}_4$ 0.720, n $^{20}_D$ 1.39236, pK^{25} 11.20.** Distil the amine from NaOH, or reflux it three minutes over Na wire or NaH, and distil it into a dry receiver under N_2. It is a strong base, store away from CO_2 and H_2O. [*Beilstein* **4** H 154, **4** I 369, **4** II 630, **4** III 274, **4** IV 510.] § A polystyrene supported version of diisopropylamine is commercially available.

Diisopropylazodicarboxylate (DIAD) *[2446-83-5]* **$C_8H_{14}N_2O_4$, M 202.2, b 75°/0.2mm, d^{25} 1.420, n $^{20}_D$ 1.420.** Purify the azo compound by distillation at as high a vacuum as possible. Since it is likely to explode, use an oil bath for heating the still, and all operations should be carried out behind an adequate shield. [Kauer *Org Synth* Coll Vol **4** 411 *1963*, DOI: 10.15227/orgsyn.000.0007; *Beilstein* **3** III 233]. This reagent is useful in the Mitsunobu reaction [Mitsunobu *Synthesis* 1 *1981*, DOI: 10.1055/s-1981-29317; Gennari et al. *J Am Chem Soc* **108** 6394 *1986*, DOI: 10.1021/ja00280a049; Hughes *Org React* **42** 335 *1992*, Dodge et al. *Org Synth* **73** 110 *1996*, DOI: 10.15227/orgsyn.073.0110; Hughes *Org Prep Proc Int* **28** 127 *1996*, DOI: 10.1080/00304949609356516; Ferguson et al. *J Am Chem Soc* **128** 4576 *2006*, DOI: 10.1021/ja058746q; see also di-*tert*-butyl azodicarboxylate and **DEAD** above].

Diisopropylethylamine (Hünig's base) *[7087-68-5]* **$C_8H_{19}N$, M 129.3, m <-51-52°, b 119°/731mm, 127°/760mm, d $^{27}_4$ 1.440, n $^{25}_D$ 1.4376, pK$_{Est}$ ~10.9.** Distil the amine from ninhydrin, then from KOH [Dryland & Sheppard, *JCS Perkin Trans 1* 125 *1986*, DOI: 10.1039/P19860000125]. It is a strong sterically hindered *strong* base and should be stored in the absence of carbon dioxide. [Hünig & Kiessel *Chem Ber* **91** 380, 387 *1958*, DOI: 10.1002/cber.19580910223; Wotiz et al. *J Org Chem* **24** 1202 *1959*, DOI: 10.1021/jo01091a009; *Beilstein* **4** IV 551.]

Diisopropyl ketone (2,4-dimethyl-3-pentanone) *[565-80-0]* **$C_7H_{14}O$, M 114.2, m -80°, b 124°/atm, d ^{25} 0.801g/cm^3, n $^{20}_D$ 1.400.** Dry the ketone with $CaSO_4$, shake it with chromatographic alumina and fractionally distil it from P_2O_5 under N_2. [*Beilstein* **1** IV 3334.]

2,3-Dimercapto-1-propanol (BAL, British Anti-Lewisite) *[59-52-9]* **$C_3H_8OS_2$, M 124.2, b 82-84°/0.8mm, 120°/15mm, d $^{20}_4$ 1.239, n $^{20}_D$ 1.5732, pK $^{25}_1$ 8.62, pK $^{25}_2$ 10.75.** Precipitate BAL as the Hg mercaptide [see Sjöberg *Chem Ber* **75** 13 *1942*, DOI: 10.1002/cber.19420750103], regenerate with H_2S, and distil it under a vacuum [Rosenblatt & Jean *Anal Chem* **27** 951 *1955*, DOI: 10.1021/ac60102a023]. *It is an antidote for heavy metal (As, Hg, Au etc) poisoning*. [*Beilstein* **1** IV 2770.]

1,3-Dimercapto-2-propanol *[584-04-3]* **$C_3H_8OS_2$, M 124.2, b 68-69°/0.8mm, 82°/1.5mm, 94°/12mm, n $^{23}_D$ 1.5696.** Purify the dithiol as for 2,3-dimercapto-1-propanol above. [Johary & Owen *J Chem Soc* 1302 *1955*, DOI: 10.1039/JR9550001302; *Beilstein* **1** IV 2773 or **2** IV 1102.]

***meso*-2,3-Dimercaptosuccinic acid (DMSA)** *[304-55-2]* **$C_4H_6O_4S_2$, M 182.2, m 191-192°(dec), 210°(dec), 210-211° (dec), pK $^{25}_{1}$ 2.71, pK $^{25}_{2}$ 3.48, pK $^{25}_{3}$ 8.89, pK $^{25}_{4}$ 10.75.** Purify the acid by dissolving it in NaOH and precipitating with dilute HCl, drying and recrystallising from MeOH. IR has ν_{max} at 2544 (SH) and 1689 (CO_2H) cm^{-1}. The ***bis*-S-acetyl** derivative has **m 183-185°** (from EtOAc or Me_2CO), and its ***Me* ester** has **m 119-120°** (from petroleum ether) [Gerecke et al. *Helv Chim Acta* **44** 955 *1961*, DOI: 10.1002/hlca.19610440410; Owen & Sultanbawa *J Chem Soc* 3105 *1949*, DOI: 10.1039/JR9490003109]. [*Beilstein* 3 III 1033.]

1,2-Dimethoxyethane (DME, glycol dimethyl ether, glyme) *[110-71-4]* **$C_4H_{10}O_2$, M 90.1, m -58°, b 84°/atm, d $^{20}_{4}$ 0.867, n $^{20}_{D}$ 1.380.** Traces of water and acidic materials have been removed from it by refluxing with Na, K or CaH_2, decanting and distilling from Na, K, CaH_2 or $LiAlH_4$. The reaction has been speeded up by using vigorous high-speed stirring with molten potassium. For virtually complete elimination of water, 1,2-dimethoxyethane has been dried with Na-K alloy until a characteristic blue colour is formed in the solvent at Dry-ice/cellosolve temperatures: the solvent is kept with the alloy until distilled for use [Ward *J Am Chem Soc* **83** 1296 *1961*, DOI: 10.1021/ja01467a010]. *Alternatively*, glyme, refluxed with benzophenone and Na-K, is dry enough if, on distillation, it gives a blue colour of the ketyl immediately on addition to benzophenone and sodium [Ayscough & Wilson *J Chem Soc* 5412 *1963*, DOI: 10.1039/JR9630005412]. It has also been purified by distillation under N_2 from sodium benzophenone ketyl (see above). [*Beilstein* **1** IV 2376.]

***N,N*-Dimethylacetamide (DMAc)** *[127-19-5]* **C_4H_9NO, M 87.1, m -20°, b 58.0-58.5°/11.4mm, 66-67°/15mm, 85-87°/33mm, 96°/80mm, 163-165°/760mm, d $^{20}_{4}$ 0.940, n $^{20}_{D}$ 1.4373.** Shake the amide with BaO for several days, reflux it over BaO for 1 hour, then fractionally distil it under reduced pressure. Store it over molecular sieves (4A). It is a useful organic solvent for reactions, as it is soluble in many organic solvents and in H_2O. Use it in a fume hood because over-exposure causes liver damage, jaundice, lethargy and can irritate skin. [*Beilstein* **4** IV 180.]

***β,β*-Dimethylacrylic acid (senecioic acid, 3-methyl-2-butenoic acid)** *[541-47-9]* **$C_5H_8O_2$, M 100.1, m 68°, pK^{25} -5.4 (aqueous H_2SO_4).** Crystallise the acid from hot water or petroleum ether (b 60-80°). [*Beilstein* **2** IV 1555.] It is a strong acid.

Dimethyl adipate *[627-93-0]* **$C_8H_{14}O_4$, M 174.2, m 9-11°, b 109°/10mm, 121-123°/20mm, 235°/760mm, d $^{20}_{4}$ 1.0642, n $^{20}_{D}$ 1.4292.** Dissolve it in Et_2O, wash with $NaHCO_3$, H_2O, dry over $MgSO_4$, filter, evaporate and distil it several times until the IR and NMR are consistent with its structure [Lorette & Brown *J Org Chem* **24** 261 *1959*, DOI: 10.1021/jo01084a633; Hoffmann & Weiss *J Am Chem Soc* **79** 4759 *1957*, DOI: 10.1021/ja01574a045]. [*Beilstein* **2** IV 1959.]

Dimethyl adipimidate dihydrochloride *[14620-72-5]* **$C_8H_{16}N_2O_2$. HCl, M 245.1, m 218-220°, 222-224°**. If the salt smells of HCl, then wash it with MeOH and dry Et_2O (1:3) under N_2 until the free HCl is completely removed. Recrystallise it from MeOH/Et_2O (it is very important that the solvents are super dry) [Hartman & Wold *Biochemistry* **6** 2439 *1967*, DOI: 10.1021/bi00860a021; McElvain & Shroeder *J Am Chem Soc* **71** 40 *1949*, DOI: 10.1021/ja01169a013].

Dimethylamine *[124-40-3]* **C_2H_7N, M 45.1, m -93°, b 0°/563mm, 6.9°/760mm, pK^{25} 10.73.** Dry dimethylamine by passage through a KOH-filled tower, or by standing with sodium pellets at 0° during 18 hours. It is a strong base — *do not inhale its vapours*. [*Beilstein* **4** IV 128.] § A dimethylaminomethyl polystyrene supported version is commercially available. ***Dimethylamine hydrochloride*** *[506-59-2]* **C_2H_7N. HCl, M 81.5, m 171°**, crystallises from hot $CHCl_3$ or absolute EtOH. It also recrystallises from MeOH/ether solution. Dry it in a vacuum desiccator over H_2SO_4, then P_2O_5. *Hygroscopic*. [*Beilstein* **4** IV 132.]

2-Dimethylaminoethanol *[108-01-0]* **$C_4H_{11}NO$, M 89.1, b 134.5-135.5°/atm, d $^{20}_{4}$ 1.430, n $^{20}_{D}$ 1.4362, pK^{25} 9.23.** Dry the amine with anhydrous K_2CO_3 or KOH, and fractionally distil it. [*Beilstein* **4** IV 1424.]

1-(3-Dimethylaminopropyl)-3-ethylcarbodiimide hydrochloride (EDCI, DEC, 1-ethyl-3-(3-dimethylaminopropyl) carbodiimide hydrochloride) *[25952-53-8]* **$C_8H_{17}N_3$. HCl, M 191.7, m 113.5-114.5°, 114-116°, pK_{Est} ~ 10.3.** It is an excellent H_2O-soluble peptide coupling reagent. It is purified by dissol-

ving (*ca* 1g) in CH_2Cl_2 (10ml) at room temperature and then adding dry Et_2O (~110ml) dropwise and the crystals that separate are collected, washed with dry Et_2O, recrystallised from CH_2Cl_2/Et_2O and dried in a vacuum over P_2O_5. It is important to work in a dry atmosphere or work rapidly, and then dry the solid as soon as possible. The material is moderately *hygroscopic*, but once it becomes wet it reacts slowly with H_2O. Store it away from moisture at -20° to slow down the hydrolysis process. The *free base* has **b 47-48°/0.27mm, 53-54°/0.6mm**, n_D^{25} 1.4582. The ***methiodide*** is recrystallised from $CHCl_3$/EtOAc, the crystals are filtered off, washed with dry Et_2O, recrystallised from $CHCl_3/Et_2O$, and dried *in vacuo* over P_2O_5, **m 93-95°, 94-95°**. [Sheehan et al. *J Am Chem Soc* **87** 2492 *1965*, DOI: 10.1021/ja01089a034; Sheehan & Cruickshank *Org Synth* Coll Vol **5** 555 *1973*, DOI: 10.15227/orgsyn.048.0083.] § A polymer bound version is commercially available.

***N,N*-Dimethylbiuret** *[7710-35-2]* **$C_4H_9N_3O_2$, M 131.1, m 178°.** Purify it by repeated crystallisation from the melt, or from H_2O. [Bredereck & Richter *Chem Ber* **99** 2461 *1966*, DOI: 10.1002/cber.19660990811; Dunnigan & Close *J Am Chem Soc* **75** 3615 *1953*, DOI: 10.1021/ja01111a001] [*Beilstein* **4** III 574, **4** IV 225.]

2,3-Dimethyl-1,3-butadiene *[513-81-5]* **C_6H_{10}, M 82.2, m -76°, b 68-69°/760mm, d_4^{20} 0.727, n_D^{20} 1.4385.** Distil it from $NaBH_4$, and store with 100ppm of BHT as radical inhibitor. [*Beilstein* **1** IV 1023; Fieser **1** 276.]

1,3-Dimethylbutadiene sulfone (1,3-dimethylsulfolene, 2,4-dimethyl-2,5-dihydrothiophen-1,1-dioxide) *[10033-92-8]* **$C_6H_{10}O_2S$, M 145.2, m 40.4-41.0°.** Crystallise the sulfone from diethyl ether (three times, **m 40.4-41.0°**), or from CCl_4 (**m 39.5-40°**). [For thermal dissociation see Grummitt et al. *J Am Chem Soc* **72** 5167 *1950*, DOI: 10.1021/ja01167a103; *Beilstein* **17** III/IV 161, **17/1** V 197.]

2,2-Dimethylbutane *[75-83-2]* **C_6H_{14}, M 86.2, m -100°, b 49.7°/atm, d_4^{20} 0.649, n^{25} 1.36595.** Distil it azeotropically with MeOH, then wash it with water, dry (Na_2SO_4) it, and distil it. [*Beilstein* **1** IV 367.]

2,3-Dimethylbutane *[79-29-8]* **C_6H_{14}, M 86.2, m -129°, b 58.0°/atm, d_4^{20} 1.375, n^{25} 1.37231.** Distil it from sodium, pass it through a column of silica gel (activated by heating in nitrogen to 350° before use) to remove unsaturated impurities, and again distil it from sodium. Also distil it azeotropically with MeOH, then wash with water, dry (Na_2SO_4), filter and redistil it. [*Beilstein* **1** IV 371.]

2,3-Dimethylbut-2-ene *[563-79-1]* **C_6H_{12}, M 84.2, m -75°, b 72-73°/760mm, d_4^{20} 0.708, n_D^{20} 1.41153.** Purify it by GLC on a column of 20% squalene on chromosorb P at 50° [Flowers & Rabinovitch *J Phys Chem* **89** 563 *1985*, DOI: 10.1021/j100250a003]. Also wash it with 1M NaOH solution followed by H_2O. Dry it over Na_2SO_4, distil it over powdered KOH under nitrogen and pass it through activated alumina before use. [Woon et al. *J Am Chem Soc* **108** 7990 *1986*, DOI: 10.1021/ja00285a018; Wong et al. *J Am Chem Soc* **109** 3428 *1987*, DOI: 10.1021/ja00245a039; *Beilstein* **1** IV 853.]

Dimethylcarbamoyl chloride *[79-44-7]* **C_3H_6ClNO, M 107.5, m -33°, b 34°/0.1mm, d_4^{20} 1.172, n_D^{20} 1.4511.** It must be distilled under high vacuum to avoid decomposition. It is moisture sensitive. [*Beilstein* **4** IV 224.]

Dimethyl carbonate *[616-38-6]* **$C_3H_6O_3$, M 90.1, m 2-4°, 4.65°, b 89.5°/755mm, 90.2°/atm, 90-91°/atm, d_4^{20} 1.079, n_D^{20} 1.3687.** If the reagent has broad intense bands at 3300cm^{-1} and above (i.e. OH stretching), then it should be purified further. It will contain small amounts of water and/or alcohol which form azeotropes with it. Wash it successively with 10% Na_2CO_3 solution, saturated $CaCl_2$, H_2O, and dry it by shaking mechanically for 1 hour with anhydrous $CaCl_2$, and fractionate. *Alternatively*, stand it for several days in contact with Linde type 4A molecular sieves, then fractionally distil it. The middle fraction is frozen slowly at 2°, several times, retaining 80% of the liquid at each cycle. [Bowden & Butler *J Chem Soc* 78 *1939,* DOI: 10.1039/JR9390000075; Vogel *J Chem Soc* 1833 *1948*, DOI: 10.1039/JR9480001833; *Beilstein* **3** IV 3.]

Dimethyl dicarbonate (dimethyl pyrocarbonate, DMPC) *[4525-33-1]* **$C_4H_6O_5$, M 134.1, m 15.2°, b 45-46°/5mm, d_4^{20} 1.2585, n_D^{20} 1.3950.** If the reagent has broad intense bands at 3300cm^{-1} and above (i.e. OH stretching), then it should be purified further. Dissolve it in Et_2O, shake this with a small volume of 0.1N HCl, dry the Et_2O solution (Na_2SO_4), and distil it *in vacuo* at as low pressure as possible, but below 100°, to give a clear liquid. It decomposes to CO_2 and dimethyl carbonate on heating at 123-149°. It is readily hydrolysed by

H_2O and is a yeast inhibitor. It is an **IRRITANT**. [Brysov et al. *J Org Chem USSR* **10** 2551 *1974*, Boehm & Mehta *Chem Ber* **71** 1797 *1938,* DOI: 10.1002/cber.19380710904; *Beilstein* **3** IV 17.]

1,5-Dimethyl-1,5-diazaundecamethylene polymethobromide (Hexadimethrene, Polybrene) *[28728-55-4]* **M 5000—10,000 polymer.** Purify it by chromatography on Dowex 50 and/or by filtration through alumina before use [Frank *Hoppe-Seyler's Z Physiol Chemie* **360** 997 *1979*]. It is hygroscopic, and its solubility in H_2O is 10%. The pH of a 1% solution in brine is 5-9. **Toxic.**

Dimethyldioctadecylammonium bromide (dioctadecyldimethylammonium bromide, distearyldimethylammonium bromide) *[3700-67-2]* **$C_{38}H_{80}BrN$, M 630.9, m 161-163°.** Crystallise the bromide from acetone, then MeOH [Luka *J Am Chem Soc* **106** 4386 *1984*, DOI: 10.1021/ja00328a016]. Also purify it by chromatography on alumina by washing with *C_6H_6 and eluting with Me_2CO, evaporating and crystallising from MeCN [Swain & Kreevoy *J Am Chem Soc* **77** 1122 *1955*, DOI: 10.1021/ja01610a012]. [*Beilstein* **4** IV 829.]

N,N'*-Dimethylethylenediamine [1,2-bis(methylamino)ethane]** *[110-70-3]* **$C_4H_{12}N_2$, M 88.2, b 110-112°/750mm, 119°/760mm, d_4^{20} 0.819, n_D^{20} 1.431, (pK^{25} 7.01 and 9.88).** This strong base has been prepared in various ways including hydrolysis of *N,N'-di(benzylsulfonyl)-N,N'-dimethylethylenediamine* (**m 217-219°**, from AcOH) and concentrated HCl (120-130°) [Johnson & Bailey *J Am Chem Soc* **38** 2135 *1916*, DOI: 10.1021/ja02267a024], the reaction of 1,2-dibromoethane with 21-33% aqueous $MeNH_2$ in EtOH (reflux for 2 hours, 50% yield) [Kermack & Wight *J Chem Soc* 1421 *1935*, DOI: 10.1039/JR9350001421; Woodburn & O'Gee *J Org Chem* **17** 1235 *1952*, DOI: 10.1021/jo50009a008], hydrolysis of *N,N'-di(p-toluenesulfonyl)-N,N'-dimethylethylenediamine* (1mol, **m 164°**, from AcOH) with H_2SO_4 (8.2mol) and H_2O (9mol) at 140-145°/7 hours [Boon *J Chem Soc* 307 *1947*, DOI: 10.1039/JR9470000307], LAH reduction in THF of *3-benzenesulfonyloxy-5,6-dihydrouracil* (**m 175-176°**, from iso-PrOH) and isolated as the ***dibenzoyl derivative (41%, **m 177-178°**, from *C_6H_6) [Bauer *J Am Chem Soc* **78** 1945 *1956*, DOI: 10.1021/ja01590a049]; and by catalytic hydrogenation of *N-benzyl-N,N'-dimethylethylenediamine* (**b 73-74°/0.1mm**) with 10% Pd/C [Jucker & Rissi *Helv Chim Acta* **45** 2383 *1962*, DOI: 10.1002/hlca.19620450710]. General isolation and purification procedures involve steam distillation of the product diamine, acidifying the distillate with HCl, evaporating to dryness, treating the residual salt with 10% excess of cold 32% aqueous NaOH, collecting the organic layer (**care**: very caustic solution), drying it over solid KOH, and distilling from it. Final distillation of the dry base over Na has been reported (see also [107-15-3]). The diamine is a strong base and readily absorbs CO_2 and H_2O from the atmosphere—store it in a dark stoppered bottle, wax the stopper if it should be stored for long periods. The ***dihydrochloride*** [5752-40-9] has **m 235-236° (dec)**, and the ***picrate*** has **m 160°** (from EtOH and Me_2CO in rectangular plates). It forms complexes with Cu, Ni, and Pt among other metals. Its FT-IR (neat) has ν_{max} at 3285.5, 2788.2, 1447.2, 1346.5, 1251.0, 1106.5, 1040.5, 876.9 and 763.7 cm^{-1}. [For pK and metal complexes see Gustafson & Martell *J Am Chem Soc* **81** 525 *1959*, DOI: 10.1021/ja01512a005; *Beilstein* **4** H 250, **4** I 415, **4** II 689, **4** III 512, **4** IV 1171.]

Dimethyl disulfide (DMDS) *[624-92-0]* **$C_2H_6S_2$, M 94.2, f -98°, b 40°/12mm, 110°/760mm, d_4^{20} 1.0605, n 1.5260.** Pass it through neutral alumina before use. [Trost *Chem Rev* **78** 363 *1978*, DOI: 10.1021/cr60314a002; *Beilstein* **1** IV 1281.]

***N,N*-Dimethylformamide (DMF)** *[68-12-2]* **C_3H_7NO, M 73.1, m -61°, b 40°/10mm, 61°/30mm, 88°/100mm, 153°/760mm, d_4^{20} 0.948, n^{25} 1.4269, pK^{25} -0.3.** DMF decomposes slightly at its normal boiling point to give small amounts of dimethylamine and carbon monoxide. The decomposition is catalysed by acidic or basic materials, so that even at room temperature DMF is appreciably decomposed if allowed to stand for several hours with solid KOH, NaOH or CaH_2. If these reagents are used as dehydrating agents, therefore, they should not be refluxed with the DMF. Use of $CaSO_4$, $MgSO_4$, silica gel or Linde type 4A molecular sieves is preferable, followed by distillation under reduced pressure. This procedure is adequate for most laboratory purposes. Larger amounts of water can be removed by azeotropic distillation with *benzene (10% v/v, previously dried over CaH_2), at atmospheric pressure: water and *benzene distil below 80°. The liquid remaining in the distillation flask is further dried by adding $MgSO_4$ (previously ignited overnight at 300-400°) to give 25g/L. After shaking for one day, a further quantity of $MgSO_4$ is added, and the DMF is distilled at 15-20mm pressure through a 3-ft vacuum-jacketed column packed with steel helices. However, $MgSO_4$ is an

inefficient drying agent, leaving about 0.01M water in the final DMF. More efficient drying (to around 0.001-0.007M water) is achieved by standing with powdered BaO, followed by decanting before distillation, then with alumina powder (50g/L, previously heated overnight to 500-600°), and distilling from more of the alumina, or by refluxing at 120-140° for 24 hours with triphenylchlorosilane (5-10g/L), then distilling at *ca* 5mm pressure [Thomas & Rochow *J Am Chem Soc* **79** 1843 *1957*, DOI: 10.1021/ja01565a021]. Free amine in DMF can be detected by the colour reaction with 1-fluoro-2,4-dinitrobenzene. It has also been purified by drying overnight over KOH pellets and then distilling from BaO through a 10 cm Vigreux column [Jasiewicz et al. *Exp Cell Res* **100** 213 *1976*, DOI:10.1016/0014-4827(76)90344-X]. [For efficiency of desiccants in drying dimethylformamide see Burfield & Smithers *J Org Chem* **43** 3966 *1978*, DOI: 10.1021/jo00414a038; and for a review on purification, tests of purity and physical properties, see Juillard *Pure Appl Chem* **49** 885 *1977*, doi.org.virtual.anu.edu.au/10.1351/pac197749060885.]
It has been purified by distilling from K_2CO_3 under high vacuum and fractionated in an all-glass apparatus. The middle fraction is collected, degassed (seven or eight freeze-thaw cycles) and redistilled under as high a vacuum as possible [Kosower & Mohammad *J Am Chem Soc* **93** 2713 *1971*, DOI: 10.1021/ja00740a022]. [*Beilstein* **4** IV 171.]
Rapid purification: Stir over CaH_2 (5% w/v) overnight, filter, then distil at 20mmHg. Store the distilled DMF over 3A or 4A molecular sieves. For solid phase synthesis, the DMF used must be of high quality and free from amines.

2,2-Dimethylglutaric acid (2,2-dimethylpentane-1,5-dioic acid) *[681-57-2]* **$C_7H_{12}O_4$, M 160.2, m 82-83.5°, 82-86°, b 110-145°/0.1mm, pK_1^{25} 4.28, pK_2^{25} 5.42 (H_2O).** Crystallise the acid from water, *benzene or ether/petroleum ether. Dry it in a vacuum. The ***mono-S-benzylisothiuronium salt*** has **m 177-178°** (from aqueous Me_2CO). [Karrer et al. *Helv Chim Acta* **13** 1084 *1930*, DOI: 10.1002/hlca.19300130532; Young & Linden *J Am Chem Soc* **69** 2042 *1947*, DOI: 10.1021/ja01200a066; Oroshnik et al. *J Am Chem Soc* **74** 295, 304 *1952*, DOI: 10.1021/ja01122a003; *Beilstein* **2** I 283, **2** II 590, **2** III 1750, **2** IV 2018.]

***Trans-d,l*-2,4-Dimethylglutaric acid (*d,l*-2,4-dimethylpentane-1,5-dioic acid)** *[2121-67-7]* **$C_7H_{12}O_4$, M 160.2, m 139-141°, 140-141°, 142.5-143.5°, 144-145°, pK_1 4.24, pK_2 5.82.** Distil the acid in steam and recrystallise it from ether/petroleum ether. *Alternatively*, form the Ca salt obtained by adding an equivalent of $CaCO_3$ until evolution of CO_2 is complete, recrystallise the salt from H_2O (any *cis(meso)* salt which is more soluble remains in solution). The salt is heated in excess of concentrated HCl, and the *trans-(dl)* acid separates as colourless crystals. Filter it off and dry it over KOH *in vacuo*, or recrystallise the dried acid in *C_6H_6/petroleum ether. [*Beilstein* **2** H 681, **2** I 284, **2** II 590, **21** III 1755, **2** IV 2022.]
Also prepared by the reaction of ethyl 2-bromo*iso*butyrate with sodio diethyl methylmalonate [von Auwers & Thorpe *Justus Liebigs Ann Chem* **285** 310, 315 *1895*, DOI: 10.1002/jlac.18952850304], ethyl 2-bromo*iso*butyrate with sodio ethyl 2-cyanopropionate [Auwers *Chem Ber* **28** 263 *1895*, DOI: 10.1002/cber.18950280166] or two mols of sodio ethyl 2-cyanopropionate with one mol of CH_2I_2 [Zelinsky *Chem Ber* **22** 2823 *1889*, DOI: 10.1002/cber.188902202187] which gave, after hydrolysis and decarboxylation, a mixture of approximately equal amounts of ***trans-(d,l)-*** and ***cis-(meso)- 2,4-dimethylglutaric acids*, m ~105-107°** [for discussion see: Bone & Perkin Jnr *J Chem Soc* **67** 416 *1895*, DOI: 10.1039/CT8956700416]. These can be separated by (1) the higher solubility of the Ca salt or (2) the more facile formation of the anhydride of the latter *(meso)* acid. For example, when the mixture is heated with half its weight of acetyl chloride in the cold or warmed gently for 10 min until evolution of HCl is complete, a clear solution is obtained. The *meso-* isomer readily forms the *anhydride* (see below) whereas the *trans* acid remains virtually unchanged. Evaporation of excess AcCl and drying over KOH provides a solid residue which is extracted with *C_6H_6 whereby the *cis-anhydride* is completely removed and leaves behind the solid *trans(d,l)-acid*. After crystallising the latter from hot hydrochloric acid the pure ***d,l*-acid**, **m 140-141°**, is obtained. Evaporation of the former *C_6H_6 extract leaves a semi solid ***(meso)-2,4-dimethylglutaric anhydride*** **m 93-94°**, **96°**, after crystallisation from Ac_2O [*Beilstein* **17** H 419, **17** II 436, **17/11** V 23.] Upon hydrolysis with concentrated HCl and cooling, pure white crystals of ***meso(cis)*-2,4-dimethylglutaric acid** *[2RS,4SR 3891-70-1]* **$C_7H_{12}O_4$, M 160.2, m 125-127°, 127-128°, 128.5°, b 137-138 °/4mm, n_D^{20} 1.4438, pK_1 4.28, pK_2 5.80,** separate. [Bone & Perkin jr *J Chem Soc* **67** 416 *1895*, DOI: 10.1039/CT8956700416; **68** 253 *1896*, DOI: 10.1039/CT8966900253.] Note that attempted equilibration of the *cis-anhydride* by boiling for 2 hrs with Na in EtOH followed by addition of KOH in H_2O and boiling further for 1 hr to obtain large amounts of *trans-acid* was unfavourable. Thus 153g of *cis-anhydride* gave only 18g of *trans-(d,l)-acid*. [see Allinger *J Am Chem Soc* **81** 232 *1959*, DOI: 10.1021/ja01510a053].

The ***(±)-diethyl ester*** [34022-15-6] has **b 231°/atm.**
Diethyl d,l-2,4-dimethylglutarate *[34022-15-6]* **$C_{11}H_{20}O_4$, M 216.2,** has **b 231°/atm**, and the ***d,l*-2,4-dimethylglutaric anhydride** *[3891-69-8]* **$C_7H_{10}O_3$, M 142.2**, has **m 33-34°**. 2*R*,4*R*-(-)-**2,4-Dimethylglutaric acid** *[24018-75-5]* has **m 79.5-80°** (needles from H_2O), **$[\alpha]_D^{20}$ -39.8 (H_2O)**, 2*S*,4*S*-(+)-**2,4-dimethylglutaric acid** has **m 79-80°** (needles from H_2O), **$[\alpha]_D^{20}$ +39.8 (H_2O)**, and 2*R*,4*R*-(-)-**2,4-dimethylglutaric anhydride $C_7H_{10}O_3$, M 142.2**, has **m 41.5-42.5°** (petroleum ether), **$[\alpha]_D^{20}$ +69.6 (*C_6H_6)**.

3,3-Dimethylglutaric acid *[4839-46-7]* **$C_7H_{12}O_4$, M 160.2, m 103-104°, b 89-90°/2mm, 126-127°/4.5mm, pK_1^{25} 3.85, pK_2^{25} 6.45.** Crystallise the acid from water, EtOH (needles), *benzene or ether/petroleum ether (prisms). Dry it in a vacuum. On a large scale it is better to boil it under reflux in Ac_2O for 7 hrs, evaporating, and distilling the residual liquid to give the ***anhydride*** (**m 125°, b 156-156°/20mm, 181°/25mm,** see below) which solidified on cooling. This is hydrolysed by boiling with 3 moles of aqueous KOH solution (64 w/w%) for 2.5 hrs, whereby a clear solution (containing the di potassium salt) is formed. Acidification with dilute H_2SO_4 and salting out with ammonium sulphate, extracting into Et_2O, drying (Na_2SO_4), evaporating, and a residual solid which is recrystallised from concentrated HCl. The desired glutaric acid that crystallises out is collected, and dried at 70°. It can be further recrystallised as above to give pure acid **m** 103-104°, or distilled in a vacuum; or sublimed in a vacuum. The esters are prepared in the usual way by boiling the acid in a mixture of the required pure alcohol and *benzene with some concentrated H_2SO_4 for a few hours. After workup, ***methyl 3,3-dimethylglutarate*** has **b 111°/20mm, d_4^{20} 1.0270, n_D^{20} 1.42897**; and ***ethyl 3,3-dimethylglutarate*** has **b 126°/17mm, d_4^{20} 0.9893, n_D^{20} 1.4287.** [Thole & Thorpe *J Chem Soc* **99** 422 *1911*, DOI: 10.1039/CT9119900422; Vogel *J Chem Soc* 1758 *1934*, DOI: 10.1039/JR9340001758.] [*Beilstein* **21** H 391, **21** I 334, **21** II 309, **21** III/IV 4601, **21/9** V 592.]

2,2-Dimethylglutaric anhydride *[2938-48-9]* **$C_7H_{10}O_3$, M 142.2, m 34-38°, 38.5°, 38-40°, b 150°/15mm, 158-160°/25mm, 175-180°/60mm, 270°/atm.** First check the IR to see if OH frequencies at *ca* 3000cm^{-1} are present. If present then reflux with AcCl until evolution of HCl ceases, distil and collect the fraction at **b 126°/10mm** which should not have bands for OH and should solidify with **m 37-38°**. [Rothstein & Schofield *J Chem Soc* 4566 *1965*, DOI: 10.1039/JR9650004566; *Beilstein* **17/11** V 23.] Ac_2O has also been used for dehydration by refluxing for 6 hrs [Perkin, jun. *J Chem Soc* **81** 246 (252) *1902*, DOI: 10.1039/CT9028100246; Wheeler & Almeida *J Org Chem* **27** 4448 *1962*, DOI: 10.1021/jo01059a079.]

3,3-Dimethylglutaric anhydride *[4160-82-1]* **$C_7H_{10}O_3$, M 142.2, m 125°, 124-126°, b 156-156°/20mm, 181°/25mm.** Some hydrolysis may have occurred (check IR), so purify best by boiling with redistilled Ac_2O for a few hours (e.g. 3—7 hrs, depending on how much acid is present), distilling and recrystallising the solid distillate from petroleum ether (b 100-120°), *C_6H_6/petroleum ether or Ac_2O. [Perkin *J Chem Soc* **69** 1457 *1896*, DOI: 10.1039/CT8966901457; Perkin & Thorpe *J Chem Soc* **75** 48 *1899,* DOI: 10.1039/CT8997500048; Thorpe & Wood *J Chem Soc* **103** 276 *1913*, DOI: 10.1039/CT9130300276, Thorpe & Wood *J Chem Soc* **103** 1592 *1913,* DOI: 10.1039/CT9130301586; Bruice & Bradbury *J Am Chem Soc* **87** 4838 *1965*, DOI: 10.1021/ja00949a030.] [*Beilstein* **17** H 419, **17** I 230, **17** III/IV 5853, **17/11** V 24.]

2,4-Dimethylpentane *[108-08-7]* **C_7H_{16}, M 100.2, m -1234.4°, b 80.5°/am, d_4^{20} 0.763, n_D^{20} 1.3814, n^{25} 1.37882.** Extract it repeatedly with concentrated H_2SO_4, wash with water (CARE), dry and distil it. *Alternatively*, percolate through silica gel (previously heated in N_2 to 350°). Purify it by azeotropic distillation with EtOH, followed by washing out the EtOH with water, drying and distilling. [*Beilstein* **1** IV 406.]

4,4-Dimethyl-1-pentene *[762-62-9]* **C_7H_{14}, M 98.2, b 72.5°/760mm, d_4^{20} 0.6827, n_D^{20} 1.3918.** Purify it by passing through alumina before use [Traylor et al. *J Am Chem Soc* **109** 3625 *1987*, DOI: 10.1021/ja00246a019]. [*Beilstein* **1** IV 869.]

Dimethyl peroxide *[690-02-8]* **$C_2H_6O_2$, M 62.1, b 13.5°/760mm, d_4^{20} 0.8677, n_D^{20} 1.3503.** Purify dimethyl peroxide by repeated trap-to-trap fractionation until no impurities could be detected by gas IR spectroscopy [Haas & Oberhammer *J Am Chem Soc* **106** 6146 *1984*, DOI: 10.1021/ja00333a004]. *All necessary precautions should be taken in case of* **EXPLOSION.** [*Beilstein* **1** II 271, **1** III 1194, **1** IV 1249.]

2,2-Dimethyl-1,3-propanediol (neopentyl glycol) *[126-30-7]* **$C_5H_{12}O_2$, M 104.2, m 128.4-129.4°, b 208°/760mm.** Crystallise the diol from *benzene or acetone/water (1:1). [*Beilstein* **1** IV 2551.]

2,2-Dimethyl-1-propanol (*neo*-pentyl alcohol) *[75-84-3]* **$C_5H_{12}O$, M 88.2, m 52°, b 113.1°/760mm.** It is difficult to distil because it is a solid at ambient temperatures. Purify it by fractional crystallisation and by sublimation. [*Beilstein* **1** IV 1690.]

***N,N*-Dimethylpropionamide** *[758-96-3]* **$C_5H_{11}NO$, M 101.2, m -45°, b 175-178°/atm, d_4^{20} 0.920, n_D^{20} 1.440.** Shake the amide with BaO for 1-2 days, then distil at atmospheric or reduced pressure. [*Beilstein* **4** III 126.]

2,2-Dimethylsuccinic acid *[597-43-3]* **$C_6H_{10}O_4$, M 146.1, m 141°, pK_1^{20} 4.15, pK_2^{20} 6.40.** Crystallise the acid from EtOH/ether or EtOH/chloroform. [*Beilstein* **2** IV 1996.]

***meso*-2,3-Dimethylsuccinic acid** *[608-40-2]* **$C_6H_{10}O_4$, M 146.1, m 200° (dec), 211°, pK_1^{25} 3.77, pK_2^{25} 5.36.** Crystallise the *meso*-acid from EtOH/ether or EtOH/chloroform.

(±)-2,3-Dimethylsuccinic acid *[13545-04-5]* **$C_6H_{10}O_4$, M 146.1, m 129°, pK_1^{25} 3.82, pK_2^{25} 5.98.** Crystallise the *racemic* acid from water. [*Beilstein* **2** IV 1998.]

Dimethyl sulfide (DMS) *[75-18-3]* **C_2H_6S, M 62.1, f -98.27°, b 0°/172mm, 37.5-38°/760mm, d^{21} 0.8458, n^{25} 1.4319.** Purify dimethyl sulfide *via* the Hg(II) chloride complex by dissolving 1 mole of Hg(II)Cl_2 in 1250ml of EtOH and slowly adding the boiling alcoholic solution of Me_2S to give the right ratio for $2(CH_3)_2S.3HgCl_2$. After recrystallisation of the complex to constant melting point, 500g of complex are heated with 250ml conc HCl in 750ml of water. The sulfide is separated, washed with ice-water, and dried ($CaCl_2$ and $CaSO_4$). Finally, it is distilled under reduced pressure from sodium. Precautions should be taken (*efficient fume hood*) because of its very **UNPLEASANT ODOUR** and **TOXICITY**. [*Beilstein* **1** IV 1275.] ***Dimethyl sulfone*** *[67-71-0]* **$C_2H_6O_2S$, M 94.1, m 109°, b 238°/atm**, is recrystallised from water. Dry it over P_2O_5. [*Beilstein* **1** IV 1279.]

2,4-Dimethylsulfolane (2,4-dimethyltetrahydrothiophene 1,1-dioxide) *[1003-78-7]* **$C_6H_{12}O_2S$, M 148.2, b 123°/70mm, 128°/77mm, 280-281°/atm (with some dec), d^{25} 1.1314, n_D^{20} 1.474.** Distil the yellow liquid sulfolane in a vacuum. It is soluble in hydrocarbon solvents and slightly soluble in H_2O. [*Beilstein* **17/1** IV 97.]

Dimethyl sulfoxide (DMSO) *[67-68-5]* **C_2H_6OS, M 78.1, m 18.0-18.5°, b 75.6-75.8°/12mm, 190°/760mm, d_4^{20} 1.100, n_D^{20} 1.479.** This colourless, odourless, very *hygroscopic* liquid, is synthesised from dimethyl sulfide. The main impurity is water, with a trace of dimethyl sulfone. The Karl-Fischer test is applicable. It is dried with Linde types 4A or 13X molecular sieves, by prolonged contact and passage through a column of the material, then distilled under reduced pressure. Other drying agents include CaH_2, CaO, BaO and $CaSO_4$. It can also be fractionally crystallised by partial freezing. More extensive purification is achieved by standing overnight with freshly heated and cooled chromatographic grade alumina. It is then refluxed for 4 hours over CaO, dried over CaH_2, and fractionally distilled at low pressure. For efficiency of desiccants in drying dimethyl sulfoxide see Burfield and Smithers [*J Org Chem* **43** 3966 *1978*, DOI: 10.1021/jo00414a038; Martin et al. *Angew Chem Int Ed* **6** 318 *1967*, DOI: 10.1002/anie.196703181;]. [Reddy *Pure Appl Chem* 25 457 *1971*, DOI: 10.1351/pac197125020457; *Beilstein* 1 IV 1277.]
Rapid purification: Stand over freshly activated alumina, BaO or $CaSO_4$ overnight. Filter and distil it over CaH_2 under reduced pressure (~ 12 mm Hg). Store it over 4A molecular sieves.

***N,N*-Dimethylthiocarbamoyl chloride (DMTCC)** *[16420-13-6]* **C_3H_6ClNS, M 123.6, m 42-43°, b 64-65°/0.1mm.** Crystallise it twice from pentane and/or distil it at low pressure. [Ponaras & Zaim *J Heterocycl Chem* **44** 487 *2007*, DOI: 10.1002/jhet.5570440236; *Beilstein* **4** III 147.] **TOXIC VAPOURS.**

***sym*-Dimethylurea** *[96-31-1]* **$C_6H_8N_2O$, M 88.1, m 106°, b 260-270°/atm.** Crystallise the urea from acetone/diethyl ether by cooling in an ice bath. Also crystallise it from EtOH and dry it at 50°/5mm for 24 hours [Bloemendahl & Somsen *J Am Chem Soc* **107** 3426 *1985*, DOI: 10.1021/ja00298a005]. [*Beilstein* **4** IV 207.]

2,2-Dinitropropane *[595-49-3]* **$C_3H_6N_2O_4$, M 162.1, m 53.5°, 53.7-54.3°.** Crystallise it from EtOH or MeOH. Dry it over $CaCl_2$ or *in vacuo* for 1 hour just above the melting point. Note that it has been purified by slow vacuum sublimation in the presence of P_2O_5 [Whittaker *J Phys Chem* **62** 267 *1958*, DOI: 10.1021/j150561a004]. [*Beilstein* **1** H 117, **1** II 79, **1** III 261, **1** IV 234.]

***N,N*-Dioctadecyl methylamine (proton ionophore III)** *[4088-22-6]* **$C_{37}H_{77}N$, M 536.0, m 40°, 44-46°, 48-49°, b 252-259°, pK_{Est} ~10.** It can be distilled at high vacuum, but dissolving in $*C_6H_6$, filtering and evaporating gives a waxy solid suitable for electrode use. It recrystallises from Me_2CO or MeCN. [Hoerr et al. *J Org Chem* **09** 201 *1944*, DOI: 10.1021/jo01184a011; Wu & Yu *Talanta* **34** 577 *1987*, DOI:10.1016/0039-9140(87)80193-5; *Beilstein* **4** III 435.]

Di-*n*-propyl ketone (4-heptanone) *[123-19-3]* **$C_7H_{14}O$, M 114.2, m -33°, b 143.5°, d_4^{20} 0.8143, n_D^{20} 1.40732.** Dry 4-pentanone with $CaSO_4$, then distil it from P_2O_5 under nitrogen. [*Beilstein* **1** IV 3323.]

Di-*n*-propyl sulfide *[111-47-7]* **$C_7H_{14}S$, M 118.2, m -103°, b 141-142°/atm, d_4^{20} 0.870, n_D^{20} 1.449.** Wash the sulfide with aqueous 5% NaOH, then water. Dry it with $CaCl_2$ and distil it from Na [Dunstan & Griffiths *J Chem Soc* 1344 *1962*, DOI: 10.1039/JR9620001344]. [*Beilstein* **1** IV 1452.]

***S*-1,2-Distearin (*S*-glycerol-1,2-distearate)** *[S- 1429-59-0, RS- 51063-97-9, R- 1188-58-5]* **$C_{39}H_{76}O_5$, M 625.0, m 76-77°, $[\alpha]_D^{20}$ -2.8 (c 6.3, $CHCl_3$), $[\alpha]_{546}^{20}$ +1.4 (c 10, $CHCl_3$/MeOH, 9:1).** Crystallise the glyceride from chloroform/petroleum ether. [cf. p 1014, in 'Physiologically Active …' in Chapter 6, *Beilstein* **2** IV 1231.]

1,4-Dithioerythritol (DTE, *erythro*-2,3-dihydroxy-1,4-dithiobutane) *[6892-68-8]* **$C_4H_{10}O_2S_2$, M 154.3, m 82-84°, pK_1 9.0, pK_2 9.9.** Crystallise DTE from ether/hexane and store it in the dark at 0°. [*Beilstein* **1** III 2360.]

Dithiooxamide (rubeanic acid) *[79-40-3]* **$C_2H_4O_2S_2$, M 120.2, m >300°.** Crystallise dithiooxamide from EtOH and sublime it at high vacuum. [*Beilstein* **2** IV 1871.]

***RS*-1,4-Dithiothreitol (DTT, Cleland's reagent)** *[3483-12-3, 27565-41-9]* **$C_4H_{10}O_2S_2$, M 154.3, m 42-43°, pK_1 8.3, pK_2 9.5.** Crystallise DTT from ether and sublime it at 37°/0.005mm. It should be stored at 0°. [*Beilstein* **1** III 2360.] It is also available as a 0.1M solution in H_2O.

All-cis*-4,7,10,13,16,19-Docosahexaenoic acid (DHA, Cervonic acid)** *[6217-54-5]* **$C_{22}H_{32}O_2$, M 328.5, m -44.1°, -44.7° to -44.5°, n_D^{20} 1.5017, pK_{Est} ~4.6.** Its solubility in $CHCl_3$ is 5%. It has been purified from fish oil by GLC using Argon as mobile phase and EGA as stationary phase with an ionisation detector [UV: Stoffel & Ahrens *J Lipid Res* **1** 139 *1959*], and *via* the ester by evaporative *molecular* distillation using a 'continuous molecular still' at 10^{-4} mm with the highest temperature being 110° and a total contact time with the hot surface being 60 seconds [Farmer & van den Heuvel *J Chem Soc* 427 *1938*, DOI: 10.1039/JR9380000427]. It was isolated in quantity from cod liver oil by Wright, Kuo & Corey [*J Org Chem* **52** 4399 *1987*, DOI: 10.1021/jo00228a050] who separated it from eicosapentaenoic acid *[10417-94-4] via* its ability to form an iodo-γ-lactone. The ***methyl ester *[2566-90-7]* has **b 208-211°/2mm**, d_4^{20} 0.9398, n_D^{20} 1.5035. With Br_2 it forms a ***dodecabromide* m *ca* 240°(dec)**. Also, the acid was converted to the methyl ester and purified through a three-stage molecular still [as described by Sutton *Chem Ind (London)* 11383 *1953*] at 96°, and the rate was adjusted so that one-third of the material was removed each cycle of three distillations. The distillate (numbered 4) (13g) was dissolved in EtOH (100ml containing 8g of KOH) at −70° and set aside for 4 hours at 30° with occasional shaking under a vacuum. Water (100ml) was added and the solution was extracted with pentane, washed with HCl, dried ($MgSO_4$), filtered and evaporated to give a clear oil (11.5g) **m -44.5° to -44.1°**. In the catalytic hydrogenation of the oil six mols of H_2 are absorbed and ***docosanoic acid (behenic acid)*** is produced with **m 79.0-79.3°** undepressed with an authentic sample (see docosanoic acid below) [Whitcutt *Biochem J* **67** 60 *1957*, DOI: 10.1042/bj0670060]. [*Beilstein* **2** IV 1812.]

Docosane (C22) *[629-97-0]* **$C_{22}H_{46}$, M 310.6, m 47°, b 224°/15mm.** Crystallise docosane from EtOH or ether. Disdtil it in a vacuum. [*Beilstein* **1** IV 572.]

Docosanoic acid (behenic acid) *[112-85-6]* **$C_{22}H_{44}O_2$, M 340.6, m 81-82°, pK_{Est} ~4.9.** Crystallise the acid from ligroin. [Francis & Piper *J Am Chem Soc* **61** 577 *1939*, DOI: 10.1021/ja01872a011; *Beilstein* **2** IV 1290.]

1-Docosanol (behenyl alcohol) *[661-19-8]* **$C_{22}H_{46}O$, M 182.3, m 70.8°.** Crystallise docosanol from ether or chloroform/ether. [*Beilstein* **1** IV 1906.]

***n*-Dodecane** *[112-40-3]* **$C_{12}H_{26}$, M 170.3, m -9.6°, b 97.5-99.5°/5mm, 216°/760mm, d_4^{20} 0.748, n_D^{20} 1.42156.** Pass it through a column of Linde type 13X molecular sieves. Store it in contact with, and distil it from sodium. Pass it through a column of activated silica gel. It has been crystallised from diethyl ether at -60°. Unsaturated dry material which remained after passage through silica gel has been removed by catalytic hydrogenation (Pt_2O) at 45lb/in^2 (3.06 atmospheres), followed by fractional distillation under reduced pressure [Zook & Goldey *J Am Chem Soc* **75** 3975 *1953*, DOI: 10.1021/ja01112a029]. It has also purified by partial crystallisation from the melt. [*Beilstein* **1** IV 498.]

Dodecane-1,10-dioic acid (decane-1,10-dicarboxylic acid) *[693-23-2]* **$C_{12}H_{22}O_4$, M 230.3, m 129°, b 245°/10mm, pK_{Est} ~4.8.** Crystallise the dioic acid from water, 75% or 95% EtOH (solubility is ~10%), or glacial acetic acid. Dry it *in vacuo*. [*Beilstein* **2** IV 2126.]

1-Dodecanol (dodecyl alcohol, lauryl alcohol) *[112-53-8]* **$C_{12}H_{26}O$, M 186.3, m 24°, b 91°/1mm, 135°/10mm, 167°/40mm, 213°/200mm, 259°/760mm, d^{24} 0.8309 (liquid).** Crystallise dodecanol from aqueous EtOH, and distil it through a spinning-band column under vacuum. [Ford & Marvel *Org Synth* **10** 62 *1930*, DOI: 10.15227/orgsyn.010.0062; *Beilstein* **1** IV 1844.]

1-Dodecanthiol (lauryl mercaptan) *[112-55-0]* **$C_{12}H_{26}S$, M 202.4, b 111-112°/3mm, 153-155°/24mm, d_4^{20} 0.844, n_D^{20} 1.458, pK_{Est} ~10.8.** Dry it with CaO for several days, then distil it from CaO. [*Beilstein* **1** IV 1851.]

Dodecylamine (lauryl amine) *[124-22-1]* **$C_{12}H_{27}N$, M 185.4, m 28°, 27-29°, 120-121°/2mm, 134°/15mm, 156°/33mm, pK^{25} 10.63.** Fractionally distil the amine, preferably under N_2 and in a vacuum. Store it in the absence of CO_2. It can be recrystallised from *n*-hexane at low temperature. The ***hydrochloride*** crystallises from Me_2CO (**m 182-183°**) or $CHCl_3$/petroleum ether (**m 185-187°**). [Magnien & Baltzly *J Org Chem* **23** 2029 *1958*, DOI: 10.1021/jo01106a630; *Beilstein* **4** H 200, III 406, **4** IV 794.] ***Dodecylammonium butyrate*** *[17615-97-3]* **M 273.4, m 39-40°, 39-41°, pK^{25} 10.63 (for free base)**, is recrystallised from *n*-hexane. [Kitahara *Bull Chem Soc Jpn* **28** 234 *1955*, DOI: org/10.1246/bcsj.28.234; *Beilstein* **4** III 409, **4** IV 797.] ***Dodecylammonium propionate*** *[17448-65-6]* **M 259.4, m 55-56°**, is recrystallised from hexanol/petroleum ether (b 60-80°). [Kitahara *Bull Chem Soc Jpn* **28** 234 *1955*, DOI: org/10.1246/bcsj.28.234; *Beilstein* **4** III 409, **4** IV 797.]

Dodecyldimethylamine *N*-oxide (DDAO, DDMAO) *[1643-20-5]* **$C_{14}H_{31}NO$, M 229.4, m 102°, 130-131°.** Crystallise the oxide from acetone, ethyl acetate or dry toluene which forms very hygroscopic needles. It is available as a ~30% solution in H_2O, and has a detergent action. **IT IS AN EYE AND SKIN IRRITANT.** [Bunton et al. *J Org Chem* **52** 3832 *1987*, DOI: 10.1021/jo00226a020; *Beilstein* **4** III 410, **4** IV 798.]

Dodecyl ether (didodecyl ether, lauryl ether) *[4542-57-8]* **$C_{24}H_{50}O$, M 354.6, m 32.5-33°, 33°, b 175°/0.15mm, d^{36} 0.8127, n^{39} 1.4393.** Distil the ether in a vacuum, then crystallise it from MeOH or MeOH/*benzene. [Mannich & Nadelmann *Chem Ber* **63** 796 *1930*, DOI: 10.1002/cber.19300630410; Butterworth & Hey *J Chem Soc* 388 *1940*, DOI: 10.1039/JR9400000388; *Beilstein* **1** III 1785, **1** IV 1846.]

Dodecyl methacrylate (lauryl methacrylate) *[142-90-5]* **$C_{16}H_{30}O_2$, M 254.4, m -7°, b 142°/4mm, d^{25} 0.8717, n_D^{25} 1.4330.** Purify the ester by fractional distillation in a high vacuum. Add 0.05% of hydroquinone monomethyl ether as stabiliser. [Rehberg & Fischer *Ind Eng Chem* **40** 1429 *1948*, DOI: 10.1021/ie50464a019; *Beilstein* **2** III 1290, **2** IV 1528.]

Dodecyltrimethylammonium bromide *[1119-94-4]* **$C_{15}H_{34}BrN$, M 308.4, m 246°(dec).** Purify the salt by repeated crystallisation from acetone. Wash it with diethyl ether and dry it in a vacuum oven at 60° [Dearden & Wooley *J Phys Chem* **91** 2404 *1987*, DOI: 10.1021/j100293a040]. [*Beilstein* **4** IV 798.] ***Dodecyltrimethylammonium chloride*** *[112-00-5]* **$C_{15}H_{34}ClN$, M 263.9, m 246°(dec)**, is purified by dissolving in MeOH, treating with active charcoal, filtering and drying *in vacuo* [Walderhaug *J Phys Chem* **88** 1655 *1984*, DOI: 10.1021/j150652a043], or recrystallising several times from 10% EtOH in acetone. It has also been repeatedly crystallised from EtOH/ether or MeOH. [Cella et al. *J Am Chem Soc* **74** 2061 *1952*, DOI: 10.1021/ja01128a061; *Beilstein* **4** IV 79.] A~50% solution in isopropanol/H_2O (4:1) is commercially available.

Eicosane (C20)

[112-95-8] **$C_{20}H_{42}$, M 282.6, m 36-37°, b 205°/15mm, $d^{36.7}$ 0.7779, n^{40} 1.43453.** Crystallise eicosane from EtOH, and/or distil it in a vacuum. [*Beilstein* **1** IV 563.]

***Cis*-5,8,11,14,17-Eicosapentaenoic acid (EPA, Omega-3, Timnodonic acid]** *[10417-94-4]* **$C_{20}H_{30}O_2$, M 302.5, m -54° to -54°, d^{25} 0.943, n_D^{20} 1.49865.** It is present in cod liver oil together with *docosahexanoic acid* which can be separated from it because it does not form an iodo-γ-lactone (see docosahexanoic acid above) [Wright et al. *J Org Chem* **52** 4399 *1987*, DOI: 10.1021/jo00228a050; Klenk & Eberhagen *Z Physiol Chem* **307** 42 *1957*]. Purification is as for docosahexanoic acid above using GLC and/or molecular distillation. [*Beilstein* **2** IV 1808.]

Elaidic (*trans*-oleic) acid *[112-79-8]* **$C_{18}H_{34}O_2$, M 282.5, m 44.5°, b 288°/100mm, pK^{25} 4.9.** Crystallise the acid from acetic acid, then EtOH. [*Beilstein* **2** IV 1647.]

Erucic acid (*cis*-13-docosenoic acid) *[112-86-7]* **$C_{22}H_{42}O_2$, M 338.6, m 33.8°, b 358°/400mm, pK_{Est} ~4.9.** Crystallise erucic acid from MeOH. [*Beilstein* **2** IV 1676.]

Ethane *[74-84-0]* **C_2H_6, M 30.1, f -172°, b -88°/atm, d_4^0 1.0493 (air = 1).** Ethylene can be removed by passing the gas through a sintered-glass disc into fuming H_2SO_4 then slowly through a column of charcoal saturated with bromine. Bromine and HBr are removed by passage through firebrick coated with *N,N*-dimethyl-*p*-toluidine. The ethane is also passed over KOH pellets (to remove CO_2) and dried with $Mg(ClO_4)_2$. Further purification is by several distillations of liquified ethane, using a condensing temperature of -195°. Yang and Gant [*J Phys Chem* **65** 1861 *1961*, DOI: 10.1021/j100827a042] treated ethane by standing it for 24 hours at room temperature in a steel bomb with activated charcoal treated with bromine. They then immersed the bomb in a Dry-ice/acetone bath and transferred the ethane to an activated charcoal trap cooled in liquid nitrogen. (The charcoal had previously been degassed by pumping for 24 hours at 450°.) By allowing the trap to warm slowly, the ethane distils, and only the middle third fraction is kept. Removal of methane is achieved using Linde type 13X molecular sieves (previously degassed by pumping for 24 hours at 450°) in a trap which, after cooling in Dry-ice/acetone, is saturated with ethane. After pumping for 10 minutes, the ethane is recovered by warming the trap to 25°. (The final gas contains less than 10^{-4} mole % of either ethylene or methane). [*Beilstein* **1** IV 108.]

Ethanesulfonyl chloride *[594-44-5]* **$C_2H_5ClO_2S$, M 128.6, b 55°/9mm, 62°/12mm, 74°/19mm, 76-79°/22mm, 95-98°/50mm, 177°/760mm, d_4^{20} 1.357, n_D^{20} 1.4539.** Purify the sulfonyl chloride by repeated distillation to remove HCl formed from hydrolysis. **It is a fuming, corrosive liquid, handle in a good fumehood.** It is hydrolysed by aqueous N NaOH at room temperature and is best stored in aliquots in sealed ampoules under N_2. [Davies & Dick *J Chem Soc* 484 *1932*, DOI: 10.1039/JR9320000483; Klamann & Drahowzal *Monatsh Chem* **83** 463 *1952*, DOI: 10.1007/BF00938572; Saunders et al. *Biochem J* **36** 368 *1942*, DOI: 10.1042/bj0360368; *Beilstein* **4** IV 34.]

Ethanethiol (ethyl mercaptan) *[75-08-1]* **C_2H_6S, M 62.1, b 32.9°/704mm, d^{52} 0.83147, pK^{25} 10.61.** Dissolve the thiol in aqueous 20% NaOH, extract it with a small amount of *benzene and then steam distil until clear. After cooling, the alkaline solution is acidified slightly with 15% H_2SO_4 and the thiol is distilled off, dried with $CaSO_4$, $CaCl_2$ or 4A molecular sieves, and fractionally distilled under nitrogen [Ellis & Reid *J Am Chem Soc* **54** 1674 *1932*, DOI: 10.1021/ja01343a067]. It has a foul odour, work in an efficient fume cupboard. Any exhausted vapours should be absorbed into an aqueous NaOH solution, and this should be oxidise with dilute H_2O_2

before disposal. [*Beilstein* **1** IV 1390.]

Ethanol *[64-17-5]* **C_2H_6O, M 46.1, m -114°, b 78.3°/atm, d^{15} 0.79360, d^5 0.78506, n_D^{20} 1.36139, pK^{25} 15.93.** Usual impurities of fermentation alcohol are fusel oils (mainly higher alcohols, especially pentanols), aldehydes, esters, ketones and water. With synthetic alcohol, likely impurities are water, aldehydes, aliphatic esters, acetone and diethyl ether. Traces of *benzene are present in ethanol that has been dehydrated by azeotropic distillation with *benzene. Anhydrous ethanol is very *hygroscopic*. Water (down to 0.05%) can be detected by formation of a voluminous precipitate when aluminium ethoxide in *benzene is added to a test portion. Rectified spirit (95% ethanol) is converted to *absolute* (99.5%) ethanol by refluxing with freshly ignited CaO (250g/L) for 6 hours, standing overnight and distilling with precautions to exclude moisture.

Numerous methods are available for further drying of *absolute* ethanol for making 'Super dry ethanol'. Lund and Bjerrum [*Chem Ber* **64** 210 *1931*, DOI: 10.1002/cber.19310640204] used reaction with magnesium ethoxide, prepared by placing 5g of clean dry magnesium turnings and 0.5g of iodine (or a few drops of CCl_4), to activate the Mg, in a 2L flask, followed by 50-75 ml of *absolute* ethanol, and warming the mixture until a vigorous reaction occurs. When this subsides, heating is continued until all the magnesium is converted to magnesium ethoxide. Up to 1L of ethanol is then added and, after refluxing for an hour, it is distilled off. The water content should be below 0.05%. Walden, Ulich and Laun [*Z Phys Chem* **114** 275 *1925*] used ***amalgamated aluminium*** chips, prepared by degreasing aluminium chips (by washing with Et_2O and drying in a vacuum to remove grease from the machining of Al), treating with alkali until hydrogen evolved vigorously, washing with H_2O until the washings were weakly alkaline and then stirring with 1% $HgCl_2$ solution. After 2 minutes, the chips were washed quickly with H_2O, then alcohol, then ether, and dried with filter paper. (The amalgam became warm.) These chips were added to the ethanol, which was then gently warmed for several hours until evolution of hydrogen ceased. The alcohol was distilled and aspirated for some time with pure dry air. Smith [*J Chem Soc* 1288 *1927*, DOI: 10.1039/JR9270001288] reacted 1L of *absolute* ethanol in a 2L flask with 7g of clean dry sodium, and added 25g of pure ethyl succinate (27g of pure ethyl phthalate was an alternative), and refluxed the mixture for 2 hours in a system protected from moisture, and then distilled the ethanol. A modification used 40g of ethyl formate instead, so that sodium formate separated out and, during reflux the excess of ethyl formate decomposed to CO and ethanol.

Drying agents suitable for use with ethanol include Linde type 4A molecular sieves, calcium metal, and CaH_2. The calcium hydride (2g) is crushed to a powder and dissolved in 100ml of *absolute* ethanol by gently boiling. About 70ml of the ethanol are distilled off to remove any dissolved gases before the remainder is poured into 1L of *ca* 99.9% ethanol in a still, where it is boiled under reflux for 20 hours, while a slow stream of pure, dry hydrogen (better use nitrogen or Ar) is passed through. It is then distilled [Rüber *Z Elektrochem* **29** 334 *1923*]. If calcium is used for drying, about ten times the theoretical amount should be used, and traces of ammonia (from some calcium nitride in the Ca metal) would be removed by passing dry air into the vapour during reflux. Ethanol can be freed from traces of basic materials by distillation from a little 2,4,6-trinitrobenzoic acid or sulfanilic acid. *Benzene can be removed by fractional distillation after adding a little water (the *benzene/water/ethanol azeotrope distils at 64.9°), the alcohol is then re-dried using one of the methods described above. *Alternatively*, careful fractional distillation can separate *benzene as the *benzene/ethanol azeotrope (**b** 68.2°). Aldehydes can be removed from ethanol by digesting with 8-10g of dissolved KOH and 5-10g of aluminium or zinc per L, followed by distillation. Another method is to heat under reflux with KOH (20g/L) and $AgNO_3$ (10g/L) or to add 2.5-3g of lead acetate in 5ml of water to 1L of ethanol, followed (slowly and without stirring) by 5g of KOH in 25ml of ethanol: after 1 hour the flask is shaken thoroughly, then set aside overnight before filtering and distilling. The residual water can be removed by standing the distillate over activated aluminium amalgam for 1 week, then filtering and distilling. Distillation of ethanol from Raney nickel eliminates catalyst poisons.

Other purification procedures include pre-treatment with concentrated H_2SO_4 (3ml/L) to eliminate amines, and with $KMnO_4$ to oxidise aldehydes, followed by refluxing with KOH to resinify aldehydes, and distilling to remove traces of H_3PO_4 and other acidic impurities after passage through silica gel, and drying over $CaSO_4$. Water can be removed by azeotropic distillation with dichloromethane (azeotrope boils at 38.1° and contains 1.8% water) or 2,2,4-trimethylpentane. [*Beilstein* **1** IV 1289.]

Rapid purification: Place degreased Mg turnings (grease from machining the turnings is removed by washing with dry EtOH then Et_2O, and drying in a vacuum) (5g) in a dry 2L round bottomed flask fitted with a reflux condenser (protect from air with a drying tube filled with $CaCl_2$ or KOH pellets) and flushed with dry N_2. Then

add iodine crystals (~0.5g) and gently warm the flask until iodine vapour is formed and coats the turnings. Cool, then add EtOH (50ml) and carefully heat to reflux until the iodine disappears. Cool again, then add more EtOH (to 1L) and reflux under N_2 for several hours. Distil and store over 3A molecular sieves (pre-heated at 300° –350° for several hours and cooled under dry N_2 or argon).

Ethoxycarbonyl isocyanate (ethyl isocyanatoformate) *[19617-43-7]* **$C_4H_5NO_3$, M 115.1, b 25°/10mm, 51-55°/13mm, 56°/18mm, 115-116°/781mm, d_4^{20} 1.15.** Distil it twice from P_2O_5 (1-2g) through a small Vigreux column and then through a 20-plate column. All fractional distillations should be under a vacuum. [Lamon *J Heterocycl Chem* **5** 837 *1968*, DOI: 10.1002/jhet.5570050616; *Beilstein* **3** H 36, **3** I 17.]

Ethoxycarbonyl isothiocyanate *[16182-04-0]* **$C_{18}H_{22}NO_2S$, M 131.2, b 43°/14mm, 51-55°/13mm, 56°/18mm, d_4^{20} 1.12.** Fractionally distil it through a short column. It also distils at 83°/30mm with some decomposition liberating CO_2 and sulfurous gases; best distil below 20mm vacuum. [Capp et al. *J Chem Soc* 1340, *1948*, DOI: 10.1039/JR9480001340; Lamon *J Heterocycl Chem* **5** 837 *1968*, DOI: 10.1002/jhet.5570050616; *Beilstein* **3** H 174, **3** I 71, **3** III 279, **3** IV 323.]

2-Ethoxyethanol (Cellosolve, ethylene glycol monoethyl ether) *[110-80-5]* **$C_4H_{10}O_2$, M 90.1, m -90°, b 134.8°, d_4^{20} 0.931, n_D^{20} 1.40751.** Dry it with $CaSO_4$ or K_2CO_3, filter and fractionally distil it. Peroxides can be removed by refluxing with anhydrous $SnCl_2$ or by filtration under slight pressure through a column of activated alumina. [*Beilstein* **1** IV 2377.]

2-Ethoxyethyl methacrylate *[2370-63-0]* **$C_8H_{14}O_3$, M 158.2, b 91-93°/35mm, d_4^{20} 0.965, n_D^{20} 1.429.** Purify the ester as described under methyl methacrylate below. If it has to be stored for some time add hydroxyquinone monomethyl ether *[150-76-5]* (to 50 ppm as stabiliser). [*Beilstein* **2** III 1291.]

Ethyl acetate *[141-78-6]* **$C_4H_8O_2$, M 88.1, m -84°, b 77.1°/atm, d_4^{20} 0.9003, n_D^{20} 1.37239, n^{25} 1.36979, pK^{25} -6.93 (aqueous H_2SO_4).** The most common impurities in EtOAc are water, EtOH and acetic acid. These can be removed by washing with aqueous 5% Na_2CO_3, then with saturated aqueous $CaCl_2$ or NaCl, and drying with K_2CO_3, $CaSO_4$ or $MgSO_4$. More efficient drying is achieved if the solvent is further dried with P_2O_5, CaH_2 or molecular sieves before distillation. CaO has also been used. *Alternatively*, ethanol can be converted to ethyl acetate by refluxing with acetic anhydride (*ca* 1ml per 10ml of ester), the liquid is then fractionally distilled, dried with K_2CO_3 and redistilled. [*Beilstein* **2** III 127.]
Rapid purification: Distil, dry over K_2CO_3, re-distil and store over 4A molecular sieves.

Ethyl acetimidate *[1000-84-6]* **C_4H_9NO, M 87.1, b 92-95°/atm, 89.7-90°/765mm, d_4^{20} 0.8671, n_D^{20} 1.4025, pK_{Est} ~5.5.** It is best to prepare it freshly from the *hydrochloride* (see below). Dissolve the hydrochloride (123.5g) by adding it slowly to an ice-cold mixture of H_2O (500ml), K_2CO_3 (276g) and Et_2O (200ml) and stirring rapidly. The Et_2O layer is separated, the aqueous layer is extracted with Et_2O (100ml), the combined Et_2O layers are dried ($MgSO_4$), evaporated and the residual oil is distilled through a glass helices packed column (70x1.2cm). The yield is 19g (22%). It is best to keep it as the hydrochloride (see below), and to liberate the *free base* as described when required. [Glickman & Cope *J Am Chem Soc* **67** 1012 *1945*, DOI: 10.1021/ja01222a035; Chaplin & Hunter *J Chem Soc* 1114 *1937*, DOI: 10.1039/JR9370001114; Hunter & Ludwig *Methods Enzymol* **25** 585 *1972*, DOI: 10.1016/S0076-6879(72)25058-3.]

Ethyl acetimidate hydrochloride *[2208-07-3]* **C_4H_9NO. HCl, M 123.6, m 98-100°(dec), 110-115°(dec), 112-113°(dec), m 112-114°(dec), pK_{Est} ~5.5.** Recrystallise the hydrochloride by dissolving it in the minimum volume of super dry EtOH and adding dry Et_2O, or from dry Et_2O. Dry it in a vacuum and store it in a vacuum desiccator with P_2O_5. *Alternatively*, it could be crystallised from EtOH (containing a few of drops of ethanolic HCl) and adding dry Et_2O. Filter and dry (and store) it in a vacuum desiccator over H_2SO_4 and NaOH. [Pinner *Chem Ber* **16** 1643 *1883*, DOI: 10.1002/cber.18830160235; Glickman & Cope *J Am Chem Soc* **67** 1017 *1945*, DOI: 10.1021/ja01222a034; Chaplin & Hunter *J Chem Soc* 1114 *1937*, DOI: 10.1039/JR9370001114; McElvain & Schroeder *J Am Chem Soc* **71** 40 *1949*, DOI: 10.1021/ja01169a013; McElvain & Tate *J Am Chem Soc* **73** 2233 *1951*, DOI: 10.1021/ja01149a090; *Methods Enzymol* **25** 585 *1972*, DOI: 10.1016/S0076-6879(72)25058-3; *Beilstein* **2** III 418.]

Ethyl acetoacetate *[141-97-9]* **$C_6H_{10}O_3$, M 130.1, m -43°, b 71°/12mm, 100°/80mm, d_4^{20} 1.026, n_D^{20} 1.419, pK^{25} 10.68.** Shake the ester with small amounts of saturated aqueous $NaHCO_3$ (until no further effervescence), then with water. Dry it with $MgSO_4$ or $CaCl_2$ and distil it under reduced pressure. [*Beilstein* **3** 632, **3** I 224, **3** IV 1528.]

Ethyl acrylate *[140-88-5]* **$C_4H_6O_2$, M 100.1, m -71°, b 20°/40mm, 99.5°/atm, d_4^{20} 0.922, n_D^{20} 1.406.** Wash the ester repeatedly with aqueous NaOH until free from inhibitors such as hydroquinone, then wash it with saturated aqueous $CaCl_2$ and distil it under reduced pressure. Hydroquinone should be added if the ethyl acrylate is to be stored for extended periods. [*Beilstein* **2** IV 1460.] **LACHRYMATORY.**

Ethylamine *[75-04-7]* **C_2H_7N, M 45.1, m -81°, b 16.6°/760mm, d_4^{20} 1.3663, pK^{20} 10.79.** Condense it in an all-glass apparatus cooled by circulating ice-water, and store it with KOH pellets below 0°. [*Beilstein* **4** IV 307.] ***Ethylamine hydrochloride*** *[557-66-4]* **C_2H_7N. HCl, M 81.5, m 109-110°**, is crystallised from absolute EtOH or MeOH/$CHCl_3$, washed with dry ether and dried in a vacuum. [*Beilstein* **4** IV 310.]

Ethyl bromide *[74-96-4]* **C_2H_5Br, M 109.0, m -119°, b 0°/165mm, 38°/745mm, d_4^{20} 1.460, n_D^{20} 1.4241.** The main impurities are usually EtOH and water, both of which form azeotropes with it. Ethanol and unsaturated compounds can be removed by washing with concentrated H_2SO_4 until no further coloration is produced. The ethyl bromide is then washed with water, aqueous Na_2CO_3, and water again, then dried with $CaCl_2$, $MgSO_4$ or CaH_2, and distilled from P_2O_5. Olefinic impurities can also be removed by storing the ethyl bromide in daylight with elemental bromine, later removing the free bromine by extraction with dilute aqueous Na_2SO_3, drying the ethyl bromide with $CaCl_2$ and fractionally distilling it. *Alternatively*, unsaturated compounds can be removed by bubbling oxygen containing *ca* 5% ozone through the liquid for an hour, then washing with aqueous Na_2SO_3 to hydrolyse ozonides and remove hydrolysis products, followed by drying and distillation. [*Beilstein* **1** IV 150.]

Ethyl bromoacetate *[105-36-2]* **$C_4H_7BrO_2$, M 167.0, b 158-158.5°/758mm, d_4^{20} 1.50, n_D^{20} 1.450.** Wash the ester with saturated aqueous Na_2CO_3 (three times), 50% aqueous $CaCl_2$ (three times) and saturated aqueous NaCl (twice). Dry with $MgSO_4$, $CaCl_2$ or $CaCO_3$, and distil it. [*Beilstein* **2** IV 527.] **LACHRYMATORY.**

Ethyl 6-bromohexanoate (ethyl 6-bromocaproate) *[25542-62-5]* **$C_8H_{15}BrO_2$, M 223.1, b 120-125°/14mm, 126-127°/20-21mm, 128-130°/16mm, 127-130°/19mm, d_4^{20} 1.241, d^{25} 1.254, n_D^{20} 1.458, n_D^{25} 1.4566.** 6-Bromohexanoic acid (250g) is esterified by refluxing with EtOH (600ml) containing H_2SO_4 (15ml) for 8 hours, evaporating *in vacuo*, the residue is taken up in Et_2O, washed with H_2O, then 5% of aqueous Na_2CO_3 (effervescence), the Et_2O layer is dried ($CaCl_2$), filtered, evaporated, and the residual oil is distilled to give the ester (178-218g). [Brown & Partridge *J Am Chem Soc* **66** 839 *1844*, DOI: 10.1021/ja01233a503.] It has also been prepared from 6-hydroxyhexanoic acid by reaction with PBr_3 in pyridine, or HBr (*d* 1.5) and H_2SO_4 and then esterifying in the same way [Barger et al. *J Chem Soc* 718 *1937,* DOI: 10.1039/JR9370000718]. [*Beilstein* **2** IV 940.]

Ethyl 2-(bromomethyl)acrylate *[17435-72-2]* **$C_6H_9BrO_2$, M 193.1, b 38°/0.8mm, d_4^{20} 1.398, n_D^{20} 1.479.** If it contains some free acid, add H_2O, cool, and neutralise with $NaHCO_3$ until evolution of CO_2 ceases. Extract the mixture with Et_2O (3x) and dry the combined extracts (Na_2SO_4, 3 hours). Evaporate Et_2O and distil the ester collecting fraction **b** 39-40°/0.9mm, and check spectra. [Preparation and NMR: Ramarajan et al. *Org Synth* Coll Vol **7** 210 *1990*, DOI: 10.15227/orgsyn.061.0056; *Beilstein* **2** IV 1541.]

Ethyl 2-bromopropionate *[535-11-5]* **$C_5H_9BrO_2$, M 181.0, b 69-70°/25mm, 159-160°/atm, d_4^{20} 1.39, n_D^{20} 1.447.** Wash the ester with saturated aqueous Na_2CO_3 (three times), 50% aqueous $CaCl_2$ (three times) and saturated aqueous NaCl (twice). Dry with $MgSO_4$, $CaCl_2$ or $CaCO_3$, and distil it. [*Beilstein* **2** IV 762.] **LACHRYMATORY.**

Ethyl 3-bromopropionate *[539-74-2]* **$C_5H_9BrO_2$, M 181.0, b 64-65°/5mm, 62.5°/10mm, 67-67.5°/12mm, 112°/44mm (?), 98°/49mm, d_4^{20} 1.452, n_D^{20} 1.452.** Purify by carefully fractionating through a short column under reduced pressure. Store away from light as it becomes yellow on standing. [Oae *J Am Chem Soc* **78** 4030 *1956*, DOI: 10.1021/ja01597a044; *Mozingo & Patterson Org Synth* Coll Vol **3** 576 *1955*, DOI: 10.15227/

[*Beilstein* **3** IV 23.] **LACHRYMATORY AND TOXIC.**

Ethyl *trans*-crotonate *[623-70-1]* **$C_6H_{10}O_2$, M 114.2, b 137°/atm, d_4^{20} 0.917, n_D^{20} 1.425.** Wash it with aqueous 5% Na_2CO_3, then with saturated aqueous $CaCl_2$, dry it with $CaCl_2$ and distil it. [*Beilstein* **2** IV 1500.]

Ethyl cyanoacetate *[105-56-6]* **$C_5H_7NO_2$, M 113.1, m -22°, b 206.0°/atm, d_4^{20} 1.061, n_D^{20} 1.41751.** Shake the ester several times with aqueous 10% Na_2CO_3, wash it well with water, dry with Na_2SO_4 and fractionally distil it. [*Beilstein* **2** IV 1889.]

Ethyl cyanoformate *[623-49-4]* **$C_4H_5NO_2$, M 99.1, b 113-114°/740mm, 116.5-116.8°/765.5mm, d_4^{20} 1.0112, n_D^{20} 1.3818.** Dissolve the cyanoformate in Et_2O, dry it over Na_2SO_4, filter, evaporate and distil it [Malachowski et al. *Chem Ber* **70** 1012 *1937*, DOI: 10.1002/cber.19370700527; Adickes et al. *J Prakt Chem* [2] **133** 313 *1932*, DOI: 10.1002/prac.19321331101; Grundmann et al. *Justus Liebigs Ann Chem* **577** 77 *1952*, DOI: 10.1002/jlac.19525770110]. [*Beilstein* **2** IV 1862.]

Ethyl diazoacetate *[623-73-4]* **$C_4H_6N_2O_2$, M 114.1, m -22°, b 42°/5mm, 45°/12mm, 85-86°/88mm, 140-141°/720mm, 140-143°/atm, $d_4^{17.6}$ 1.0852, $n_D^{17.6}$ 1.4588.** It is a very volatile yellow oil with a strong pungent odour. **EXPLOSIVE [distillation even under reduced pressure is dangerous and may result in an explosion — TAKE ALL THE NECESSARY PRECAUTIONS IF DISTILLATION IS TO BE CARRIED OUT].** It explodes in contact with concentrated H_2SO_4-trace acid causes rapid decomposition. It is slightly soluble in H_2O, but is miscible with EtOH, $*C_6H_6$, petroleum ether and Et_2O. To purify, dissolve it in Et_2O [using CH_2Cl_2 instead of Et_2O, protects the ester from acid], wash it with 10% aqueous Na_2CO_3, dry ($MgSO_4$), filter and repeat as many times as possible until the Et_2O layer loses its yellow colour, then remove the solvent below 20° (vacuum). Note that prolonged heating may lead to rapid decomposition and low yields. It can also be purified by steam distillation under reduced pressure but with considerable loss in yield. Place the residual oil in a brown bottle, keep below 10°, and use as soon as possible without distilling. For preparing esters usually the ethereal solution is used directly without purification. [Womack & Nelson *Org Synth* Coll Vol **3** 392 *1955*, DOI: 10.15227/orgsyn.024.0056; UV: Miller & White *J Am Chem Soc* **79** 5974 *1957*, DOI: 10.1021/ja01579a035; Fieser **1** 367 *1967*, *Beilstein* **3** IV 1495.]

Ethyl dibromoacetate *[617-33-4]* **$C_4H_6Br_2O_2$, M 245.9, b 81-82°/14.5mm, 194°/atm, d^{22} 1.9081, n^{22} 1.4973.** Wash the ester briefly with concentrated aqueous $NaHCO_3$, then with aqueous $CaCl_2$. Dry it with $CaSO_4$ and distil it under reduced pressure. [Hornyak & Amis *J Am Chem Soc* **79** 2079 *1957*, DOI: 10.1021/ja01566a015; *Beilstein* **2** H 219, **2** I 97, **2** III 484, **2** IV 533.]

Ethyl dichloroacetate *[535-15-9]* **$C_4H_6Cl_2O_2$, M 157.0, b 54-55°/11mm, 131.0-131.5°/40mm, d_4^{20} 1.28, n_D^{20} 1.438.** Shake the ester with aqueous 3% $NaHCO_3$ to remove free acid, wash with distilled water, dry for 3 days with $CaSO_4$ and distil it under reduced pressure. [*Beilstein* **2** IV 501.]

Ethyl 3,3-diethoxypropionate *[10601-80-6]* **$C_9H_{18}O_4$, M 190.2, b 58.5°/1.5mm, 65°/2mm, 95-96°/12mm, d_4^{20} 0.78, n_D^{25} 1.4101.** Dissolve it in dry Et_2O, and dry with solid $NaHCO_3$, filter, distil and carefully fractionate it [Dyer & Johnson *J Am Chem Soc* **56** 222 *193*, DOI: 10.1021/ja01316a070]. [*Beilstein* **3** II 411.]

Ethylene (ethene) *[74-85-1]* **C_2H_4, M 28.0, m -169.4°, b -102°/700mm.** Purify ethylene by passage through a series of towers containing molecular sieves, or anhydrous $CaSO_4$, or cuprous ammonium solution, then concentrated H_2SO_4, followed by KOH pellets. *Alternatively*, it has been condensed in liquid nitrogen, with melting, freezing and pumping to remove air before passage through an activated charcoal trap, followed by a further condensation in liquid air. A sputtered sodium trap was used to remove oxygen. [*Beilstein* **1** IV 677.]

Ethylenediamine (1,2-diaminoethane) *[107-15-3]* **$C_2H_8N_2$, M 60.1, f 11.0°, m -8.5°, b 117.0°/atm, d_4^{20} 0.897, n_D^{20} 1.45677, n^{30} 1.4513, pK_1^{25} 6.86, pK_2^{25} 9.92.** It forms a constant-boiling (**b 118.5°**, ***monohydrate***, **m 10°**) mixture with water (23w/w%). [It is *hygroscopic* and miscible with water.] Recommended purification procedure [Asthana & Mukherjee in J.F .Coetzee (ed), *Purification of Solvents,* Pergamon Press, Oxford, 1982 cf. p 53]: to 1L of ethylenediamine is added 70g of type 5A Linde molecular sieves and shaken for 12 hours. The liquid is decanted and shaken for a further 12 hours with a mixture of CaO (50g) and KOH (15g). The supernatant is fractionally distilled (at 20:1 reflux ratio) in contact with freshly activated molecular sieves. The fraction distilling at 117.2°/760mm is collected. Finally it is fractionally distilled from sodium metal. All distillations and storage of ethylenediamine should be carried out under nitrogen to prevent reaction with CO_2 and water. The material containing 30% water is dried with solid NaOH (600g/L) and heated on a water bath for 10 hours. Above 60°, separation into two phases takes place. The hot ethylenediamine layer is decanted off, refluxed with 40g of sodium for 2 hours and distilled [Putnam & Kobe *Trans Electrochem Soc* **74** 609 *1938*, DOI:10.1149/1.3494023]. Ethylenediamine is usually distilled under nitrogen. *Alternatively*, it is dried over type 5A Linde molecular sieves (70g/L), then a mixture of 50g of CaO and 15g of KOH/L, with further dehydration of the supernatant with molecular sieves followed by distillation *from* molecular sieves and, finally, from sodium metal. A spectroscopically improved material is obtained by shaking with freshly baked alumina (20g/L) before distillation. [*Beilstein* **4** IV 1166.] ***Ethylenediamine dihydrochloride*** *[333-18-6]* **$C_2H_8N_2$, 2HCl. M 133.0, m >300°, pK_1^{25} 6.86, pK_2^{25} 9.92**, is recystallised from H_2O or H_2O/EtOH. Wash the crystals with EtOH and dry them *in vacuo*. It sublimes on heating. [*Beilstein* **4** IV 1168.]

***N,N'*-Ethylenediaminediacetic acid (EDDA)** *[5657-17-0]* **$C_6H_{12}N_2O_4$, M 176.2, m 222-224°(dec), pK_1^{25} 6.48, pK_2^{25} 9.57 (for NH groups).** Crystallise EDDA from H_2O. [*Beilstein* **4** IV 2446.]

Ethylenediaminetetraacetic acid (EDTA) *[60-00-4]* **$C_{10}H_{18}N_2O_8$, M 292.2, m 253°(dec), pK_1^{25} 0.26 pK_2^{25} 0.96, pK_3^{25} 2.60, pK_4^{25} 2.67, pK_5^{25} 6.16, pK_6^{25} 10.26.** Dissolve EDTA in aqueous KOH or ammonium hydroxide, and precipitate it twice with dilute HCl or HNO_3. Boil it twice with distilled water to remove mineral acid, then recrystallise it from water or dimethylformamide. Dry it at 110°. It also recrystallises from boiling 1N HCl; wash the crystals with distilled H_2O and dry them *in vacuo*. [Ma & Ray *Biochemistry* **19** 751 *1980*, DOI: 10.1021/bi00545a022s; *Beilstein* **4** IV 2449.] It is a sequestering agent and a useful buffer

Ethylene dimethacrylate (ethylene glycol dimethacrylate) *[97-90-5]* **$C_{10}H_{14}O_4$, M 198.2, b 98-100°/5mm, d_4^{20} 1.053, n_D^{20} 1.456.** Distil it through a short Vigreux column (p 11) at about 1mm pressure, in the presence of 3% (w/w) of phenyl-ß-naphthylamine. [*Beilstein* **2** IV 1532.]

Ethylene dimyristate [1,2-bis(myristoyloxy)ethane] *[627-84-9]* **$C_{30}H_{58}O_4$, M 482.8, m 61.7°.** Crystallise the ester from *benzene/MeOH or diethyl ether/MeOH, and dry it in a vacuum desiccator. It forms an inclusion compound with 25.9 mols of urea. [McGreer et al. *J Am Chem Soc* **74** 3541 *1952*, DOI: 10.1021/ja01134a025; *Beilstein* **2** H 366, **2** II 327, **2** III 924, **2** IV 1133.]

Ethylene dipalmitate [1,2-bis(palmitoyloxy)ethane] *[624-03-3]* **$C_{34}H_{66}O_4$, M 538.9, m 69.1°, 71.2°.** Crystallise the ester from *benzene/MeOH , diethyl ether/MeOH or Me_2CO and dry it in a vacuum desiccator. It forms an inclusion compound with 28.2 mols of urea. [McGreer et al. *J Am Chem Soc* **74** 3541 *1952*, DOI: 10.1021/ja01134a025; *Beilstein* **2** H 373, **2** I 166, **2** II 338, **2** III 926, **2** IV 1169.]

Ethylene distearate [1,2-bis(stearoyloxy)ethane] *[627-83-8]* **$C_{38}H_{74}O_4$, M 595.0, m 74.4-75°, 75.3°, 77°.** Crystallise the ester from *benzene/MeOH, diethyl ether/MeOH or Me_2CO and dry it in a vacuum desiccator. It forms an inclusion compound with 31 mols of urea. [McGreer et al. *J Am Chem Soc* **74** 3541 *1952*, DOI: 10.1021/ja01134a025; *Beilstein* **2** H 380, **2** II 354, **2** III 1021, **2** IV 1223.]

Ethylene glycol *[107-21-1]* **$C_2H_6O_2$, M 62.1, m -13°, b 68°/4mm, 197.9°/760mm, d_4^{20} 1.0986, n^{15} 1.43312, n^{25} 1.43056, pK^{25} 10.6.** It is very *hygroscopic*, and also likely to contain higher diols. Dry it with CaO, $CaSO_4$, $MgSO_4$ or NaOH and distil it under vacuum. Dry further by reaction with a small amount of sodium under N_2 (to remove moisture), reflux for several hours and distil. The distillate is then passed through a column of Linde type 4A molecular sieves and finally distil under nitrogen, from more molecular sieves. Then fractionally distil

it. [*Beilstein* **1** IV 2369.] ***Ethylene glycol diacetate*** *[111-55-7]* **$C_6H_{10}O_4$, M 146.2, m -41°, b 190.1°, 79-81°/11mm, d^{25} 1.4188, n_D^{20} 1.4150**, should be dried with $CaCl_2$, filtered (excluding moisture), and fractionally distil it under reduced pressure. [*Beilstein* **2** IV 217 1541.]

Ethylene glycol-bis(2-aminoethylether)-*N,N,N',N'*-tetraacetic acid (EGTA, Egtazic acid) *[67-42-5]* **$C_{14}H_{24}N_2O_{10}$, M 380.4, m >245°(dec), pK_1^{20} 1.15 (2.40), pK_2^{20} 2.40 (2.50), pK_3^{20} 8.40 (8.67), pK_4^{20} 8.94 (9.22).** Dissolve EGTA in aqueous NaOH, precipitate it by adding aqueous HCl, wash it with water and dry at 100° *in vacuo*. [*Beilstein* **4** IV 2483.] it is a useful buffer.

Ethylene glycol dibutyl ether *[112-48-1]* **$C_{10}H_{22}O_2$, M 174.3, b 78-80°/16mm, 200-201°/760mm, d_4^{20} 1.105, n_D^{20} 1.42.** Shake the ether with aqueous 5% Na_2CO_3, dry with $MgSO_4$ and store it with chromatographic alumina to prevent peroxide formation. [*Beilstein* **1** III 2083, **1** IV 2382.]

Ethylene glycol diethyl ether (1,2-diethoxyethane) *[629-14-1]* **$C_6H_{14}O_2$, M 118.2, m -74°, b 121.5°/atm, d_4^{20} 0.842, n_D^{20} 1.392.** After refluxing for 12 hours, a mixture of the ether (2L), concentrated HCl (27ml) and water (200ml) is added with slow passage of nitrogen. The solution is cooled, and KOH pellets are added slowly and with shaking until no more dissolves. The organic layer is decanted, treated with some KOH pellets and again decanted. It is then refluxed with, and distilled from sodium immediately before use. *Alternatively*, after removal of peroxides by treatment with activated alumina, the ether is refluxed in the presence of the blue ketyl formed by sodium-potassium alloy with benzophenone, then distilled. [*Beilstein* **1** H 468, **1** II 519, **1** III 2078, **1** IV 2379.]

Ethyl formate *[109-94-4]* **$C_3H_6O_2$, M 74.1, m -80°, b 54.2°/atm, d_4^{20} 0.921, d^{30} 0.909, n_D^{20} 1.35994, n^{25} 1.3565.** Free acid or alcohol is removed by standing the ester over anhydrous K_2CO_3, with occasional shaking, then decanting and distilling from P_2O_5. *Alternatively*, the ester can be kept over CaH_2 for several days, then distilled from fresh CaH_2. It cannot be dried with $CaCl_2$ because it reacts rapidly with the ester to form a crystalline compound. [*Beilstein* **2** IV 23.]

Ethyl iodide (iodoethane) *[75-03-6]* **C_2H_5I, M 156.0, m -108°, b 72.4°/atm, d_4^{20} 1.933, n^{15} 1.5682, n^{25} 1.5104.** Drying the iodide with P_2O_5 is unsatisfactory, and with $CaCl_2$ it is incomplete. It is probably best to dry it with sodium wire and distil [Hammond et al. *J Am Chem Soc* **82** 704 *1960*, DOI: 10.1021/ja01488a051]. Exposure of ethyl iodide to light leads to rapid decomposition, with the liberation of iodine. Free iodine can be removed by shaking with several portions of dilute aqueous $Na_2S_2O_3$ (until the colour is discharged), followed by washing with water, drying (with $CaCl_2$, then sodium), and distilling. The distilled ethyl iodide is stored, over some mercury, in a dark bottle away from direct sunlight. Other purification procedures include passage through a 60cm column of silica gel, followed by distillation, and treatment with elemental bromine, extraction of free halogen with $Na_2S_2O_3$ solution, followed by washing with water, drying and distilling. Free iodine and HI have also been removed by direct distillation through a LeBel-Henninger column containing copper turnings. Purification by shaking with alkaline solutions, and storage over silver, are reported to be unsatisfactory. [*Beilstein* **1** IV 163.]

Ethyl isobutyrate *[97-62-1]* **$C_6H_{12}O_2$, M 116.2, b 110°/atm, d_4^{20} 0.867, n_D^{20} 1.388.** Wash the ester with aqueous 5% Na_2CO_3, then with saturated aqueous $CaCl_2$. Dry it over $CaSO_4$ and distil. [*Beilstein* **1** IV 846.]

Ethyl isocyanate *[109-90-0]* **C_3H_5NO, M 71.1, b 559.8°/759mm, 59-61°/760mm, 60-63°/~760mm, d_4^{20} 0.9031, n_D^{20} 1.3808.** Fractionate the isocyanate through an efficient column preferably in an inert atmosphere and store it in aliquots in sealed tubes [Bieber *J Am Chem Soc* **74** 4700 *1952*, DOI: 10.1021/ja01138a501; Slocombe et al. *J Am Chem Soc* **72** 1888 *1950*, DOI: 10.1021/ja01161a009]. [*Beilstein* **4** IV 402.]

Ethyl isovalerate *[108-64-5]* **$C_7H_{14}O_2$, M 130.2, m -99°, b 134.7°/atm, d_4^{20} 0.8664, n_D^{20} 1.39621, n^{25} 1.3975.** Wash the ester with aqueous 5% Na_2CO_3, then saturated aqueous $CaCl_2$. Dry it over $CaSO_4$ and distil. [*Beilstein* **2** IV 898.]

Ethyl levulinate (4-oxopentanoic acid ethyl ester) *[539-88-8]* **$C_7H_{12}O_3$, M 144.2, m 37.2°, b 106-108°/2mm,**

138.8°/8mm, 203-205°/atm, d_4^{20} 1.012, n_D^{20} 1.423. Stir the ester with Na_2CO_3 and charcoal, filter and distil. It is freely soluble in H_2O and EtOH [IR, NMR: Sterk *Monatsh Chem* **99** 1770 *1968*, DOI:10.1007/BF00904307; Thomas & Schuette *J Am Chem Soc* **53** 2324 *1931*, DOI: 10.1021/ja01357a043; Cox & Dodds *J Am Chem Soc* **55** 3391 *1933*, DOI: 10.1021/ja01335a059]. [*Beilstein* **3** IV 1562.]

Ethyl malonate monoamide *[7597-56-0]* **$C_5H_9NO_3$, M 131.1, m 47-50°, 49.5-50°, 50°, b 130-135°/2mm.** The amide crystallises from Et_2O, or by slow evaporation of an aqueous solution as colourless crystals [Snyder & Elston *J Am Chem Soc* **76** 3039 *1954*, DOI: 10.1021/ja01640a060; McElvain & Schroeder *J Am Chem Soc* **71** 45 *1949*, DOI: 10.1021/ja01169a014; Rising et al. *J Biol Chem* **89** 1 *1930*, http://www.jbc.org/content/89/1/1]. [*Beilstein* **2** IV 1887.]

Ethyl methacrylate *[97-63-2]* **$C_6H_{10}O_2$, M 114.2, b 59°/100mm, 118-119°/atm, d_4^{20} 0.915, n_D^{20} 1.515.** Wash the ester successively with 5% aqueous $NaNO_2$, 5% $NaHSO_3$, 5% NaOH, then water. Dry it over $MgSO_4$, add 0.2% (w/w) of phenyl-ß-naphthylamine, and distil it through a short Vigreux column [Schultz *J Am Chem Soc* **80** 1854 *1958*, DOI: 10.1021/ja01541a020]. [*Beilstein* **2** IV 1523.]

Ethyl methyl ether *[540-67-0]* **C_3H_8O, M 60.1, b 7°/760mm, d^o 0.725, n^4 1.3420.** Dry the ether with $CaSO_4$, pass it through an alumina column (to remove peroxides), then fractionally distil it while collecting fractions in receivers kept below 0°. It has a high solubility in H_2O. [*Beilstein* **1** H 314, **1** I 158, **1** II 311, **1** III 1288, **1** IV 1314.] **HIGHLY FLAMMABLE.**

3-Ethyl-2-methyl-2-pentene *[19780-67-7]* **C_8H_{16}, M 112.1, b 109°/757mm, 114.5°/760mm, d_4^{20} 0.72468, n_D^{20} 1.4124.** Purify it by preparative GLC on a column of 20% squalene on Chromosorb P at 70°. *Alternatively*, fractionate it under an inert atmosphere. It forms an azeotrope with methoxyethanol. [*Beilstein* **1** H 222, **1** III 8471, **1** IV 890.]

Ethyl nitroacetate *[626-35-7]* **$C_4H_7NO_4$, M 133.1, b 42-43°/0.2mm, 71-72°/3mm, 93-96°/9mm, 194-195°/atm, d_4^{20} 1.1953, n_D^{20} 1.4260, pK^{25} 5.82.** Purify the ester by repeated distillation. IR has ν_{max} at 1748 (CO_2), 1570 and 1337 (NO_2), and 800cm^{-1} [Haszeldine *J Chem Soc* 2525 *1953,* DOI: 10.1039/JR9530002525]. The ***hydrazine salt*** crystallises from 95% EtOH or MeOH as yellow crystals **m 104-105°** [Ungnade & Kissinger *J Org Chem* **22** 1662 *1957*, DOI: 10.1021/jo01363a034; Emmons & Freeman *J Am Chem Soc* **77** 4391 *1955*, DOI: 10.1021/ja01621a060]. [*Beilstein* **2** IV 537.]

Ethyl propionate *[105-37-3]* **$C_5H_{10}O_2$, M 102.1, b 99.1°/atm, d_4^{20} 0.891, n^{15} 1.38643, n_D^{20} 1.38394.** Treat the ester with anhydrous $CuSO_4$ and distil it under nitrogen. [*Beilstein* **2** IV 705.]

Ethyl pyruvate *[617-35-6]* **$C_5H_8O_3$, M 116.1, m -50°, b 44-45°/10mm, 56°/20mm, 69-71°/42mm, 63°/23mm, 155.5°/760mm, d_4^{20} 1.047, n_D^{20} 1.4052.** Shake the ester with 10ml portions of saturated aqueous $CaCl_2$ solution (removes ethyl acetate) and the organic layer is removed by centrifugation, decantation and filtration, and is distilled under reduced pressure. Purification of small quantities is carried out *via* the bisulfite adduct: the ester (2.2ml) is shaken with saturated $NaHSO_3$ (3.6ml), chilled in a freezing mixture when crystals separate rapidly (particularly if seeded). After 5 minutes EtOH (10ml) is added and the crystals are filtered off, washed with EtOH and Et_2O and dried. Yield *ca* 3g of *bisulfite adduct*. Then treat the adduct (16g) with saturated aqueous $MgSO_4$ (32ml) and 40% formaldehyde (5ml) and shake, whereby the ester separates as an oil which is extracted with Et_2O. The extract is dried ($MgSO_4$), filtered, evaporated and the residue is distilled (**b 56°/20mm**), and then redistilled (**b 147.5°/750mm**) to give 5.5g of pure ester. [Cornforth *Org Synth* Coll Vol **4** 467 *1963*, DOI: 10.15227/orgsyn.031.0059; *Beilstein* **3** IV 1513.]

Ethyl stearate *[111-61-5]* **$C_{20}H_{40}O_2$, M 312.5, m 33°, b 213-215°/15mm.** The solid portion is separated from the partially solid starting material, then recrystallised twice from EtOH, dried by azeotropic distillation with *benzene, and fractionally distilled through a spinning-band column at low pressure [Welsh *Trans Faraday Soc* **55** 52 *1959*, DOI: 10.1039/TF9595500052]. [*Beilstein* **2** IV 1218.]

Ethyl thiocyanate (ethyl rhodanide) *[542-90-5]* **C_3H_5NS, M 87.1, b 144-145°/atm, d_4^{20} 1.011, n_D^{20} 1.462.**

Fractionally distil the ester at atmospheric pressure. [*Beilstein* **2** IV 1218.] **(CARE LACHRYMATOR.)**

Ethyl thioglycolate (ethyl 2-mercaptoacetate) *[623-51-8]* **$C_4H_8O_2S$, M 120.2, b 50-51°/10mm, 55°/17mm, 62.5-64°/22mm, 67-68°/24mm, 155-158°/atm, d_4^{20} 1.096, n_D^{20} 1.457.** Dissolve the thioglycolate in Et_2O, wash with H_2O, dry it over Na_2SO_4, filter, evaporate and distil the residue under reduced pressure [Bredereck et al. *Chem Ber* **90** 1837 *1957*, DOI: 10.1002/cber.19570900923]. The ***Ni complex [Ni(SCH$_2$CO$_2$Et)$_2$]*,** when recrystallised twice from EtOH, gives crystals which become black when dried in a vacuum over H_2SO_4, **m 104-105°** [Draney & Cefola *J Am Chem Soc* **76** 1975 *1954*, DOI: 10.1021/ja01636a081]. [*Beilstein* **3** H 255, **3** IV 616]

***N*-Ethylthiourea** *[625-53-6]* **$C_3H_8N_2S$, M 104.2, m 110°.** Crystallise the thiourea from EtOH, MeOH or ether. [*Beilstein* **4** IV 374.]

Ethyl trichloroacetate *[515-84-4]* **$C_4H_5Cl_3O_2$, M 191.4, b 100-100.5°/30mm, 168°/atm, d_4^{20} 1.383, n_D^{20} 1.453.** Shake the ester with saturated aqueous Na_2CO_3 (three times), aqueous 50% $CaCl_2$ (three times), saturated aqueous NaCl (twice), then distil it over $CaCl_2$, and redistil it under reduced pressure. [*Beilstein* **2** IV 514.]

Ethyl trifluoroacetate *[383-63-1]* **$C_4H_5F_3O_2$, M 142.1, b 61.3°/750, 60-62°/atm, 62-64°/755mm, d_4^{20} 1.191, n_D^{20} 1.30738.** It has been prepared by treating sodium trifluoroacetate with Et_2SO_4, or the acid with excess of EtOH and a small amount of H_2SO_4, distilling the azeotropic mixture of ester and EtOH, removing the latter with $CaCl_2$, filtering and fractionally distilling [Henne et al *J Am Chem Soc* **69** 1819 *1947*, DOI: 10.1021/ja01199a075]. Fractionate it through a long Vigreux column. IR has ν_{max} at 1800 (CO_2) and 1000 (OCO) cm^{-1} [Fuson et al. *J Chem Phys* **20** 1627 *1952*, DOI: org.virtual.anu.edu.au/10.1063/1.1700229; Bergman *J Org Chem* **23** 476 1958, DOI: 10.1021/jo01097a039]. [*Beilstein* **2** II 186, **2** III 427, **2** IV 463.]

Ethyl 4,4,4-trifluoroacetoacetate (ethyl 3-oxo-4,4,4-trifluorobutyrate) *[372-31-6]* **$C_6H_7F_3O_3$, M 184.1, b 47-49°/25mm, 129-130°/atm, 131.8°/atm, d_4^{25} 1.259, n_D^{20} 1.375.** The ester was prepared by the method of Swarts [*Bull Acad Roy Belg* **13** 175 *1927*] in which ethyl trifluoroacetate (1mol) was added slowly to a stirred suspension of NaOEt (1mol) in EtOH (exothermic reaction), followed EtOAc (1mol), and refluxed overnight.
An improved purification was by treatment with a concentrated aqueous solution of $NaHSO_4$ (very small molar excess), followed by addition of a clear aqueous solution of $Cu(OAc)_2$**,** and the organic layer was distilled off. The Cu derivative was filtered off and recrystallised from EtOH, washed with Et_2O to give green crystals of the ***copper chelate*** **m 189°** [UV has λ_{max} at 220nm (ε 11,000) and 270nm (ε 21,000), 3.0mg % in EtOH]. The dry Cu chelate was suspended in Et_2O (some dissolved) and H_2S was bubbled through until precipitation of CuS was complete. The CuS was filtered off, and the filtrate was carefully fractionation (to avoid losses) to provide the *ester* in 54% overall yield. Its UV has λ_{max} at 238nm (ε 3000) and 288nm (ε 400), in cyclohexane [Breslow et al. *J Am Chem Soc* **68** 100, *1946*, DOI: 10.1021/ja01205a032; Henne et al. *J Am Chem Soc* **69** 1819 *1947*, DOI: 10.1021/ja01199a075; Haszeldine et al. *J Chem Soc* 609 *1951*, DOI: 10.1039/JR9510000609; *Beilstein* **3** II 425, **3** III 1206, **3** IV 1548].

Ethyl trifluoromethanesulfonate *[425-75-2]* **$C_3H_5F_3O_3S$, M 178.1, b 115°/atm, 118-120°/atm, d_4^{20} 1.378, n_D^{20} 1.336.** The ester reacts slowly with H_2O and aqueous alkali. If its IR has no OH bands (~3000 cm^{-1}) then purify it by redistillation. If OH bands are present, then dilute with dry Et_2O and shake (carefully) with aqueous $NaHCO_3$ until effervescence ceases, then wash with H_2O and dry ($MgSO_4$), filter, evaporate and distil the residue under a slight vacuum then at atmospheric pressure in a N_2 atmosphere. **It is a powerful alkylating agent, and the fumes are very toxic — perform all operations in an efficient fume cupboard.** [Gramstad & Haszeldine *J Chem Soc* 173 *1956*, DOI: 10.1039/JR9560000173; Howells & McCown *Chem Rev* **77** 69 *1977*, DOI: 10.1021/cr60305a005; *Beilstein* **3** IV 34.]

S-Ethyl trifluorothioacetate *[383-64-2]* **$C_4H_5F_3OS$, M 158.1, b 88-90°/atm, 90.5°/760mm, d_4^{20} 1.255, n_D^{20} 1.372.** If IR is free of OH bands then fractionally distil it; otherwise dilute the thio-ester with dry Et_2O, wash with 5% KOH and H_2O, dry over $MgSO_4$ and fractionate it through an efficient column [Hauptschein et al. *J Am Chem Soc* **74** 4005 *1952*, DOI: 10.1021/ja01136a010]. [*Beilstein* **2** IV 567.] *Powerful obnoxious odour.*

Ethyl vinyl ether (ethoxyethylene) *[109-92-2]* **C_4H_8O, M 72.1, m -116°, b 35.5°/atm, d_4^{20} 0.755.** It usually contains polymerisation inhibitors (usually amines, e.g. triethanolamine) which can be removed by fractional distillation. Redistil it from sodium. [*Beilstein* **1** IV 2049.] **LACHRYMATORY.**

Fluoroacetamide *[640-19-7]* **$C_2H_2F_3NO$, M 77.1, m 108°.** Crystallise fluoroacetamide from chloroform and dry it in a vacuum. **TOXIC** [*Beilstein* **2** IV 454.]

Formaldehyde *[50-00-0]* **CH_2O, M 30.0, m -92°, b -79.6°/20mm, -19.5°/760mm, d_4^{20} 0.815, pK^{25} 13.27 (hydrate).** Technical aqueous formaldehyde (***formalin***) solution commonly contains added MeOH (8-10%) to inhibit oxidation to formic acid. As a rough guide the d_4^{18} ***vs* [*concentration in g of HCHO/100ml (100g) of aqueous solution*]** is as follows: 1.0054 [2.24 (2.23)], 1.0126 [4.66 (4.60)], 1.0311 [11.08 (10.74)], 1.0410 [14.15 (13.59)], 1.0568 [19.89 (18.82)], 1.0719 [25.44 (23.73)], 1.0853 [30.17 (27.80)], 1.1057 [37.72 (34.11)] and 1.1158 [41.87 (37.53)]; values in curved brackets are from alternative determinations. [Marvel & Porter *Org Synth* Coll Vol **I** 377 *1941*, DOI: 10.15227/orgsyn.009.0058]. If pure formaldehyde is required, add KOH solution (1 mole KOH: 100 moles HCHO) to ~37% by weight of aqueous formaldehyde solution (*formalin*), or evaporate formalin to dryness, to give ***paraformaldehyde polymer*** {$HO(CH_2O)_nH$, [30525-89-4] **m 120-170°** depending on ***n***} as a white solid which, after washing with water, is dried in a vacuum desiccator over P_2O_5 or H_2SO_4. Formaldehyde is regenerated by heating the paraformaldehyde to 120° under vacuum, or by decomposing it with barium peroxide. The *monomer*, a colourless flammable gas, is passed through a glass-wool filter cooled to -48° in a $CaCl_2$/ice mixture to remove particles of polymer, then dried by passage over P_2O_5 and either condensed in a bulb immersed in liquid nitrogen or absorbed in ice-cold conductivity water. The gas or aqueous solutions have *pungent suffocating odours*, are LACHRYMATORY and SUSPECTED CARCINOGEN; handle carefully. Formalin is a disinfectant and a preservative of dead animal and plant tissues. [*Beilstein* **1** IV 3017.]

Formaldehyde dimethyl acetal (dimethoxymethane, methylal, formal) *[109-87-5]* **$C_3H_8O_2$, M 76.1, m -108°, b 41-42°/736mm, 41-43°/atm, 42-46°/atm, d_4^{20} 0.8608, n_D^{20} 1.35335.** It is a volatile flammable liquid which is soluble in three parts of H_2O, and is readily hydrolysed by acids. Purify it by shaking with an equal volume of 20% aqueous NaOH, stand for 20 minutes, dry over fused $CaCl_2$, filter and fractionally distil it through an efficient column. Store it over molecular sieves. [Buehler et al. *Org Synth* Coll Vol **3** 468 *1955*, DOI: 10.15227/orgsyn.020.0059; Rambaud & Besserre *Bull Soc Chim Fr* 45 *1955*, IR: Wilmshurst *Can J Chem* **36** 285 *1958*, DOI: 10.1139/v58-040; *Beilstein* **1** IV 3026.]

Formaldehyde dimethyl mercaptal (bis-[methylthio]methane) *[1618-26-4]* **$C_3H_8S_2$, M 108.2, b 44-47°/13mm, 45.5°/18mm, 148-149°/~760mm, d_4^{20} 1.0594, n_D^{20} 1.5322. Work in an efficient fume cupboard as the substance may contain traces (or more) of methylmercaptan which has a very bad odour and is toxic.** Dissolve the mercaptal in Et_2O, shake it with aqueous alkalis then dry it over anhydrous K_2CO_3, filter and distil it over K_2CO_3 under a stream of N_2. If the odour is very strong, then allow all gas effluents to bubble through 5% aqueous NaOH solution which is then treated with dilute $KMnO_4$ in order to oxidise MeSH to odourless products. Its UV has λ_{max} at 238 nm (log ε 2.73) [Fehnel & Carmack *J Am Chem Soc* **71** 84 *1949*, DOI: 10.1021/ja01169a025; Fehér & Vogelbruch *Chem Ber* **91** 996 *1958*, DOI: 10.1002/cber.19580910521; Bøhme & Marz *Chem Ber* **74** 1667 *1941*, DOI: 10.1002/cber.19410741009]. Oxidation with aqueous $KMnO_4$ yields ***bis-(methylsulfonyl)methane*** which has **m 142-143°** [Fiecchi et al. *Tetrahedron Lett* 1681 *1967*, DOI: 10.1016/S0040-4039(00)90698-1]. [*Beilstein* **1** IV 3088.]

Formamide *[75-12-7]* **CH_3NO, M 45.0, f 2.6°, b 103°/9mm, 210.5°/760mm(dec), d_4^{20} 1.13, n_D^{20} 1.44754, n^{25} 1.44682.** Formamide is easily hydrolysed by acids and bases. It also reacts with peroxides, acid halides, acid anhydrides, esters and (on heating) alcohols, while strong dehydrating agents convert it to a nitrile. It is very *hygroscopic*. Commercial material often contains acids and ammonium formate. Verhoek [*J Am Chem Soc* **58** 2577 *1956*, DOI: 10.1021/ja01303a059] added some bromothymol blue to formamide and then neutralised it with NaOH before heating to 80-90° under reduced pressure to distil off ammonia and water. The amide is again neutralised and the process is repeated until the liquid remained neutral on heating. Sodium formate is added, and the formamide is concentrated under reduced pressure at 80-90°. The distillate is again neutralised and re-

distilled. It is then fractionally crystallised in the absence of CO_2 and water by partial freezing. Formamide (specific conductance 2 x 10^{-7} ohm^{-1} cm^{-1}) of low water content is dried by passage through a column of 3A molecular sieves, then deionized by treatment with a mixed-bed ion-exchange resin loaded with H^+ and $HCONH^-$ ions (using sodium formamide in formamide) [Notley & Spiro *J Chem Soc (B)* 362 *1966*, DOI: 10.1039/J29660000362]. [*Beilstein* **2** IV 45.]

Formamidine acetate *[3473-63-0]* **CH_4N_2. $C_2H_4O_2$, M 104.1, m 159-161°(dec), 164°(dec), pK_{Est} ~12.** Unlike the hydrochloride below, the acetate salt is not hygroscopic. Prepared from $(EtO)_3CH$ in AcOH by passing NH_3 gas through at 125-130° for 20 to 30 minutes when the acetate starts to crystallise out. Cool, filter the crystals off, wash them with cold EtOH and dry them *in vacuo*. It is recrystallised from a small volume of acetic acid, by addition of EtOH, and the crystals are washed with cold EtOH then Et_2O and dried in a vacuum. It is stable to storage and can be used directly in place of free formamidine. It is less hygroscopic than the hydrochloride below. [Taylor & Rabinovitz *Biochemical Preparations* **5** 102 *1957*, Taylor and Ehrhart *J Am Chem Soc* **82** 3138 *1960*, DOI: 10.1021/ja01497a039; Taylor et al. *Org Synth* **46** 39 *1966*, DOI: 10.15227/orgsyn.046.0039; *Beilstein* **2** IV 82.]

Formamidine hydrochloride *[6313-33-3]* **CH_4N_2. HCl, M 80.1, m 76-78°, 78°, 84-87°, 85-87°(dec), pK_{Est} ~12.** The hydrochloride is hygroscopic unlike the acetate salt (see preceding entry). It has been prepared by catalytic reduction of freshly prepared cyanamide in 9% aqueous HCl (to form the hydrochloride) or 12% of aqueous H_2SO_4 (to form the hemisulfate, see below) with 1.4% of Pd/C and hydrogen. The reduction is usually complete in 10 minutes. The hygroscopic *hydrochloride*, obtained in 92% yield, is recrystallised from MeOH and is stored in a vacuum.

Formamidine hemisulfate *[77269-36-4; 77269-37-5]* **CH_4N_2. 0.5 H_2SO_4, M 93.1,** has **m 156-158°** after recrystallisation from MeOH. ***Formamidine picrate*** **CH_4N_2. $C_5H_3N_3O_7$,** has **m 246-247°** after recrystallisation from hot H_2O, and can be readily converted to the ***hydrochloride*****, m 78°**. [Odo et al. *J Org Chem* **22** 1715 *1957*, DOI: 10.1021/jo01363a620; Shirai et al. *J Org Chem* **23** 100 *1958*, DOI: 10.1021/jo01095a608; Taylor et al. *Org Synth* **46** 39 *1966*, DOI: 10.15227/orgsyn.046.0039; *Beilstein* **3** H 90, **2** I 38, **2** III 125, **2** IV 82.]

Formamidine sulfinic acid (thiourea-S-dioxide) *[1758-73-2]* **$CH_4N_2O_2S$, M 108.1, m 124-126°(dec).** Dissolve it in five parts of aqueous 1:1% $NaHSO_3$ at 60-63° (charcoal), then allow it to crystallise slowly, with agitation, at 10°. Filter and dry it immediately at 60° [Koniecki & Linch *Anal Chem* **30** 1134 *1958*, DOI: 10.1021/ac60138a041; Havel & Kluttz *Synth Commun* **4** 389 *1974*, DOI: 10.1080/00397917408064100]. [*Beilstein* **3** I 36, **3** IV 145.]

Formic acid *[64-18-6]* **CH_2O_2, M 46.0 (anhydrous), f 8.3°, b 25°/40mm, 100.7°/760mm, d_4^{20} 1.22, n 1.37140, n^{25} 1.36938, pK^{25} 3.74.** Anhydrous formic acid can be obtained by direct fractional distillation under reduced pressure, the receiver being cooled in ice-water. The use of P_2O_5 or $CaCl_2$ as dehydrating agents is unsatisfactory. Reagent grade 88% formic acid can be dried satisfactorily by refluxing with phthalic anhydride for 6 hours and then distilling it. *Alternatively*, if it is left in contact with freshly prepared anhydrous $CuSO_4$ for several days about one half of the water is removed from 88% formic acid; distillation then removes the remainder. Boric anhydride (prepared by melting boric acid in an oven at a high temperature, cooling in a desiccator, and powdering) is a suitable dehydrating agent for 98% formic acid; after prolonged stirring with the anhydride the formic acid is distilled under vacuum. Formic acid can be further purified by fractional crystallisation using partial freezing. [*Beilstein* **2** IV 3.]

***N*-Formyl *tert*-butylamine (*N-tert*-butylformamide)** *[2425-74-3]* **$C_5H_{11}NO$, M 101.2, m 16°, b 48°/0.2mm, 78-83°/9mm, 135-136°/107mm, 202°/760mm, d_4^{25} 0.903, n_D^{20} 1.4330.** If the IR indicates some hydrolysis, then dissolve it in Et_2O, wash it with 20% aqueous Na_2CO_3, dry it ($MgSO_4$), filter and fractionate it. Collect the fraction that solidifies on cooling and recrystallise it from Et_2O at low temperature if necessary. [Emmons *J Am Chem Soc* **79** 5739 *1957*, DOI: 10.1021/ja01578a043; *Beilstein* **4** III 324, **4** IV 661.]

***N*-Formyl ethylamine (*N*-ethylformamide)** *[627-45-2]* **C_3H_7NO, M 73.1, b 29°/0.5mm, 176-179°/758mm,**

d_4^{20} 0.950, n_D^{20} 1.4346. If the IR is good, then distil it and collect the middle fraction and redistil if necessary; otherwise proceed as for the previous amide. [Erickson *J Org Chem* **20** 1569 *1955*, DOI: 10.1021/jo01128a016; *Beilstein* **4** H 109, **4** I 352, **4** II 601, **4** III 207, **4** IV 346.]

Formyl hydrazine (formic acid hydrazide) *[624-84-0]* **CH_4N_2O, M 60.1, m 54°, 54-57°, pK_{est} ~ 2.5.** Recrystallise it from EtOH and dry it *in vacuo*. Store below 10°; it may disproportionate on storage to 1,2-diformyl hydrazine and hydrazine. It forms a blue $[Cu(CH_4N_2O)]SO_4$ salt with $CuSO_4$. [*Beilstein* **2** H 93, **2** III 127, **2** IV 85.]

Formyloxy acetonitrile (cyanomethyl formate) *[150760-95-5]* **$C_3H_3NO_2$, M 85.1, b 62-64°/12mm, 172-173°/atm, d_4^{25} 0.903, n_D^{20} 1.4330.** Purify it by fractional distillation and redistilling the middle fraction. It is useful for the formylation of alcohols and amines. The ^{13}C NMR has δ ($CDCl_3$) at 47.87, 114.47 and 159.46 ppm. [Deutsch & Niclas *Synth Commun* **23** 1561 *1993*, DOI: 10.1080/00397919308011251; Duczek et al. *Synthesis* 37 *1996*, DOI: 10.1055/s-1996-4153.] [*Beilstein* **3** H 243.]

Fumaraldehyde bis(dimethyl acetal) (*trans*-1,1,4,4-tetramethoxybut-2-ene) *[6068-62-8]* **$C_8H_{16}O_4$, M 176.2, b 100-103°/15mm, 101-103°/25mm, d_4^{20} 1.011, n_D^{20} 1.425.** Dry it over fused $CaCl_2$ and distil it *in vacuo*. The maleic (*cis*) isomer has **b 112°/11mm**, and d^{23} 0.932 and n_D^{25} 1.4243. [Zeik & Heusner *Chem Ber* **90** 1869 *1957*, Clauson-Kaas et al. *Acta Chem Scand* **9** 111 *1955,* DOI: 10.3891/acta.chem.scand.09-0111; Clauson-Kaas *Acta Chem Scand* **6** 569 *1952*, DOI: 10.3891/acta.chem.scand.06-0569; *Beilstein* **1** IV 3754.]

Fumaric (*trans*-but-2-ene-1,4-dioic) acid *[110-17-8]* **$C_4H_4O_4$, M 116.1, m 289.5-291.5°(sealed tube), pK_1^{25} 3.10, pK_2^{25} 4.60 (4.38).** Crystallise it from hot M HCl or water and dry it at 100°. [*Beilstein* **2** IV 2202.]

Geraniol (*trans*-3,7-dimethyl-2,6-octadien-1-ol) *[106-24-1]* **$C_{10}H_{18}O$, M 154.3, b 114-115°/11-12mm, 230°, d_4^{20} 0.879, n_D^{20} 1.4766.** Purify geraniol by ascending chromatography or by thin layer chromatography on plates of kieselguhr G with acetone/water/liquid paraffin (130:70:1) as solvent system. Hexane/ethyl acetate (1:4) is also suitable. Also purify it by GLC on a silicone-treated column of Carbowax 20M (10%) on Chromosorb W (60-80 mesh). [Porter *Pure Appl Chem* **20** 449 *1969*, DOI: 10.1351/pac196920040449.] Store it in full, tightly sealed containers in the cool and protect from light. It has a pleasant odour of geraniums. [*Beilstein* **1** IV 2277.]

Glutaraldehyde *[111-30-8]* **$C_5H_8O_2$, M 100.1, b 71°/10mm, as 50% aqueous solution.** Likely impurities are oxidation products-acids, semialdehydes and polymers. It can be purified by repeated washing with activated charcoal (Norit) followed by vacuum filtration, using 15-20g charcoal/100ml of glutaraldehyde solution. Distil it at 60-65°/15mm, discarding the first 5-10%, then dilute with an equal volume of freshly distilled water at 70-75°, using magnetic stirring under nitrogen. The solution is stored at low temperature (3-4°), in a tightly stoppered container, and protected from light. Standardise by titration with hydroxylamine. [Anderson *J Histochem Cytochem* **15** 652 *1967*, DOI: 10.1177/15.11.652; *Beilstein* **1** IV 3659.] **TOXIC.**

Glutaric acid *[110-94-1]* **$C_5H_8O_4$, M 132.1, m 97.5-98°, pK_1^{25} 4.35, pK_2^{25} 5.40.** Crystallise the acid from *benzene, $CHCl_3$, distilled water or *benzene containing 10% (w/w) of diethyl ether. Dry it under vacuum. [*Beilstein* **2** IV 1934.]

dl*–Glyceraldehyde** *[56-82-6]* **$C_3H_6O_3$, M 90.1, m 145°, distils (bath temperature 140-150°) at ~ 0.8mm.** Crystallise it from EtOH/diethyl ether. Its solubility in H_2O at 18° is 3g/100ml. It is insoluble in hydrocarbon solvents, and forms an ***osazone* m 138°**. The **D(*R* +)-*enantiomer [453-17-8] is a syrup (~70% + H_2O) with $[\alpha]_D^{25}$ +14, +8.7 (c 2, H_2O) and the ***dimethyl acetal*** has **b 124-127°/14mm** and $[\alpha]_D^{15}$ +21 (c 18, H_2O). The **L(*S* -)-*enantiomer*** [497-09-6] has $[\alpha]_D^{25}$ -14.3 (c 5, H_2O) *and mutarotates from* $[\alpha]_D^{20}$ *-13.8 to -7.8 in 8 days* [Baer & Fischer *J Am Chem Soc* **61** 761 1939, DOI: 10.1021/ja01873a001]; and the ***dimethyl acetal*** has **b 126-129°/17-20mm** and $[\alpha]_D^{15}$ -20.9 (c 9.2, H_2O). [Fischer & Baer *Chem Ber* **65** 345 *1932*, DOI: 10.1002/cber.19320650244; *Beilstein* **1** H 845, **1** IV 4418.]

Glycerol *[56-81-5]* **$C_3H_8O_3$, M 92.1, m 18.2°, b 182°/20mm, 290°/760mm, d_4^{20} 1.261, n_D^{25} 1.47352, pK^{25} 14.4.** Glycerol is dissolved in an equal volume of *n*-butanol (or *n*-propanol, amyl alcohol or liquid ammonia) in a water-tight container, cooled and seeded while slowly revolving in an ice-water slurry. The crystals are collected by centrifugation, then washed with cold acetone or isopropyl ether. [Hass & Patterson *Ind Eng Chem (Anal Ed)* **33** 615 *1941*, DOI: 10.1021/ie50377a015.] Coloured impurities can be removed from substantially dry glycerol by extraction with 2,2,4-trimethylpentane. *Alternatively*, glycerol can be decolorised and dried by treatment with activated charcoal and alumina, followed by filtering. Glycerol can be distilled at 15mm in a stream of dry nitrogen, and stored in a desiccator over P_2O_5. Crude glycerol can be purified by digestion with concentrated H_2SO_4 and then saponification with a lime paste, re-acidification with H_2SO_4, filtration, treatment with an anion exchange resin and fractional distillation in a vacuum. [*Beilstein* **1** IV 2751.]

Glyceryl trinitrate (TNG, trinitroglycerine, nitroglycerin, 1,2,3-trinitroxypropane, 'Blasting Oil', Transiderm-nitro, Nitrolingual, and many other trade names) *[55-63-0]* **$C_3H_5N_3O_9$, M 227.1, m 14°, b 50°/atm (dec, explosive), d^{20} 1.60g/cm^3, n_D^{15} 1.474.** Sobrero [*Justus Liebigs Ann Chem* **64** 398 *1847*, DOI: 10.1002/jlac.18480640364; Williamson *Justus Liebigs Ann Chem* **92** 305 *1854*, DOI: 10.1002/jlac.18540920309] was first to prepare the ester by dissolving syrupy glycerin dropwise into a cold mixture of H_2SO_4 (2 parts) and HNO_3 (1 part) until no more reaction occurred. It was then poured into cold H_2O whereby an oil separated which was washed several times with H_2O by decantation, dissolved in EtOH and the oil separated on adding H_2O and repeating the process. The olive-yellow oil was dissolved in Et_2O (separated from any aqueous layer) and evaporated (**TAKE GREAT CARE HERE AS THIS IS VERY EXPLOSIVE**) to give pure oil which was dried over H_2SO_4. It detonated on attempted heating. *Alternatively*, it was prepared by nitrating glycerol with white fuming HNO_3 and keeping the temperature as low as possible. **NO ATTEMPT SHOULD BE MADE TO DISTIL IT** at atmospheric pressure. If it has to be distilled then very small volumes could be transferred from one bulb to another very cold one under vacuum and great precautions should be taken (its vapour pressure at 20°/atm is 0.00026mm).
The tri-nitrate ester is a pale yellow oil which explodes on concussion, is volatile and is sweet smelling. It should not be allowed to come into contact with skin because it is readily absorbed, and on **no account** should it be inhaled as it causes nausea and throbbing headaches (**use a well ventilating fume hood**). Its solubility (%w/w) is 0.13 in H_2O, 0.83 in CS_2, 5.6 in MeOH and 25.0 in EtOH; and it is very soluble in most organic solvents except for light petroleum and glycerol.
TNG is an ingredient of explosives used by the military and in the construction industry. Medicinally, it is a potent vasodilator which increases blood flow and widely used in patients with heart conditions, e.g. angina and heart failure [Di Carlo 'Nitroglycerin Revisited: Chemistry, Biochemistry, Interactions' *Drug Metabolism Reviews* **4** 1 *1975*, DOI: 10.3109/03602537508993747. PMID 812687.]

Glycolic (α-hydroxyacetic) acid *[79-14-1]* **$C_2H_4O_3$, M 76.1, m 81°, pK^{25} 3.62.** Crystallise it from diethyl ether. [*Beilstein* **3** IV 571.]

Guanidine *[113-00-8]* **CH_5N_3, M 59.1, m 47.5-48.5°, 48-49°, ~50°, pK^{25} 13.6.** Crystallise it from water/EtOH under nitrogen. It is very deliquescent and absorbs CO_2 from the air readily. [Davis *Org Synth* Coll Vol **1** 302 *1941*, DOI: 10.15227/orgsyn.007.0046; Jones *Trans Faraday Soc* **55** 524 *1959*, DOI: 10.1039/TF9595500524; *Beilstein* **3** H 82, **3** I 39, **3** II 69, **3** III 154, **3** IV 148.]

Guanidine carbonate *[593-85-1]* **CH_5N_3. H_2CO_3, M 90.1, m 197°, 230°.** Crystallise it from MeOH. [*Beilstein* **3** H 86, **3** I 41, **3** II 72, **3** III 161, **3** IV 152.]

Guanidine hydrochloride *[50-01-1]* **CH_5N_3. HCl, M 95.5, m 181-183°.** Crystallise the hydrochloride from hot methanol by chilling to about -10°, with vigorous stirring. The fine crystals are filtered through fritted glass, washed with cold (-10°) methanol, dried at 50° under vacuum for 5 hours. (The product is purer than that obtained by crystallisation at room temperature from methanol by adding large amounts of diethyl ether.)

[Kolthoff et al. *J Am Chem Soc* **79** 5102 *1957*, DOI: 10.1021/ja01576a007; *Beilstein* **3** III 160, **3** IV 150.]

Heptadecanoic acid (margaric) *[506-12-7]* **$C_{17}H_{34}O_2$, M 270.5, m 60-61°, 61.3°, b 227°/100mm, pK_{Est} ~4.9.** Crystallise this C-17 (odd number of carbon atoms) acid from MeOH or petroleum ether (colourless plates). Its solubilities at 20° are: H_2O (0.00042), AcOH (1.2), MeOH (2.5), 95% EtOH (4.17), *C_6H_6 (9.3) and Et_2O (very soluble). [Occurrence in butterfat: Hansen et al. *Nature* **179** 98 1957, DOI:10.1038/179098a0; isolation from shark liver oil: Morice & shortland *Biochem J* **61** 453 *1955*, DOI: 10.1042/bj0610453; from degradation of stearic acid: Levene & West *J Biol Chem* **16** 475 *1914*; synthesis: Kaufmann & Stamm *Chem Ber* **91** 2121 *1958*, DOI: 10.1002/cber.19580911018; *Beilstein* **2** IV 1193.] The triglyceride, **glyceryl 1,2,3-triheptadecanoate (triheptadecanoin)** [2438-40-6] **$C_{54}H_{104}O_6$, M 849.4,** has **m 64°, 64-67°, b 786.8°/760mm**, and is crystallised from $CHCl_3$/petroleum ether or aqueous EtOH. Store under N_2 at -20°. [Gas chromatographic separation of triglycerides: Kail et al. *J Chromatogr Sci* **50** 934 *2012*, DOI: 10.1093/chromsci/bms093; *Beilstein* **2** III 986.]

1-Heptadecanol *[1454-85-9]* **$C_{17}H_{36}O$, M 256.5, m 54°.** Crystallise it from acetone. [*Beilstein* **1** IV 1884.]

Heptafluoro-2-iodopropane *[677-69-0]* **C_3F_7I, M 295.9, b 39°/735mm, 41°/760mm, d_4^0 2.1306, n_D^{20} 1.3281.** Purify it by gas chromatography on a triacetin (glyceryl triacetate) column, followed by bulb-to-bulb distillation at low temperature. Store it over Cu powder to stabilise it. UV has ν_{max} at 271nm (ε 240) in petroleum ether (b 60-80°). [Haszeldine *J Chem Soc* 1764, 3761 *1953*, DOI: 10.1039/JR9530001764; DOI: 10.1039/JR9530003761; *Beilstein* **1** III 255, **1** IV 225.]

***n*-Heptaldehyde** *[111-71-7]* **$C_7H_{14}O$, M 114.2, m -43°, b 40.5°/12mm, 152.8°/760mm, d_4^{20} 0.819, n_D^{25} 1.4130.** Dry *n*-heptaldehyde with $CaSO_4$ or Na_2SO_4 and fractionally distil it under reduced pressure. More extensive purification is by precipitation as the bisulfite compound (formed by adding the aldehyde to saturated aqueous $NaHSO_3$) which is filtered off and recrystallised from hot H_2O. The crystals, after being filtered and washed well with H_2O, are hydrolysed by adding 700ml of aqueous Na_2CO_3 (12.5% w/w of anhydrous Na_2CO_3) per 100g of aldehyde. The aldehyde is then steam distilled off, separated, dried with $CuSO_4$ and distilled under reduced pressure in a slow stream of nitrogen. [McNesby & Davis *J Am Chem Soc* **76** 2148 *1954*, DOI: 10.1021/ja01637a031; *Beilstein* **1** H 695, **1** I 357, **1** II 750, **1** III 2844, **1** IV 3314.]

***n*-Heptaldoxime** *[629-31-2]* **$C_7H_{15}NO$, M 129.2, m 53-55°.** Separate the *cis*(Z) and *trans*(E) oximes by liquid chromatography through a silica gel column and eluting with petroleum ether (b 40-65°)/EtOAc (50:10) at a flow rate of 2-3.4 ml/sec where the *trans-isomer* comes through first and is a liquid with n_D^{22} 1.38512, followed by the *cis-isomer* which is a solid, and crystallises from 60% aqueous EtOH with **m** 55°. They are identified by TLC on 0.2mm silica gel G by eluting with *C_6H_6/EtOAc (50/10) and visualising with I_2 vapour: the *trans-isomer* has R_F 0.6 and the *cis-isomer* has R_F 0.5 [Pejkovic-Tadic et al. *J Chromatogr* **21** 239 *1966*, DOI: 10.1016/S0021-9673(01)91297-X; Emmons & Pagano *J Am Chem Soc* **77** 4557 *1955*, DOI: 10.1021/ja01622a036]. [*Beilstein* **1** H 698, **1** I 358, **1** II 752, **1** III 2850.]

***n*-Heptane** *[142-18-5]* **C_7H_{16}, M 100.2, m -90°, b 98.4°/atm, d_4^{20} 0.684, n_D^{20} 1.38765, n_D^{25} 1.38512.** Pass it through a silica gel column which greatly reduces the ultraviolet absorption of *n*-heptane. (The silica gel is previously heated to 350° before use.) For more extensive purification, heptane is shaken with successive small portions of concentrated H_2SO_4 until the lower (acid) layer remains colourless. The heptane is then washed successively with water, aqueous 10% Na_2CO_3, water (twice), and dried with $CaSO_4$, $MgSO_4$ or $CaCl_2$. It is distilled from sodium. *n*-Heptane can be distilled azeotropically with methanol, then the methanol is washed out with water and, after drying, the heptane is redistilled. Other purification procedures include passage through activated basic Al_2O_3, drying with CaH_2, storage with sodium, and stirring with 0.5*N* $KMnO_4$ in 6N H_2SO_4 for 12 hours after treatment with concentrated H_2SO_4. Carbonyl-containing impurities have been removed by percolation through a column of impregnated Celite made by dissolving 0.5g of 2,4-dinitrophenylhydrazine in 6ml of 85% H_3PO_4 by grinding together, then adding 4ml of distilled water and 10g Celite. [Schwartz & Parks *Anal Chem* **33** 1396 *1961*, DOI: 10.1021/ac60178a036; *Beilstein* **1** IV 376.]

Hept-1-ene *[592-76-7]* **C_7H_{14}, M 98.2, m -119°, b 93°/771mm, d_4^{20} 0.698, n_D^{20} 1.400.** Distil hept-1-ene from sodium, then carefully fractionally distilling it using an 18-in gauze-packed column. It can also be purified by azeotropic distillation with EtOH. It usually contains the 2- and 3-isomers as impurities. These can be removed by gas chromatography using a Carbowax column at 70°. [*Beilstein* **1** IV 857.]

***n*-Heptyl alcohol (1-heptanol)** *[111-70-6]* **$C_7H_{16}O$, M 116.2, m -36°, b 175.6°/atm, d 0.825, n_D^{20} 1.425.** Shake the alcohol with successive lots of alkaline $KMnO_4$ until the colour persists for 15 minutes, then dry it with K_2CO_3 or CaO, and fractionally distil it. [*Beilstein* **1** IV 1731.]

***n*-Heptylamine** *[111-68-2]* **$C_7H_{17}N$, M 115.2, b 155°/atm, d_4^{20} 0.775, n_D^{20} 1.434, pK^{25} 10.66.** Dry it in over KOH pellets for 24 hours, then decant it and fractionally distil it. Store away from CO_2. [*Beilstein* **4** IV 734.]

***n*-Heptyl bromide** *[629-04-9]* **$C_7H_{15}Br$, M 179.1, m -58°, b 70.6°/19mm, 180°/760mm, d_4^{20} 1.140, n_D^{20} 1.45.** Shake it with conc H_2SO_4, wash with water, dry it with K_2CO_3, and fractionally distil. [*Beilstein* **1** IV 391.]

Hexachloro-1,3-butadiene (perchlorobutadiene) *[87-68-3]* **C_4Cl_6, M 260.8, m -22° to -19°, b 144.1°/100mm, 210-212°/760mm, d_4^{20} 1.683, n_D^{20} 1.5556.** Wash the diene with four or five 1/10th volumes of MeOH (or until the yellow colour has been extracted), then stir it for 2 hours with H_2SO_4, wash it with distilled water until neutral and filter it through a column of P_2O_5. Distil it under reduced pressure through a packed column. [Rutner & Bauer *J Am Chem Soc* **82** 298 *1960*, DOI: 10.1021/ja01487a012; *Beilstein* **1** IV 998.]

Hexachloroethane *[67-72-1]* **C_2Cl_6, M 236.7, m 187°.** Steam distil it, then crystallise it from 95% EtOH. Dry it in the dark under vacuum. [*Beilstein* **1** IV 148.]

Hexacosane (C-26) *[630-01-3]* **$C_{26}H_{54}$, M 366.7, m 56.4°, b 169°/0.05mm, 205°/1mm, 262°/15mm.** Distil hexacosane under vacuum and recrystallise it from diethyl ether. [*Beilstein* **1** IV 583.]

Hexacosanoic acid (cerotic acid, cerotinic acid) *[506-46-7]* **$C_{26}H_{52}O_2$, M 396.7, m 86-87°, 88-89°, pK_{Est} ~4.9.** Crystallise the acid from EtOH, aqueous EtOH and petroleum ether/Me_2CO. [*Beilstein* **2** IV 1310.]

***n*-Hexadecane (Cetane)** *[544-76-3]* **$C_{16}H_{34}$, M 226.4, m 18.2°, b 105°/0.1mm, 287°/atm, d_4^{20} 0.773, n_D^{20} 1.4345, n^{25} 1.4325.** Pass cetane through a column of silica gel and distil it under vacuum in a column packed with Pyrex helices. Store it over silica gel. It also crystallises from acetone, or is fractionally crystallised by partial freezing. [*Beilstein* **1** IV 537.]

1,14-Hexadecanedioic acid (Thaspic acid) *[505-54-4]* **$C_{16}H_{30}O_4$, M 286.4, m 126°, $pK_{Est(1)}$ ~4.5, $pK_{Est(2)}$ ~5.5.** Recrystallise thaspic acid from EtOH, ethyl acetate or $*C_6H_6$. [*Beilstein* **2** IV 2162.]

Hexadecanoic acid (palmitic acid) *[57-10-3]* **$C_{16}H_{32}O_2$, M 256.4, m 62-63°, b 215°/15mm, pK^{25} 6.46 (50% aqueous EtOH), 5.0 (H_2O).** Purify palmitic acid by slow (overnight) recrystallisation from hexane. Some samples are also crystallised from acetone, EtOH or EtOAc. The crystals are kept in air to lose solvent, or are pumped dry of solvent on a vacuum line. [Iwahashi et al. *JCS Faraday Trans 1* **81** 973 *1985*, DOI: 10.1039/F19858100973; pK: White *J Am Chem Soc* **72** 1859 *1950*, DOI: 10.1021/ja01160a530; *Beilstein* **2** IV 1157.]

1,5-Hexadiene *[592-42-7]* **C_6H_{10}, M 82.2, m -141°, b 59.6°/atm, d_4^{20} 0.694, n_D^{20} 1.4039.** Distil 1,5-hexadiene from $NaBH_4$ and store under Ar or N_2. [*Beilstein* **1** IV 1013.]

Hexafluoroacetone *[684-16-2, 34202-69-2 ($3H_2O$)]* **C_3F_6O, M 166.1, m -43-45° (sealed capillary) -129°, b -26°, -28°, (trihydrate m 18-21°, b 55-56°/80mm).** Dehydrate hexafluoroacetone by passing the vapours over P_2O_5. Ethylene is removed by passing the dried vapours through a tube containing Pyrex glass wool moistened with conc H_2SO_4. Further purification is by low temperature distillation using Warde-Le Roy stills and Dry Ice. Store it in the dark at -78° or at liquid nitrogen temperature. Henne et al. used ***Engler*** distillation [Henne et al. *J Am Chem Soc* **72** 3577 *1960*, DOI: 10.1021/ja01164a070; Holmes & Kutschke *Trans Faraday Soc* **58** 333

1962, DOI: 10.1039/TF9625800333; *Beilstein* **1** IV 3215 3210.]

Hexafluoroacetylacetone (1,1,1,5,5,5-hexafluoro-2,4-pentanedione, hfacac) *[1522-22-1]* **$C_5H_2F_6O_2$, M 208.1, b 63-65°/atm, 68°/736mm, 70-70.2°/760mm, 68-71°/atm, d_4^{20} 1.490, n_D^{20} 1.333.** Hfacac has been prepared from a mixture of Na wire (0.34mole) covered with dry Et_2O and CF_3CO_2Et (0.27mole see [383-63-1]) at 0°, to which was added trifluoroacetone (0.27mol, see [421-50-1]) at -78°. The mixture was then set aside overnight at ~25°, and any trifluoroacetone which distilled out was made to condense back into the reaction mixture which was stirred at ~25° until all the Na dissolved [Haszeldine et al. *J Chem Soc* 609 *1951*, DOI: 10.1039/JR9510000609; compare with Henne et al. *J Am Chem Soc* **69** 1819 *1947*, DOI: 10.1021/ja01199a075]. The reddish-brown mixture was treated with an excess of 2N H_2SO_4 and extracted with ether. The organic layer was dried (Na_2SO_4), and distilled to give *hfacac* (20g, 37%). By using NaOEt instead of Na metal, Henne and coworkers obtained a 72% yield of *hfacac*, which gave the *copper chelate* as bright grass green crystals (see below) [Henne et al. *J Am Chem Soc* **69** 1819 *1947*, DOI: 10.1021/ja01199a075]. Hfacac (100g) is purified by shaking twice with 98% H_2SO_4 (300ml, *use protective clothing*) until it is completely dispersed, and set aside overnight. The anhydrous facac is separated and distilled through a glass-helices packed column with fraction b 70.2-70.5°/atm (~20g, analytically pure) being retained for metal complex studies [Buckingham et al. *Aust J Chem* **20** 281 *1967*, DOI:10.1071/CH9670281]. The oil readily forms a solid white stable *covalent dihydrate* [CF_3-$C(OH)_2$-CH_2-$C(OH)_2$-CF_3] which is caused by the strong electron-withdrawing effect of the fluorine atoms. The dihydrate has no UV absorption spectrum; compare with λ_{max} ($CHCl_3$) 273nm (ε 7,800) for the anhydrous diketone. The dihydrate decomposes at ~90°. The hydrate (10g) can also be dehydrated by heating with anhydrous $CaSO_4$ (Drierite, 30g) and distilling; the distillate is treated with more $CaSO_4$ and redistilled (see above). When the distillate is treated with aqueous NaOH and heated, the dihydrate crystallises on cooling. The *Cu (II) complex* is more easily prepared from the anhydrous than from the hydrated diketone which needs to be dehydrated in the reaction medium, and has **m 135°** (after sublimation or crystallisation from CCl_4). Store hfacac as the dihydrate; but the anhydrous diketone should be kept in an anhydrous atmosphere. [Gilman et al. *J Am Chem Soc* **78** 2790 *1956*, DOI: 10.1021/ja01593a038; Belford et al. *J Inorg Nucl Chem* **2** 11 *1956*, DOI:10.1016/0022-1902(56)80100-0; *Beilstein* **1** III 3123, **1** IV 3681.]

Hexafluoroethane (CFC-116) *[76-16-4]* **C_2F_6, M 138.0, m -100°, b -79°/atm.** Purify it for pyrolysis studies by passing through a copper vessel containing CoF_3 at *ca* 270°, and held for 3 hours in a bottle with a heated (1300°) platinum wire. It is then fractionally distilled in a vacuum line. [Steunenberg & Cady *J Am Chem Soc* **74** 4165 *1962*, DOI: 10.1021/ja01136a062; *Beilstein* **1** III 132.]

Hexafluoropropene (hexafluoropropylene, perfluoropropene, *F*-propene) *[116-15-4]* **C_3F_6, M 150.0, m -153°, -156.2°, b -28°/atm, -29.4°/atm, d_4^{20} 1.583.** *F*-Propene is a gas that is available commercially in brass cylinders and is very **corrosive**, **toxic**, attacks skin and tissue membranes. It is prepared by treating $CFCl_2CFClCF_3$ with Zn in boiling EtOH (3 days), but is faster under pressure at 100°. The gas is best handled in a vacuum line and should be scrubbed over caustic alkali in a brass tube, as any HF present in it will attack glass. [Henne & Waalkes *J Am Chem Soc* **68** 496 *1946*, DOI: 10.1021/ja01207a041; Henne & Hinkamp *J Am Chem Soc* **67** 1194 *1945*, DOI: 10.1021/ja01223a051; *Beilstein* **1** III 697, **1** IV 735.]

1,1,1,3,3,3-Hexafluoropropan-2-ol (HFIP) *[920-66-1]* **$C_3H_2F_6O$, M 168.1, m -4°, b 57-58°/760mm, d_4^{20} 1.4563, n^{22} 1.2750, pK^{25} 9.30.** Distil it from 3A molecular sieves, retaining the middle fraction. It has been prepared by reduction of *hexafluoroacetone* in tetrahydrofuran (THF). In this case hexafluoropropanol forms a stable ***1:1 THF complex*** which distils at **99-100°/760mm** (n_D^{25} 1.3283). The complex is decomposed by mixing with 20% oleum and distilling in a vacuum; the distillate is redistilled to give pure hexafluoropropan-2-ol with **b** 59°/760mm. The ^1H NMR shows a doublet at 4.52ppm ($J_{H,H}$ = 2Hz). The ***benzoyl*** derivative, [10315-85-2] M 272.1, has **m 53.9°** after crystalllisation from pentane at -50°, and its IR has ν_{max} at 1760cm^{-1}. [Middleton & Lindsey *J Am Chem Soc* **86** 4948 *1964*, DOI: 10.1021/ja01076a041; Urry et al. *J Org Chem* **32** 347 *1967*, DOI: 10.1021/jo01288a021.] It has very high peptide solubilising properties, alone or with CH_2Cl_2 [use as a solvent: Narita et al. *Bull Chem Soc Jpn* **61** 281 *1988*, DOI: org/10.1246/bcsj.61.281; Halverson et al. *Biochemistry* **29** 2639 *1990*, DOI: 10.1021/bi00463a003.] It is **CORROSIVE, causes severe eye irritation.**

Hexamethylenediamine (1,6-diaminohexane) *[124-09-4]* **$C_6H_{16}N_2$, M 116.2, m 42°, b 46-47°/1mm, 84.9°/**

9mm, 100°/20mm, 204-205°/760mm, pK_1^{25} 10.24, pK_2^{25} 11.02. Crystallise it in a stream of nitrogen. It sublimes in a vacuum. [*Beilstein* **4** IV 1320.]

Hexamethylenediamine dihydrochloride *[6055-52-3]* **$C_6H_{16}N_2$. HCl, M 189.2, m 248°, 256-257°.** Crystallise the salt from water or EtOH. [*Beilstein* **4** IV 1320.]

Hexamethylene glycol (1,6-hexanediol) *[629-11-8]* **$C_6H_{14}O_2$, M 118.2, m 41.6°, 43-45°, b 134°/10mm, 250°, n_D^{20} 1.458.** Fractionally crystallise it from its melt or from water. Distil it *in vacuo*. [*Beilstein* **1** IV 2556.]

***n*-Hexane** *[110-54-3]* **C_6H_{14}, M 86.2, m -95°, b 68.7°/atm, d_4^{20} 0.660, n 1.37486, n^{25} 1.37226.** Purify as for *n*-heptane. Modifications include the use of chlorosulfonic acid or 35% fuming H_2SO_4 instead of concentrated H_2SO_4 in washing the alkane, and final drying and distilling from sodium hydride. Unsaturated impurities can be removed by shaking the hexane with nitrating acid (58% H_2SO_4, 25% concentrated HNO_3, 17% water, or 50% HNO_3, 50% H_2SO_4), then washing the hydrocarbon layer with concentrated H_2SO_4, followed by H_2O, drying, and distilling over sodium or *n*-butyl lithium. It can also be purified by distillation under nitrogen from sodium benzophenone ketyl solubilised with tetraglyme. Also purify it by passage through a silica gel column followed by distillation [Kajii et al. *J Phys Chem* **91** 2791 *1987*, DOI: 10.1021/j100295a029]. It is a **FLAMMABLE** liquid and a possible nerve toxin. [*Beilstein* **1** IV 338.]
Rapid purification: Distil, discarding the first forerun and store over 4A molecular sieves.

(±)-1,2-Hexanediol *[6920-22-5]* **$C_6H_{14}O_2$, M 118.2, b 96-98°/1mm, 118.4-118.5°/13mm, 214-215°/760mm, d_4^{20} 0.951, n_D^{20} 1.442.** Fractionally distil it, preferably in a vacuum. *Alternatively*, dissolve it in Et_2O, dry with K_2CO_3 then Na_2SO_4, filter, evaporate and distil it in a vacuum. The ***bis*-4-nitrobenzoyl** derivative has **m 101.5-102.5°**. [Rudloff *Can J Chem* **36** 486 *1958*, DOI:10.1139/v58-069; *Beilstein* **1** I 251, **1** III 2200, **1** IV 2554.]

1-Hexene *[592-41-6]* **C_6H_{12}, M 84.2, b 63°/atm, d 0.674, n_D^{20} 1.388.** Purify it by stirring over Na/K alloy for at least 6 hours, then fractionally distil it from sodium under nitrogen. [*Beilstein* **1** IV 828.]

***cis*-2-Hexene** *[7688-21-3]* **C_6H_{12}, M 84.2, b 68-70°/atm, d_4^{20} 0.699, n_D^{20} 1.399.** Purify it as for 1-hexene above. [*Beilstein* **1** IV 833.]

***trans*-2-Hexene** *[4050-45-7]* **M 84.2, m -98.5 to -98°, b 65-67°/atm, n_D^{20} 1.390.** Purify it as for 1-hexene above. [*Beilstein* **1** IV 834.]

***cis*-3-Hexene** *[7642-09-3]* **C_6H_{12}, M 84.2, b 66-68°/atm, d_4^{20} 0.681, n_D^{20} 1.395.** Purify it as for 1-hexene above. [*Beilstein* **1** IV 830.]

***trans*-3-Hexene** *[13269-52-8]* **C_6H_{12}, M 84.2, b 67-69°/atm, d_4^{20} 0.678, n_D^{20} 1.393.** Purify it as for 1-hexene above. [*Beilstein* **1** IV 837.]

***n*-Hexyl alcohol (1-hexanol)** *[111-27-3]* **$C_6H_{14}O$, M 102.2, m -52°, b 157.5°/atm, d_4^{20} 0.818, n^{15} 1.4198, n^{25} 1.4158.** The commercial material usually contains other alcohols which are difficult to remove. A suitable method is to esterify with hydroxybenzoic acid, recrystallise the ester and saponify. [Olivier *Recl Trav Chim Pays-Bas* **55** 1027 *1936*, DOI:10.1002/recl.19360551207.] Drying agents include K_2CO_3 and $CaSO_4$, followed by filtration and distillation. (Some decomposition to the olefin occurs when Al amalgam is used as drying agent at room temperature, even if the amalgam is removed prior to distillation.) If the alcohol is required anhydrous, the redistilled material can be refluxed with the appropriate alkyl phthalate or succinate, as described under *Ethanol*. [*Beilstein* **1** IV 1694.]

***n*-Hexylamine** *[111-26-2]* **$C_6H_{15}N$, M 101.2, m -23°, b 131°/atm, d_4^{20} 0.765, n_D^{20} 1.419, pK^{25} 10.64.** Dry with, and fractionally distil the hexylamine from, KOH or CaH_2. Store away from CO_2. [*Beilstein* **4** IV 709.]

***n*-Hexyl bromide** *[111-25-1]* **$C_6H_{13}Br$, M 165.1, m -85°, b 87-88°/90mm, 155°/743mm, d_4^{20} 1.176, n_D^{20} 1.448.** Shake the bromide with H_2SO_4, wash with water, dry (K_2CO_3) and fractionally distil. Store in the dark.

[*Beilstein* **1** IV 352.]

***n*-Hexyl methacrylate** *[142-09-6]* **$C_{10}H_{18}O_2$, M 170.3, b 65-66°/4mm, 88-88.5°/14mm, 203°/atm, d_4^{20} 0.8849, n_D^{20} 1.4320.** Purify it as for *methyl methacrylate*. [IR Walton & Hughes *J Am Chem Soc* **79** 3985 *1957*, DOI: 10.1021/ja01572a008; *Beilstein* **2** III 1288, **2** IV1527.]

Hexyltrimethylammonium bromide *[2650-53-5]* **$C_9H_{22}BrN$, M 224.3, m 186°.** Recrystallise it from acetone. It is extremely *hygroscopic*, store accordingly. [McDowell and Kraus *J Am Chem Soc* **73** 2170 *1951*, DOI: 10.1021/ja01149a074; *Beilstein* **4** IV 710.]

1-Hexyne *[693-02-7]* **C_6H_{10}, M 82.2, m -132°, b 12.5°/75mm, 71°/760mm, d_4^{20} 0.7156, n_D^{20} 1.3989.** Distil it from $NaBH_4$ to remove peroxides. Stand over sodium for 24 hours, then fractionally distil it under reduced pressure. Also dry it by repeated vacuum transfer into freshly activated 4A molecular sieves, followed by vacuum transfer onto Na/K alloy, and stirring for 1 hour before fractionally distilling. [*Beilstein* **1** IV 1006.]

2-Hexyne *[764-35-2]* **C_6H_{10}, M 82.2, b 83.8°/760mm, d_4^{20} 0.73146, n_D^{20} 1.41382.** Purify as for 1-hexyne above. [*Beilstein* **1** IV 1009.]

3-Hexyne *[928-49-4]* **C_6H_{10}, M 82.2, b 81°/760mm, d_4^{20} 0.7231, n_D^{20} 1.4115.** Purify as for 1-hexyne above. [*Beilstein* **1** IV 1009.]

(±)-5-Hexyn-3-ol (4-hydroxy-1-hexyne) *[19780-84-8]* **$C_6H_{10}O$, M 98.1, b 58-59°/25mm, 73-76°/60mm, d_4^{20} 0.8918, n_D^{20} 1.4437.** Purify the hexynol by fractionation in a vacuum. The ***carbamoyl*** derivative (prepared by reaction with $COCl_2$/toluene followed by NH_3) is crystallised by dissolving in the minimum volume of toluene and adding excess of petroleum ether (b 40-60°), and has **m 70-71°**. [Läuger et al. *Helv Chim Acta* **42** 2379 *1959*, DOI: 10.1002/hlca.19590420710; *Beilstein* **1** IV 2235.]

Hydrazine *N,N*'-dicarboxylic acid diamide *[110-21-4]* **$C_2H_6NO_2$, M 116.1, m 245-246°(dec), 248°.** Crystallise the diamide from water, wash the crystals with EtOH then Et_2O and dry in vacuum over P_2O_5. It does **not** decompose on drying at 110° /48 hours. Its solubility in H_2O is 1% at 0°. [Audrieth & Mohr *Inorg Synth* **4** 26 *1953*, *Beilstein* **3** H 116, **3** I 56, **3** II 95, **3** III 229.]

3-Hydroxy-2-butanone (acetoin) *[513-86-0]* **$C_6H_8O_2$, M 88.1, m 15°, b 144-145°, [m 100-105° dimer].** Wash acetoin with EtOH until colourless, then with diethyl ether or acetone to remove biacetyl. Dry it in air by suction and dry further in a vacuum desiccator. [*Beilstein* **1** IV 3991.]

(±)-α-Hydroxy-γ-butyrolactone *[19444-84-9, S(-)- 733-52-4, 52079-23-9; R(±) 56881-90-4]* **$C_4H_6O_3$, M 102.1, b 84°/0.2mm, 133°/10mm, d_4^{20} 1.310, n_D^{20} 1.4656.** It has been purified by repeated fractionation and forms a colourless liquid. It has to be distilled at high vacuum; otherwise it will dehydrate. The ***acetoxy*** derivative has **b 94°/0.2mm**. The *S-enantiomer* [52079-23-9] has d_4^{20} 1.309, n_D^{20} 1.467, $[\alpha]_D^{25}$ -82 (c 2, MeOH), $[\alpha]_D^{25}$ -68 (c 1.15, $CHCl_3$). [NMR: Daremon & Rambaud *Bull Soc Chim Fr* 294 *1971*, Schmitz et al. *Chem Ber* **108** 1010 *1975*, DOI: 10.1002/cber.19751080405; *Beilstein* **18/1** V 3.]

12-Hydroxydodecanoic acid (12-hydroxylauric acid) *[505-95-3]* **$C_{12}H_{24}O_3$, M 216.3, m 86-88°, pK_{Est} ~4.8.** Recrystallise the acid from toluene. [Sadownik et al. *J Am Chem Soc* **108** 7789 *1986,* DOI: 10.1021/ja00284a050]. [*Beilstein* **3** III 658.]

***N*-[2-Hydroxyethyl]ethylenediamine [2-(2-aminoethylamino)ethanol]** *[111-41-1]* **$C_4H_{12}N_2O$, M 104.1, b 91.2°/5mm, 238-240°/752mm, d_4^{20} 1.030, n_D^{20} 1.485, pK_1^{20} 3.75, pK_2^{20} 9.15.** Distil the amine twice through a Vigreux column. Redistil it from solid NaOH, then from CaH_2. *Alternatively*, it can be converted to the dihydrochloride and recrystallised from water. It is then dried, mixed with excess of solid NaOH and the free base is distilled from the mixture. It is finally redistilled from CaH_2. [Drinkard et al. *J Am Chem Soc* **82** 2992 *1960*, DOI: 10.1021/ja01497a004; *Beilstein* **4** IV 1558.]

***N*-[2-Hydroxyethyl]ethylenediaminetriacetic acid (HEDTA)** *[150-39-0]* **$C_{10}H_{18}N_2O_7$, M 278.3, m 212-214°(dec), pK_1^{20} 2.51, pK_2^{20} 5.31, pK_3^{20} 9.86.** Crystallise HEDTA from warm H_2O, after filtering, by addition of 95% EtOH and allowing to cool. The crystals, collected on a sintered-glass funnel, are washed three times with cold absolute EtOH, then again crystallised from H_2O. After leaching with cold H_2O, the crystals are dried at 100° under vacuum. [Spedding et al. *J Am Chem Soc* **78** 34 *1956*, DOI: 10.1021/ja01582a007; *Beilstein* **4** IV 2449.] It is useful buffer.

***N*-Hydroxyethyliminodiacetic acid (HIMDA, ethanol diglycine)** *[93-62-9]* **$C_6H_{11}NO_5$, M 177.2, m 181°(dec), pK_1^{25} 2.16, pK_2^{25} 8.72, pK_3^{25} 13.7 (OH).** Crystallise HIMDA from water. [*Beilstein* **4** IV 2432.]

2-Hydroxyethylimino-tris(hydroxymethyl)methane (MONO-TRIS) *[7343-51-3]* **$C_6H_{15}NO_4$, M 165.2, m 91°, pK_{Est} ~9.8.** Crystallise it twice from EtOH. Dry it under vacuum at 25°. The pure ***hydrochloride*** was isolated as a syrup [Pierce & Wotiz *J Am Chem Soc* **66** 879 *1944*, DOI: 10.1021/ja01234a010.] [*Beilstein* **4** III 858.] It is useful buffer.

2-Hydroxyethyl methacrylate *[868-77-9]* **$C_6H_{10}O_3$, M 130.1, b 67°/3.5mm, d_4^{20} 1.071, n_D^{20} 1.452.** Dissolve the ester in water and extract with *n*-heptane to remove ethylene glycol dimethacrylate (checked by gas-liquid chromatography and by NMR) and distil it twice under reduced pressure [Strop et al. *J Phys Chem* **80** 694 *1976*, DOI: 10.1021/j100548a008]. [*Beilstein* **2** IV 1530.]

***dl*-2-Hydroxy-2-methylbutyric acid** *[3739-30-8]* **$C_5H_{10}O_3$, M 118.1, m 72-73°, pK^{25} 3.73.** Crystallise the acid from *benzene, and sublime it at 90°. [*Beilstein* **3** H 324.] **IRRITANT.**

***dl*-2-Hydroxy-3-methylbutyric (α-hydroxyisovaleric) acid** *[4026-18-0]* **$C_5H_{10}O_3$, M 118.1, m 86°, pK_{Est} ~3.9.** Crystallise the acid from ether/pentane. [*Beilstein* **3** IV 618.] **IRRITANT.**

***R*(-)-γ-Hydroxymethyl-γ-butyrolactone** *[52813-63-5]* **$C_5H_8O_3$, M 116.1, b 101-102°/0.048mm, d_4^{20} 1.2238, n_D^{20} 1.471, $[\alpha]_{546}^{20}$ -38, $[\alpha]_D^{20}$ -33 (c 3, EtOH), $[\alpha]_D^{30}$ -53.5° (c 3, EtOH).** Purify it by column chromatography on Silica gel 60 (Merck 70-230 mesh) and elute with 7% EtOH/73% $CHCl_3$. Its IR (film) has ν_{max} at 3400 (OH), 1765 (C=O) and 1180 (COC) cm^{-1}. [Eguchi & Kakuta *Bull Chem Soc Jpn* **47** 1704 *1974*, DOI: org/10.1246/bcsj.47.1704; IR and NMR: Ravid et al. *Tetrahedron* **34** 1449 *1978,* DOI: 10.1016/0040-4020(78)80164-1; *Beilstein* **3** III 620, **18** V/1 13]

3-Hydroxy-3-methylglutaric acid (Meglutol) *[503-49-1]* **$C_6H_{10}O_5$, M 162.1, m 99-102°, 108-109°, 100°, $pK_{Est(1)}$ ~4.0, $pK_{Est(2)}$ ~5.0.** Recrystallise the acid from diethyl ether/hexane and dry it under a vacuum at 60° for 1 hour. [*Beilstein* **3** IV 1166.]

4-Hydroxy-4-methyl-2-pentanone (diacetone alcohol) *[123-42-2]* **$C_6H_{12}O_2$, M 116.2, b 166°, d_4^{20} 0.932, n_D^{20} 1.4235, n_D^{25} 1.4213.** The pentanone loses water when heated. It can be dried with $CaSO_4$, then fractionally distilled under reduced pressure. [*Beilstein* **1** IV 4023.]

2-Hydroxy-2-methylpropionic acid (α-hydroxyisobutyric acid, 2-methyllactic acid) *[594-61-6]* **$C_4H_8O_3$, M 104.1, m 79°, b 114°/12mm, 212°/760mm, pK^{25} 3.78.** Distil the acid in steam, crystallise it from Et_2O or *benzene, dry it under vacuum, or sublime it at 50°. [*Beilstein* **3** IV 782.]

(±)-2-Hydroxyoctanoic acid (2-hydroxycaprylic acid) *[617-73-2, 6482-96-2 non-specific]* **$C_8H_{16}O_3$, M 160.2, m 69.5°, b 160-165°/10mm, pK_{Est} ~3.7.** Crystallise the (±)-acid from EtOH/petroleum ether or ether/ligroin. The (±)-racemic and *laevo* 2-hydroxy acids were prepared by a general procedure of anodic coupling in a cooled electrolytic cell with Platinum-foil electrodes in methanolic solution using a current of 1 amp and at 50 Volts, and run until the solution became neutral (~ 10—15 hrs). Thus a mixture of *ethyl O-acetylmalic acid mono-α-ester* (racemic or chiral, only the isomer with the free un-esterified γ-carboxy group reacts) and n-*hexanoic acid* decarboxylate and couple to give the respective ***(±)-2-hydroxyoctanoic acid*** or, when the mono ester derived from *S(-)-malic acid* is used, the chiral ***S*(+)-2-hydroxyoctanoic acid** [70267-27-5] which, after distillation followed by recrystallisation from isopropyl ether (fine needles) has **m 70.2-70.6°, $[\alpha]_D^{19}$**

+6.2 (*l* 0.5, c 9.2, $CHCl_3$), $[\alpha]_D^{19}$ **+1.5 (*l* 0.5, c 6.8, EtOH)**, $[\alpha]_D^{19}$ **+3.0 (*l* 0.5, c 4.27, H_2O** containing **10—15% of MeOH)**. ***S*(-)-2-hydroxyoctanoic acid sodium salt**, obtained by titration with one mol of aqueous 0.185 N NaOH, has $[\alpha]_D^{19}$ **-18 (*l* 0.5, c 5.05, 50% aqueous EtOH)**, and $[\alpha]_D^{19}$ **-10.3 (*l* 0.5, c 10.1, H_2O)**. ***Methyl S*(+)-2-hydroxyoctanoate** [85549-54-8] **$C_9H_{18}O_3$, M 174.2,** has **b 118°/22mm,** d_4^{16} **0.9686,** n_D^{18} **1.4342,** $[\alpha]_D^{16}$ **+2.80 (neat)**, $[\alpha]_D^{16}$ **+11 (*l* 0.5, c 10.03, $CHCl_3$)**. ***N*-Hydroxysuccinimide** *[6066-82-6]* **$C_4H_5NO_3$, M 115.1, m 96-98°, pK^{25} 6.0.** Recrystallise from EtOH/ethyl acetate [Manesis & Goodman *J Org Chem* **52** 5331 *1987*, DOI: 10.1021/jo00233a006]. [*Beilstein* **21/9** V 498.]

(±)-2-Hydroxy-*n*-tetradecanoic acid (α-hydroxymyristic acid) *[2507-55-3]* **$C_{14}H_{28}O_3$, M 244.4, m 81-82°, pK_{Est} ~3.7.** Crystallise the acid from chloroform or twice from MeOH (**m 85.8-86.6°**) [Horn & Pretorius *J Chem Soc* 1460 *1954,* DOI: 10.1039/JR9540001460; Chibnall et al. *Biochem J* **30** 100 *1936*, DOI: 10.1042/bj0300100; *Beilstein* **3** H 361, **3** I 130, **3** II 246, **3** III 660, **3** IV 921].

R*(-)-2-Hydroxy-*n*-tetradecanoic acid** *[26632-17-7]* **$C_{14}H_{28}O_3$, M 244.4, m 88-2-88.5°, $[\alpha]_D^{20}$ -3.1 ($CHCl_3$).** Crystallise the acid from $CHCl_3$, or first from Me_2CO, then hexane at -30°. Obtained by liquid-liquid extraction (counter-current distribution of liquids) of the *methyl ester* isolated from wool wax, hydrolysed and recrystallised. ***Methyl R*(-)-2-hydroxy-n-tetradecanoate** [149948-89-0] **$C_{15}H_{30}O_3$,** M **258.4**, was purified by distillation, **b 133.5-136.5°/1mm**, followed by recrystallisation from Et_2O then Me_2CO at low temperature to provide a white powder with **m 34.8-35.0°, $[\alpha]_D^{20}$ -3.6 (c 9, $CHCl_3$)**. [Horn & Pretorius *J Chem Soc* 1460 *1954,* DOI: 10.1039/JR9540001460; Horn et al. *J Chem Soc* 177 *1954*, DOI: 10.1039/JR9540000177; *Beilstein* **3** III 660.] The ***S*(+)-enantiomer** [67253-09-2] was isolated from *Salmonella* polysaccharide. ***Methyl S*(+)-2-hydroxy-n-tetradecanoate** has [149948-88-9], and the ***racemic methyl ester has [130823-84-6].

Iminodiacetic acid *[142-73-4]* **$C_4H_7NO_4$, M 133.1, m 225°(dec), pK_1^{25} 2.50, pK_2^{25} 9.40.** Recrystallise iminodiacetic acid from water and dry it in a vacuum over P_2O_5. [*Beilstein* **4** IV 2428.]

Iodoacetamide *[144-48-9]* **$C_2H_4INO_2$, M 185.0, m 93-94°, 92-95°.** It has been prepared from chloroacetamide and NaI in Me_2CO [Hellstrom *Z physic Chem* [A] **157** 246 *1931*]. Crystallise it from water $CHCl_3$, or CCl_4. It is used for tagging proteins. [Gurd *Methods Enzymol* **25** 424 1972, DOI: 10.1016/S0076-6879(72)25038-8; *Beilstein* **2** H 223, **2** III 487, **2** IV 537.]

Iodoacetic acid *[64-69-7]* **$C_2H_3IO_2$, M 186,0, m 78°, pK^{25} 3.19.** Crystallise it from petroleum ether (b 60-80°) or $CHCl_3/CCl_4$. Soluble in H_2O. [*Beilstein* **2** IV 534.]

2-Iodobutane (*sec*-butyl iodide) *[513-48-4]* **C_4H_9I, M 184.0, m -104°, b 120°/atm,** d_4^{20} **1.50,** n_D^{25} **1.4973.** Purify the iodide by shaking with concentrated H_2SO_4, then washing it with water, aqueous Na_2SO_3 and again with water. Dry ($MgSO_4$) and distil. *Alternatively*, pass it through a column of activated alumina before distillation, or treat with bromine, followed by extraction of the free halogen with aqueous $Na_2S_2O_3$, thoroughly washing with H_2O, drying and distilling. Store over Ag powder and distilled before use. [*Beilstein* **1** IV 272.]

Iodoform *[75-47-8]* **CHI_3, M 393.7, m 119°, d^{25} 4g/ml.** Crystallise it from MeOH, EtOH or EtOH/EtOAc. It is steam volatile. It is soluble (in g/100ml) in cold EtOH (1.7), boiling EtOH (6.3), cold $CHCl_3$ (10.0), Et_2O (13.3), glycerol (1.2), CS_2 (33.3), olive oil (2.9), freely soluble in $*C_6H_6$ and Me_2CO slightly soluble in petroleum ether and very slightly soluble in H_2O. It is a disinfectant. [*Beilstein* **1** IV 97.]

***N*-Iodosuccinimide** *[516-12-1]* **$C_4H_4INO_2$, M 225.0, m 200-201°.** Crystallise it from dioxane/CCl_4. It is soluble in Me_2CO, MeOH, and dioxane but almost insoluble in CCl_4 or Et_2O and is decomposed by H_2O. It is decomposed by light. It is an iodinating agent and iodinates arenes in triflic acid. [Olah et al *J Org Chem* **58** 3194 *1993*, DOI: 10.1021/jo00063a052; *Beilstein* **21/9** V 544.]

Isoamyl acetate (1-butyl-3-methyl acetate, isopentyl acetate) *[123-92-2]* **$C_7H_{14}O_2$, M 130.2, m -78°, b**

142°/atm, d_4^{20} 0.871, n_D^{20} 1.40535. Dry the acetate with finely divided K_2CO_3 and fractionally distil it. [*Beilstein* **2** IV 157.]

Isoamyl alcohol (3-methyl-1-butanol, 1-butyl-3-methyl alcohol) *[123-51-3]* **$C_5H_{12}O$, M 88.2, m -117°, b 128°/750mm, 132°/760mm, d^{15} 0.8129, n^{15} 1.4085, n_D^{20} 1.4075.** Dry the alcohol by heating with CaO and fractionally distilling, then heating with BaO and redistilling. *Alternatively*, boil it with concentrated KOH solution, wash it with dilute H_3PO_4, and dry it with K_2CO_3, then anhydrous $CuSO_4$, before fractionally distilling it. If very dry alcohol is required, the distillate is refluxed with the appropriate alkyl phthalate or succinate as described for *ethanol*. It is separated from 2-methyl-1-butanol by fractional distillation, fractional crystallisation and preparative gas chromatography. [*Beilstein* **1** IV 1677.]

Isoamyl bromide (1-butyl-3-methyl bromide) *[107-82-4]* **$C_5H_{11}Br$, M 151.1, f -112°, b 119.2°/ 737mm, d_4^{20} 1.208, n 1.444.** Shake the bromide with concentrated H_2SO_4, wash with water, dry with K_2CO_3 and fractionally distil it. [*Beilstein* **1** IV 328.]

Isoamyl chloride (1-butyl-3-methyl chloride) *[107-84-6]* **$C_5H_{11}Cl$, M 106.6, b 99°/734mm, d_4^{20} 0.8704, n_D^{20} 1.4084.** Shake the chloride vigorously with 95% H_2SO_4 until the acid layer no longer becames coloured during 12 hours, then wash it with water, saturated aqueous Na_2CO_3, and more water. Dry it with $MgSO_4$, filter and fractionally distil it. *Alternatively*, a stream of oxygen containing 5% of ozone is passed through the chloride for a time, three times longer than is necessary to cause the first coloration of starch iodide paper by the exit gas. Subsequent washing of the liquid with aqueous $NaHCO_3$ hydrolyses the ozonides and removes organic acids. After drying and filtering, the isoamyl chloride is distilled. [Chien & Willard *J Am Chem Soc* **75** 6160 *1953*, DOI: 10.1021/ja01120a016; *Beilstein* **1** IV 287.]

Isoamyl ether [diisopentyl ether, di-(1-butyl-3-methyl) ether] *[544-01-4]* **$C_{10}H_{22}O$, M 158.3, b 173.4°/atm, d_4^{20} 0.778, n_D^{20} 1.40850.** This is a mixture of 2- and 3-methylbutyl ether. It is purified by refluxing with sodium for 5 hours, then it is distilled under reduced pressure, to remove alcohols. Isoamyl ether can also be dried with $CaCl_2$ and fractionally distilled from P_2O_5. [*Beilstein* **1** IV 1682.]

Isobutane (2-methylpropane) *[75-28-5]* **C_4H_{10}, M 58.1, m -160°, b -10.2°/atm, d_4^{20} 0.557.** Olefins and moisture can be removed by passage at 65° through a bed of silica-alumina catalyst which has previously been evacuated at about 400°. *Alternatively*, water and CO_2 can be removed by passage through P_2O_5, then asbestos impregnated with NaOH. Treatment with anhydrous $AlBr_3$ at 0° then removes traces of olefins. Inert gases can be separated by freezing the isobutane at -195° and evacuating out the system. [*Beilstein* **1** IV 282.]

Isobutene (2-methylpropene, isobutylene) *[115-11-7]* **C_4H_8, M 56.1, b -6.6°/760mm.** Dry isobutene by passage through anhydrous $CaSO_4$ at 0°. Purify it further by freeze-pump-thaw cycles and trap-to-trap distillation. [*Beilstein* **1** IV 796.]

Isobutyl bromide (1-bromo-2-methylpropane) *[78-77-3]* **C_4H_9Br, M 137.0, b 91.2°/atm, d_4^{20} 1.260, n_D^{20} 1.437.** Partially hydrolyse it to remove any tertiary alkyl halide, fractionally distil it, then wash it with concentrated H_2SO_4, water and aqueous K_2CO_3, then redistil it from dry K_2CO_3. [Dunbar & Hammett *J Am Chem Soc* **72** 109 *1950*, DOI: 10.1021/ja01157a030; *Beilstein* **1** IV 294.]

Isobutyl chloride (1-chloro-2-methylpropane) *[513-36-0]* **C_4H_9Cl, M 92.6, m -131°, 68.8°/760mm, d_4^{20} 0.877, n_D^{20} 1.398.** Use the same methods as described under *isoamyl chloride* above. [*Beilstein* **1** IV 287.]

Isobutyl chloroformate *[543-27-1]* **$C_5H_9ClO_2$, M 136.6, b 123-127°/atm, 128.8°/atm, d_4^{20} 1.053, n_D^{20} 1.4070.** It can be dried over $CaCl_2$ and fractionated at atmospheric pressure while keeping moisture out. Its purity can be checked by conversion to the *phenyl urethane* derivative with PhNCO [Saunders et al. *J Am Chem Soc* **73** 3796 *1951*, DOI: 10.1021/ja01152a069.] Its IR (film) has ν_{max} at 1780cm^{-1}. [Thompson & Jameson *Spectrochim Acta* **13** 236 *1959*, Röse *Justus Liebigs Ann Chem* **205** 227 *1880*, DOI: 10.1002/jlac.18802050208]. [*Beilstein* **3** IV 26.]

Isobutyl formate *[542-55-2]* **$C_5H_{10}O_2$, M 102.1, b 98.4°/atm, d_4^{20} 0.885, n_D^{20} 1.38546.** Wash the formate with saturated aqueous $NaHCO_3$, in the presence of saturated aqueous NaCl solution until no further reaction occurs, then with saturated aqueous NaCl, dry ($MgSO_4$) and fractionally distil it. [*Beilstein* **2** H 21, **2** I 18, **2** II 30, **2** III 41, **2** IV 29.]

Isobutyl iodide (1-iodo-2-methylpropane) *[513-38-2]* **C_4H_9I M 184.0, b 83°/250mm, 120°/760mm, d_4^{20} 1.60, n_D^{20} 1.495.** Shake the iodide with concentrated H_2SO_4, and wash it with water, aqueous Na_2SO_3, and water, dry with $MgSO_4$ and distil it. *Alternatively*, pass it through a column of activated alumina before distillation. Store it under nitrogen with some mercury in a brown bottle or in the dark. [*Beilstein* **1** IV 299.]

Isobutyl vinyl ether *[109-53-5]* **$C_6H_{12}O$, M 100.2, m -112°, b 108-110°/atm, d_4^{20} 0.768, n_D^{20} 1.398.** Wash the ether three times with equal volumes of aqueous 1% NaOH, dry it with CaH_2, reflux it with sodium for several hours, then fractionally distil it from sodium. [*Beilstein* **1** IV 2054.]

Isobutyraldehyde (2-methylpropionaldehyde) *[78-84-2]* **C_4H_8O, M 72.1, m -65°, b 62.0°/atm, d_4^{20} 0.789, n_D^{20} 1.377.** Dry isobutyraldehyde with $CaSO_4$ and use it immediately after distillation under nitrogen because of the great difficulty in preventing oxidation. It can be purified through its acid bisulfite derivative. [*Beilstein* **1** IV 3262.]

Isobutyramide (2-methylpropionamide) *[563-83-7]* **C_4H_9NO, M 87.1, m 128-129°, b 217-221°/760mm.** Crystallise the amide from acetone, *C_6H_6, $CHCl_3$, EtOAc or water, then dry it under vacuum over P_2O_5 or 99% at H_2SO_4, or at 70°/3 hours in a desiccator. Sublime it under vacuum. [Kent & McAlvain *Org Synth* Coll Vol **3** 490 *1955*, DOI: 10.15227/orgsyn.025.0058; *Beilstein* **2** H 293, **2** I 129, **2** II 262, **2** III 654, **2** IV 852.]

Isobutyric acid (2-methylpropionic acid) *[79-31-2]* **$C_4H_8O_2$, M 88.1, b 78°/34mm, 154-154.5°/760mm, d_4^{20} 0.949, n_D^{20} 1.393, pK^{25} 4.60.** Distil the acid from $KMnO_4$, then redistil it from P_2O_5. [*Beilstein* **2** H 288, **2** I 126, **2** II 257, **2** III 637, **2** IV 843.]

Isobutyronitrile (2-methylpropionitrile, isopropyl cyanide) *[78-82-0]* **C_4H_7N, M 69.1, m -72°, b 103.6°/760mm, d^{25} 0.7650, n_D^{20} 1.378.** Shake the nitrile with concentrated HCl (to remove isonitriles), then with water and aqueous $NaHCO_3$. After a preliminary drying with silica gel or Linde type 4A molecular sieves, it is shaken or stirred with CaH_2 until hydrogen evolution ceases, then decanted and distilled from P_2O_5 (not more than 5g/L, to minimise gel formation) or Drierite (**b** 101-103°/760mm). Finally it is refluxed with, and slowly distilled from CaH_2 (5g/L), taking precautions to exclude moisture. [*Beilstein* **2** H 294, **2** I 129, **2** II 263, **2** III 655, **2** IV 853.]

Isonitrosoacetone (*anti*-pyruvic aldehyde-1-oxime) *[31915-82-9]* **$C_3H_5NO_2$, M 87.1, m 65-67°, 69°, pK^{25} 8.3.** Crystallise isonitrosoacetone from *C_6H_6, ether/petroleum ether or CCl_4. It sublimes at 90-100° (water bath temperature)/0.05mm [Kahovec & Kohlrausch *Chem Ber* **75** 1541 *1942*, DOI: 10.1002/cber.19420751219]. It forms an iron and a Cu^{2+} salt (**m** 170° dec). [*Beilstein* **1** H 763, **1** I 396, **1** II 822, **1** III 3092, **1** IV 3632.]

(±)-Isononane (3,3,4-trimethylhexane) *[34464-40-9]* **C_9H_{20}, M 128.3, b 142°/760mm, 142°/760mm, d_4^{20} 0.7454, n_D^{20} 1.4178.** Isononane is passed through columns of activated silica gel and basic alumina (activity 1) and distilled under high vacuum from Na/K alloy. [*Beilstein* **1** III 517, **1** IV 462.]

Isopentyl formate *[110-45-2]* **$C_6H_{12}O_2$, M 116.2, b 27°/10mm, 123-123.6°/760mm, 123-124°/atm, d_4^{20} 0.8713, n_D^{20} 1.391.** The colourless liquid ester is soluble in 300 volumes of H_2O and is soluble in common organic solvents. It is purified by repeated distillation using an efficient column at atmospheric pressure. [*Beilstein* **2** H 22, **2** I 18, **2** II 31, **2** III 43, **2** IV 30.]

Isoprene (2-methyl-1,3-butadiene) *[78-79-5]* **C_5H_8, M 68.1, b 34.5-35°/762mm, d_4^{20} 0.681, n^{25} 1.4225.** Reflux it with sodium then distil it from sodium or $NaBH_4$ under nitrogen, and pass it through a column containing KOH, $CaSO_4$ and silica gel. *tert*-Butylcatechol (0.02% w/w) is added, and the isoprene is stored in this way until redistilled before use. The inhibitor (*tert*-butylcatechol) in isoprene can be removed by several

washings with dilute NaOH and water. The isoprene is then dried over CaH_2, distilled under nitrogen at atmospheric pressure, and the fraction distilling at 32° is collected. Store it under nitrogen at -15°. [*Beilstein* **1** H 252, **1** IV 1001.]

Isopropenyl acetate (1-methylvinyl acetate, 2-acetoxypropene) *[108-22-5]* **$C_5H_8O_2$, M 100.1, b 96.7°/749mm, 97.2-97.4°/757mm, d_4^{25} 0.909, n_D^{20} 1.4010.** Prepared by reacting ketene with a mixture of Me_2CO and polyphosphoric acid [Wacher US Patent 2 867 653 *1957*], fractionally distilling through a 75cm packed column, and collecting the fraction with **b 96.7°/749mm**. It forms an azeotrope with H_2O. Its equivalent weight is determined by hydrolysis in 90% EtOH containing twice the required amount of NaOH and titrating the excess of alkali; which should give an equivalent weight of ~100.1. Its heat of hydrolysis has been determined [Sunner *Acta Chem Scand* **11** 1757 *1957*, DOI: 10.3891/acta.chem.scand.11-1757]. It is a good source the $=CMe_2$ group, as in the preparation of Meldrum's acid (see [2033-24-1]), because it is the activated enol ester of acetone. Its FT-IR (neat) has ν_{max} at 1757.3, 1673.0, 1431.4, 1372.5, 1253.1, 1198.2, 1027.9, 900.0 and 871.4 cm^{-1}; the ^1H NMR (60MHz, $CDCl_3$, TMS) has δ at 1.92 (s, 3H, ester Me), 2.13 (s, 3H, isoPr-Me) and 7.00 (d, J = ~6Hz, 2H, $=CH_2$); and the ^{13}C NMR (15MHz, $CDCl_3$, TMS) has δ at 19.54, 21.05, 102.05, 152.94 and 169.04. [*Beilstein* **2** III 278, **2** IV 179.]

Isopropanol (propan-2-ol) *[67-63-0]* **C_3H_8O, M 60.1, m -89.5°, b 82.5°/atm, d_4^{20} 0.783, $n^{25.8}$ 1.3739, pK^{25} 17.1.** Isopropyl alcohol is prepared commercially by dissolution of propene in H_2SO_4, followed by hydrolysis of the sulfate ester. Major impurities are water, lower alcohols and oxidation products such as aldehydes and ketones. Purification of isopropanol follows substantially the same procedure as for *n*-propyl alcohol.
Isopropanol forms a constant-boiling mixture, **b** 80.3°, with water. Most of the water can be removed from this 91% isopropanol by refluxing with CaO (200g/L) for several hours, then distilling. The distillate can be dried further with CaH_2, magnesium ribbon, BaO, $CaSO_4$, calcium, anhydrous $CuSO_4$ or Linde type 5A molecular sieves. Distillation from sulfanilic acid removes ammonia and other basic impurities. Peroxides [indicated by liberation of iodine from weakly acid (HCl) solutions of 2% KI] can be removed by refluxing with solid stannous chloride or with $NaBH_4$ then the alcohol is fractionally distilled. To obtain isopropanol containing only 0.002M of water, sodium (8g/L) is dissolved in material dried by distillation from $CaSO_4$. Isopropyl benzoate (35ml) is then added and, after refluxing for 3 hours, the alcohol is distilled through a 50-cm Vigreux column [Hine & Tanabe *J Am Chem Soc* **80** 3002 *1958*, DOI: 10.1021/ja01545a026]. Other purification steps for isopropanol include refluxing with solid aluminium isopropoxide, refluxing with $NaBH_4$ for 24 hours, and removing acetone by treatment with, and distillation from 2,4-dinitrophenylhydrazine. Peroxides re-form in isopropanol if it is kept for several days in contact with air. [*Beilstein* **1** IV 1461.]

Isopropyl acetate *[108-21-4]* **$C_5H_{18}O_2$, M 102.1, m -73°, b 88.4°/atm, d_4^{20} 0.873, n_D^{20} 1.3773.** Wash the acetate with 50% aqueous K_2CO_3 (to remove acid), then with saturated aqueous $CaCl_2$ (to remove any alcohol). Dry it with $CaCl_2$ and fractionally distil it. [*Beilstein* **2** IV 141.]

Isopropyl acrylamide *[2210-25-5]* **$C_6H_{11}NO$, M 113.2, m 60-63°, b 89-92°/2mm, 110-115°/15mm.** Fractionate the amide under reduced pressure, and recrystallise the solid distillate from hexane (**m** 59°), $*C_6H_6$ (**m** 62°) or $*C_6H_6$/hexane (**m** 62-63°). Store it with 0.05% of 4-*tert*-butylcatechol. It is used for making water soluble swellable hydrogels. [*Beilstein* **4** IV 517.]

Isopropyl bromide (2-bromopropane) *[75-26-3]* **C_3H_7Br, M 123.0, m -89°, b 0°/69.2mm, 59.4°/760mm, d_4^{20} 1.31, n^{15} 1.42847, n_D^{20} 1.4251.** Wash the bromide with 95% H_2SO_4 (concentrated acid partially oxidised it) until a fresh portion of acid did not become coloured after several hours, then with water, aqueous $NaHSO_3$, aqueous 10% Na_2CO_3 and again with water. (The H_2SO_4 can be replaced by concentrated HCl.) Prior to this treatment, isopropyl bromide has been purified by bubbling a stream of oxygen containing 5% ozone through it for 1 hour, followed by shaking with 3% hydrogen peroxide solution, neutralising with aqueous Na_2CO_3, washing with distilled water and drying. *Alternatively*, it has been treated with elemental bromine and stored for 4 weeks, then extracted with aqueous $NaHSO_3$ and dried with $MgSO_4$. After the acid treatment, isopropyl bromide can be dried with Na_2SO_4, $MgSO_4$ or CaH_2, and fractionally distilled. [*Beilstein* **1** IV 208.]

Isopropyl chloride (2-chloropropane) *[75-29-6]* **C_3H_7Cl, M 78.5, m -118°, b 34.8°/atm, d_4^{20} 0.864, n_D^{20}**

1.3779, n^{25} 1.3754. Purify the chloride with 95% H_2SO_4 as described for *isopropyl bromide*, then dry with $MgSO_4$, P_2O_5 or CaH_2, and fractionally distil it from Na_2CO_3 or CaH_2. *Alternatively*, a stream of oxygen containing *ca* 5% ozone is passed through the chloride for about three times as long as is necessary to obtain the first coloration of starch iodide paper by the exit gas, and the liquid is then washed with $NaHCO_3$ solution to hydrolyse ozonides and remove organic acids before drying and distilling. [*Beilstein* **1** IV 191.]

Isopropyl ether (diisopropyl ether) *[108-20-3]* **$C_6H_{14}O$, M 102.2, m -85°, b 68.3°/atm, d_4^{20} 0.719, n_D^{20} 1.3688, n^{25} 1.36618.** Common impurities are water and peroxides [detected by the liberation of iodine from weakly acid (HCl) solutions of 2% KI]. Peroxides can be removed by shaking with aqueous Na_2SO_3 or with acidified ferrous sulfate (0.6g $FeSO_4$ and 6ml concentrated H_2SO_4 in 110ml of water, using 5-10g of solution per L of ether), or aqueous $NaBH_4$ solution. The ether is then washed with water, dried with $CaCl_2$ and distilled. *Alternatively*, refluxing with $LiAlH_4$ or CaH_2, or drying with $CaSO_4$, then passage through an activated alumina column, can be used to remove water and peroxides. Other dehydrating agents used with isopropyl ether include P_2O_5, sodium amalgam and sodium wire. (The ether is often stored in brown bottles, or in the dark, with sodium wire.) Bonner and Goishi (*J Am Chem Soc* **83** 85 *1961*, DOI: 10.1021/ja01462a018) treated isopropyl ether with dilute sodium dichromate/sulfuric acid solution, followed by repeated shaking with a 1:1 mixture of 6M NaOH and saturated $KMnO_4$. The ether is washed several times with water, dilute aqueous HCl, and water, with a final washing with, and storage over, ferrous ammonium sulfate acidified with H_2SO_4. Blaustein and Gryder (*J Am Chem Soc* **79** 540 *1957*, DOI: 10.1021/ja01560a012*),* after washing with alkaline $KMnO_4$, then water, treated the ether with ceric nitrate in nitric acid, and again washed it with water. Hydroquinone is added before drying with $CaCl_2$ and $MgSO_4$, and refluxing with sodium amalgam (108g Hg/100g Na) for 2 hours under nitrogen. The distillate (nitrogen atmosphere) is made 2 x 10^{-5}M in hydroquinone to inhibit formation of peroxides (which is negligible if the ether is stored in the dark). Catechol (pyrocatechol) and resorcinol are alternative inhibitors. [*Beilstein* **1** IV 1471.]

Isopropyl iodide (2-iodopropane) *[75-30-9]* **C_3H_7I, M 170.0, m -90°, b 88.9°/atm, d_4^{20} 1.70, n_D^{20} 1.4987.** Treat the iodide with bromine, followed by extraction of free halogen with aqueous $Na_2S_2O_3$ or $NaHSO_3$, washing with water, drying ($MgSO_4$ or $CaCl_2$) and distilling. (The treatment with bromine is optional.) Other purification methods include passage through activated alumina, or shaking with copper powder or mercury to remove iodine, drying with P_2O_5 and distilling. Washing with concentrated H_2SO_4 or concentrated HCl (to remove any alcohol), water, aqueous Na_2SO_3, water and aqueous Na_2CO_3 has also been used. Treatment with silica gel causes some liberation of iodine. Distillations should be carried out at slightly reduced pressure. Purified isopropyl iodide is stored in the dark in the presence of a little mercury. [*Beilstein* **1** IV 223.]

Isopropyl methyl ether *[598-53-8]* **$C_4H_{10}O$, M 74.1, b 32.5°/777mm, d^{15} 0.724, n_D^{20} 1.3576.** Purify the ether by drying with $CaSO_4$, passing through a column of alumina (to remove peroxides) and fractional distillation. [*Beilstein* **1** H 362, **1** II 381, **1** III 1458, **1** IV 1471.]

Isovaleric acid (3-methylbutyric acid) *[502-74-2]* **$C_5H_{10}O_2$, M 102.1, m -29°, b 176.5°/762mm, d_4^{20} 0.927, n^{15} 1.4064, n_D^{20} 1.40331, pK^{25} 4.77.** Dry the acid (Na_2SO_4), then fractionally distil. [*Beilstein* **2** IV 895.]

Itaconic acid (2-propen-1,2-dicarboxylic acid) *[97-65-4]* **$C_5H_6O_4$, M 130.1, m 165-166°, pK_1^{25} 3.63, pK_2^{25} 5.00.** Crystallise itaconic acid from EtOH, EtOH/water or EtOH/*benzene. [*Beilstein* **2** IV 2228.]

Itaconic anhydride (2-propen-1,2-dicarboxylic anhydride) *[2170-03-8]* **$C_5H_4O_3$, M 112.1, m 66-68°, 67-68°, 68°, b 114-115°/12mm, 139-140°/30mm.** Crystallise the anhydride from $CHCl_3$/petroleum ether. It can be distilled under reduced pressure. Distillation at atmospheric pressure, or prolonged distillation causes rearrangement to citraconic anhydride (2-methylmaleic anhydride). If the material (as seen in the IR spectrum) contains much free acid, then heat with acetyl chloride or $SOCl_2$, evaporate and distil at as high a vacuum as possible. The crude anhydride deposits crystals of itaconic acid on standing probably due to hydrolysis by H_2O — store it in sealed ampoules under dry N_2. [Shriner et al. *Org Synth* Coll Vol **2** 368 *1943*, DOI: 10.15227/orgsyn.011.0070; IR: Nagai *Bull Chem Soc Jpn* **37** 369 *1964*, DOI:org/10.1246/bcsj.37.369; Kelly & Segura *J Am Chem Soc* **56** 2497 *1934*, DOI: 10.1021/ja01326a503; *Beilstein* **17/11** V 66.]

Kerosene *[8008-20-6]* **(mixture of hydrocarbons) b ~175-225°/atm, ~190-250°/atm, d_4^{20} 0.75-0.82, n_D^{20} 1.443.** Stir it with concentrated H_2SO_4 until a fresh portion of acid remains colourless, then wash with water, dry with solid KOH and distil it in a Claisen flask. For more complete drying, the kerosene can be refluxed with Na, and distilled from Na.

Ketene *[463-51-4]* **C_2H_2O, M 42.0, m - 678°, -150°, b -56°/atm, -41°/atm, d_4^{20} 1.093, n_D^{20} 1.441.** Ketene is prepared by pyrolysis of acetic anhydride. Purify it by passing through a trap at -75° and collecting in a liquid-nitrogen-cooled trap. Ethylene is removed by evacuating it in an isopentane-liquid-nitrogen slush pack at -160°. Store it at room temperature in a suitable container in the dark or better at -80°, but do not store it under pressure as it may **EXPLODE**. It is a strong **IRRITANT** when inhaled and is as **POISONOUS** as phosgene. See diketene in 'Heterocyclic Compounds', in this Chapter. [Hurd *Org Synth* Coll Vol **I** 330 *1941*, DOI: 10.15227/orgsyn.004.0039; Andreades & Carlson *Org Synth* Coll Vol **5** 679 *1973*, DOI: 10.15227/orgsyn.045.0050.]

Ketene diethyl acetal (1,1-diethoxyethene) *[2678-54-8]* **$C_6H_{12}O_2$, M 116.2, b 85-87°/200mm,124-126°/atm, d_4^{25} 0.87760, n_D^{25} 1.4101.** It can be prepared by the removal of HI from diethyl iodoacetal with *tert*-BuOK in ~52% yield. The ketene diethyl acetal is distilled off using a Widmer column preferably under vacuum. It is then fractionated again under a vacuum. Distilling is possible at atmospheric pressure but the clear water-like liquid distillate slowly becomes turbid on standing. When distilled under a vacuum the distillate takes a much longer time to become turbid. It should be stored in a dry atmosphere. It reacts rapidly with H_2O or EtOH to liberate heat and form EtOAc or ethyl orthoacetate. It polymerises on heating. [Beyerstedt & McElvain *J Am Chem Soc* **58** 529 *1936*, DOI: 10.1021/ja01294a039; also cf. McElvain & McShane Jr. *J Am Chem Soc* **74** 2662 *1952*, DOI: 10.1021/ja01130a057.] **[***Beilstein* **1** III 2948, **1** IV 3420.]

Ketene dimethyl acetal (1,1-dimethoxyethane) *[922-69-0]* **$C_4H_8O_2$, M 88.1, b 89°/atm, d_4^{25} 0.9294, n_D^{25} 1.4050, 1.3962.** It can be prepared from anhydrous pinacol and sodium which was made to react with dimethyl chloroacetal and the dimethyl ketene acetal formed is distilled off. It is then refractionated to constant refractive index to give pure acetal with **b 89-89.5°/740mm.** [McElvain & McShane Jr. *J Am Chem Soc* **74** 2662 *1952,* DOI: 10.1021/ja01130a057; *Beilstein* **1** III 2947, **1** IV 3420.]

L(+)-Lactic acid **(*S*(+)-2-hydroxypropionic acid)** *[79-33-4]* **$C_3H_6O_2$, M 90.1, m 52.8°, b 105°/0.1mm, $[\alpha]_D^{20}$ +3.82 (H_2O), -13.5 (c 2.5, 1.5M NaOH), pK^{31} 3.83.** Purify lactic acid by fractional distillation at 0.1mm pressure, followed by fractional crystallisation from diethyl ether/isopropyl ether (1:1, dried with sodium). [Borsook et al. *J Biol Chem* **102** 449 *1933*, http://www.jbc.org/content/102/2/449.citation.] The solvent mixture, *benzene/diethyl ether (1:1) containing 5% petroleum ether (b 60-80°) has also been used. Most salts of (+)-lactic acid are *levorotatory* accounting for the negative rotation of alkaline solutions. It tends to form varying amounts of intermolecular esterification. [Brin *Biochemical Preparations* **3** 61 *1953*, *Beilstein* **3** IV 633.]

Lanthanide shift reagents A variety of these reagents are available commercially, and they are generally quite stable and should not deteriorate on long storage in a dry state and in the absence of light. [See J.R. Campbell *Aldrichimica Acta* **4** 55 *1971*, G.R. Sullivan in *Top Stereochem* (Eliel & Allinger Eds) J Wiley & Sons Vol 10 287 *1978*, T.C. Morrill Ed. *Lanthanide Shift Reagents* Deerfield Beach Florida *1986*, ISBN 0895731193.]

Lauraldehyde (1-dodecanal, dodecyl aldehyde) *[112-54-9]* **$C_{12}H_{24}O$, M 184.3, b 99.5-100°/3.5mm, 185°/100mm, d_4^{20} 0.831, n_D^{20} 1.435. $n^{24.7}$ 1.4328.** Convert lauraldehyde to the bisufite addition compound by shaking with saturated aqueous $NaHSO_3$ for 1 hour. The precipitate is filtered off, washed with ice cold water, EtOH and ether, then decomposed with aqueous Na_2CO_3. The aldehyde is extracted into diethyl ether which, after drying and evaporating, gives an oil which is fractionally distilled under vacuum. [*Beilstein* **1** IV 3380.]

Lauric acid (1-dodecanoic acid) *[143-07-7]* **$C_{12}H_{24}O_2$, M 200.3, m 44.1°, b 141-142°/0.6-0.7mm, 225°/100mm, d^{25} 0.883, pK^{20} 5.3.** Distil the acid in a vacuum. Also crystallise it from absolute EtOH, or from acetone at -25°. *Alternatively*, purify it *via* its *methyl ester* (**b 140.0°/15mm**), as described for *capric* acid (see

[334-48-5]). It has also been purified by zone melting. [cf. *Beilstein* **1** III 2913, **3** IV 1082]

Lauroyl peroxide (di-[dodecanoyl] peroxide) *[105-74-8]* **$C_{24}H_{46}O_4$, M 398.6, m 53-54°.** Crystallise it from *n*-hexane or *benzene and store it below 0°. Potentially **EXPLOSIVE**. [*Beilstein* **2** IV 1102.]

_Z_-Maleamic acid (*cis*-maleic acid monoamide) *[557-24-4]* **$C_4H_5NO_3$, M 115.1, m 172°, 172-173°(dec), 178-180°, pK_{Est} ~2.65.** Crystallise it from EtOH. [*Beilstein* **2** H 752, **2** II 646, **2** III 1927, **2** IV 1927.] **IRRITANT**.

Maleic acid (toxilic acid, *cis*-butenedioic acid) *[110-16-7]* **$C_4H_4O_4$, M 116.1, m 143.5°, pK_1^{25} 1.91, pK_2^{25} 6.33.** Crystallise the acid from acetone/petroleum ether (b 60-80°) or hot water. Dry it at 100°. [*Beilstein* **2** H 748, **2** I 303, **2** II 641, **2** III 1911, **2** IV 2199.]

Maleic anhydride see furan-2,5-dione; **Maleic hydrazide** see pyridazine-3,6-diol, and **Maleimide** See pyrrol-2,5-dione all in 'Heterocyclic Compounds', in this Chapter.

Maleuric acid (Z-*N*-carbamoylmaleamic acid) *[105-61-3]* **$C_5H_6N_2O_4$, M 158.1, m 158.5°(dec), 167-168°(dec), pK_{Est} ~ 2.** Crystallise the acid from hot water. Dry it at ~100° over H_2SO_4. It is prepared from maleic anhydride and urea, and is not soluble in most solvents. In H_2O it has λ max at 235nm with ε of 8720. The ***methyl ester*, m 113-114°,** is soluble in hot H_2O, MeOH, EtOH, Me_2CO and dioxane. The ***butyl ester*, m 96-98°**, is soluble in EtOH, Me_2CO, $CHCl_3$ and *C_6H_6. [Batt et al. *J Am Chem Soc* **76** 3663 *1954*, DOI: 10.1021/ja01643a018.] *Beilstein* **3** H 68, **3** III 314, **3** IV 124.]

***dl*-Malic acid (2-hydroxysuccinic acid)** *[617-48-1 and 6915-15-7]* **$C_4H_6O_5$, M 134.1, m 128-129°, 131-132°, pK_1^{25} 3.46, pK_2^{25} 5.10.** Crystallise the acid from acetone, then from acetone/CCl_4, or from ethyl acetate by adding petroleum ether (b 60-70°). Dry it at 35° under 1mm pressure to avoid formation of the anhydride. It is soluble (in g/100ml at 20°) in MeOH (82.7), H_2O (55.8), EtOH (45.3), dioxane (22.7), Me_2CO (17.8), Et_2O (0.8) and *C_6H_6 (~0) [*Beilstein* **3** IV 1124.]

L-Malic acid [*S*(-)-2-hydroxysuccinic acid] *[97-67-6]* **$C_4H_6O_5$, M 134.1, m 104.5-106°, $[\alpha]_D^{20}$ -2.3 (c 8.5, H_2O), $[\alpha]_D^{20}$ -30 (c 5.5, pyridine), pK_1^{25} 3.46, pK_2^{25} 5.10.** Crystallise *S*-malic acid (charcoal) from ethyl acetate/petroleum ether (b 55-56°), keeping the temperature below 65°. Or dissolve it by refluxing in fifteen parts of anhydrous diethyl ether, decant, concentrate to one-third volume and crystallise it at 0°, repeatedly to constant melting point. The **D-enantiomer (*R*(+)-2-hydroxysuccinic acid)** *[636-61-3]* has identical properties except that the optical rotations are positive. [*Beilstein* **3** IV 1123.]

Malonamide (malondiamide) *[108-13-4]* **$C_3H_6N_2O_2$, M 102.1, m 170°, 172-175°.** Crystallise the amide from water. [*Beilstein* **2** IV 1887.]

Malonic acid *[141-82-2]* **$C_3H_4O_4$, M 104.1, m 136°(dec). pK_1^{25} 2.58, pK_2^{25} 5.69.** Crystallise malonic acid from *benzene/diethyl ether (1:1) containing 5% of petroleum ether (b 60-80°), wash with diethyl ether, then re-crystallise it from H_2O or acetone. Dry it under vacuum over concentrated H_2SO_4. It sublimes in high vacuum. It is soluble (in g/10ml at room temperature) in H_2O (15.4), MeOH (10), EtOH (5), *iso*-Pr (3.3), pyridine (1.4) and Et_2O (0.8). [*Beilstein* **2** IV 1874.]

Malononitrile (dicyanomethane) *[109-77-3]* **$C_3H_2N_2$, M 66.1, m 32-34°, b 109°/20mm, 113-118°/25mm, 220°/760mm.** Crystallise the nitrile from water, EtOH, *benzene or chloroform. Distil it in a vacuum from, and store over, P_2O_5. [Bernasconi et al. *J Am Chem Soc* **107** 3612 *1985*, DOI: 10.1021/ja00298a035; Grootenhuis *J Am Chem Soc* **109** 8044 *1987*, DOI: 10.1021/ja00260a016; *Beilstein* **2** IV 1892.]

Meprobamate [2,2-di(carbamoyloxymethyl)pentane] *[57-53-4]* **$C_9H_{18}N_2O_4$, M 218.3, m 104-106°.** Crystallise it from hot water [solubility is 0.34% (w/w) at 20°, and 0.79% (w/w) at 37°], aqueous EtOH (**m 104-105.5°**) or xylene (**m 104.1-105.3°**). It is soluble in most organic solvents. Its aqueous solutions are neutral,

and it is stable in dilute acid and alkaline solutions. It can be an addictive depressant drug. [Ludwig & Piech *J Am Chem Soc* **73** 5779 *1951*, DOI: 10.1021/ja01156a086; *Beilstein* **3** IV 73.]

2-Mercaptoethanol *[60-24-2]* **C_2H_6OS, M 78.1, b 44°/4mm, 53.5°/10mm, 58°/12mm, 68°/20mm, 78.5°/40mm, 96-97° (92°)/100mm, 157°/748mm, d_4^{20} 1.114, n_D^{20} 1.500, pK^{25} 9.72 (9.43).** Purify it by distilling in a vacuum. Distilling at atmospheric pressure causes some oxidation and should be done in an inert atmosphere. [Woodward *J Chem Soc* 1892 *1948*, DOI: 10.1039/JR9480001892.] It has a foul odour, is irritating to the eyes, nose and skin — should be handled in an efficient **fume cupboard.** It is miscible with H_2O, EtOH, Et_2O and *C_6H_6 and the UV has λ_{max} at 235nm. The ***2,4-dinitrophenyl thioether*** has **m 101-102°** (from EtOH or aqueous MeOH) [Grogan et al. *J Org Chem* **20** 50 *1955*, DOI: 10.1021/jo01119a009]. [*Beilstein* **1** IV 2428.]

Mesaconic acid (methylfumaric acid) *[498-24-8]* **$C_5H_6O_4$, M 130.1, m 204-205°, b 204-205°/atm (dec), pK_1^{25} 3.02, pK_2^{25} 4.82.** Crystallise it from H_2O, EtOH (needles) or EtOAc (platelets) and sublime it *in vacuo*. Its solubility in H_2O, is 2.7% w/w at 18° and 118% w/w at the boiling point; in 90% EtOH its solubility is 31%w/w at 17° and 96% w/w at the boiling point; it is soluble in Et_2O but sparingly in $CHCl_3$, CS_2 and light petroleum. It has been prepared by reaction of citraconic anhydride with nitric acid. The ***dimethyl ester*** **$C_7H_{10}O_4$** has **b 204-206°/atm, d_4^{20} 1.1201, n_D^{20} 1.4557.** The ***diethyl ester*** **$C_9H_{14}O_4$** has **b 229°/atm, d_4^{20} 1.0467, n_D^{20} 1.4494.** [Shriner et al. *Org Synth* **11** 74 *1931,* DOI: 10.15227/orgsyn.011.0074; Katakis et al. *JCS Dalton Trans* 1491 *1986*, DOI: 10.1039/DT9860001491]. [*Beilstein* **2** H 763, **2** I 308, **2** II 650, **2** III 1934, **2** IV 2231.]

Mesityl oxide (4-methyl-3-penten-2-one) *[141-79-7]* **$C_6H_{10}O$, M 98.2, m -53°, b 57°/55mm, 128-129°/745mm, 112°/760mm, n^{24} 1.4412, d 0.854, pK^{20} -5.36 (H_o scale, aqueous H_2SO_4).** Purify it by distillation, preferably in a vacuum or *via* the ***semicarbazone*** **(m 165°)** which is decomposed to pure ketone. The ***2,4-dinitrophenylhydrazone*** **(m 205-206°)** crystallises from EtOH. [Johnson *J Am Chem Soc* **73** 5888 *1951*, DOI: 10.1021/ja01156a530; Johnson *J Am Chem Soc* **75** 2720 *1953*, DOI: 10.1021/ja01107a051; Erskine & Waight *J Chem Soc* 3425 *1960*, DOI: 10.1039/JR9600003425; *Beilstein* **1** H 736, **1** I 382, **1** II 793, **1** III 2995, **1** IV 3471.]

α-Methacraldehyde (methacrolein) *[78-85-3]* **C_4H_6O, M 68.1, m -81°, b 68.4°/atm, d_4^{20} 0.849, n_D^{20} 1.416.** Fractionally distil it under nitrogen through a short Vigreux column. Store it in sealed ampoules. (Slight polymerisation may occur.) [*Beilstein* **1** IV 3455.]

Methacrylamide *[79-39-0]* **C_3H_7NO, M 85.1, m 111-112°.** Crystallise the amide from *benzene or ethyl acetate and dry it under vacuum at room temperature. [*Beilstein* **2** IV 1538.]

Methacrylic acid (2-methylpropenoic acid) *[79-41-4]* **$C_4H_6O_2$, M 86.1, m 12-16°, b 72°/14mm, 160°/760mm, 163°/atm d_4^{20} 1.015, n_D^{20} 1.431, pK^{25} 4.65.** Aqueous methacrylic acid (90%) is saturated with NaCl (to remove the bulk of the water), then the organic phase is dried with $CaCl_2$ and distilled under vacuum. Polymerisation inhibitors should be added to the corrosive distillate and include 0.25% *p*-methoxyphenol, 0.1% hydroquinone, or 0.05% *N*,*N*'-diphenyl-*p*-phenylenediamine. [*Beilstein* **2** IV 1518.]

Methacrylic anhydride *[760-93-0]* **$C_8H_{10}O_3$, M 154.2, b 65°/2mm, d_4^{20} 1.040, n_D^{20} 1.454.** Distil the anhydride at 2mm pressure, immediately before use, in the presence of hydroquinone. [*Beilstein* **2** IV 1537.]

Methacrylonitrile *[126-98-7]* **C_4H_5N, M 67.1, m -35.8°, b 90.3°/atm, d_4^{20} 0.800, n_D^{20} 1.4007, n^{30} 1.3954.** Wash it with saturated aqueous $NaHSO_3$ (to remove inhibitors such as *p-tert*-butylcatechol), 1% NaOH in saturated NaCl and then with saturated NaCl. Dry it with $CaCl_2$ and fractionally distil it under nitrogen to separate it from impurities such as methacrolein and acetone. [*Beilstein* **2** IV 1537.]

Methacryloyl chloride *[920-46-7]* **$C_4H_{15}ClO$, M 104.5, m -60°, b 95-96°/760mm, 98.4°/772mm, d^{25} 1.076, n_D^{20} 1.4432.** Purify the ester by fractional distillation. If it contains the acid (OH bands in the IR) then add redistilled $SOCl_2$ (with cooling) and cuprous chloride (ca to 2%), reflux the mixture gently for 1 hour and fractionate it through a 1 metre column packed with glass helices. Redistillation then provides the acid chloride

in high purity as a colourless liquid. It is necessary to keep the apparatus moisture free (use $CaCl_2$ tubes). Stabilise it with 0.05% of 2,6-di-*tert*-butyl-4-methylphenol. [Lal & Green *J Org Chem* **20** 1030 *1955*, DOI: 10.1021/jo01365a013; *Beilstein* **2** IV 1537.]

Methane *[74-82-8]* **CH_4, M 16.0, m -184°, b -164°/760mm, -130°/6.7atmospheres, d_4^0 0.554** (cf. **d_4^0 1.00 for air).** Dry methane by passing over $CaCl_2$ and P_2O_5, then through a Dry-ice trap and fractionally distil it from a liquid-nitrogen trap. Oxygen can be removed by prior passage in a stream of hydrogen over reduced copper oxide at 500°, and higher hydrocarbons can be removed by chlorinating about 10% of the sample: the hydrocarbons, chlorides and HCl are readily separated from the methane by condensing the sample in the liquid nitrogen trap and fractionally distilling it. Methane has also been washed with concentrated H_2SO_4, then solid NaOH and then 30% NaOH solution. It is dried with $CaCl_2$, then P_2O_5, and condensed in a trap at liquid air temperature, then transferred to another trap cooled in liquid nitrogen. CO_2, O_2, N_2 and higher hydrocarbons can be removed from methane by adsorption on charcoal. [Eiseman & Potter *J Res Nat Bur Stand* **58** 213 *1957*, DOI: org/10.6028/jres.058.028; *Beilstein* **1** IV 3.] **HIGHLY FLAMMABLE.**

Methanesulfonic acid *[75-75-2]* **CH_5O_3S, M 96.1, m 20°, b 134.5-135°/3mm, d_4^{20} 1.483, n_D^{20} 1.432, pK^{25} -1.86 (-1.2).** Dry the acid, either by azeotropic removal of water with *benzene or toluene, or by stirring 20g of P_2O_5 with 500ml of the acid at 100° for 0.5 hours. Then distil it under vacuum and fractionally crystallise it by partial freezing. Sulfuric acid, if present, can be removed by prior addition of $Ba(OH)_2$ to a dilute solution, filtering off the $BaSO_4$ and concentrating under reduced pressure; and is sufficiently pure for most applications. [*Beilstein* **4** IV 10.]

Methanesulfonyl chloride *[124-63-0]* **CH_5ClO_2S, M 114.5. b 55°/11mmm, d_4^{20} 1.474, n_D^{20} 1.452.** Distil the sulfonyl chloride from P_2O_5 under vacuum. It is a strong **IRRITANT**. [*Beilstein* **4** IV 27.]

Methanol (methyl alcohol) *[67-56-1]* **CH_4O, M 32.0, m -98°, b 64.5°/atm, 64.7°/atm, d^{15} 0.79609, d^{25} 1.32663, n^{15} 1.33057, n^{25} 1.32663, pK^{25} 15.5.** Almost all methanol is now obtained synthetically. Likely impurities are water, acetone, formaldehyde, ethanol, methyl formate and traces of dimethyl ether, methylal, methyl acetate, acetaldehyde, carbon dioxide and ammonia. Most of the water (down to about 0.01%) can be removed by fractional distillation. Drying with CaO is unnecessary and wasteful. Anhydrous methanol can be obtained from 'absolute' material by passage through Linde type 4A molecular sieves, or by drying with CaH_2, $CaSO_4$, or with just a little more sodium than required to react with the water present, in all cases the methanol is then distilled. Two treatments with sodium reduces the water content to about 5×10^{-5}%. [Friedman et al. *J Am Chem Soc* **83** 4050 *1961*, DOI: 10.1021/ja01480a023.] Lund and Bjerrum [*Chem Ber* **64** 210 *1931*, DOI: 10.1002/cber.19310640204] warmed clean dry magnesium turnings (5g) and iodine (0.5g) with 50-75ml of 'absolute' methanol in a flask until the iodine disappeared and all the magnesium was converted to the methoxide. Up to 1L of methanol was added and, after refluxing for 2-3 hours, it was distilled off, excluding moisture from the system. Redistillation from tribromobenzoic acid removes basic impurities and traces of magnesium oxides, and leaves conductivity-quality material. The method of Hartley and Raikes [*J Chem Soc* **127** 524 *1925*, DOI: 10.1039/CT9252700524] gives a slightly better product. This consists of an initial fractional distillation, followed by distillation from aluminium methoxide, and then ammonia and other volatile impurities are removed by refluxing for 6 hours with freshly dehydrated $CuSO_4$ (2g/L) while dry air is passed through: the methanol is finally distilled. (The aluminium methoxide is prepared by warming with aluminium amalgam (3g/L) until all the aluminium has reacted. The amalgam is obtained by warming pieces of sheet aluminium with a solution of $HgCl_2$ in dry methanol.) This treatment also removes aldehydes.
If acetone is present in the methanol, it is usually removed prior to drying. Bates, Mullaly and Hartley [*J Chem Soc* 401 *1923*, DOI: 10.1039/CT9232300401] dissolved 25g of iodine in 1L of methanol and then poured the solution, with constant stirring, into 500ml of M NaOH. Addition of 150ml of water precipitated iodoform. The solution was allowed to stand overnight, filtered, then boiled under reflux until the odour of iodoform disappeared, and fractionally distilled. (This treatment also removes formaldehyde.) Morton and Mark [*Ind Eng Chem (Anal Edn)* **6** 151 *1934*] refluxed methanol (1L) with furfural (50ml) and 10% NaOH solution (120ml) for 6-12 hours, the refluxing resin carries down with it the acetone and other carbonyl-containing impurities. The alcohol was then fractionally distilled. Evers and Knox [*J Am Chem Soc* **73** 1739 *1951*, DOI: 10.1021/ja01148a090], after refluxing 4.5L of methanol for 24 hours with 50g of magnesium, distilled off 4L of

it, which they then refluxed with $AgNO_3$ for 24 hours in the absence of moisture or CO_2. The methanol was again distilled, shaken for 24 hours with activated alumina before being filtered through a glass sinter and distilled under nitrogen in an all-glass still. Material suitable for conductivity work was obtained.
Variations of the above methods have also been used. For example, a sodium hydroxide solution containing iodine has been added to methanol and, after standing for 1 day, the solution has been poured slowly into about a quarter of its volume of 10% $AgNO_3$, shaken for several hours, then distilled. Sulfanilic acid has been used instead of tribromobenzoic acid in Lund and Bjerrum's method. A solution of 15g of magnesium in 500ml of methanol has been heated under reflux, under nitrogen, with hydroquinone (30g), before degassing and distilling the methanol, which was subsequently stored with magnesium (2g) and hydroquinone (4g per 100ml). Refluxing for about 12 hours removes the bulk of the formaldehyde from methanol: further purification has been obtained by subsequent distillation, refluxing for 12 hours with dinitrophenylhydrazine (5g) and H_2SO_4 (2g/L), and again fractionally distilling. [*Beilstein* **1** IV 1227.]
Rapid purification: Methanol purification is the same as for ethanol. Another simple purification procedure consists of adding 2g of $NaBH_4$ to 1.5L methanol, gently bubbling argon through it and refluxing for a day at 30°, then adding 2g of freshly cut sodium (washed with methanol) and refluxing for 1 day before distilling. The middle fraction is taken. [Jou & Freeman *J Phys Chem* **81** 909 *1977*, DOI: 10.1021/j100524a021.] **VERY TOXIC SHOULD NOT BE SWALLOWED.**

Methoxyacetic acid *[625-45-6]* **$C_3H_6O_3$, M 90.1, m 7-9°, b 97°/13-14mm, 202-204°/atm, d_4^{20} 1.175, n_D^{20} 1.417, pK^{25} 3.57.** Fractionally crystallise the acid by repeated partial freezing, then fractionally distil it under vacuum through a vacuum-jacketed Vigreux column ~20cm long. [*Beilstein* **3** IV 574.]

Methoxyamine hydrochloride (*O*-methylhydroxylamine HCl) *[593-56-6]* **CH_5NO. HCl, M 83.5, m 151-152°, pK^{25} 4.60.** Crystallise the hydrochloride from absolute EtOH or EtOH by addition of diethyl ether. [Kovach et al. *J Am Chem Soc* **107** 7360 *1985*, DOI: 10.1021/ja00311a024; *Beilstein* **1** IV 1252.]

2-Methoxyethanol (methylcellosolve) *[109-86-4]* **$C_3H_8O_2$, M 76.1, m -85°, b 124.4°/atm, d_4^{20} 0.964, n_D^{20} 1.4017, pK^{25} 14.8.** Peroxides can be removed by refluxing with stannous chloride or by filtration under slight pressure through a column of activated alumina. 2-Methoxyethanol can be dried with K_2CO_3, $CaSO_4$, $MgSO_4$ or silica gel, then distilled from sodium. Aliphatic ketones (and water) can be removed by making the solvent 0.1% in 2,4-dinitrophenylhydrazine and allowing to stand overnight with silica gel before fractionally distilling. [*Beilstein* **1** IV 2375.]

2-Methoxyethoxymethylchloride (MEMCl) *[3970-21-6]* **$C_4H_9ClO_2$, M 124.6, b 50-52°/13mm, 140-145°(dec)/atm, d_4^{20} 1.092, n_D^{20} 1.427.** Possible impurities are methoxyethanol (**b** 124°/atm), HCHO and HCl which can be removed below the boiling point of MEMCl. Purify MEMCl by fractional distillation in a vacuum. If too impure, prepare it from methoxyethanol (152g) and *s*-trioxane (66g) by bubbling a stream of dry HCl (with stirring) until a clear mixture is obtained. Dilute with pentane (900ml), dry (3 hours over 100g $MgSO_4$, at 5°), evaporate and the residue is distilled in a vacuum. It is MOISTURE SENSITIVE and **TOXIC.** The ***MEM.NEt$_3^+$Cl$^-$* salt**, prepared by reaction with 1.3 equivalents of Et_3N (16 hours/25°) and dried in a vacuum, has **m 58-61°**, and is moisture sensitive. [Corey et al. *Tetrahedron Lett* 809 *1976*, DOI: 10.1021/ie50367a005; Yoshimatsu et al. *J Org Chem* **59** 1011 *1994*, DOI: 10.1021/jo00084a017; Greene & Wuts *Protective Groups in Organic Synthesis* 3rd edn, J Wiley & Sons NY *1991*.] **CARCINOGEN.**

2-Methoxyethylamine *[109-85-3]* **C_3H_9NO, M 75.1, b 94°/atm, d_4^{20} 0.874, n_D^{20} 1.407, pK^{25} 9.40.** An aqueous 70% solution of the amine is dehydrated by azeotropic distillation with *benzene or methylene chloride and the amine is distilled twice from zinc dust. Store it in a tight container as it absorbs CO_2 from the atmosphere. [*Beilstein* **4** IV 1411.]

***N*-Methylacetamide** *[79-16-3]* **C_3H_7NO, M 73.1, m 30°, b 70-71°/2.5-3mm, pK_1^{25} -3.70, pK_2^{25} -0.42.** Fractionally distil it under vacuum, then fractionally crystallise it twice from its melt. Likely impurities include acetic acid, methyl amine and H_2O. For a detailed purification procedure, see Knecht and Kolthoff, *Inorg Chem* **1** 195 *1962*, DOI: 10.1021/ic50002a002. Although *N*-methylacetamide is commercially available it is often extensively contaminated with acetic acid, methylamine, water and an unidentified impurity. The recommended

procedure is to synthesise it in the laboratory by direct reaction. The gaseous amine is passed into hot glacial acetic acid, to give a partially aqueous solution of methylammonium acetate which is heated to *ca* 130° to expel water. Chemical methods of purification such as extraction by petroleum ether, treatment with H_2SO_4, K_2CO_3 or CaO can be used but are more laborious.
Tests for purity include the Karl Fischer titration for water; this can be applied directly. Acetic acid and methylamine can be detected polarographically.
In addition to the above, purification of *N*-methylacetamide can be achieved by fractional freezing, including zone melting, repeated many times, or by vacuum distillation under reduced pressures. For details of zone melting techniques, see Knecht in *Recommended Methods for Purification of Solvents and Tests for Impurities*, Coetzee Ed. Pergamon Press *1982*. [*Beilstein* **4** IV 176.]

Methyl acetate *[79-20-9]* **$C_3H_6O_2$, M 74.1, m -98°, b 56.7-57.2°/atm, d_4^{20} 0.934. n_D^{20} 1.36193, n_D^{25} 1.3538, pK^{20} -7.28 (H_o scale, aqueous H_2SO_4).** Methanol in methyl acetate can be detected by measuring its solubility in water. At 20°, the solubility of methyl acetate in water is *ca* 35g per 100ml, but 1% MeOH confers complete miscibility. Methanol can be removed by conversion to methyl acetate, by refluxing for 6 hours with acetic anhydride (85ml/L), followed by fractional distillation. Acidic impurities can be removed by shaking with anhydrous K_2CO_3 and distilling. An alternative treatment is with acetyl chloride, followed by washing with concentrated NaCl and drying with CaO or $MgSO_4$. (Solid $CaCl_2$ cannot be used because it forms a crystalline addition compound.) Distillation from copper stearate destroys peroxides. Free alcohol or acid can be eliminated from methyl acetate by shaking with strong aqueous Na_2CO_3 or K_2CO_3 (three times), then with aqueous 50% $CaCl_2$ (three times), saturated aqueous NaCl (twice), drying with K_2CO_3 and distilling it from P_2O_5. [*Beilstein* **2** IV 122.]

Methyl acetimidate hydrochloride *[14777-27-6]* **C_3H_7NO. HCl, M 109.6, m 93-95°, 105°(dec), pK_{Est} ~ 5.5.** Crystallise the imidate from methanol by adding dry ether to a ratio of 1:1 and cooling at 0°. Filter off the crystals in a cold room, wash them with methanol/ether (1:2), then dry in a vacuum. [Hunter & Ludwig *J Am Chem Soc* **84** 3491 *1962*, DOI: 10.1021/ja00877a016.] The ***free base*** has **b 90-91°/765mm**, d_4^{20} 0.867, n_D^{20} 1.403. [Hunter & Ludwig *Methods Enzymol* **25** 585 *1972*, DOI: 10.1016/S0076-6879(72)25058-3; *Beilstein* **2** IV 181.]

Methyl acrylate *[96-33-3]* **$C_4H_6O_2$, M 86.1, m -75°, b 80°/atm, d_4^{20} 0.9535, n_D^{20} 1.4040.** Wash the ester repeatedly with aqueous NaOH until free from inhibitors (such as hydroquinone), then wash it with distilled water, dry ($CaCl_2$) and fractionally distil it under reduced pressure in an all-glass apparatus. Seal it under nitrogen and store it at 0° in the dark. [Bamford & Han *JCS Faraday Trans 1* **78** 855 *1982*, DOI: 10.1039/F19827800855; *Beilstein* **2** IV 1457.]

Methylamine (gas) *[74-89-5]* **CH_5N, M 31.1, m -93°, b -7.55°/719mm, pK^{25} 10.62.** Dry the amine with sodium or BaO. It is commercially available in metal cylinders. It is a strong organic base. [*Beilstein* **4** IV 118.]

Methylamine hydrochloride *[593-51-1]* **CH_5N. HCl, M 67.5, m 231.8-233.4°, b 225-230°/15mm, pK^{25} 10.62.** Crystallise the salt from *n*-butanol, absolute EtOH or MeOH/$CHCl_3$. Wash it with $CHCl_3$ to remove traces of dimethylamine hydrochloride. Dry it under vacuum first with H_2SO_4 then P_2O_5. It is deliquescent; store it in a desiccator over P_2O_5. [*Beilstein* **4** IV 122.]

Methyl bromide *[74-83-9]* **CH_3Br, M 94.9, m -94°, b 3.6°/atm.** Purify it by bubbling through conc H_2SO_4, followed by passage through a tube containing glass beads coated with P_2O_5. Also purify it by distillation from $AlBr_3$ at –80°, by passage through a tower of KOH pellets and by partial condensation. [*Beilstein* **1** IV 68.]

2-Methylbutane (isopentane) *[78-78-4]* **C_5H_{12}, M 72.2, b 27.9°/atm, d_4^{20} 0.621, n_D^{20} 1.35373, n_D^{25} 1.35088.** Stir isopentane for several hours in the cold with concentrated H_2SO_4 (to remove olefinic impurities), then wash it with H_2O, aqueous Na_2CO_3 and H_2O again. Dry it with $MgSO_4$ and fractionally distil it using a Todd column packed with glass helices. Material transparent down to 180nm is obtained by distilling from sodium wire, and passing through a column of silica gel which had previously been dried in place at 350° for 12 hours before use. [Potts *J Chem Phys* **20** 809 *1952*, DOI: 10.1063/1.1700572; *Beilstein* **1** IV 320.]

2-Methyl-1-butanol *[137-32-6, RS(±) 34713-94-5, S(-) 1565-80-6]* **$C_5H_{12}O$, M 88.2, b 130°(*RS*), m -70°, 128.6°(*S*), $[\alpha]_D^{25}$ −5.8 (neat), d_4^{20} 0.809, n^{52} 1.4082.** Reflux the butanol with CaO, distil, reflux with magnesium and again fractionally distil it. A small sample of highly purified material is obtained by fractional crystallisation after conversion into a suitable ester such as the trinitrophthalate or the 3-nitrophthalate. The latter is converted to the cinchonine salt in acetone and recrystallised from $CHCl_3$ by adding pentane. The salt is saponified, extracted with ether, and fractionally distilled. [Terry et al. *J Chem Eng Data* **5** 403 *1960*, DOI: 10.1021/je60008a002; *Beilstein* **1** IV 1666.]

2-Methyl-2-butanol (*tert*-pentyl alcohol) *[75-85-4]* **$C_5H_{12}O$, M 88.2, m -12°, b 50°/60m, 66°/165mm, 102°/atm, d_4^{20} 0.805, n_D^{20} 1.405.** Reflux it with magnesium, then fractionally distil it with high reflux ratio. It forms azeotropic mixtures with many organic liquids. [Cottle & Power *J Am Chem Soc* **58** 2267, DOI: 10.1021/ja01302a052; Urry et al. *J Am Chem Soc* **76** 450 *1954*, DOI: 10.1021/ja01631a037.] [*Beilstein* **1** H 388, **1** I 195, **1** II 422, **1** III 1622, **1** IV 1668.]

3-Methyl-1-butanol (*iso*-pentyl alcohol) *[123-51-3]* **$C_5H_{12}O$, M 88.2, m -117°, b 130°/atm, 132°/760mm, d_4^{25} 0.812, n_D^{25} 1.406.** It is a major component of fusel oil. Reflux it with magnesium, then fractionally distil it with high reflux ratio. It was synthesised from the Grignard reagent, 2-propane magnesium bromide, and ethylene oxide in 85% yield, and the ***α-naphthylurethane*** had **m 67°** [Huston & Agett *J Org Chem* **06** 123 *1941*, DOI: 10.1021/jo01201a012]. It is an **IRRITANT**. The ***acetate ester*** [123-92-2] **$C_7H_{14}O_2$, M 130.1,** on the other hand is a liquid with a fruity odour and has **b 142°/atm, d_4^{15} 0.876, n_D^{21} 1.3997.** [*Beilstein* **1** H 392, **1** I 196, **1** II 426, **1** III 1633, **1** IV 1677.]

and fractionally distil it. It has been distilled from $AlCl_3$ at -80°. *Alternatively*, pass it through towers containing $AlCl_3$, soda-lime and P_2O_5, then condense and fractionally distil it. Use low temperature techniques. Store it as a gas. [*Beilstein* **1** IV 28.]

Methyl chloroacetate *[96-34-4]* **$C_3H_5ClO_2$, M 108.5, m -33°, b 129-130°/atm, d_4^{20} 1.230, n_D^{20} 1.423.** Shake the ester with saturated aqueous Na_2CO_3 (three times), aqueous 50% $CaCl_2$ (three times), saturated aqueous NaCl (twice), dry (Na_2SO_4) and fractionally distil it. **Very toxic.** [*Beilstein* **2** IV 480.]

***R*-(+) Methyl 2-chloropropionate** *[77287-29-7]* **$C_4H_7ClO_2$, M 122.6, b 49-50°/35mm, 78-80°/120mm, 132-134°/760mm, d_4^{20} 1.152, n_D^{20} 1.417, $[\alpha]_D^{20}$ +26 (19.0) (neat).** Purify the ester by repeated distillation [Walker *J Chem Soc* **67** 914 *1895*, DOI: 10.1039/CT8956700914; Walden *Chem Ber* **28** 1293 *1985*, see also Gless *Synth Commun* **16** 633 *1986*, DOI: 10.1080/00397918608057732]. [*Beilstein* **2** H 248.] The racemate ***RS*-methyl 2-chloropropionate** *[17639-93-9]* has **b 132-134°/760mm, d_4^{25} 1.075, n_D^{20} 1.417.**

Methyl cyanoacetate *[105-34-0]* **$C_4H_5NO_2$, M 99.1, f -13°, b 115°/36mm, 200.4-200.9°/761mm, d_4^{20} 1.128, n_D^{20} 1.420.** Purify the ester by shaking with 10% Na_2CO_3 solution, wash well with water, dry with anhydrous Na_2SO_4, and distil it. [*Beilstein* **2** H 584, **2** I 253, **2** II 530, **2** III 1628, **2** IV 1889.]

Methyl cyanoformate *[17640-15-2]* **$C_3H_3NO_2$, M 85.1, b 81°/47mm, 97°/751mm, 100-101°/760mm, 104-107°/atm, d_4^{20} 1.072, n_D^{20} 1.37378.** Purify the ester by fractionation through a 45cm glass helices packed column or a 30cm spinning band column. [Sheppard *J Org Chem* **27** 3756 *1962*, DOI: 10.1021/jo01058a003.] It has been distilled through a short Vigreux column, and further purified by recrystallisation from Et_2O at -40° as white crystals which melt at room temperature. NMR: δ 4.0 (CH_3), and the IR has ν_{max} at 2250 (CN) and 1750 (CO) cm^{-1}. [Childs & Weber *J Org Chem* **41** 3486 *1976*, DOI: 10.1021/jo00883a041; *Beilstein* **2** III 1587, **2** IV1889.]

Methyl decanoate (methyl caprate) *[110-42-9]* **$C_{11}H_{22}O_2$, M 186.3, m -14° to -11°, b 114°/15mm, 224°/760mm, d_4^{20} 0.874, n_D^{20} 1.426.** Pass the ester through alumina before use and distil in a vacuum. [*Beilstein* **2** IV 1044.]

N*-Methyldiethanolamine [MDEA, *N,N*-bis(hydroxyethyl)methylamine, 2,2'-methyliminodiethanol]** *[105-59-9]* **$C_5H_{13}NO_2$, M 119.2, b 75-77°/0.5mm, 115°/5mm, 131°/10mm, 141-142°/18mm, 246-248°/atm, d_4^{25} 1.038, n_D^{20} 1.469, pK^{25} 8.57, pK^{35} 8.31, pK^{45} 8.13, pK^{60} 7.87.** Purify MDEA by fractional distillation preferably under vacuum in a stream of N_2, and store it under N_2. The colourless distillate darkens in air and absorbs CO_2 under pressure [Goodridge *Trans Faraday Soc* **51** 1703 *1955*, DOI: 10.1039/TF9555101703]. It is a tertiary base, hence it does not form an *N-carbamate salt* like primary and secondary amines, but **does** form a *carbonate salt* in the presence of carbonic acid (i.e. $CO_2 + H_2O = H_2CO_3$). It is soluble in H_2O and EtOH, but slightly soluble in Et_2O. The *hydrochloride* is very hygroscopic; the ***O,O'-diacetyl ester has **b 110°/4mm, 133°/15mm, b 251°/atm**, the ***O,O'-bis(4-nitrobenzoyl) ester*** has **m 112-113°**, the ***Reineckate salt*** has **m 168°**, the ***picrate*** crystallises from EtOAc with **m 95-96°**, and with a strong aqueous solution of $AuCl_3$/HCl the ***chloroaurate salt*, m 101-102°**, is formed which crystallises from H_2O. With $PtCl_4$/HCl, the ***chloroplatinate salt*** is obtained, forming orange-yellow rhombic crystals upon recrystallisation from a concentrated aqueous solution which sinter at **145°** and decompose at **148-150°**. The IR spectrum in CCl_4 has C-H str at ν_{max} (ε $mole^{-1}$ $L.cm^{-1}$) 2779 (93), 2844 (81), 2877 (99) and 2948 (107) cm^{-1}. [Hanby & Rydon *J Chem Soc* 513 *1947*, DOI: 10.1039/JR9470000513; Hill & Meakins *J Chem Soc* 760 *1958*, DOI: 10.1039/JR9580000760; Knorr & Matthes *Chem Ber* **31** 1069 *1898*, DOI: 10.1002/cber.189803101193; *Beilsten* **4** H 284, **4** II 729, **4** III 692, **4** IV 1517.]

Methyl dodecanoate (methyl laurate) *[111-82-0]* **$C_{13}H_{26}O_2$, M 214.4, m 5°, b 141°/15mm, d_4^{20} 0.870, n^{50} 1.4199.** Pass the ester through alumina before use, and distil it in a vacuum. [*Beilstein* **2** IV 1090.]

***N*-Methyleneaminoacetonitrile (MAAN)** *[109-82-0]* **$(C_3H_4N_2)_3$ = $C_9H_{12}N_6$, M 68.1, m 129°.** The reaction involving ammonia, formaldehyde and cyanide provided a crystalline substance originally thought to be CH_2=NCH2CN. However, it turned out to be a trimeric form (see further). After washing the crude product thoroughly with cold H_2O, drying at 50-60° and recystallising from 95% EtOH a 52% yield of colourless cryst-

als **m 129°** (*orthorhombic*) were obtained which turned out to be a ***trimeric form***. From the ethanolic mother liquors a ***second trimeric form*** with **m 86°** (monoclinic crystals) was isolated in a relative proportion of ~8%. These could be recrystallised from Me_2CO. Their reactivities, however are different. It crystallises nicely from H_2O but reacts with it with considerable loss of material. It is sparingly soluble in $*C_6H_6$. It is an inhibitor of bone growth. [Johnson & Rinehart *J Am Chem Soc* **46** 768, 1653 *1924*, DOI: 10.1021/ja01668a031; Adams & Langley *Org Synth* Coll Vol **I** 355 *1941*, DOI: 10.15227/orgsyn.004.0047.]

Methyl ether (dimethyl ether) *[115-10-6]* **C_2H_6O, M 46.1, m -141°, b -63.5°/96.5mm, -24°/~760mm, d^{25} 1.918/L (at 1 atmosphere relative to air as 1).** Dry methyl ether by passing over alumina and then BaO, or over CaH_2, followed by fractional distillation at low temperatures. Its solubility is 37ml per ml of H_2O at 18°, and it is very soluble in EtOH and Et_2O. [*Beilstein* **1** IV 1245.]

***N*-Methyl ethylamine hydrochloride** *[624-60-2]* **C_3H_9N. HCl, M 95.6, m 126-130°, pK^{25} 10.9 (free base).** Crystallise the hydrochloride from absolute EtOH or diethyl ether. Dry it *in vacuo*. [*Beilstein* **4** H 94.]

***N*-Methyl formamide** *[123-39-7]* **C_2H_5NO, M 59.1, m -3.5°, b 100.5°/25mm, d_4^{20} 1.005., n 1.4306** Dry it over molecular sieves for 2 days, then distil it under reduced pressure through a column packed with glass helices. Fractionally crystallise it by partial freezing and the solid portion is distilled in a vacuum. [*Beilstein* **4** IV 170.]

Methyl formate *[107-31-3]* **$C_2H_4O_2$, M 60.1, m -100°, b 31.5°/atm, 34°/atm, d_4^{20} 0.971, n^{15} 1.34648, n_D^{20} 1.34332.** Wash the formate with strong aqueous Na_2CO_3, dry it with solid Na_2CO_3 and distil it from P_2O_5. (Procedure removes free alcohol or acid.) [*Beilstein* **2** IV 20.]

2-Methylglutaric acid *[18069-17-5]* **$C_6H_{10}O_4$, M 146.1, m 79°, 80-82°, b 214-215°/22mm, pK_1^{25} 4.36, pK_2^{25} 5.37.** Crystallise the acid from distilled water, then dry it under vacuum over concentrated H_2SO_4. [*Beilstein* **2** IV 1989.]

3-Methylglutaric acid *[626-51-7]* **$C_6H_{10}O_4$, M 146.1, m 87°, pK_1^{25} 4.35, pK_2^{25} 5.44.** Crystallise the acid from distilled water, then dry it under vacuum over concentrated H_2SO_4. [*Beilstein* **2** IV 1992.]

Methylglyoxal *[78-98-8]* **$C_3H_4O_2$, M 72.1, b *ca* 72°/760mm.** Commercial 30% (w/v) aqueous solution is diluted to about 10% and distilled twice, taking the fraction boiling below **50°/20mm**. (This treatment does not remove lactic acid). It is *hygroscopic* and polymerises readily. The aqueous solution is more stable probably because it forms a hydrate, i.e. the 1,1-diol. [*Beilstein* **1** IV 3631.]

Methylglyoxal 1,1-dimethyl acetal (1,1-dimethoxyacetone, pyruvaldehyde-1-dimethyl acetal) *[6342-56-9]* **$C_5H_{10}O_3$, M 118.1, b 40°/10mm, 63-66°/35mm, 141°/760mm, 144-147°/atm, d_4^{25} 0.976, n_D^{24} 1.4480, n_D^{25} 1.4102.** Purify by careful fractionation, preferably under reduced pressure. If however it is too impure (cf. IR and NMR) then add at least an equal volume of absolute MeOH, and saturate the solution with dry HCl. Any precipitated salt is filtered off, the filtrate is allowed to stand at room temperature in a stoppered vessel. The mixture is neutralised (to litmus) with methanolic NaOMe, the precipitated salts are filtered off and the filtrate is evaporated under diminished pressure. The residue is mixed with an equal volume of $*C_6H_6$, the $*C_6H_6$— immiscible layer is removed and the benzene solution is distilled. [Royals & Robinson III *J Am Chem Soc* **78** 4161 *1956*, DOI: 10.1021/ja01597a083; Braude & Evans *J Chem Soc* 3324 *1955*, DOI: 10.1039/JR9550003324.] [*Beilstein* **1** I 395, **1** IV 3631.]

2-Methylhexane (isoheptane) *[591-76-4]* **C_7H_{16}, M 100.2, m -118°, b 90.1°/atm, d_4^{20} 0.678, n_D^{20} 1.38485, n_D^{20} 1.38227.** Purify it by azeotropic distillation with MeOH, then wash it with water (to remove the MeOH), dry it over type 4A molecular sieves and distil it. [*Beilstein* **1** IV 397.]

3-Methylhexane *[589-34-4]* **C_7H_{16}, M 100.2, m -119°, b 91.9°/atm, d_4^{20} 0.687, n_D^{20} 1.38864, n_D^{20} 1.38609.** Purify it as for 2-methylhexene. [*Beilstein* **1** IV 399.]

Methyl hexanoate (methyl caproate) *[106-70-7]* **$C_7H_{14}O_2$, M 130.2, m -71°, b 52°/15mm, 150°/760mm, d_4^{20} 0.885, n_D^{20} 1.410.** Pass it through alumina and distil it before use. [*Beilstein* **2** IV 921.]

Methylhydrazine *[60-34-4]* **CH_6N_2, M 46.1, b 87°/745mm, d_4^{20} 0.876, n_D^{20} 1.436, pK^{30} 7.87.** Dry with BaO, then distil it in a vacuum. Store it under nitrogen away from CO_2. [*Beilstein* **4** IV 3322.]

Methyl hydrazinocarboxylate *[6294-89-9]* **$C_2H_6N_2O_2$, M 90.1, m 70-73°, b 108°/12mm.** To remove impurities, the material is melted and pumped under vacuum until the vapours are spectroscopically pure [Caminati et al. *J Am Chem Soc* **108** 4364 *1986*, DOI: 10.1021/ja00275a023]. Distil it in a vacuum. [*Beilstein* **3** I 46.]

Methyl iodide *[74-88-4]* **CH_3I, M 141.9, m -64°, b 42.8°/atm d_4^{20} 2.281, n_D^{20} 1.5315.** Methyl iodide deteriorates rapidly with liberation of iodine if exposed to light. It is usually purified by shaking it with dilute aqueous $Na_2S_2O_3$ or $NaHSO_3$ until colourless, then washing with water, dilute aqueous Na_2CO_3, and more water, drying with $CaCl_2$ and distilling. It is stored in a brown bottle away from sunlight in contact with a small amount of mercury, powdered silver or copper. (Prolonged exposure of mercury to methyl iodide forms methylmercuric iodide.) Methyl iodide can be dried further using $CaSO_4$ or P_2O_5. An alternative purification is by percolation through a column of silica gel or activated alumina, then distillation. The solution can be degassed by using repeated freeze-pump-thaw cycles. Cu metal can be added as stabiliser. [*Beilstein* **1** IV 87.]

O*-Methylisourea hydrogen sulfate (2-methylpseudourea sulfate, *O*-methylisourea bisulfate)** *[29427-58-5]* **$C_2H_6N_2O$. 0.5 H_2SO_4, M 172.2, m 114-118°, 119°.** Recrystallise the salt from MeOH/Et_2O (327g of salt dissolved in 1L of MeOH and 2.5L of Et_2O is added) [Fearing & Fox *J Am Chem Soc* **76** 4382 *1954*, DOI: 10.1021/ja01646a033]. The ***picrate has **m 192°** [Odo et al. *J Org Chem* **23** 1319 *1958*, DOI: 10.1021/jo01103a020]. [*Beilstein* **3** IV 143.]

***N*-Methyl maleimide** *[930-88-1]* **$C_5H_5NO_2$, M 111.1, m 94-96°.** Crystallise the imide three times from diethyl ether. Dry it *in vacuo*. [*Beilstein* **21/10** V 5.]

Methylmalonic acid (2-methylpropanedioic acid) *[516-05-2]* **$C_4H_6O_4$, M 118.1, m 135°(dec), pK_1^{25} 3.05, pK_2^{25} 5.76.** The acid crystallises as the *hydrate* from water. [*Beilstein* **2** IV 1932.]

Methyl methacrylate *[80-62-6]* **$C_5H_9O_2$, M 100.1, f -50°, b 46°/100mm, 100°/~760mm, d_4^{20} 0.937, n_D^{20} 1.4144.** Wash the ester twice with aqueous 5% NaOH (to remove inhibitors such as hydroquinone) and twice with water. Dry it with $CaCl_2$, Na_2CO_3, Na_2SO_4 or $MgSO_4$, then with CaH_2 under nitrogen under reduced pressure. The distillate is stored at low temperatures and redistilled before use. Prior to distilling, inhibitors such as hydroquinone (0.004%), β-naphthylamine (0.2%) or di-β-naphthol are sometimes added. Also purify it by boiling with aqueous H_3PO_4 solution and finally with saturated NaCl solution. It is dried for 24 hours over anhydrous $CaSO_4$, distilled at 0.1mm Hg at room temperature, and stored at -30° [Albeck et al. *JCS Faraday Trans 1* **1** 1488 *1978*, DOI: 10.1039/F19787401488]. [*Beilstein* 2 II 398, 2 III 1279, 2 IV 1519.]

Methyl methanesulfonate *[66-27-3]* **$C_2H_6O_3S$, M 110.3, b 59°/0.6mm, 96-98°/19mm, 202-203°/atm, d_4^{20} 1.300, n_D^{20} 1.4140.** Purify the ester by careful fractionation and collecting the middle fraction. Suspected **CARCINOGEN.** (Note that $MeSO_3H$ has **b 167-167.5°/10mm** and methanesulfonic anhydride has **b 138°/10mm**)—both are possible impurities. [*Beilstein* **4** IV 11.]

S-Methyl methanethiolsulfonate *[2949-92-0]* **$C_2H_6O_2S_2$, M 126.2, b 69-71°/0.4mm, 96-97°/4.5mm, 104-105°/10mm, 119°/16mm, d_4^{20} 1.226, n_D^{20} 1.515.** Purify it by fractional distillation under reduced pressure, the IR has ν_{max} at 1350, 750 cm^{-1}. [Slusarchyk et al. *J Org Chem* **38** 943 *1973*, DOI: 10.1021/jo00945a023; *Beilstein* **4** IV 31.]

Methyl nitrate *[598-58-3]* **CH_3NO_3, M 77.0, b 5°/50mm, explodes at 65°/760mm, d^5 1.2322, d^{15} 1.2167, d^{25} 1.2032.** Wash $MeONO_2$ once with H_2O then again with H_2O containing a few drops of concentrated NaOH to keep it slightly alkaline (litmus). Dry the ester over anhydrous $CaCl_2$, decant it and use it directly. It is poss-

ible to distil it under a vacuum with slow and gentle heating, as a sudden rise in temperature can cause decomposition with copious release of nitrous fumes (use extreme precautions and protection). The middle fraction can then be subjected to several freeze-pump-thaw cycles. **TAKE ALL NECESSARY SAFETY PRECAUTIONS as the VAPOUR CAN EXPLODE ON HEATING EVEN IN THE ABSENCE OF OXYGEN.** [Black & Babers *Org Synth* Col Vol **2** 412 *1943*, DOI: 10.15227/orgsyn.019.0064.] [*Beilstein* **1** H 284, **1** I 141, **1** II 273, **1** III 1201, **1** IV 1254.]

Methyl nitrite *[624-91-9]* **CH_3NO_2, M 61.0, b -18°/atm, -17°/atm, d^{15} (liquid) 0.991.** Condense MeONO in a liquid nitrogen trap. Distil the greenish liquid under vacuum (preferably in a vacuum line), into the first trap containing dry Na_2CO_3 to free it from acid impurities then into further Na_2CO_3 and fused $CaCl_2$ traps before collection at -78°. It has been distilled through columns that are surrounded by Et_2O/Dri-ice cooled to -30°. [Leermakers & Ramsperger *J Am Chem Soc* **54** 1838 *1932*, DOI: 10.1021/ja01344a015; Thompson & Purkis *Trans Faraday Soc* **32** 674 *1936*, DOI: 10.1039/TF9363200674; *Beilstein* **1** H 284, **1** I 141, **1** II 273, **1** III 1201, **1** IV 1253.] **CARCINOGEN.**

It decomposes on attempted distillation at 10mm. Its solubility in H_2O is 80g/100ml at 20°. It can be distilled at 10mm pressure (take precautions). [Gabriel *Ind Eng Chem* **32** 887 *1940*, DOI: 10.1021/ie50367a005.] [*Beilstein* **1** H 489, **1** II 547, **1** III 2190, **1** IV 2537.]

2-Methyl-2-nitro-1-propanol *[76-39-1]* **$C_4H_9NO_3$, M 119.1, m 87-88°, 93-96°, b 60-61°/~1mm, 75°/2mm, 94-95°/10mm, d_D^{25} 1.303, n_D^{25} 1.4425.** Distil it under vacuum and/or crystallise it from petroleum ether or MeOH. [Astle & Abbott *J Org Chem* **21** 1228 *1956*, DOI: 10.1021/jo01117a007; Kambe & Yasuda *Bull Soc Chem Jpn* **41** 1444 *1968*, DOI:org/10.1246/bcsj.41.1444; *Beilstein* **1** H 378, **1** III 1546, **1** IV 1604.]

2-Methyloctane *[3221-61-2]* **C_9H_{20}, M 128.3, f.p -80.1°, b 141.6°/727.5mm, 142.8°/760mm, d_4^{20} 0.7107, n_D^{20} 1.40285.** It is present in petroleum and is a major constitutent in *Hypericum perfloratum*. Take it through a silica gel column and distil it. If too crude then wash sequentially with 70% H_2SO_4, 85% H_2SO_4, then concentrated H_2SO_4 (handle with necessary protection from the strong acid) until the hydrocarbon liquid is almost free from the yellow colour. Cool the organic layer then wash with ice cold H_2O, twice with 25% NaOH solution, dry over Na, then carefully fractionate from Na-K alloy using high reflux ratios (30—60:1). [Whitmore & Southgate *J Am Chem Soc* **60** 2571 *1938*, DOI: 10.1021/ja01278a003; Whitmore & Orem *J Am Chem Soc* **60** 2573 *1938*, DOI: 10.1021/ja01278a004, and for fractionating columns see Whitmore & Lux *J Am Chem Soc* **54** 3448 *1932*, DOI: 10.1021/ja01347a071]. [*Beilstein* **1** III 507, **1** IV 454]

3-Methyloctane *[2216-33-3]* **C_9H_{20}, M 128.3, m b -108°/atm, 142-144°/760mm, d_4^{20} 0.719, n_D^{20} 1.407.** It was isolated from a petroleum fraction [Jamison, Lesslie and Turner *J Inst Petr* **75** 595 *1949*]. Take it through a silica gel column and distil it. *Alternatively*, purify it like the preceding 2-methyloctane. [Klassen & Ross *J Phys Chem* **91** 3668 *1987*, DOI: 10.1021/j100297a041; *Beilstein* **1** III 507, **1** IV 455]

***S*(+)-3-Methyloctane C_9H_{20}, M 128.3, b 32-42°/10mm, n_D^{20} 1.4080, 144°/atm, n_D^{20} 1.4081, $[\alpha]_{5461}^{19}$ +8.39, $[\alpha]_{5896}^{19}$ +7.54 (c 9.8, $CHCl_3$).** Prepared by catalytic reduction of optically active 6-methyloct-3-ene-1-ol using $Pd/BaSO_4/H_2$ in Et_2O overnight (complete H_2 uptake; i.e. apparently the OH is replaced by H before reduction of the double bond — allylic OH hydrogenolysis) whose absolute configuration at the chiral centre had been correlated with that of *S*(-)-glyceraldehyde. Removal of catalyst, evaporation, followed by two distillations gave pure chiral hydrocarbon. [Crombie & Harper *J Chem Soc* 2685 *1950*, DOI: 10.1039/JR9500002685; *Beilstein* **1** IV 455.] ***R*(-)-3-Methyloctane C_9H_{20}, M 128.3,** has **b 143°/atm, n_D^{25} 1.4052, $[\alpha]_D^{27}$ -8.5 ($CHCl_3$)**, Levene & Marker *J Biol Chem* **91** 77 (102) *1931*, http://www.jbc.org/content/91/1/77.citation].

Methyl octanoate (methyl caprylate) *[111-11-5]* **$C_9H_{18}O_2$, M 158.2, b 83°/15mm, 193-194°/760mm, d^{25} 0.877g/ml, n_D^{20} 1.419.** Pass the ester through alumina and distil it before use. [*Beilstein* **2** IV 986.]

Methyl oleate (methyl *cis*-9-octadecenoate) *[112-62-9]* **$C_{19}H_{36}O_2$, M 296.5, f -19.9°, b 217°/16mm, d_4^{20}**

0.874, n_D^{20} 1.4522. Purify the oleate by fractional distillation under reduced pressure, and by low temperature crystallisation from acetone. Store it in the dark under N_2. [*Beilstein* **2** IV 1649.]

Methylpentane (mixture of isomers) C_6H_{14}. Pass the mixture through a long column of activated silica gel (or alumina) and collect material that is transparent down to 200nm in the UV.

2-Methylpentane {isohexane) *[107-83-5]* **C_6H_{14}, M 86.2, m -154°, b 60.3°, d_4^{20} 0.655, n_D^{20} 1.37145, n_D^{25} 1.36873.** Purify it by azeotropic distillation with MeOH, followed by washing out the MeOH with water, drying ($CaCl_2$, then sodium), and distilling it. [Forziati et al. *J Res Nat Bur Stand* **36** 129 *1946*, DOI: org/10.6028/jres.036.005; *Beilstein* **1** IV 358.]

3-Methylpentane *[96-14-0]* **C_6H_{14}, M 86.2, b 63.3°/atm, d_4^{20} 0.664, n_D^{20} 1.37652, n_D^{25} 1.37384.** Purify it by azeotropic distillation with MeOH, as for 2-methylpentane. Purify it for ultraviolet spectroscopy by passing it through columns of silica gel or alumina activated by heating for 8 hours at 210° under a stream of nitrogen. *Alternatively*, treat it with conc (or fuming) H_2SO_4, then wash it with water, aqueous 5% NaOH, water again, then dry ($CaCl_2$, then sodium), and distil it through a long, glass helices-packed, column. [*Beilstein* **1** IV 363.]

RS*-2-Methyl-2,4-pentanediol (MPD, pinecon, hexylene glycol)** *[107-41-5]* **$C_6H_{14}O_2$, M 118.2, m -40°, b 97°/10mm, 102°/12mm, 107.5-108.5°/25mm, 135-136°/40mm, 197°/760mm, d^{25} 0.922g/ml, n_D^{20} 1.4265.** It is present in *Santolina rosemarinifolia*. Dry the diol with Na_2SO_4, then CaH_2, and fractionally distil it under reduced pressure through a helices packed column, taking precautions to avoid absorption of water. It is soluble in H_2O, EtOH, Et_2O, pentane and hexane. It is a reagent for characterising aldehydes by forming cyclic acetates. A 20% solution can be used for the extraction of Boron. The *RS*-diacetate*** *[99113-75-4]* **$C_{10}H_{18}O_4$, M 202.2** is a liquid with **m -40°, b 95°/15mm, 92°/18mm. It has very harmful vapours; use efficient fume cupboard** as it irritates eyes, skin throat and lungs, causing headaches and nausea and is a CNS depressant. The ***bis*-4-nitrobenzoyl ester** forms pale yellow flakes from aqueous EtOH, **m 155-157°.** The ***R(-) enantiomer*** *[99210-90-9]* has **b 108-110°/6mm, $[\alpha]_D^{25}$ -14.7 (neat 87% ee).** The ***S*(+)-*enantiomer*** *[99210-91-0]* has **b 87-90°/6mm, $[\alpha]_D^{25}$ +15 (c 1, EtOH, 92% ee).** [For optical resolutions using yeast or porcine pancreatic lipases in nearly anhydrous organic solvents see Kirchner et al. *J Am Chem Soc* **107** 7072 *1985*, DOI: 10.1021/ja00310a052.] [*Beilstein* **1** H 486, **1** I 252, **1** II 552, **1** III 2206, **1** IV 2565.]

2-Methyl-1-pentanol *[105-30-6]* **$C_6H_{14}O$, M 102.2, b 65-66°/60mm, 146-147°/760mm, d_4^{20} 0.827, n_D^{20} 1.420.** Dry the 1-pentanol with Na_2SO_4 and distil it. [*Beilstein* **1** IV 1713.]

4-Methyl-2-pentanol (isobutyl methyl carbinol) *[108-11-2]* **$C_6H_{14}O$, M 102.2, m -90°, b 47°/10mm 131-132°/atm d_4^{20} 0.810, n_D^{20} 1.413.** Wash the 2-pentanol with aqueous $NaHCO_3$, dry and distil it. Purify it further by converting it to the phthalate ester by adding 120ml of dry pyridine and 67g of phthalic anhydride per mole of alcohol, purifying the ester and steam distilling it in the presence of NaOH. The distillate is extracted with ether, and the extract is dried and fractionally distilled. The ***phenylurethane*** has **m 143°**, and the ***2,4-dinitrobenzoate*** has **m 60.5-61.5°**. ***R*(-)-4-Methyl-2-pentanol** *[16404-54-9]* has **b 132°/atm, d_4^{25} 0.802, n_D^{20} 1.4630, $[\alpha]_D^{22}$ -18.5 (c 1,** $CHCl_3$), **-20.8 (neat)** and the ***1-naphthylurethane*** has **m 86-87°**, **$[\alpha]_D^{22}$ -3.7 (EtOH)**. ***S*(+)-4-methyl-2-pentanol** *[14898-80-7]* has **b 63-64°/45mm, 138°/atm, d_4^{25} 0.802, n_D^{20} 1.4790, $[\alpha]_D^{22}$ +18.0 (c 1,** $CHCl_3$), **+21.4 (neat).** [Levine & Walti *J Biol Chem* **94** 367 *1931*, http://www.jbc.org/content/ 94/2/373.citation; for optical resolution *via* the brucine salts of the *o*-carboxybenzoate ester followed by acidification and hydrolysis see Kenyon & Strauss *J Chem Soc* 2153 *1949*, DOI: 10.1039/JR9490002153; for chiral synthesis of the alcohols *via* reduction of the respective ketone using {LiAlH(OR') (*N*-methylephedrine) see Vigneron & Jacquet *Tetrahedron* **32** 939 *1976*, DOI: 10.1016/0040-4020(76)85053-3; and for absolute configuration see Bell *Aust J Chem* **32** 2625 *1979*, DOI: 10.1071/CH9792625; *Beilstein* **1** H 410, **1** I 203, **1** II 440, **1** III 1669, **1** IV 1717.]

3-Methyl-3-pentanol carbamate (Emylcamate) *[78-28-4]* **$C_7H_{15}NO_2$, M 145.2, m 56-58.5°, b 24°/0.7mm, 35°/10mm.** It crystallises in needles with the odour of camphor from 30% aqueous EtOH, and is dried over a dessicant. It distils at a low temperature in a vacuum. Its solubility in H_2O at room temperature is 0.4g/100mL. This drug reduces anxiety. [*Beilstein* **1** IV 1773.]

4-Methyl-2-pentanone (methyl isobutyl ketone) *[108-10-1]* **$C_6H_{12}O$, M 100.2, m -80°, b 115.7°/~760mm d $_4^{20}$ 0.801, n $_D^{20}$ 1.3958, n $_D^{25}$ 1.3938.** Reflux the ketone with a little $KMnO_4$, wash it with aqueous $NaHCO_3$, dry with $CaSO_4$ and distil it. Acidic impurities are removed by passage through a small column of activated alumina. [*Beilstein* **1** IV 3305.]

2-Methyl-1-pentene *[763-29-1]* **C_6H_{12}, M 84.2, m -126°, b 61.5-62°/atm, d $_4^{20}$ 0.680, n $_D^{20}$ 1.395.** Water is removed, and formation of peroxides is prevented by several vacuum distillations of 2-methyl-1-pentene from sodium. It is stored with sodium-potassium alloy. [*Beilstein* **1** IV 841.]

4-Methyl-1-pentene *[691-37-2]* **C_6H_{12}, M 84.2, b 61.5-62°/atm, d ^{25} 0.680g/ml, n $_D^{20}$ 1.395.** Water is removed, and formation of peroxides is prevented by several vacuum distillations of 2-methyl-1-pentene from sodium. It is stored with sodium-potassium alloy. [*Beilstein* **1** IV 846.]

***cis*-4-Methyl-2-pentene** *[691-38-3]* **C_6H_{12}, M 84.2, m -134.4°, b 57.7-58.5°/atm, d $_4^{20}$ 0.672, n $_D^{20}$ 1.388.** Dry the *cis*-pentene with CaH_2, and distil it. [*Beilstein* **1** IV 841.]

***trans*-4-Methyl-2-pentene** *[674-76-0]* **C_6H_{12}, M 84.2, m -140.8°, b 58.5°/atm, d $_4^{20}$ 0.669, n $_D^{20}$ 1.389.** Dry the *trans*-isomer with CaH_2, and distil it. [*Beilstein* **1** IV 844.]

2-Methylpropane-1,2-diamine (1,2-diamino-2-methylpropane) *[811-93-8]* **$C_4H_{12}NO_2$, M 88.2, b 47-48°/17mm, 50°/20mm, 59°/20mm (mono hydrate?), pK $_1^{25}$ 6.25 (6.18), pK $_2^{25}$ 9.82 (9.42).** Dry the diamine with sodium for 2 days, then distil it from sodium under reduced pressure. The ***dihydrochloride*** [15444-85-6] **m 306° (dec)** forms plates from aqueous EtOH. The anhydrous ***picrate*** has **m 241°**. It complexes with Cu^{2+}, Cr^{3+}, Co^{2+} and Ni^{2+}. [Bosnich et al. *Aust J Chem* **19** 2045 *1966*, DOI:10.1071/CH9662045; Basolo et al. *J Am Chem Soc* **75** 1478 *1953*, DOI: 10.1021/ja01102a507.] [*Beilstein* **4** H 264, **4** II 707, **4** III 581, **4** IV 1306.]

2-Methylpropane-1-thiol (isobutylmercaptan) *[513-44-0]* **$C_4H_{10}S$, M 90.2, b 41.2°/142mm, 88.5°/760mm, n $_D^{25}$ 1.43582, pK_{Est} ~10.8.** Dissolve the thiol in EtOH, and add to 0.25M $Pb(OAc)_2$ in 50% aqueous EtOH. The precipitated lead mercaptide is filtered off, washed with a little EtOH, and impurities are removed from the molten salt by steam distillation. After cooling, dilute HCl is added dropwise to the residue, and the mercaptan is distilled directly from the flask. Water is separated from the distillate, and the mercaptan is dried (Na_2CO_3) and distilled under nitrogen. [Mathias *J Am Chem Soc* **72** 1897 *1950*, DOI: 10.1021/ja01161a012; *Beilstein* **1** H 378, **1** I 191, **1** II 412, **1** III 1565, **1** IV 1605.]

2-Methylpropane-2-thiol (*tert*-butylmercaptan) *[75-66-1]* **$C_4H_{10}S$, M 90.2, m -0.5°, b 61.6°/701mm, 66°/760mm, d $_4^{25}$ 0.79426, n $_D^{25}$ 1.41984, pK^{25} 11.22.** Dry the thiol for several days over CaO, then distil it from CaO. Purify it as for *2-methylpropane-1-thiol* above. [*Beilstein* **1** H 383, **1** II 416, **1** III 1589, **1** IV 1634.]

2-Methyl-1-propanol (isobutanol) *[78-83-1]* **$C_4H_{10}O$, M 74.1, m -108°, b 107.9°760mm, d $_4^{20}$ 0.804, n^{15} 1.39768, n $_D^{25}$ 1.3939.** Isobutanol is dried by refluxing with CaO and BaO for several hours, followed by treatment with calcium or aluminium amalgam, then fractional distilling it from sulfanilic or tartaric acids. More exhaustive purifications involve formation of phthalate or borate esters. Heating it with phthalic anhydride gives the *acid phthalate* which, after crystallisation to constant melting point (**m** 65°) from petroleum ether, is hydrolysed with aqueous 15% KOH. The alcohol is distilled off as the water azeotrope and dried (K_2CO_3, then anhydrous $CuSO_4$), and finally magnesium turnings, followed by fractional distillation. [Hückel & Ackermann *J Prakt Chem* **136** 15 *1933*.] The borate ester is formed by heating the dried alcohol for 6 hours in an autoclave at 160-175° with a quarter of its weight of boric acid. After fractional distillation under vacuum, the ester is hydrolysed by heating for a short time with aqueous alkali and the alcohol is dried with CaO and distilled. [Michael et al. *J Am Chem Soc* **38** 653 *1916*, DOI: 10.1021/ja02260a018.] *Alternatively*, dry the alcohol with K_2CO_3, $CaSO_4$ or $CaCl_2$, filter and fractionally distil it. For further drying, the redistilled alcohol can be refluxed with the appropriate alkyl phthalate or succinate as described under *ethanol*. [*Beilstein* **1** IV 1588.]

Methyl propiolate *[922-67-8]* **$C_4H_4O_2$, M 84.1, b 100°/atm, 102°/atm, 103-105°/atm, d $_4^{20}$ 0.945, n $_D^{20}$ 1.4080.** Purify the propiolate by fractional distillation and collecting the middle fraction, note that propiolic acid

has a higher boiling point [**144°(dec)/760mm**]. [*Beilstein* **2** IV 1688.] **LACHRYMATORY**.

***N*-Methylpropionamide** *[1187-58-2]* **C_4H_9NO, M 87.1, f -30.9°, m -43°, b 103°/12-13mm, d_4^{20} 0.934, n_D^{25} 1.4356.** The amide is a colourless, odourless, neutral liquid at room temperature with a high dielectric constant. The amount of water present can be determined directly by Karl Fischer titration, GLC and NMR have been used to detect unreacted propionic acid. Commercial material of high quality is available, probably from the condensation of anhydrous methylamine with 50% excess of propionic acid. Rapid heating to 120-140° with stirring favours the reaction by removing water either directly or as the ternary xylene azeotrope. The quality of the distillate improves during the distillation.
N-Methylpropionamide can be dried over CaO. Water and unreacted propionic acid are removed as their xylene azeotropes. It is then distilled in a vacuum. Material used as an electrolyte solvent (specific conductance less than 10^{-6} ohm^{-1} cm^{-1}) is obtained by fractional distillation under reduced pressure, and storage over BaO or molecular sieves because it readily absorbs moisture from the atmosphere on prolonged storage. [Hoover *Pure Appl Chem* **37** 579 *1974*, DOI: org.virtual.anu.edu.au/10.1351/pac197437040579; *Recommended Methods for Purification of Solvents and Tests for Impurities,* Coetzee Ed., Pergamon Press, *1982*, *Beilstein* **4** IV 183.]

Methyl propionate *[554-12-1]* **$C_4H_8O_2$, M 88.1, m -88°, b 79.7°/atm, d^{25} 0.915 g/ml, n_D^{20} 1.376.** Wash the ester with saturated aqueous NaCl, then dry it with Na_2CO_3 and distil it from P_2O_5. (This removes any free acid and alcohol.) It has also been dried with anhydrous $CuSO_4$. [*Beilstein* **2** IV 704.]

Methyl *n*-propyl ether *[557-17-5]* **$C_4H_{10}O$, M 74.1, b 39°/743mm, 38.8°/atm, d_4^{20} 0.736, n^{14} 1.3602, pK^{25} -3.79 (aqueous H_2SO_4).** Dry it with $CaSO_4$, then pass the ether through a column of alumina (to remove peroxides) and fractionally distil it. Its solubility in H_2O at 25° is 5% v/v. It is a **FLAMMABLE** anaesthetic. [Bennett & Phillip *J Chem Soc* 1930 *1928,* DOI: 10.1039/JR9280001930; *Beilstein* **1** H 354, **1** I 178, **1** II 367, **1** III 1413, **1** IV 1421.]

Methyl *n*-propyl ketone (pentan-2-one) *[107-87-9]* **$C_5H_{10}O$, M 86.1, m -78°, b 102.4°/atm, d_4^{20} 0.807, n_D^{20} 1.3903.** Purify the ketone by refluxing it with a little $KMnO_4$, dry it with $CaSO_4$ and distil it. It can be converted to its bisulfite addition compound by shaking with excess saturated aqueous $NaHSO_3$ at room temperature, cooling to 0°, filtering, washing with diethyl ether and drying. Steam distillation of the adduct gives a distillate from which the ketone is recovered, washed with aqueous $NaHCO_3$ and distilled water, dried (K_2CO_3) and fractionally distilled. **IRRITANT**. [Waring & Garik *J Am Chem Soc* 78 5198 *1956*, DOI: 10.1021/ja01601a019; *Beilstein* **1** IV 3271.]5198 *1956*,

Mucochloric acid (2,3-dichloro-4-oxo-2-butenoic acid) *[87-56-9]* **$C_4H_2Cl_2O_3$, M 169.0, m 124-126°, pK^{25} 4.20.** Crystallise the acid twice from water (charcoal). [*Beilstein* **3** IV 1720.]

***trans, trans*-Muconic acid (hexa-2,4-dienedioic acid)** *[3588-17-8]* **$C_6H_6O_4$, M 142.1, m 300°, pK^{25} 4.51, for *cis,cis*-acid** *[1119-72-8]* **m 194-195°, pK^{25} 4.49.** Crystallise the diacid from H_2O. [*Beilstein* **2** IV 2298.]

Myristic acid (tetradecanoic acid) *[544-63-8]* **$C_{14}H_{28}O_2$, M 228.4, m 58°, b 250°/100mm pK^{20} 6.3 (50% aqueous EtOH), pK_{Est} ~4.9 (H_2O).** Purify the acid *via* the ***methyl ester*** **(b 153-154°/10mm**, n^{25} 1.4350), as for capric acid. [Trachtman & Miller *J Am Chem Soc* **84** 4828 *1962*, DOI: 10.1021/ja00883a039.] Also purify it by zone melting. It crystallises from petroleum ether, and is dried in a vacuum desiccator containing shredded wax. [*Beilstein* **2** IV 1126.]

Neopentane (2,2-dimethylpropane, tetramethylmethane) *[463-82-1]* **C_5H_{12}, M 72.2, flash point 79.3°, m –19.8°, b 9.5°/760mm, d_4^{20} 0.6737, n_D^{20} 1.38273.** It was prepared by the reaction of *tert*-butyl chloride and methyl magnesium chloride in toluene at 45-60° in 42-50% yield. The crude hydrocarbon was freed from isobutene by passage over concentrated H_2SO_4 or P_2O_5, and through silica gel. It was then fractionated through a packed column (42 x 1.2 cm) provided with a total condenser and a variable take-off. The jacket of the column was kept at 9-10° and the reflux condenser at 0-3° by circulating cooled water through them. Fractions were collected and their freezing points measured. Those with freezing points close to **-19°** were pooled, the vapour was scrubbed through 85% H_2SO_4 then 25% KOH, dried with P_2O_5, condensed, and re-fractionated as before. The fraction with **b 9.4°/760mm**, and **m –19.8°** was collected. [Whitmore & Flemming *J Am Chem Soc* **55** 3803 *1933*, DOI: 10.1021/ja01336a058; Whitmore et al. *J Am Chem Soc* **56** 749 *1934*, DOI: 10.1021/ja01318a508; *Beilstein* **1** H 141, **1** I 50, **1** II 104, **1** 369, **1** IV 333.]

Nerolidol (3,7,11-trimethyl-1,6,10-dodecatrien-3-ol) $C_{15}H_{26}O_2$, M 222.4 *[cis/trans 7212-44-4]* **b 122°/3mm, d_4^{20} 0.73, n_D^{20} 1.477,** *[cis 3790-78-1]* **b 70°/0.1mm,** *[trans 40716-66-3]* **b 78°/0.2mm, 145-146°/2mm.** Purify it by TLC on plates of Kieselguhr G [McSweeney *J Chromatogr* **17** 183 *1965*, DOI: 10.1016/S0021-9673(00)99850-9] or silica gel impregnated with $AgNO_3$, using 1,2-CH_2Cl_2/$CHCl_3$/EtOAc/PrOH (10:10:1:1) as solvent system. Also by GLC on butanediol succinate (20%) on Chromosorb W. Stored it under N_2 at ~5° in the

dark. [*Beilstein* **1** IV 2336.]

Nitrilotriacetic acid [tris(carboxymethyl)amine, NTA, Complexone 1] *[139-13-9]* **$C_6H_9NO_6$, M 191.1, m 247°(dec), pK_1 0.8, pK_2 1.71, pK_3 2.47, pK_4 9.71.** Crystallise it from water and dry it at 110° in a vacuum. [*Beilstein* **4** IV 2441.]

Nitroethane *[79-24-3]* **$C_2H_5NO_2$, M 75.1, m -90°, b 115°/atm, d_4^{20} 1.049, n_D^{20} 1.3920, n_D^{25} 1.39015, pK^{25} 8.60 (8.46, pH equilibrium requires *ca* 5 minutes).** Purify it as described for *nitromethane* below. A spectroscopic impurity can be removed by shaking it with activated alumina, decanting and distilling it rapidly. [*Beilstein* **1** IV 170.]

Nitroguanidine *[556-88-7]* **$CH_4N_4O_2$, M 104.1, m 239°(dec), 246-246.5°(dec), 257°, pK_1^{25} -0.55, pK_2^{25} 12.20.** Crystallise it from water (20ml/g). The ***nitrate*** has **m 147°(dec)** (prisms, H_2O). [*Beilstein* **3** H 126, **3** III 236.]

Nitromethane *[75-52-5]* **CH_3NO_2, M 61.0, f -28.5°, b 101.3°/atm, d_4^{20} 1.13749, d^{30} 1.12398, n_D^{20} 1.3819, n^{30} 1.37730, pK^{25} 10.21.** Nitromethane is generally manufactured by gas-phase nitration of methane. The usual impurities include aldehydes, nitroethane, water and small amounts of alcohols. Most of these can be removed by drying with $CaCl_2$ or by distillation to remove the water/nitromethane azeotrope, followed by drying with $CaSO_4$. Phosphorus pentoxide is **no**t suitable as a drying agent as it forms a sol in $MeNO_2$, and a white solid is deposited in the condenser when it is distilled [Wright et al. *J Chem Soc* 199 *1931*, DOI: 10.1039/JR9310000199]. In an early preparation, Whitmore and Whitmore [*Org Synth* **3** 83 *1923* DOI: 10.1002/0471264180.os003.24] synthesised nitromethane from sodium nitrite and sodium chloroacetate. The purified material should be stored in dark bottles, away from strong light, in a cool place. Purifications using extraction are commonly used. For example, Van Looy and Hammett [*J Am Chem Soc* **81** 3872 *1959*, DOI: 10.1021/ja01524a019] mixed about 150ml of concentrated H_2SO_4 with 1L of nitromethane and allowed it to stand for 1 or 2 days. The solvent was washed with water, aqueous Na_2CO_3, and again with water, then dried for several days with $MgSO_4$, filtered again with $CaSO_4$. It was fractionally distilled before use. Smith, Fainberg and Winstein [*J Am Chem Soc* **83** 618 *1961*, DOI: 10.1021/ja01464a029] washed it successively with aqueous $NaHCO_3$, aqueous $NaHSO_3$, water, 5% H_2SO_4, water and dilute $NaHCO_3$. The solvent was dried with $CaSO_4$, then percolated through a column of Linde type 4A molecular sieves, followed by distillation from some of this material (in powdered form). Buffagni and Dunn [*J Chem Soc* 5105 *1961*, DOI: 10.1039/JR9610005105] refluxed it for 24 hours with activated charcoal while bubbling a stream of nitrogen through the liquid. The suspension was filtered, dried (Na_2SO_4) and distilled, then passed through an alumina column and re-distilled. It has also been refluxed over CaH_2, distilled and kept under argon over 4A molecular sieves.
It has been purified by zone melting at low temperature, or by distillation under a vacuum at 0°, subjecting the middle fraction to several freeze-pump-thaw cycles. An impure sample containing higher nitroalkanes and traces of cyanoalkanes was purified (on the basis of its NMR spectrum) by crystallisation from Et_2O at -60° (cooling in Dry-Ice) [Parrett & Sun *J Chem Educ* **54** 448 *1977*, DOI: 10.1021/ed054p448].
Fractional crystallisation is more effective than fractional distillation from Drierite in purifying nitromethane for conductivity measurements. [Coetzee & Cunningham *J Am Chem Soc* **87** 2529 *1965*, DOI: 10.1021/ja01090a001.] Specific conductivities around 5 x 10^{-9} $ohm^{-1}cm^{-1}$ were obtained. [*Beilstein* **1** IV 100.]

1-Nitropropane *[108-03-2]* **$C_3H_7NO_2$, M 89.1, b 131.4°/atm, d_4^{20} 1.004, n_D^{20} 1.40161, n_D^{25} 1.39936, pK^{25} 8.98.** Purify it as for *nitromethane*. [*Beilstein* **1** IV 229.]

2-Nitropropane *[79-46-9]* **$C_3H_7NO_2$, M 89.1, b 120.3°/atm, d_4^{20} 0.989, n_D^{20} 1.3949, n_D^{25} 1.39206, pK^{25} 7.68.** Purify it as for *nitromethane*. [*Beilstein* **1** IV 230.]

***N*-Nitrosodiethanolamine (NDELA)** *[1116-54-7]* **$C_4H_{10}N_2O_3$, M 134.4, b 100°/2.6x10^{-5}mm, 125°/0.01mm, n_D^{20} 1.4849.** Purify NDELA by dissolving the amine (0.5g) in 1-propanol (10ml) and 5g of anhydrous Na_2SO_4 added with stirring. After standing for 1-2 hours, it is filtered and passed through a chromatographic column packed with 10ml of AG 50W x 8 (H^+form 50-100mesh, a strongly acidic cation exchanger). The eluent and washings (50 ml EtOH) are combined and evaporated to dryness at 35°. It has also been extracted with EtOH

from the nitrosation mixture of ethanolamine, filtered and distilled under high vacuum. [Fukuda et al. *Anal Chem* **53** 2000 *1981*, DOI: 10.1021/ac00236a013; Jones & Wilson *J Chem Soc* 547 *1949*, DOI: 10.1039/JR9490000547; *Beilstein* **1** III 721, see Spiegelhalder et al. *N-Nitroso Compounds*: *Occurrence Biological Effects and Relevance in Human Cancer* (eds. O'Neill et al. IARC Scientific Publications No 57; IARC Lyon p943 *1984*.] *Possible* **CARCINOGEN.**

Nitrourea *[556-89-8]* **$CH_3N_3O_3$, M 105.1, m 158.4-158.8°(dec), pK^{20} 2.15.** Crystallise it from EtOH/petroleum ether. Dry it *in vacuo* ~50°. [Ingersoll & Armendt *Org Synth* Coll Vol **I** 417 *1941*, DOI: 10.15227/orgsyn.005.0085.]

***n*-Nonane** *[111-84-2]* **C_9H_{20}, M 128.3, m -53°, b 150.8°/atm, d_4^{20} 0.719, n_D^{20} 1.40542, n_D^{25} 1.40311.** Fractionally distil *n*-nonane, then stir it with successive volumes of concentrated H_2SO_4 for 12 hours each until no further coloration is observed in the acid layer. Then wash it with water, dry with $MgSO_4$ and fractionally distil it. *Alternatively*, it is purified by azeotropic distillation with 2-ethoxyethanol, followed by washing out the alcohol with water, drying and distilling it. [Forziati et al. *J Res Nat Bur Stand* **36** 129 *1946*, DOI: org/10.6028/jres.036.005; *Beilstein* **1** IV 447.]

Nylon powder. Pellets are purified by dissolving them in ethylene glycol under reflux, then precipitating nylon as a white powder by adding EtOH at 25°. This is washed with EtOH and dried at 100° under vacuum.

***n*-Octacosane** *[630-02-4]* **$C_{28}H_{58}$, M 394.8, m 62.5°, b 278°/15mm.** Purify it by forming its adduct with urea, washing it and crystallising it from acetone/water. [McCubbin *Trans Faraday Soc* **58** 2307 *1962*, DOI: 10.1039/TF9625802307.] Crystallise it then from hot filtered isopropyl ether solution (10ml/g). [*Beilstein* **1** IV 588.]

***n*-Octacosanol (octacosyl alcohol)** *[557-61-9]* **$C_{28}H_{58}O$, M 410.8, m 83.4°, 84°.** It has been prepared from behenic acid (see docosanoic acid above). Recrystallise it from large volumes of Me_2CO. Sublime it at 200-250°/1mm instead of distilling it. It is insoluble in H_2O but soluble in organc solvents, fats, oils and CS_2. [Bleyberg & Ulrich *Ber* **64** 2504 *1931*, DOI: 10.1002/cber.19310640929; *Beilstein* **2** IV 1318.]

Also purify it by column chromatography. Free it from cetyl alcohol by zone refining. [*Beilstein* **1** IV 1888.]

n*-Octadecylamine (1-aminooctadecane, stearylamine, ODA)** *[124-30-1]* **$C_{18}H_{39}N$, M 269.5, m 49-52°, 50-52°, 52-54°, b 183.0-183.1°/5mm, 232°/32mm, pK^{25} 10.60.** *n*-Octadecylamine can be prepared from nonadecanoic acid (*n*-nonadecylic acid, [646-30-0]) by Schmidt's hydrazoic acid method whereby the carboxylic acid (15.8g, 53mmol) in *C_6H_6 (500ml) is treated carefully with concentrated H_2SO_4 (30ml), stirred vigorously at 40° and hydrazoic acid (52ml of a 5.3% solution in *C_6H_6, 1.2 equivalents, i.e. 63.3mmol; see [7782-79-8], **POISONOUS** use efficient fumehood] is added slowly. After evolution of N_2 and CO_2 have ceased (~2 hours) the acid layer is poured into cold H_2O whereby octadecylamine sulfate precipitates (~96% yield decomposing at ~200°). [see Briggs et al *J Chem Soc* 61 *1942*, DOI: 10.1039/JR9420000061.] The free base is obtained by shaking with 10% KOH solution, extracting into Et_2O, drying (K_2CO_3), evaporating and distilling the residue in a vacuum. Its FT-IR (film) has ν_{max} at 2923.9, 1466.3, 792.4, 720.9 cm^{-1}; its ^{1}H NMR (300MHz, $CDCl_3$, TMS) has δ at 0.89 (t, *J* = 7 Hz, 3H, CH_3), 1.01 (s), 1.25 (s, 10H), 1.43 (m, 2H), 2.67 (t, *J* = ~7 Hz, 2H, CH_2-N); and the ^{13}C NMR (75MHz, $CDCl_3$, $CHCl_3$ standard) has δ at 42.35, 33.99, 31.95, 29.72, 29.56, 29.39, 26.94, 22.71, 14.11. It has also been prepared by the Gabriel Synthesis whereby octadecanol is converted to octadecyl iodide, m 29-32° (by reaction with P_2O_5/KI), then with potassium phthalimide in DMF, to the *N-n*-octdecylphthalimide, m 80-81°, followed by hydrazinolysis with 85% $NH_2NH_2.H_2O$, and isolation as the ***hydrochloride [1838-08-0] **m 162-163°** after crystallisation from EtOH/Et_2O [Wood *J Chem Soc* 3327 *1953*, DOI: 10.1039/JR9530003313]. Another method of prepartion include reduction of stearic amide with LAH in ~60% yield using a Soxhlet extractor with the amide in the thimble and LAH/Et_2O in the boiling flask [Murr & Lester *J Am Chem Soc* **77** 1684 *1955*, DOI: 10.1021/ja01611a089]. The ***N-acetyl derivative*** has **m 84-85°** (EtOH/Et_2O), and the ***N-methyl derivative*** [2439-55-6] has **m 42-46°**, **b 155°/0.5mm**. [*Beilstein* **4** II 661, **4** III 431, **4** IV 825.] It is a strong base and should be stored in a dry CO_2-free atmosphere. The base and its derivatives are **skin and eye irritants**, and release histamine.

Octadecyl ether (dioctadecyl ether) *[6297-03-6]* **$C_{36}H_{74}O$, M 523.0, m 59.4°, n_D^{60} 1.440.** Distil the ether in a vacuum, then crystallise it from MeOH/*C_6H_6, MeOH (**m** 58.5-59.5°) or Me_2CO (**m** 59.5°). It has an α form **m 57.8°** and a β form **m 40°**. [*Beilstein* **1** IV 1891.]

Octafluoropropane (profluorane) *[76-19-7]* **C_3F_8, M 188.0, m -183°, b -36°/atm -38°/atm** Purify it for pyrolysis studies by passage through a copper vessel containing CoF_3 at about 270°, then fractionally distil it. [Steunenberg & Cady *J Am Chem Soc* **74** 4165 *1952*, DOI: 10.1021/ja01136a062.] Also purify it by several trap-to-trap distillations at low temperatures. From the reaction of carbon and fluorine several fluorocarbons were obtained and separated by using a low temperature column packed with glass helices at 200mm, and the temperature remained constant within ±1°. Each fraction was redistilled and their molecular weights were determined from the density balance. Thus obtained were **C_3F_8 (188), C_4F_{10} (234, 238), C_5F_{12} (277, 278)** and **C_6F_{14} (328, 228)**. The redistilled fractions had relatively sharp melting points. The *Critical Temperature* of **C_3F_8** is **343.7K**. [Simons & Block *J Am Chem Soc* **59** 1407 *1937*, DOI: 10.1021/ja01286a512]. [*Beilstein* **1** III 219, **1** IV 189.]

***n*-Octane** *[111-65-9]* **C_8H_{18}, M 114.2, m -56.8°, b 19.2°/10mm, 125.6°/760mm, d_4^{20} 0.704, n_D^{20} 1.39743, n_D^{25} 1.39505.** Extract the octane repeatedly with concentrated H_2SO_4 or chlorosulfonic acid, then wash it with water, dry and distil it. *Alternatively*, purify it by azeotropic distillation with EtOH, followed by washing with water to remove the EtOH, drying and distilling it. For further details, see n-*heptane*. It is also purified by zone melting at low temperatures. [*Beilstein* **1** H 159, **1** I 60, **1** II 122, **1** III 457, **1** IV 412.]

RS*-Octane-1,2-diol** *[1117-86-8]* **$C_8H_{18}O_2$, M 146.2, m 30-30.5°, 36°, b 103-105°/0.5mm, 131-132°/10mm.** Distil the diol *in vacuo* and/or recrystallise it from petroleum ether. The ***α-naphthylurethane has **m 112-114°**. [*Beilstein* **1**III 2217, **1** IV 2590.] *S*-(-)-*Octane-1,2-diol* [87720-91-0] also crystallises from petroleum ether with **m 35-37°** and $[\alpha]_D^{17}$ -4.7 (c 35, EtOH) [Späth et al. *Chem Ber* **66** 591 *1933*, DOI: 10.1002/cber.19330660430]; *R*-(+)-*octane-1,2-diol* [87720-90-9] has similar properties but with a positive optical rotation.

Octane-4,5-diol (dipropyl glycol) *[110-98-5]* **$C_8H_{18}O_2$, M 134.2, b 109-110°/8mm (mostly *d,l*), d_4^{20} 1.022, n_D^{20} 1.441.** Fractionally distil the diol below 15mm pressure, using a packed column and taking precautions to avoid absorption of water. [*Beilstein* **1** H 490, **1** II 556, **1** III 2219, **1** IV 2493.] Note that kilograms of a 1:1 mixture of *d,l*- and *meso*- dipropenylglycol (**b 113.4-114.4°/9mm**) can be obtained in *ca* 67% yield from *trans*-

crotonaldehyde by reaction with Zn—Cu couple in dilute acetic acid. When this glycol is reduced in 95% EtOH with a Pt catalyst (Adam's) it gives a 1:1 mixture of *d,l-* and *meso-* dipropyl glycol in >90% yield. After removal of Pt and evaporation of the solvent through a Hemple column, a pasty solid, m 20-90°, is obtained. Recrystallisation of the pasty solid from petroleum ether gives ***meso*-dipropyl glycol m 123.5-124.5°**, whose ***bis-3,5-dinitrobenzoate*** (prepared in dry pyridine, precipitation in the usual way, dissolving the crude ester in warm nitrobenzene and adding EtOH) has **m 200.3-200.4°**. The ***bis-phenylurethane*** has **m 191.2°**. Evaporation of the petroleum ether filtrate and repeated fractional distillation (using a 90 cm Claisen-Head column packed with glass rings and fitted wih a Hopkins condenser) gives pure ***d,l*-dipropyl glycol m 28°**, **b 109.8-110°/9mm**, $\mathbf{n_D^{25}}$ **1.4419**, whose ***bis-3,5-dinitrobenzoate*** has **m 125-125.3°**. The ***bis-phenylurethane*** has **m 133.3°**. Studies of the melting points *versus* molar composition of mixtures of *meso* and *d,l* forms displayed a ***eutectic*** mixture of 5% *meso-* and 95% of *d,l-* dipropyl glycol at 20.0-20.5 °. Also the melting points of the *bis*-3,4-dinitrobenzoates of mixtures of these are indicative of their ratios [Young et al. *J Am Chem Soc* **58** 2274 *1936*, DOI: 10.1021/ja01302a054]. Separation of *meso* and *d,l* forms can be achieved by chromatography in petroleum ether on Al_2O_3. [*Beilstein* **1** I 490, **1** II 556, **1** III 2219, **1** IV 2493.]

Octane-1,8-diol (octamethylene glycol) *[629-41-4]* **$C_8H_{18}O_2$, M 146.2, m 59-61°, b 172°/20mm.** Recrystallise the diol from EtOH and distil it in a vacuum. [*Beilstein* **1** IV 2592.]

1-Octanethiol *[111-88-6]* **$C_8H_{18}S$, M 146.3, b 86°/15mm, 197-200°/760mm, d_4^{20} 0.8433, n_D^{20} 1.4540, pK^{25} 10.72(dilute *t*-BuOH).** Pass the thiol through a column of alumina and work under N_2, or Argon. Distil it under N_2 and a vacuum. Store it under N_2, or Argon in the dark. [Fletcher *J Am Chem Soc* **68** 2726 *1946*, DOI: 10.1021/ja01216a505]. [*Beilstein* **1** III 1710, **1** IV 1767.]

1-Octene *[111-66-0]* **C_8H_{16}, M 112.2, m -101°, b 121°/742mm, d_4^{20} 0.716, n_D^{20} 1.4087.** Distil 1-octene under nitrogen from sodium which removes water and peroxides. Peroxides can also be removed by percolation through dried, acid washed, alumina. Store it under N_2, or Argon in the dark. [Strukul & Michelin *J Am Chem Soc* **107** 7563 *1985*, DOI: 10.1021/ja00311a056; *Beilstein* **1** H 221, **1** II 199, **1** IV 874.]

***trans*-2-Octene** *[13389-42-9]* **C_8H_{16}, M 112.2, b 124-124.5°/760mm, d_4^{20} 0.722, n_D^{20} 1.4132.** Purify it as for 1-octene above. [*Beilstein* **1** IV 879.]

***n*-Octyl alcohol** *[111-87-5]* **$C_8H_{18}O$, M 130.2, m -15°, b 98°/19mm, 195.3°/760mm, d_4^{20} 0.828, n_D^{20} 1.43018.** Fractionally distil it under reduced pressure. Dry it with sodium and again fractionally distil or reflux with boric anhydride and re-distilled (**b** 195-205°/5mm), the distillate being neutralised with NaOH and again fractionally distilled. Also purify it by distillation from Raney nickel and by preparative GLC. [*Beilstein* **1** IV 1756.]

n*-Octylamine (1-aminooctane, caprylamine)** *[111-86-4]* **$C_8H_{19}N$, M 129.2, m -5° to -1°, b 62-64°/11mm 175-177°/745mm, 185-187°/atm, d_4^{20} 0.7819, d_4^{25} 0.728, n_D^{20} 1.4292, pK^{25} 10.57.** *n*-Octylamine has been prepared from nonanoic acid (pelargonic acid, see [112-05-0]) by Schmidt's hydrazoic acid method as described for octadecylamine above. [Adamson & Kenner *J Chem Soc* 838 *1934*, DOI: 10.1039/JR9340000838.] The syntheses decribed below for octadecyl amine can be used for preparing octylamine. A more recent preparation involves formation of tri-*n*-octylborane from 1-octene and BH_3.THF *in situ*, then reaction with NaN_3/HCl to give a 79% yield of octylamine [Kabalka et al. *Organometallics* **6** 1369 *1987*, DOI: 10.1021/om00149a046]. The free base can be isolated from its salts or the picrate by treatment with strong aqueous alkaline solution, extraction into Et_2O or CH_2Cl_2, drying (K_2CO_3), evaporating and distilling the residue preferably in a vacuum. Solubility in H_2O is ~2%. It is a strong base which readily absorbs CO_2 in moist air and should be stored under N_2. Its FT-IR (film) has ν_{max} at 3371.9, 2924.6, 1617.3, 1467.0, 1378.3, 1072.7, 822.1, 722.9 cm^{-1}; its ^1H NMR (300MHz, $CDCl_3$, TMS) has δ at 0.89 (t, J = ~7 Hz, 3H, CH_3), 1.15 (s), 1.29 (s, $6CH_2$), 1.42 (t, J = ~7 Hz, NH_2), 2.69 (t, J = ~7 Hz, 2H, CH_2-N) ppm; and the ^{13}C NMR (300MHz, $CDCl_3$, $CHCl_3$ standard) has δ at 42.32, 33.96, 31.88, 29.51, 29.34, 26.94, 22.69, 14,10 ppm. The ***picrate [78498-55-2] crystallises as plates with **m 111.5-112.5°**, the ***N-acetyl derivative*** [7462-62-6] has **b 148-149°/3mm**, and the ***N-methyl derivative*** [2439-54-5] has **b 60-65°/3mm**, **75-78°/13mm**. [*Beilstein* **4** H 196, **4** I 386, **4** II 655, **4** III 379, **4** IV 751.] *n*-Octylamine is quite a strong primary base capable of forming a carbamate salt of the type $RNHCO_2^-$ RNH_3^+ in the presence of CO_2 and H_2O (see storage above). The free base and its derivatives are **skin and eye irritants**.

***n*-Octylammonium hexadecanoate** *[88020-97-7]* **$C_{24}H_{51}NO_2$, M 385.7, m 52-53°.** Purify it by several recrystallisations from *n*-hexane or ethyl acetate. The solid is then washed with cold anhydrous diethyl ether, and dried *in vacuo* over P_2O_5. [*Beilstein* **4** IV 751 for octylamine.]
***n*-Octylammonium octadecanoate** *[32580-92-0]* **$C_{26}H_{55}NO_2$, M 413.7, m 56-57°.** Purify it as for the *hexadecanoate* above.
***n*-Octylammonium tetradecanoate** *[17463-35-3]* **$C_{22}H_{47}NO_2$, M 357.6, m 46-48°.** Purify it as the *hexadecanoate* above.

***n*-Octyl bromide** *[111-83-1]* **$C_8H_{17}Br$, M 193.1, m -55°, b 201.5°/atm, d_4^{20} 1.118, n^{25} 1.4503.** Shake the bromide with H_2SO_4, wash it with water, dry with K_2CO_3 and fractionally distil it. [*Beilstein* **1** IV 422.]

1-Octyne *[629-05-0]* **C_8H_{14}, M 110.2, m -80°, b 76-77°/150mm, 126.2°/760mm, d_4^{20} 0.717, n^{25} 1.4159.** Distil 1-octyne from $NaBH_4$ to remove peroxides. Fractionate it through a 10inch Widmer column at 125-126°/759mm. [Sletzinger & Dawson *J Org Chem* **14** 849 *1949*, DOI: 10.1021/jo01157a018.] [*Beilstein* **1** III 1005, **1** IV 1034.]

Oleic acid (OLA, *cis*-9-octadecenoic acid, olainic acid) *[112-80-1]* **$C_{18}H_{34}O_2$, M 282.5, m 13-14°, 16°, b 145°/0.1mm, 194-195°/1.2mm, 228-229°/15mm, 360°(dec), d_4^{20} 0.891, n^{30} 1.4571, pK^{25} 6.42 (50% aqueous EtOH), pK_{Est} ~4.8 (H_2O).** Purify the acid by fractional crystallisation from its melt, followed by molecular distillation at 10^{-3}mm, or by conversion to its methyl ester, the free acid can be crystallised from acetone at -40° to -45° (12ml/g). For purification by the use of lead and lithium salts see Keffler and McLean [*J Soc Chem Ind* **54** 176T *1935*, DOI: 10.1002/jctb.5000542514]. Purification based on direct crystallisation from acetone is described by Brown and Shinowara [*J Am Chem Soc* **59** 6 *1937*, DOI: 10.1021/ja01280a003; pK White *J Am Chem Soc* **72** 1859 *1950*, DOI: 10.1021/ja01160a530]. [Purification *via* urea adduct see Rubin & Paisley: *Biochem Preparations* **9** 113 *1962*, Synthesis: Robinson & Robinson *J Chem Soc* **127** 175 *1925*, DOI: 10.1039/CT9252700175; *Beilstein* **2** H 463, **2** I 198, **2** II 429, **2** III 1387, **2** IV 1641.]

Oleyl alcohol *[143-28-2]* **$C_{18}H_{36}O$, M 268.5, m 1-5°, b 182-184°/1.5mm, 207°/13mm, d_4^{20} 0.847, $n^{27.5}$ 1.4582.** Purify it by fractional crystallisation at -40° from acetone, then distil it under vacuum. [*Beilstein* **2** IV 2204.]

Oxalic acid ($2H_2O$) *[6153-56-6]* **$C_2H_2O_4$, M 90.0, m 101.5°,** *[anhydrous 144-62-7]* **m 189.5°, pK_1^{25} 1.08 (1.37), pK_2^{25} 3.55 (3.80).** Crystallise oxalic acid from distilled water. Dry it in a vacuum over H_2SO_4. The anhydrous acid can be obtained by drying at 100° overnight. [*Beilstein* **2** IV 1819.]

Oxaloacetic acid *[328-42-7]* **$C_4H_4O_5$, M 132.1, m 160°(decarboxylates), pK_1^{25} 2.22, pK_2^{25} 3.89, pK_3^{25} 13.0.** Crystallise it from boiling EtOAc, or from hot Me_2CO/hot $*C_6H_6$. [*Beilstein* **3** IV 1808.]

2-Oxoglutaric acid (2-oxopentane-1,5-dioic, α-ketoglutaric acid) *[328-50-7]* **$C_5H_6O_5$, M 146.1, m 114°, 115-117°, (pK_{Est} see oxaloacetic acid above).** Crystallise the keto-acid repeatedly from Me_2CO/*benzene, EtOAc or ethyl propionate. Dry it *in vacuo*. [*Beilstein* **3** IV 1813.]

Oxamide *[471-46-5]* **$C_2H_4N_2O_2$, M 88.1, m >320°(dec).** Crystallise oxamide from water, grind it and dry it in an oven at 150°. [*Beilstein* **2** IV 1860.]

Palmitic acid anhydride (hexadecanoic anhydride) *[623-65-4]* **$C_{32}H_{62}O_3$, M 494.9, m 63-64°, 64°, d^{82} 0.838, n^{68} 1.436.** It is moisture sensitive and hydrolyses in water. Purify it by refluxing with acetic anhydride for 1 hour, evaporating and freeing the residue of acetic acid and anhydride by drying the residue at high vacuum and recrystallising from petroleum ether at low temperature. [*Beilstein* **2** IV 1181.]

Paraffin (oil) *[8012-95-1]* **d_4^{20} 0.880, n_D^{20} 1.482.** Treat the oil with fuming H_2SO_4 (care), then wash it with water and dilute aqueous NaOH, then percolate it through activated silica gel.

Paraffin Wax *[8012-74-2]* **C_nH_{2n+2}, d_4^{20} 0.82, n_D^{20} 1.45 (extra light).** A colourless (white), odourless wax from petroleum which is commercially available in fractions which solidify at various temperatures, e.g. with **solidification points at 44-46°** (in large white chunks), **50-52°** (white pellets), **54-56°** (white pellets), **58-60°** (white pellets), and **68-70°** (white pellets). Also available are waxes with **melting point ranges of 53-57°, 58-62°, ≥ 65°, and 70-80°.** Melt the wax in the presence of NaOH, wash it with water until all of the base had been removed. The paraffin is allowed to solidify after each wash. Finally, 5g of paraffin is melted by heating it on a water-bath, then shaken for 20-30 minutes with 100ml of boiling water and dry the melt under vacuum.

Pelargonic acid (nonanoic acid) *[112-05-0]* **$C_9H_{18}O_2$, M 158.2, m 15°, b 98.9°/1mm, 225°/760mm, 268-269°/760mm, pK^{25} 4.96.** Esterify the acid with ethylene glycol and distil the ester. (This removes dibasic acids as undistillable residues.) The acid is regenerated by hydrolysing the ester in the usual way and is distilled *in vacuo*. [*Beilstein* **2** IV 1018.]

Pelargononitrile (octyl cyanide) *[2243-27-8]* **$C_9H_{17}N$, M 139.2, m -34°, b 92°/10mm, 224°, d_4^{20} 0.818, n_D^{20} 1.4255.** Stir the nitrile with P_2O_5 (~5%), distil it from P_2O_5 and redistil it under a vacuum. IR should have CN but no OH bands. [*Beilstein* **2** IV 1204.]

Pelargonyl chloride (nonanoyl chloride) *[764-85-2]* **$C_9H_{17}ClO$, M 176.7, b 88°/12mm, 108-110°/22mm, d_4^{20} 0.941, n_D^{20} 1.436.** Reflux it with acetyl chloride (~ 3 volumes) for 1 hour, then distil off AcCl followed by the nonanoyl chloride at ~12mm. It is moisture sensitive and should be stored in sealed ampoules. [*Beilstein* **2** IV 1023.]

Pentabromoacetone *[79-49-2]* **C_3HBr_5O, M 452.6, m 76°, pK^{25} 8.0 (MeOH), pK_{Est} ~4.6 (H_2O).** Crystallise it from Et_2O, EtOH or aqueous EtOH (**m** 73.2°). Its solubility in H_2O is 0.01mg/100ml. It sublimes at its melting point. [*Beilstein* **1** H 659, **1** I 345, **1** III 2753, **1** IV 3226.]

Pentachloroethane (pentalin) *[76-01-7]* **C_2HCl_5, M 202.3, b 69°/37mm, 152.2°/64mm, 162.0°/~760mm, d_4^{20} 1.678, n^{15} 1.50542.** Usual impurities include trichloroethylene. It partially decomposes if it is distilled at atmospheric pressure. Drying it with CaO, KOH or sodium is unsatisfactory because of the elimination of the elements of HCl. It can be purified by steam distillation, or by washing with concentrated H_2SO_4, water, and then aqueous K_2CO_3, drying with solid K_2CO_3 or $CaSO_4$, and fractionally distilling under reduced pressure. [*Beilstein* **2** IV 147.]

Pentadecafluoro octanoic acid (perfluorocaprylic acid) *[335-67-1]* **$C_8HF_{14}O_2$, M 414.1, m 54.9-55.6°, b 189°/736mm, pK_{Est} <0.** Crystallise the acid from CCl_4 and toluene, and distil it. It forms micelles in H_2O and the solubility is 1% in H_2O. The ***acid chloride*** has **b 129-130°/744mm**. The ***amide*** has **m 138°**. [Bernett & Zisman *J Phys Chem* **63** 1911 *1959*, DOI: 10.1021/j150581a028; Bro & Sperati *J Polym Sci* **38** 289 *1959*, DOI: 10.1002/pol.1959.1203813401; *Beilstein* **2** IV 994.]

Pentadecanoic acid *[1002-84-2]* **$C_{15}H_{30}O_2$, M 242.4, m 51-53°, 80°, b 158°/1mm, 257°/100mm, d_4^{80} 0.8424, pK_{Est} ~5.0.** Crystallise the acid from Et_2O and distil it *in vacuo*. It is very *hygroscopic*. See the purification of palmitic acid. [*Beilstein* **2** IV 1147.]

Pentadecanolide (1-oxacyclohexadecan-2-one, pentadecanoic-ω-lactone, 15-hydroxypentadecanoic lactone, exaltolide, Tibetolide) *[106-02-5]* **$C_{15}H_{28}O_2$, M 240.4, m 34-36°, 37-37.5°, 37-38°, b 102-103°/0.03mm, 112-114°/0.2mm, 137°/2mm, 169°/10-11mm, d_4^{40} 0.9401.** It has been recrystallised from MeOH (4 parts) at -15°, and distilled under high vacuum. [Hunsdiecker & Erlbach *Chem Ber* **80** 129 *1947*, DOI: 10.1002/cber.19470800207; Galli & Mandolini *Org Synth* **58** 98 *1978*, DOI: 10.15227/orgsyn.058.0098; Demole & Enggist *Helv Chim Acta* **11** 2318 *1978*, DOI: 10.1002/hlca.19780610705; *Beilstein* **17/9** V 106.]

Penta-1,3-diene *[cis: 1574-41-0, trans: 2004-70-8]* **C_8H_{28}, M 68.1, m -87°, b 42°/atm, d_4^{20} 0.680, n_D^{20} 1.4316.** Distil the diene from $NaBH_4$. Purify it also by preparative gas chromatography. [Reimann et al. *J Am Chem Soc* **108** 5527 *1986*, DOI: 10.1021/ja00278a026; *Beilstein* **1** IV 994.]

Penta-1,4-diene *[591-93-5]* **C_8H_{28}, M 68.1, m -1.5°, b 25.8-26.2°/756mm, d_4^{20} 0.645, n_D^{20} 1.3890.** Distil it from $NaBH_4$. Purify it by preparative gas chromatography or distillation and stabilise it with 0.1% of 2,6-di-*tert*-butyl-*p*-cresol. [Reimann et al. *J Am Chem Soc* **108** 5527 *1986*, DOI: 10.1021/ja00278a026; *Beilstein* **1** IV 998.]

Pentaethylenehexamine (3,6,9,12-tetraazatetradecane-1,4-diamine) *[4067-16-7]* **$C_{10}H_{28}N_6$, M 232.4, d_4^{20} 0.950, n_D^{20} 1.510, pK_1 1.2, pK_2 2.7, pK_3 4.3, pK_4 7.8, pK_5 9.1, pK_6 9.9 (all estimated).** Fractionally distil it twice at 10-20mm, the fraction boiling at 220-250° being collected. It can be further purified *via* the *hydrochloride*. Its solution in MeOH (40ml of base in 250ml) is cooled in an ice-bath and concentrated HCl (~50ml) is added dropwise with stirring. The precipitated *hydrochloride* is filtered off, washed with Me_2CO, and Et_2O, then dried in a vacuum desiccator. The free base is then obtained by basification, extraction into Et_2O, drying (NaOH), filtering, evaporating and distilling the residue. It forms a Cu complex $[Cu(C_{10}H_{28}N_6)]^{2+}$. [Jonassen et al. *J Am Chem Soc* **79** 4279 *1957*, DOI: 10.1021/ja01573a011; *Beilstein* **4** IV 1245.]

2,2,3,3,3-Pentafluoropropan-1-ol (PFPOH) *[422-05-9]* **$C_3H_3F_5O$, M 150.1, b 80°/~760mm, d_4^{20} 1.507, n_D^{20} 1.288, pK^{25} 12.74.** Shake the alcohol with alumina for 24 hours, dry with anhydrous K_2CO_3, and distil it, collect the middle fraction (**b** 80-81°) and redistil it. [*Beilstein* **1** IV 1438.]

***n*-Pentane** *[109-66-0]* **C_5H_{12}, M 72.2, m -130°, b 36.1°/atm, d_4^{20} 0.626, n_D^{25} 1.35472.** Stir the pentane with successive portions of concentrated H_2SO_4 until there is no further coloration during 12 hours, then with 0.5N $KMnO_4$ in 3M H_2SO_4 for 12 hours, wash with water and aqueous $NaHCO_3$. Dry it with $MgSO_4$ or Na_2SO_4, then P_2O_5 and fractionally distil it through a column packed with glass helices. It is also purified by passage through a column of silica gel, followed by distillation and storage with sodium hydride. An alternative purification is by azeotropic distillation with MeOH, which is subsequently washed out from the distillate (using water), followed by drying and re-distilling. For removal of carbonyl-containing impurities, see n-*heptane*. Also purify it by fractional freezing (*ca* 40%) on a copper coil through which cold air is passed, then wash with concentrated H_2SO_4 and fractionally distil it. [*Beilstein* **1** IV 303.]

Pentane-1-thiol *[110-66-7]* **$C_5H_{12}S$, M 104.2, m -76°, b 122.9°/697.5mm, d^{25} 0.8375, pK_{Est} ~10.1.** Dissolve the thiol in aqueous 20% NaOH, then extract with a small amount of diethyl ether. The aqueous solution is acidified slightly with 15% H_2SO_4, and the thiol is distilled out, dried with $CaSO_4$ or $CaCl_2$, and fractionally distilled under nitrogen. [Ellis & Reid *J Am Chem Soc* **54** 1674 *1932*, DOI: 10.1021/ja01343a067; *Beilstein* **1** IV 1453.]

RS*-Pentan-2-ol (*sec*-amyl alcohol)** *[13403-73-1, 6032-29-7 non-specific]* **$C_5H_{12}O$, M 88.2, b 73-73.5°/735mm, 118-118.5°/749mm, 119.9°/~760mm, d_4^{20} 0.810, n_D^{20} 1.41787, n_D^{25} 1.4052.** Reflux it with CaO, distil it, then reflux it with magnesium and again fractionally distil it. Its solubility in H_2O is 16.6% w/v at 20°. The ***acetate*,** [626-38-0] **$C_7H_{14}O_2$, M 130.1**, has **b 133.5°/atm**, and the ***1-naphthylurethane [111994-17-1] crystallises from petroleum ether with **m 76°**. 1.339. Purify the fluoro-iodide by fractional distillation. Store it over Cu as stabiliser. [*Beilstein* **1** IV 225.]

Perfluorotributylamine (heptacosafluorotributylamine, PFTBA) *[311-89-7]* **$C_{12}F_{27}N$, M 671.1, b 177.6°/760mm, 178°/760mm, d_4^{20} 1.881, n_D^{20} 1.291, pK_{Est} ~5.0.** Purify it as for perfluorodimethylcyclohexane (see [335-27-3]); see also perfluorotripropylamine below [Haszeldine *J Chem Soc* 102 *1951*, DOI: 10.1039/JR9510000102]. [*Beilstein* **2** IV 819.]

Perfluorotripropylamine (heneicosafluorotripropylamine FTPA) *[338-83-0]* **$C_9F_{21}N$, M 521.1, b 129.5-130.5°/atm, 130°/atm, 129.5-130.5°/atm, d_4^{20} 1.822, n_D^{20} 1.279, pK_{Est} ~5.6.** Purify it as for *perfluorodimethylcyclohexane* (see [335-27-3]) [Haszeldine *J Chem Soc* 102 *1951,* DOI: 10.1039/JR9510000102; for azeotropes see Simons & Linevsky *J Am Chem Soc* **74** 4750 *1972*, DOI: 10.1021/ja01139a007.] **IRRITANT.**

Petroleum ether (ligroin) *[8032-32-4]* **b 35-60°, d_4^{20} 0.640, n_D^{20} 1.363.** Shake it several times with concentrated H_2SO_4, then 10% H_2SO_4 and concentrated $KMnO_4$ (to remove unsaturated, including aromatic, hydrocarbons) until the permanganate colour persists. Wash it with water, aqueous Na_2CO_3 and again with water. Dry it with $CaCl_2$ or Na_2SO_4, and distil it. It can be dried further using CaH_2 or sodium wire. Passage through a column of activated alumina, or treatment with CaH_2 or sodium, removes peroxides. For the elimination of carbonyl-containing impurities without using permanganate, see *n-heptane*. These procedures could be used for all fractions of petroleum ethers. See skellysolve below.
Rapid purification: Pass it through an alumina column and fractionally distilling, collecting the desired boiling fraction.

Phorone (2,6-dimethylhepta-2,5-dien-4-one) *[504-20-1]* **$C_9H_{14}O$, M 138.2, m 28°, b 88°/17mm, 197°/743mm.** Purify by fractional distillation or distillation and/or repeatedly recrystallise from EtOH. It can be converted to its ***2,4-dinitrophenylhyrazone*** by adding it to a moderate excess of 0.4% of 2,4-dinitrophenyl hydrazine in 2N-aqueous HCl which precipitates within 24 hours. The derivative can be washed, dried and recrystallised from EtOH, or chromatographed on alumina, eluting with benzene and recrystallising from MeOH to provide red crystals **m 118-118.5°**. [Braude & Timmons *J Chem Soc* 2000 *1950*, DOI: 10.1039/JR9500002000; Connolly *J Chem Soc* 338 *1944*, DOI: 10.1039/JR9440000338; Joseph & Blumenthal *J Org Chem* **24** 1371 *1959*, DOI: 10.1021/jo01091a626; *Beilstein* **1** IV 3564.]

Pimelic acid (heptane-1,7-dioic acid) *[111-16-0]* **$C_7H_{12}O_4$, M 160.2, m 105-106°, m 212°/10mm, pK_1^{25} 4.46, pK_2^{25} 5.58.** Crystallise the acid from water or from *benzene containing 5% diethyl ether. [*Beilstein* **1** IV 2003.]

Pinacol (hexahydrate) *[6091-58-3 ($6H_2O$), 76-09-5 (anhydrous)]* **$C_6H_{14}O_2$. $6H_2O$, M 194.3, m 46.5°, b 59°/4mm.** Distil pinacol, then crystallise it repeatedly from water. (See also below.) [*Beilstein* **1** IV 2575.]

Pinacol (anhydrous) (2,3-dimethyl-2,3-butanediol) *[76-09-5]* **$C_6H_{14}O_2$, M 118.1, m 41.1°, 171-172°/739mm, b 172°/atm.** The hydrate is rendered anhydrous by azeotropic distillation of water with *benzene. Recrystallise it from *benzene or toluene/petroleum ether, absolute EtOH or dry diethyl ether. It recrystallises from water to give the *hexahydrate*. [*Beilstein* **1** IV 2575.]

Pinacolone see ***tert*-butyl methyl ketone.**

Pinacolone oxime *[2475-93-6]* **$C_6H_{13}NO$, M 115.2, m 75.5-76°, 78°, 78.5-79.5°, 171.6°/748mm.** Crystallise the oxime from aqueous EtOH, EtOH (small needles) or petroleum ether (plates). [Markownikoff *Chem Ber* **32** 1445 *1899*, DOI: 10.1002/cber.18990320221; Smith & Adkins *J Am Chem Soc* **60** 657 *1938*, DOI: 10.1021/ja01270a048; Whitmore et al. *J Am Chem Soc* **61** 683 *1939*, DOI: 10.1021/ja01872a043; *Beilstein* **1** H 694, **1** II 750, **1** III 2842, **1** IV 3310.]

Pivalic acid (trimethylacetic acid) *[75-98-9]* **$C_5H_{10}O_2$, M 102.1, m 35.4°, b 71-73°/0.1mm, 163-164°/atm, pK^{25} 5.03.** Fractionally distil the acid under reduced pressure, then fractionally crystallise it from its melt. Re-

crystallise it from *benzene. [*Beilstein* **2** IV 908.]

Pivaloyl chloride (trimethylacetyl chloride) *[3282-30-2]* **C_5H_9ClO, M 120.6, b 57.6°/150mm, 70.5-71/250mm, 104°/754mm, 104-105°/atm, 105-108°/atm, d_4^{20} 1.003, n_D^{20} 1.4142.** First check the IR to see if OH bands are present. If absent, or present in small amounts, then redistil it under a moderate vacuum. If present in large amounts then treat it with oxalyl chloride or thionyl chloride and reflux for 2-3 hours, evaporate and distil the residue. **Strongly LACHRYMATORY - work in a fume cupboard.** Store it in sealed ampoules under N_2. [Traynham & Battiste *J Org Chem* **22** 1551 *1957*, DOI: 10.1021/jo01363a004; for Grignard reactions: Whitmore et al. *J Am Chem Soc* **63** 643 *1941*, DOI: 10.1021/ja01848a004; *Beilstein* **2** IV 912.]

Polyacrylonitrile *[25014-41-9]* **$(C_3H_3N)_n$, M 150,000 (average).** Precipitate it from dimethylformamide by addition of MeOH.

Poly(diallyldimethylammonium) chloride *[26062-79-3]***.** Precipitate it from water with acetone, and dry the salt in a vacuum for 24 hours. [Hardy & Shriver *J Am Chem Soc* **107** 3823 *1985*, DOI: 10.1021/ja00299a012.]

Polyethylene *[9002-88-4]* **$H(CH_2\text{-}CH_2)_nH$**. It is available in several molecular weight averages (from M_W~4000 to 6000.000) as well as in low, medium and high density packages. Crystallise it from thiophen-free *benzene and dry it over P_2O_5 under vacuum.

Polymethyl acrylate *[9003-21-8]*. Precipitate it from a 2% solution in acetone by addition of water.

Polyvinyl acetate *[9003-20-7]*. Precipitate it from acetone by addition of *n*-hexane.

Polyvinyl chloride *[9002-81-2]*. Precipitate it from cyclohexanone by addition of MeOH.

Propane *[74-98-6]* **C_3H_8, M 44.1, m -189.7°, b -42.1°/760mm, d_4^{20} 0.5005, n_D^{20} 1.2898.** Purify propane by bromination of the olefinic contaminants. Propane is treated with bromine for 30 minutes at 0°. Unreacted bromine is quenched, and the propane is distilled through two -78° traps and collected at -196° [Skell et al. *J Am Chem Soc* **108** 6300 *1986*, DOI: 10.1021/ja00280a030]. It autoignites at 450° and the flash point is -104°. It is highly **FLAMMABLE** and is available in metal cylinders. [*Beilstein* **1** H 103, **1** I 33, **1** II 71, **1** III 204, **1** IV 175.]

Propane-1,2-diamine (propylenediamine) *[78-90-0]* **$C_3H_{10}N_2$, M 74.1, b 120.5°/~760mm, d_4^{20} 0.868, n_D^{20} 1.446, pK_1^{25} 6.61, pK_2^{25} 9.82.** Purify this hygroscopic diamine by azeotropic distillation with toluene. Then redistil it. Store it in a CO_2 free atmosphere. **SKIN IRRITANT**. [Horton et al. *Anal Chem* **27** 269 *1955*, DOI: 10.1021/ac60098a025; for optical resolutions *via* the *d*-tartrate salts or the Co(II) complexes see Dwyer et al. *J Am Chem Soc* **81** 290 *1959*, DOI: 10.1021/ja01511a009, see also Smith et al. *J Am Chem Soc* **96** 2908 *1974*, DOI: 10.1021/ja00816a041; *Beilstein* **4** IV 1255.]

***R*(-)-propane-1,2-diamine** *[6852-78-4]* **$C_3H_{10}N_2$**, has **b 120.5°/~760mm, $[\alpha]_D^{25}$ -35 (c 0.97, * C_6H_6)** and is purified by distillation. The optical rotation is inverted in the ***R*(+)-propane-1,2-diamine dihydrochloride** *[19777-67-4]* **$C_3H_{10}N_2$. 2HCl, M 147.1,** which has **m 241-244°, $[\alpha]_D^{25}$ +4.0 (c 20,** H_2O) [*Beilstein* **4** IV 1255].

***S*(+)-propane-1,2-diamine** *[15967-73-3]* **$C_3H_{10}N_2$**, has **b 120.5°/~760mm, $[\alpha]_D^{25}$ +34.8 (c 0.97, * C_6H_6)** and is purified by distillation, and the ***S*(-)-propane-1,2-diamine dihydrochloride** *[19777-66-3]* **$C_3H_{10}N_2$. 2HCl, M 147.1,** has **m 227-229, $[\alpha]_D^{25}$ -4.0 (c 20,** H_2O) [*Beilstein* **4** 258, **4** IV 1255].

Propane-1,3-diamine (trimethylenediamine) *[109-76-2]* **$C_3H_{10}N_2$, M 74.1, m -12°, b 140°/~760mm, d_4^{25} 0.888, n_D^{20} 1.458, pK_1^{25} 8.29, pK_2^{25} 10.30.** Purify like the preceding diamine. [*Beilstein* **4** IV 1255.] The **dihydrochloride** *[10517-44-9]* **$C_3H_{10}N_2$. 2HCl, M 147.1,** has **m 243°, 246-250°.** [*Beilstein* **4** H 261.]

(±)-Propane-1,2-diol (propyleneglycol) *[57-55-6]* **$C_3H_8O_2$, M 76.1, m -60°, b 45.5°/1.0mm, 70.8°/5.0mm, 83.2°/10mm, 96.4°/20mm, 104°/32mm, 111.2°/40mm, 119.9°/60mm, 132.0°/100mm, 149.7°/200mm, 168.1°/**

400mm, 188.2°/atm, d_4^{20} 1.040, n_D^{20} 1.433. Dry the diol over Na_2SO_4, decant and distil it under reduced pressure. It is soluble in H_2O, Me_2CO, $CHCl_3$, many oils, is used as an antifreeze in dairies and breweries; and is a substitute for glycerol or ethylene glycol. [*Beilstein* **1** IV 2468.]

***R*-(-)- and *S*-(+)- Propane-1,2-diol (*R*- and *S*- propylene glycol)** *[R(-) 4254-14-2: S(+) 4254-15-3]* **$C_3H_8O_2$, M 76.1, b 78.5°/10mm, 94-96°/14mm, 186-188°/765mm, d_4^{20} 1.036, n_D^{20} 1.432, $[\alpha]_D^{25}$ (-) or (+) 17.5 (neat).** The laevo *R-enantiomer* can be obtained from reduction of hydroxyacetone by yeast [Levene & Walti *Org Synth* Coll Vol **2** 545 *1943*, DOI: 10.15227/orgsyn.010.0084], and the dextro *S-enantiomer* is obtained by reduction of *S*-(+)-lactic acid. Thus (+)-lactic acid (33.4g, 370mmol) in dry THF (200ml) is added dropwise to a suspension of LAH (32.1g, 850mmol) in dry THF (500ml) at 0° during 2 hours, allowed to warm to 25°, refluxed for 2 hours, cooled, then quenched by careful addition of ice-cold H_2O (32ml), followed by 4N NaOH (32ml) and again H_2O (96ml). The white precipitate is coagulated by refluxing the mixture for 0.5 hours, filtered, washed with THF, the white cake is slurred with hot THF (4 x ~100ml), the combined THF layers are evaporated *in vacuo* (~40°), and the residual oil is distilled through a vacuum jacketed Vigreux column under vacuum to give the *S*-diol as a colourless liquid (23,9g, 85%). [Fryzuk & Bosnich *J Am Chem Soc* **100** 5491 *1978*, DOI: 10.1021/ja00485a037; *Beilstein* **1** IV 2468.]

Propane-1,3-diol *[504-63-2]* **$C_3H_8O_2$, M 76.1, m -27°, b 110-122°/12mm, d_4^{20} 1.053, $n^{18.5}$ 1.4398.** Dry this diol with K_2CO_3 and distil it under reduced pressure. More extensive purification involves conversion with benzaldehyde to *2-phenyl-1,3-dioxane* (**m 47-48°**) which is subsequently decomposed by shaking with 0.5M HCl (3ml/g) for 15 minutes and standing overnight at room temperature. After neutralisation with K_2CO_3, the benzaldehyde is removed by steam distillation and the diol is recovered from the remaining aqueous solution by continuous extraction with $CHCl_3$ for 1 day. The extract is dried with K_2CO_3, the $CHCl_3$ is evaporated and the diol is distilled. [Foster et al. *Tetrahedron* **16** 177 *1961*, DOI: 10.1016/0040-4020(61)80068-9; *Beilstein* **1** IV 2493.] The **bis-p-tosylate** *[5469-66-9]* **$C_{12}H_{20}O_6S_2$, M 384.5**, prepared in the usual way (see below), has **m 90-92°** [*Beilstein* **11** II 49].

***S*-(-)-Propane-1,2-diol bis(*p*-toluenesulfonate)** *[60434-71-1]* **$C_{12}H_{20}O_6S_2$, M 384.5, m 68-70° (62°), $[\alpha]_D^{25}$ -20° (c 1, $CHCl_3$)**, is prepared in much the same way as for *S,S*-butane-2,3-diol bis-tosylate (see above) from *S*-(+)-propane-1,2-diol (310mmol) in dry pyridine (30ml) and toluene-*p*-sulfonyl chloride (700mmol, recrystallised from hexane) in dry pyridine (135ml) at 0° during 0.5 hours, then at 25° for 17 hours. The crude ester is purified by dissolving in CH_2Cl_2 and cyclohexane is added to cloud point at 40°, then allowed to crystallise at 25° when more cyclohexane is added and set aside (5°/12 hours) to give the *bis-tosylate* as white feathery crystals which are dried over $CaCl_2$ *in vacuo* (114g, 95%). [Fryzuk & Bosnich *J Am Chem Soc* **100** 5491 *1978*, DOI: 10.1021/ja00485a037.] This *S*-(-)-2,3-ditosylate provides the chiral ligand *R*-(+)- [cf. 15629-92-2], which involves inversion of configuration at the chiral centre.

Propane-1-thiol *[107-03-9]* **C_3H_8S, M 76.1, m -113°, b 65.3°/702mm, d_4^{25} 0.83598, n_D^{25} 1.43511, pK^{20} 10.82.** Purify the thiol by dissolving it in aqueous 20% NaOH, extracting with a small amount of *benzene and steam distilling until clear. After cooling, the solution is acidified slightly with 15% H_2SO_4, and the thiol is distilled out, dried with anhydrous $CaSO_4$ or $CaCl_2$, and fractionally distilled under nitrogen. [Mathias & Filho *J Phys Chem* **62** 1427 *1958*, DOI: 10.1021/j150569a018.] Also purify it by liberating the mercaptan by adding dilute HCl to the residue remaining after steam distilling. After direct distillation from the flask, and separation of the water, the mercaptan is dried (Na_2SO_4) and distilled under nitrogen. [*Beilstein* **1** IV 1449.]

Propane-2-thiol (Isopropyl mercaptan) *[75-33-2]* **C_3H_8S, M 76.1, m -131°, b 49.8°/696mm, d_4^{25} 0.80895, n_D^{25} 1.42154, pK^{25} 10.86.** Purify it as for propane-1-thiol above. [*Beilstein* **1** IV 1498.]

Propargyl alcohol (2-propyn-1-ol) *[107-19-7]* **C_3H_4O, M 56.1, m -53°, b 54°/57mm, 113.6°/760mm, d_4^{20} 0.947, n_D^{20} 1.432.** The commercial material contains a stabiliser. An aqueous solution of propargyl alcohol can be concentrated by azeotropic distillation with butanol or butyl acetate. Dry it with K_2CO_3 and distil it under reduced pressure, in the presence of about 1% succinic acid, through a glass helices-packed column. [*Beilstein* **1** IV 2214.]

Propargyl chloride (3-chloropropyne) *[624-65-7]* **C_3H_5Cl, M 74.5, b 58°/760mm, 65°/760mm, d_4^{20} 1.03, n_D^{20} 1.435.** Purify the chloride by fractional distillation at atmospheric pressure. Note that a possible impurity is **propargyl alcohol** which has **b 114-115°/~760mm** (see above). [Henry *Chem Ber* **8** 398 *1875*, DOI: 10.1002/cber.187500801129.] **HIGHLY TOXIC** and **FLAMMABLE**. [*Beilstein* **1** IV 963.]

Propene (propylene) *[115-07-1]* **C_3H_6, M 42.1, m -185.2°, b -47.8°/750mm, d_4^{20} 0.519, n^{-71} 1.357.** Purify it by freeze-pump-thaw cycles and trap-to-trap distillation. [*Beilstein* **1** IV 725.]

β-Propiolactone see oxetan-2-one in 'Heterocyclic Compounds', in this Chapter.

Propionaldehyde (propanal) *[123-38-6]* **C_3H_6O, M 58.1, m -81°, b 48.5-48.7°/atm, d_4^{20} 0.804, n_D^{20} 1.3733, n_D^{25} 1.37115.** Dry the aldehyde with $CaSO_4$ or $CaCl_2$, and fractionally distil it under nitrogen or in the presence of a trace of hydroquinone (to retard oxidation). Blacet and Pitts [*J Am Chem Soc* **74** 3382 *1952*, DOI: 10.1021/ja01133a049] repeatedly distilled the middle fraction in a vacuum until it no longer gave a solid polymer when cooled to -80°. It is stored with $CaSO_4$. **IRRITANT.** The ***oxime*** [627-39-4] **C_3H_7NO, M 73.0**, distils at **77°/100mm, 130-131°/atm**, the distillate solidifies and the solid crystallises from EtOH with **m 40°**. It is a colorimetric reagent for Pd(II). [*Beilstein* **1** H 629, **1** I 333, **1** II 687, **1** III 1682, **1** IV 3165.] The ***2,4-dinitrophenylhydrazone*** [725-00-8] has **m 142-148°**. [Hurd & Meinert *Org Synth* Coll Vol 2 541 *1943*, DOI: 15227/orgsyn.012.0064.] The **cyanohydrin (3-hydroxybutyronitrile)** *[4476-02-2]* **C_4H_7NO, M 85.1** has **b 62-64°/2mm, 96-98°/15mm, 105°/20mm, d_4^{20} 0.962, n_D^{20} 1.414,** and is purified by fractional distillation, taking precautions as some HCN (**POISONOUS**) may be liberated (work in an efficient fume cupboard). The *cyanohydrin* forms a ***2,4-dinitrobenzoate*** with **m 83-84°**. [Stevens et al. *J Am Chem Soc* **76** 2695 *1954*, DOI: 10.1021/ja01639a029; *Beilstein* **3** H 305, **3** II 217, **3** III 564, **3** IV 757.]

Propionamide *[79-05-0]* **C_3H_7NO, M 73.1, m 79.8-80.8°, pK^{24} -0.9 (H_o scale, aqueous H_2SO_4).** Crystallise it from acetone, *benzene, $CHCl_3$, water or acetone/water, then dry it in a vacuum desiccator over P_2O_5 or concentrated H_2SO_4. [*Beilstein* **2** H 243, **2** I 108, **2** II 223, **2** III 542, **2** IV 725.]

Propionic acid *[79-09-4]* **$C_3H_6O_2$, M 74.1, m -24° to -23°, b 141°/atm, d_4^{20} 0.992, n_D^{20} 1.3865, n_D^{25} 1.3843, pK_1^{25} -6.8 (H_o scale, aqueous H_2SO_4), pK_2^{25} 4.88.** Dry the acid with Na_2SO_4 or by fractional distillation, then redistil after refluxing with a few crystals of $KMnO_4$. An alternative purification uses conversion to the ethyl ester, fractional distillation and hydrolysis. [Bradbury *J Am Chem Soc* **74** 2709 *1952*, DOI: 10.1021/ja01131a005]. Propionic acid can also be heated for 0.5 hour with an amount of benzoic anhydride equivalent to the amount of water present (in the presence of CrO_3 as catalyst), followed by fractional distillation. [Chan & Israel *J Chem Soc* 196 *1960*, DOI: 10.1039/JR9600000196; *Beilstein* **2** IV 695.]

Propionic anhydride *[123-62-6]* **$C_6H_{10}O_3$, M 130.2, m -43°, b 67°/18mm, 168°/780mm, d_4^{20} 1.407, n_D^{20} 1.012.** Shake the anhydride with P_2O_5 for several minutes, then distil. [*Beilstein* **2** IV 722.]

Propionitrile (ethyl cyanide) *[107-12-0]* **C_3H_5N, M 55.1, m -93°, b 97.2°/atm, d_4^{20} 1.407, n^{15} 1.36812, n^{30} 1.36132.** Shake the nitrile with dilute HCl (20%), or with concentrated HCl until the odour of isonitrile has gone, then wash with water, and aqueous K_2CO_3. After a preliminary drying with silica gel or Linde type 4A molecular sieves, it is stirred with CaH_2 until hydrogen evolution ceases, then decant and distil from P_2O_5 (not more than 5g/L, to minimise gel formation). Finally, it is refluxed with, and slowly distilled from CaH_2 (5g/L), taking precautions to exclude moisture. [*Beilstein* **2** IV 728.]

***n*-Propyl acetate** *[109-60-4]* **$C_5H_{10}O_2$, M 102.1, m -95°, b 101.5°/atm, d_4^{20} 0.887, n_D^{20} 1.38442, pK^{25} -7.18 (H_o scale, aqueous H_2SO_4).** Wash the ester with saturated aqueous $NaHCO_3$ until neutral, then with saturated aqueous NaCl. Dry it with $MgSO_4$ and fractionally distil it. [*Beilstein* **2** IV 138.]

***n*-Propyl alcohol (1-propanol)** *[71-23-8]* **C_3H_8O, M 60.1, m -127°, b 97.2°/atm, d_4^{25} 0.79995, n_D^{20} 1.385, pK^{25} 16.1.** The main impurities in *n*-propyl alcohol are usually water and 2-propen-1-ol, reflecting the commercial production by hydration of propene. Water can be removed by azeotropic distillation either directly (azeotrope contains 28% water) or by using a ternary system, e.g. by also adding *benzene. *Alternatively*, for

removal of gross amounts of water, reflux over CaO for several hours is desirable, followed by distillation and a further drying. To obtain more nearly anhydrous alcohol, suitable drying agents are firstly NaOH, $CaSO_4$ or K_2CO_3, then CaH_2, aluminium amalgam, magnesium activated with iodine, or a small amount of sodium. *Alternatively*, the alcohol can be refluxed with *n*-propylsuccinate or phthalate in a method similar to the one described under EtOH. Allyl alcohol is removed by adding bromine (15ml/L), and then fractionally distilling from a small amount of K_2CO_3. Propionaldehyde, also formed in the bromination, is removed as the 2,4-dinitrophenylhydrazone. *n*-Propyl alcohol can be dried down to 20 ppm of water by passage through a column of pre-dried molecular sieves (type 3 or 4A, heated for 3 hours at 300°) in a current of nitrogen. Distillation from sulfanilic or tartaric acids removes impurities.
Albrecht [*J Am Chem Soc* **82** 3813 *1960*, DOI: 10.1021/ja01500a004] obtained spectroscopically pure material by heating with charcoal to 50-60°, filtering and adding 2,4-dinitrophenylhydrazine and a few drops of concentrated H_2SO_4. After standing for several hours, the mixture is cooled to 0°, filtered and distilled in a vacuum. Gold and Satchell [*J Chem Soc* 1938 *1963*, DOI: 10.1039/JR9630001938] heated *n*-propyl alcohol with 3-nitrophthalic anhydride at 76-110° for 15 hours, then recrystallised the resulting ester from H_2O, *benzene/petroleum ether (b 100-120°)(3:1), and *benzene. The ester was hydrolysed under reflux with aqueous 7.5M NaOH for 45 minutes under nitrogen, followed by distillation (also under nitrogen). The fraction with **b** 87-92° is dried with K_2CO_3 and stirred under reduced pressure in the dark over 2,4-dinitrophenylhydrazine, then freshly distilled. Also purify it by adding 2g $NaBH_4$ to 1.5L of alcohol, gently flushing with argon and refluxing for 1 day at 50°. Then 2g of freshly cut sodium (washed with propanol) is added and refluxed for one day, and finally distilled, taking the middle fraction [Jou & Freeman *J Phys Chem* **81** 909 *1977*, DOI: 10.1021/j100524a021]. [*Beilstein* **1** IV 1413.]

***n*-Propylamine** *[107-10-8]* **C_3H_9N, M 59.1, m -83°, b 48.5°/atm, d_4^{20} 0.716, n_D^{20} 1.38815, pK^{25} 10.69.** Distil the amine from zinc dust, under reduced pressure, in an atmosphere of nitrogen. [*Beilstein* **4** IV 464.]

***n*-Propyl bromide** *[106-94-5]* **C_3H_7Br, M 123.0, m -110°, b 71.0°/atm, d_4^{20} 1.354, n^{15} 1.43695, n_D^{25} 1.43123.** Likely contaminants include *n*-propyl alcohol and isopropyl bromide. The simplest purification procedure uses drying with $MgSO_4$ or $CaCl_2$ (with or without a preliminary wash of the bromide with aqueous $NaHCO_3$, then water), followed by fractional distillation away from bright light. Chien and Willard [*J Am Chem Soc* **79** 4872 *1957*, DOI: 10.1021/ja01575a013] bubbled a stream of oxygen containing 5% ozone through *n*-propyl bromide for 1 hour, then stirred it with 3% hydrogen peroxide solution, neutralised it with aqueous Na_2CO_3, washed it with distilled water and dried it. This was followed by vigorous stirring with 95% H_2SO_4 until fresh acid did not discolour within 12 hours. The propyl bromide was separated, neutralised, washed, dried with $MgSO_4$ and fractionally distilled. The centre cut was stored in the dark. Instead of ozone, Schuler and McCauley [*J Am Chem Soc* **79** 821 *1957*, DOI: 10.1021/ja01561a010] added bromine and stored it for 4 weeks, the bromine then being extracted with aqueous $NaHSO_3$ before the sulfuric acid treatment was applied and finally distilled. Further purification is by preparative gas chromatography on a column packed with 30% SE-30 (General Electric ethylsilicone rubber) on 42/60 Chromosorb P at 150° and 40psi, using helium as carrier gas. [Chu *J Chem Phys* **41** 226 *1964*, DOI: 10.1063/1.1725626; *Beilstein* **1** IV 205.]

***n*-Propyl chloride** *[540-54-5]* **C_3H_7Cl, M 78.5, m -123°, b 46.6°/atm, d_4^{20} 0.890, n_D^{20} 1.3880.** Dry the chloride with $MgSO_4$ and fractionally distil. It can be more extensively purified using extraction with H_2SO_4 as for *n*-propyl bromide. *Alternatively*, Chien and Willard [*J Am Chem Soc* **75** 6160 *1953*, DOI: 10.1021/ja01120a016] passed a stream of oxygen containing about 5% ozone through the *n*-propyl chloride for three times as long as was needed to cause the first coloration of starch iodide paper by the exit gas. After washing with aqueous $NaHCO_3$ to hydrolyse ozonides and remove organic acids, the chloride was dried with $MgSO_4$ and fractionally distilled. [*Beilstein* **1** IV 189.]

Propylene glycol diacetate (1,2-diacetoxypropane, propylene diacetate) *[623-84-7]* **$C_7H_{12}O_4$, M 160.2, b 84-85°/12mm, 191°/760mm, d_4^{25} 1.050, n_D^{20} 1.414.** Wash the ester with aqueous $NaHCO_3$ in the presence of solid NaCl, dry it with $MgSO_4$ and fractionally distil it. [*Beilstein* **2** H 142, **2** II 156, **2** III 312, **2** IV 220.]

Propylene glycol 1-methylether (1-methoxy-2-propanol) *[RS(±) 107-98-2, R(-) 4984-22-9, S(+) 26550-55-0]* **$C_4H_{10}O_2$, M 90.1, b 118.5°/740mm, 119-120°/atm for *RS*, 131-132°/atm for *R* or *S*, d_4^{25} 0.922, n_D^{20} 1.403.**

Wash the ethers with aqueous $NaHCO_3$ in the presence of solid NaCl, dry them with $MgSO_4$ and fractionally distil them. The ***RS-acetate*** [108-65-6] **M** 132.2 has **b 145-146°/atm**, and the ***3,5-dinitrobenzoate*** has **m 95°** (from ligroin). The *RS*-alcohol was converted into the *o-carboxyphenylbenzoate* (oil) and the optical resolution of its brucine salt in Me_2CO was achieved. The free acid phthalates were released (as oils), then hydrolysed with aqueous NaOH (2 equivalents) and the alcohols distilled off as azeotropes. Pure alcohols were obtained by saturating the azeotropes with K_2CO_3, drying the alcohol layer from CaO and distilling.
The ***R(-) and S(+) enantiomers*** have **b 119-120°/atm, $[\alpha]_D^{20}$ - and + 3.3 or 3.8 (neat), 20.5 (c 10, H_2O), 20.1 (c 10, $CHCl_3$), 21.1 (c 10, *C_6H_6),** and **4.1 (c 10, EtOH).** [Inoue et al. *Macromol Khem* **90** 131 *1966*, DOI: 10.1002/ macp.1966.020900112; Butcher & Westheimer *J Am Chem Soc* **77** 2420 *1955*, DOI: 10.1021/ja01614a018.] [*Beilstein* **1** II 536, **1** III 2146, **1** IV 2471.]

***n*-Propyl ether (dipropyl ether)** *[111-43-3]* **$C_6H_{14}O$, M 102.2, m -123°, b 90.1°/atm, d_4^{20} 0.740, n^{15} 1.38296, n_D^{20} 1.3803, pK^{25} -4.40 (aqueous H_2SO_4).** Purify the ether by drying with $CaSO_4$, by passage through an alumina column (to remove peroxides), and by fractional distillation. [*Beilstein* **1** III 2146, **1** IV 1422.]

Propyl formate *[110-74-7]* **M 88.1, m -93°, b 81.3°/atm, d_4^{20} 0.9058, n_D^{20} 1.3779.** Distil the formate, then wash it with saturated aqueous NaCl, and with saturated aqueous $NaHCO_3$ in the presence of solid NaCl, dry it with $MgSO_4$ and fractionally distil it. [*Beilstein* **2** IV 26.]

***n*-Propyl iodide (1-iodopropane)** *[107-08-4]* **C_3H_7I, M 170.0, m -101°, b 38°/80mm, 102.5°/atm, d_4^{20} 1.745, n_D^{20} 1.5041.** It should be distilled first under reduced pressure to avoid decomposition. Dry the iodide with $MgSO_4$ or silica gel and fractionally distil it. Store it under nitrogen with mercury in a brown bottle. Prior to distillation, free iodine can be removed by shaking with copper powder or by washing with aqueous $Na_2S_2O_3$ and drying. *Alternatively*, the *n*-propyl iodide can be treated with bromine, then washed with aqueous $Na_2S_2O_3$, dried and distilled. See also *n-butyl iodide*. [*Beilstein* **1** IV 222.]

2-Propylpentanoic acid (Valproic acid, VPA, di-*n*-propylacetic acid) *[99-66-1]* **$C_8H_{16}O_2$, M 144.2, b 120-121°/14mm, 219.5°/760mm, 220°/atm, d_4^{20} 0.91, n_D^{20} 1.425, pK^{25} 4.61.** Purify VPA in the same way as for propionic acid using $KMnO_4$ (see [79-09-4]). It distils as a colourless oil with a characteristic smell and is soluble in most organic solvents. Its solubility in H_2O is 1.3mg/ml at room temperature. Its FT-IR (film) has ν_{max} at 3572.9, 2969.9, 2885.0, 1771.8, 1465.6, 1388.2, 1102.6, 738.5, 586.5 cm^{-1}; its ^1H NMR (300MHz, $CDCl_3$, TMS) has δ at 0.92 (t, *J* = 7Hz, 2 CH_3), 1.40 (m, 6H), 1.60 (m, 2H), 2.29 (m, 1H), 12.2 (brs, OH); and the ^{13}C NMR (75MHz, $CDCl_3$, $CHCl_3$ standard) has δ at 183.41, 45.20, 34.37, 20.59, 13.99.
The ***ethyl ester*** [17022-31-0] M 172.2 has **b 183°/760mm**. It forms a ***1:1 Na salt (sodium valproate, Depakin among other trade names)*** [1069-66-5] M 166.2 as a white, crystalline, odourless, hygroscopic solid with the following solubilities in g/ml: 2.5 in H_2O, 0.66 in EtOH, 0.2 in MeOH, and is insoluble in organic solvents. It also forms a ***2:1 Na salt* [*sodium hydrogen bis(2-propylpentanoate), valproate semisodium*]** [76584-70-8] M 310.4, a ***Magnesium salt (Depamag)***, and the pro-drug amide, ***Valpromide (Depramide)*** [2430-27-5] M 143.2, **m 123°, 122-124°, 125-126°**, obtained as needles by heating the acid with NH_3 at 180°, is a bitter, crystalline white powder [*Beilstein* **2** IV 695]. These are all commercially available drugs for the treatment of epilepsy, dipolar disorders and migraine. They are **toxic** at high concentrations. [Wiemann et al. *Bull Soc Chim Fr* 189 *1958*, Nau et al. *Pharmacol Toxicol* **69** 310 *1991*, DOI: 10.1111/j.1600-0773.1991.tb01303.x; Löscher **58** 31 *1999*, DOI: 10.1016/S0301-0082(98)00075-6; *Beilstein* **2** H 350.]

***n*-Propyl propionate** *[106-36-5]* **$C_6H_{12}O_2$, M 116.2, m -76°, b 122°/atm, d_4^{20} 0.881, n 1.393.** Treat the ester with anhydrous $CuSO_4$, then distil it under nitrogen. [*Beilstein* **2** IV 707.]

Propyne *[74-99-7]* **C_3H_4, M 40.1, m -101.5°, b -23.2°/760mm, d^{-50} 0.7062, n^{-40} 1.3863.** Purify it by preparative gas chromatography. [*Beilstein* **1** 246.]

Pyruvic acid (2-oxopropionic acid) *[127-17-3]* **$C_3H_4O_3$, M 88.1, m 13°, b 21°/0.1mm, 57.8°/10mm, 85°/40mm, 165°(dec)/atm, pK^{25} 2.39 (2.60).** Distil it twice under high vacuum, then fractionally crystallise it by partial freezing. It polymerises with decomposition on standing unless pure and in a sealed container. [Howard & Frazer *Org Synth* Coll Vol 1 475 *1941*, DOI: 10.15227/orgsyn.004.0063; *Beilstein* **3** IV 1505.]

Ricinoleic acid (***R* 12-hydroxy-*cis*-9-octadecenoic acid, 12-hydroxyoleic acid**) *[141-22-0]* **$C_{18}H_{34}O_3$, M 298.5, m 7-8° (α-form), 5.0° (γ-form), n_D^{20} 1.4717, pK_{Est} ~4.5.** Purify it as the ***methyl acetylricinoleate*** [Rider *J Am Chem Soc* **53** 4130 *1931,* DOI: 10.1021/ja01362a031], fractionally distilling it at **180-185°/0.3mm**, then 87g of this ester is hydrolysed by refluxing with KOH (56g), water (25ml), and MeOH (250ml) for 10 minutes. The free acid is separated on acidification and extraction into Et_2O, dried (Na_2SO_4), filtered, evaporated and the residue is crystallised from acetone at -50°, and distilled in small batches, **b 180°/0.005mm**. The ***R-enantiomer*** has **m 5.5°**, **b 245°/10mm** and **$[\alpha]_D^{26}$ +7.2 (c 5, Me_2CO).** [Bailey et al. *J Chem Soc* 3027 *1957*, DOI: 10.1039/JR9570003027; *Beilstein* **3** IV 1026, 1207.]

Sebacic acid (**1,10-decanedioic acid**) *[111-20-6]* **$C_{10}H_{18}O_4$, M 202.3, m 134.5°, b 232°/10mm, 234°/15mm, 273°/50mm, 294.5°/100mm, pK_1^{25} 4.58, pK_2^{25} 5.54.** Purify sebacic acid *via* the disodium salt which, after crystallisation from boiling water (charcoal), is then converted to the free acid. The free acid is crystallised repeatedly from hot distilled water or from Me_2CO/petroleum ether (in plates), and is dried under vacuum. It sublimes slowly at its melting point. It is slightly soluble in hydrocarbon and chlorinated solvents; its solubility in Et_2O is ~0.1% (20°), and in H_2O in%w/v it is 0.004% (0°), 0.10% (20°), 0.42% (65°) and 2.0% (100°). When castor oil is heated at 40° with 40% aqueous NaOH or KOH for 1hr, cooled, the upper layer is separated, mixed with solid NaOH or KOH and heated in a Cu or Fe basin until the odour of octanol vanishes (3hrs), poured into cold H_2O, acidified with HCl and collected to give sebacic acid (20-40% yield) [Dominques et al. *J Chem Ed* **29** 446 *1952*, DOI: 10.1021/ed029p446]. [*Beilstein* **2** IV 2078.]

Sebacic acid monomethyl ester *[818-88-2]* **$C_{11}H_{20}O_4$, M 216.1, m 40-41°, 42-43°, b 148°/0.025mm, 157°/1mm, 169-171°/4mm, 208°/20mm.** Obtained by partial hydrolysis of dimethyl sebacate (17.22 moles, m 26.5-27.5°) with KOH (13.1 moles) in MeOH and isolation of the mono-ester. The crude mono-ester was fractionated in several batches at very low pressure through a 120 cm perforated-disk column (5 theoretical plates) specially designed to permit a minimum pressure gradient (i.e. minimise the unavoidable formation of the diester which is the most volatile component — keep reflux ratio low). Recrystallise the ester from Me_2CO/petroleum ether or petroleum ether at low temperature and distil it in a vacuum. The viscous liquid ester distillate solidifies. ***9-Methoxycarbonylnonanoyl chloride*** obtained by usual treatment with $SOCl_2$ distils as a water white oil at **143°/3.5mm** (96% yield) which solidified on cooling, **m 16.5-17°**. When dissolved in petroleum ether (b 35-60°) and saturated with dry NH_3, the ***ester-amide*****, m 74.5-76°** (also **77.4°**) is obtained in 83% yield after recrystallisation from MeOH-Me_2O (4:1). The amide provided ***9-methoxycarbonyl-nonanonitrile*** (95% yield) after further treatment with $SOCl_2$ (45°, 6 hrs) as a water-white oil which distils at **131-132°/1.6 mm** (also **b 178°/14mm**) and solidifies readily, **m 3-4°**. [Soffer et al. *J Am Chem Soc* **69** 1684 *1947*, DOI: 10.1021/ja01199a035.] [*Beilstein* **2** IV 608.]

Sebaco-1,10-diamidine dihydrochloride (decane-1,10-diamidine dihydrochloride) *[5578-81-4 free base]* **$C_{10}H_{22}N_4$. 2HCl, M 271.2, m 175-175.5°.** The solubility of the salt in H_2O is ~60%. Recrystallise it from a small volume of H_2O, or dissolve in EtOH and add Et_2O. It has antimicrobial activity [Fuller *Biochem J* **36** 548 *1942*, DOI: 10.1042/bj0360548] and is a rabbit liver amine oxidase inhibitor [Blaschko & Duthie *Biochem J* **39** 347 *1945*, DOI: 10.1042/bj0390347]. The ***picrate*** crystallises from Et_2O/pyridine with **m 175-175.5°.** [Broom *J Pharmacol Exp Therap* **57** 81 *1936*, Lee et al. *J Med Chem* **38** 3053 *1995*, DOI: 10.1021/jm00016a008; *Beilstein* **2** III 1817.]

Sebaconitrile (decanedinitrile) *[1871-96-1]* **$C_{10}H_{16}N_2$, M 164.3, m 8°, b 127°/0.2mm, n_D^{20} 1.4479.** Mix the nitrile with P_2O_5 (10% by wt), distil the dinitrile from it, then redistil it. [Kaufman & Whittaker *J Chem Phys* **24** 1104 *1956*, DOI: 10.1063/1.1742690; *Beilstein* **2** H 720, **2** II 610, **2** III 1817, **2** IV 2089.]

Sebacoyl chloride (sebacyl chloride, 1,10-decanedioyl dichloride) *[111-19-3]* **$C_{10}H_{16}Cl_2O_2$, M239.1, -5 to -3°, b 168°/12mm, d_4^{25} 1.121, n_D^{20} 1.468.** Check for OH bands in the IR spectrum. If absent the distil carefully under a vacuum; but if present then some hydrolysis must have occurred. In this case add excess of $SOCl_2$ and boil gently until liberation of HCl and SO_2 stops. Evaporate and distil. Note that it is an acid chloride and is reactive towards H_2O and protic solvents. Store in tight containers, or better in sealed tubes. **Eye and skin irritant.** [*Beilstein* **2** IV 2088.] It readily forms the ***diamide*** [1740-54-1] **$C_{10}H_{20}N_2O_2$, M 200.2,** with ammonia

and has **m 210°.**

Semicarbazide hydrochloride (hydrazine carboxamide hydrochloride) *[563-41-7]* **$C_{10}H_{16}N_2O$. HCl, M 111.5, m 173°(dec), 175°(dec), pK^{24} 3.66.** Crystallise the salt from aqueous 75% EtOH and dry it under vacuum over $CaSO_4$. *Alternatively*, crystallise it from a mixture of 3.6 mole % MeOH and 6.4 mole % of water. [Kovach et al. *J Am Chem Soc* **107** 7360 *1985*, DOI: 10.1021/ja00311a024.] It IR has ν_{max} at 700, 3500 cm^{-1} [Ingersoll et al. *Org Synth* Coll Vol **I** 485 *1941*, DOI: 10.15227/orgsyn.005.0093; Davison & Christie *J Chem Soc* 3389 *1955*, DOI: 10.1039/JR9550003389; Thiele & Stange *Chem Ber* **27** 31 *1894*, DOI: 10.1002/cber.18940270109; pK: Bartlett *J Am Chem Soc* **54** 2853 *1923*, DOI: 10.1021/ja01346a027]. The ***free base*** crystallises as prisms from absolute EtOH, **m** 96°. [Curtius & Heidenreich *Chem Ber* **27** 55 1894, DOI: 10.1002/cber.18940270114; *Beilstein* **3** IV 177.] **TOXIC ORALLY**, possible **CARCINOGEN** and **TERATOGEN**.

Senecialdehyde (3,3-dimethylacraldehyde, 3-methyl-2-butenal) *[107-86-8]* **C_5H_8O, M 84.1, b 78-80°/70mm, 133-135°/atm, d_4^{20} 0.911, n_D^{20} 1.428.** This flammable oil oxidises readily and should be fractionated under N_2. It should be stored under N_2 and/or vacuum. The UV has λ_{max} at 235.5nm. The ***semicarbazone*** has **m** 221-222° (from MeOH) and the ***2,4-dinitrophenylhydrazone*** has **m 184-185°** (from MeOH). [Forbes & Shilton *J Org Chem* **24** 436 *1959*, DOI: 10.1021/jo01085a617; *Beilstein* **1** III 2990, **1** IV 3464.]

Skellysolve A is essentially *n*-pentane, **b** 28-30°/atm,
Skellysolve B is essentially *n*-hexane, **b** 60-68°/atm,
Skellysolve C is essentially *n*-heptane, **b** 90-100°/atm,
Skellysolve D is mixed heptanes, **b** 75-115°/atm,
Skellysolve E is mixed octanes, **b** 100-140°/atm,
Skellysolve F is petroleum ether, **b** 30-60°/atm,
Skellysolve G is petroleum ether, **b** 40-75°/atm,
Skellysolve H is hexanes and heptanes, **b** 69-96°/atm,
Skellysolve L is essentially octanes, **b** 95-127°/atm. For methods of purification, see **petroleum ether**.

Solanone [*S*(+)-*trans*-2-methyl-5-isopropyl-1,3-nonan-8-one] *[1937-54-8]* **$C_{13}H_{22}O$, M 194.3, b 60°/1mm, n_D^{20} 1.4755, $[\alpha]_D^{20}$ +14° (neat).** Purify solanone by high vacuum distillation and store it in sealed ampules [Kohda & Sato *JCS Chem Commun* 951 *1981*, DOI: 10.1039/C39810000951]. It has UV (hexane) at λ_{max} 230nm (ε 11,800). The ***semicarbazone*** crystallises from aqueous EtOH or toluene with **m** 160.5-161.5°. [Johnson et al. *J Org Chem* **30** 2918 *1965*, DOI: 10.1021/jo01020a009.]

Sorbic acid (2,4-hexadienoic acid) *[110-44-1]* **$C_6H_8O_2$, M 112.1, m 134°, pK^{25} 4.76.** Crystallise the acid from water. Dry it in air or in a desiccator over P_2O_5. [*Beilstein* **2** IV 1701.]

Stearic acid (octadecanoic acid) *[57-11-4]* **$C_{18}H_{36}O_2$, M 284.5, m 71.4°, 72°, b 144-145°/27mm, 383°/760mm, d_4^{20} 0.911, n_D^{20} 1.428, pK^{25} 4.78.** Crystallise stearic acid from acetone, acetonitrile, EtOH (5 times), aqueous MeOH, ethyl methyl ketone or petroleum ether (b 60-90°), or by fractional precipitation by dissolving in hot 95% EtOH and pouring into distilled water, with stirring. The precipitate, after washing with distilled water, is dried under vacuum over P_2O_5. It has also been purified by zone melting and partial freezing. [Tamai et al. *J Phys Chem* **91** 841 *1987*, DOI: 10.1021/j100288a017; *Beilstein* **2** IV 1206.]

Suberic acid (hexane-1,6-dicarboxylic acid) *[505-48-6]* **$C_8H_{14}O_4$, M 174.2, m 141-142°, b 230°/15mm, pK_1^{25} 4.12, pK_2^{25} 5.40.** Crystallise it from acetone. It sublimes at 300° without decomposition. [*Beilstein* **2** IV 2028.]

Succinamic acid (succinic acid amide) *[638-32-4]* **$C_6H_7NO_3$, M 117.1, m 155°, 156-157°, pK^{25} 4.54.** Crystallise the amide from Me_2CO or H_2O and dry it in a vacuum. It is not very soluble in MeOH. It is converted into succinimide above 200°. [*Beilstein* **2** H 614.]

Succinamide *[110-14-5]* **$C_4H_8N_2O_2$, M 116.1, m 262-265°(dec).** Crystallise it from water. [*Beilstein* **2** IV 1922.]

Succinic acid *[110-15-6]* **$C_4H_6O_4$, M 118.1, m 185-185.5°, pK_1^{25} 4.21, pK_2^{25} 5.72.** Wash it with diethyl ether. Crystallise it from acetone, distilled water, or *tert*-butanol. Dry it under vacuum over P_2O_5 or concentrated H_2SO_4. Also purify it by conversion to the disodium salt which, after crystallisation from boiling water (charcoal), is treated with mineral acid to regenerate the succinic acid. The acid is then recrystallised and dried in a vacuum. [*Beilstein* **2** H 606, **2** IV 1908.]

Succinic anhydride (dihydro-2,5-furandione) *[108-30-5]* **$C_4H_4O_3$, M 100.1, m 119-120°, b 261°/atm.** Crystallise the anhydride from redistilled acetic anhydride or $CHCl_3$, then filter, wash with diethyl ether and dry it in a vacuum. [*Beilstein* **17** H 606, **17** V 6.]

Succinimide (2,5-pyrrolidindione) *[123-56-8]* **M 99.1, m 124-125°, b 285-290°/atm, pK^{25} 9.62.** Crystallise the imide from EtOH (1ml/g) or water. [*Beilstein* **21** H 369, **21/9** V 438.]

Succinonitrile (1,2-dicyanoethane) *[110-61-2]* **$C_4H_4N_2$, M 80.1, m 57.9°, b 108°/1mm, 267°/760mm.** Purify the nitrile by vacuum sublimation, and/or crystallisation from acetone. [*Beilstein* **2** H 615, **2** IV 1923.]

D*(-)-Tartaric acid** (*2S,3S*-threaric acid *[147-71-7]* **$C_4H_6O_6$,M 150.1, m 169.5-170°, 170-171°** (**2*S*,3*S*-form, natural) $[\alpha]_{546}^{20}$ -15 (c 10, H_2O), $[\alpha]_{546}^{20}$ -12 (c 20, H_2O); m 208°, 210-212°, (2*RS*,3*RS*-form, DL** ***[133-37-9]**), pK_1^{25} 3.03, pK_2^{25} 4.46, pK_3^{25} 14.4.** Crystallise the acid from distilled H_2O or *benzene/diethyl ether containing 5% of petroleum ether (b 60-80°) (1:1). Soxhlet extraction with diethyl ether has been used to remove an impurity absorbing at 265nm. It has also been crystallised from absolute EtOH/hexane and dried in a vacuum for 18 hours [Kornblum & Wade *J Org Chem* **52** 5301 *1987*, DOI: 10.1021/jo00233a001]. The ***non-natural 2*R,3*S*(+) tartaric acid** ***[87-69-4]*** has **m 171-172°, $[\alpha]_{546}^{20}$ +12 (c 20, H_2O).** [*Beilstein* **3** IV 1229.]

***meso*-Tartaric acid [*2RS,3SR*(±)-tartaric acid)]** *[147-73-9]* **$C_4H_6O_6$, M 150.1, m 165-166°; monohydrate** *[5990-63-6]* **$C_4H_6O_6$. H_2O, M 168.1, m 139-141°; pK_1^{25} 3.17, pK_2^{25} 4.91.** Crystallise it from water (solubility in H_2O at 20° is 125%w/v), wash it with cold MeOH and dry it at 60° under vacuum. This form is optically inactive and was prepared by racemising (isomerising) L-tartaric acid in boiling alkali [Holleman *Org Synth* Coll Vol **I** 497 *1941,* DOI: 10.15227/orgsyn.006.0082]. [*Beilstein* **3** IV 1218.]

Tetra-*n*-amylammonium bromide (tetra-*n*-pentylammonium bromide) *[866-97-7]* **$C_{20}H_{44}N$. Br, M 378.5, m 100-101°.** Crystallise it from petroleum ether, *benzene or acetone/ether mixtures and dry in vacuum at 40-50° for 2 days. It is used in ion-paired chromatography (Sagara et al. *J Chromatogr* **328** 289 *1985*, DOI:10.1016/S0021-9673(01)87399-4). [*Beilstein* **4** IV 677.]

Tetra-*n*-amylammonium iodide *[2498-20-6]* **$C_{20}H_{44}N$. I, M 425.5, m 135-137°.** Crystallise the iodide from EtOH and dry it at 35° under a vacuum. It has also been purified by dissolving in acetone and precipitating by adding diethyl ether, and drying at 50° for 2 days. [*Beilstein* **4** IV 677.]

1,1,2,2,-Tetrabromoethane *[79-27-6]* **$C_2H_2Br_4$, M 345.7, f 0.0°, b 119°/15mm, 243.5°/atm, d_4^{20} 2.965, n_D^{20} 1.63533.** Wash it successively with conc H_2SO_4 (three times) and H_2O (three times), dry it with K_2CO_3 and $CaSO_4$ and distil it in a vacuum or at ~760mm. [*Beilstein* **1** IV 162.]

Tetra-*n*-butylammonium bromide *[1643-19-2]* **$C_{16}H_{36}N$. Br, M 322.4, m 102-106°, 119.6°.** Recrystallise the salt from *benzene (5ml/g) at 80° by adding hot *n*-hexane (three volumes) and allowing to cool. Dry it over P_2O_5 or $Mg(ClO_4)_2$, under vacuum. The salt is *very hygroscopic*. It can also be crystallised from ethyl acetate or dry acetone by adding diethyl ether and dried *in vacuo* at 60° for 2 days. It has been crystallised from acetone by addition of diethyl ether. It is so *hygroscopic* that all manipulations should be carried out in a dry-box. It has been purified by precipitation from a saturated solution in dry CCl_4 on addition of cyclohexane or by recrystallisation from ethyl acetate, then heating in vacuum to 75° in the presence of P_2O_5. [Symons et al. *JCS*

Faraday Trans 1 **76** 2251 *1980*, DOI: 10.1039/F19807602251.] It also recrystallises from CH_2Cl_2/diethyl ether and is dried in a vacuum desiccator over P_2O_5. [Blau & Espenson *J Am Chem Soc* **108** 1962 *1986*, DOI: 10.1021/ja00268a039; *Beilstein* **4** IV 657.]

Tetra-*n*-butylammonium chloride *[1112-67-0]* **$C_{16}H_{36}N$. Cl, M 277.9, m 15.7°.** Crystallise the chloride from acetone by addition of diethyl ether. It is very **hygroscopic** and forms crystals with $3 4H_2O$ [37451-68-6] and **m 41-44°**. It is used in ion-paired chromatography (Sagara et al. *J Chromatogr* **328** 289 *1985*, DOI:10.1016/S0021-9673(01)87399-4). [*Beilstein* **4** IV 557.]

Tetra-*n*-butylammonium hexafluorophosphate *[3109-63-5]* **$C_{16}H_{36}N$. PF_4, M 387.5, m 239-241°, 244-246°.** Recrystallise it from saturated EtOH/water and dry it for 10 hours in a vacuum at 70°. Also recrystallise it three times from absolute EtOH and dry it for 2 days in a drying pistol under a vacuum at boiling toluene temperature [Bedard & Dahl *J Am Chem Soc* **108** 5933 *1986*, DOI: 10.1021/ja00279a044]. It is a stable supporting electrolyte in organic solvents [Baiser in *Organic Electrochemistry* M. Dekker NY p228 *1973*.]

Tetra-*n*-butylammonium hydrogen sulfate *[32503-27-8]* **$C_{16}H_{36}N$. HSO_4, M 339.5, m 171-172°.** The sulfate crystallises from Me_2CO. It has been used as a phase transfer catalyst (see 'Catalysts, Part 1' in Chapter 5).

Tetra-*n*-butylammonium iodide *[311-28-4]* **$C_{16}H_{36}N$. I, M 369.4, m 141-143°, 146°.** Crystallise the iodide from toluene/petroleum ether (see entry for the corresponding bromide), acetone, ethyl acetate, EtOH/diethyl ether, nitromethane, aqueous EtOH or water. Dry it at room temperature under a vacuum. It has also been dissolved in MeOH/acetone (1:3, 10ml/g), filtered and allowed to stand at room temperature to evaporate to *ca* half its original volume. Distilled water (1ml/g) is then added, and the precipitate is filtered off and dried. It can also be dissolved in acetone, precipitated by adding ether and dried in a vacuum at 90° for 2 days. It has also been recrystallised from CH_2Cl_2/petroleum ether or hexane, or anhydrous methanol and stored in a vacuum desiccator over H_2SO_4. [Blau & Espenson *J Am Chem Soc* **108** 1962 *1986*, DOI: 10.1021/ja00268a039; *Beilstein* **4** IV 558.]

Tetra-*n*-butylammonium nitrate *[1941-27-1]* **$C_{16}H_{36}N$. NO_3, M 304.5, m 116-118°, 119°.** Crystallise it from *benzene (7ml/g), EtOH or EtOAc (**m** 121-122°); dry it in a vacuum over P_2O_5 at 60° for 2 days. [*Beilstein* **4** IV 558.]

Tetra-*n*-butylammonium perchlorate *[1923-70-2]* **$C_{16}H_{36}N$. $NClO_4$, M 341.9°, m 210°(dec).** Crystallise the perchlorate from EtOH, ethyl acetate, *n*-hexane or diethyl ether/acetone mixture, or hot CH_2Cl_2. Dry it in a vacuum at room temperature over P_2O_5 for 24 hours. [Anson et al. *J Am Chem Soc* **106** 4460 *1984*, DOI: 10.1021/ja00328a028; Ohst & Kochi *J Am Chem Soc* **108** 2897 *1986*, DOI: 10.1021/ja00271a019; Collman et al. *J Am Chem Soc* **108** 2916 *1986*, DOI: 10.1021/ja00271a021; Blau & Espenson *J Am Chem Soc* **108** 1962 *1986*, DOI: 10.1021/ja00268a039; Gustowski et al. *J Am Chem Soc* **108** 7553 *1986*, DOI: 10.1021/ja00284a019; Ikezawa & Kutal *J Org Chem* **52** 3299 *1987*, DOI: 10.1021/jo00391a022; *Beilstein* **4** IV 557.]

Tetra-*n*-butylammonium picrate *[914-45-4]* **$C_{16}H_{36}N$. $C_6H_2N_3O_7$, M 490.6, m 106.5-107°.** Crystallise the picrate from EtOH. Dry it in a vacuum desiccator over P_2O_5. [*Beilstein* **6** II 271, **4** III 292.]

Tetra-*n*-butylammonium tetrabutylborate (Bu_4N^+ Bu_4B^-) *[23231-91-6]* **$C_{32}H_{72}BN$, M 481.7, m 106-109°, 155°, 161.8°**. Dissolve it in MeOH or acetone, and crystallise by adding distilled water. It also crystallises from EtOH or EtOAc. Dry it in a vacuum at 70°. It has also been successively recrystallised from isopropyl ether, isopropyl ether/acetone (50:1) and isopropyl ether/EtOH (50:1) for 10 hours, then isopropyl ether/acetone for 1 hour, and dried at 65° under reduced pressure for 1 week. [Kondo et al. *JCS Faraday Trans 1* **76** 812 *1980*, DOI: 10.1039/F19807600812; *Beilstein* **4** III 293, **4** III 558.]

Tetra-*n*-butylammonium tetrafluoroborate *[429-42-5]* **$C_{16}H_{36}N$. BF_4, M 329.3, m 155-161°, 161.8°, 161-163°, pK^{25} -4.9 (for HBF_4)**. Recrystallise it from H_2O, aqueous EtOH or from EtOAc by cooling in Dry-ice. Also recrystallise it from ethyl acetate/pentane or dry acetonitrile. Dry it at 80° under vacuum. [Detty & Jones *J Am Chem Soc* **109** 5666 *1987*, DOI: 10.1021/ja00253a017; Hartley & Faulkner *J Am Chem Soc* **107** 3436

1985, DOI: 10.1021/ja00298a007.] The ***acetate*** has **m 118±2°** (from BuCl), the ***bromide*** has **m 118°** (from EtOAc), and the ***nitrate*** has **m 120°** (from $*C_6H_6$). [Witschonke & Kraus *J Am Chem Soc* **69** 2472 *1947*, DOI: 10.1021/ja01202a067; Wheeler & Sandstedt *J Am Chem Soc* **77** 2024 *1955*, DOI: 10.1021/ja01612a102; *Beilstein* **4** IV 558.]

1,1,2,2-Tetrachloro-1,2-difluoroethane *[72-12-0]* **$C_2Cl_2F_4$, M 203.8, f 26.0°, b 92.8°/760mm, d_4^{25} 1.6252, n_D^{25} 1.4130.** Purify it as for trichlorotrifluoroethane. [*Beilstein* **1** III 165, **1** III 146.]

***sym*-Tetrachloroethane (acetylene tetrachloride)** *[79-34-5]* **$C_2H_2Cl_4$, M 167.9, m -43°, b 62°/100mm, 146.2°/atm, d_4^{20} 1.588, n_D^{15} 1.49678.** Stir the ethane, on a steam-bath, with concentrated H_2SO_4 until a fresh portion of acid remains colourless. The organic phase is then separated, distilled in steam, dried ($CaCl_2$ or K_2CO_3), and fractionally distilled in a vacuum. [*Beilstein* **1** IV 144.]

Tetrachloroethylene (PCE, pechloroethylene) *[127-18-4]* **C_2Cl_4, M 165.8, b 62°/80mm, 121.2°, d_4^{15} 1.63109, d_4^{20} 1.623, n_D^{15} 1.50759, n_D^{20} 1.50566.** It decomposes under similar conditions to $CHCl_3$, to give phosgene and trichloroacetic acid. Inhibitors of this reaction include EtOH, diethyl ether and thymol (effective at 2-5 ppm). Tetrachloroethylene should be distilled under a vacuum (to avoid formation of phosgene) and stored in the dark out of contact with air. It can be purified by washing with 2M HCl until the aqueous phase no longer becomes coloured, then with water, drying with Na_2CO_3, Na_2SO_4, $CaCl_2$ or P_2O_5, and fractionally distilling just before use. 1,1,2-Trichloroethane and 1,1,1,2-tetrachloroethane can be removed by counter-current extraction with EtOH/water. [*Beilstein* **1** IV 715.]

Tetracosane (C24) *[646-31-1]* **$C_{24}H_{50}$, M 338.7, m 49-52°, 54°, b 243-244°/15mm, 391°/atom.** Crystallise it from diethyl ether and/or distil it under high vacuum. [*Beilstein* **1** IV 578.]

Tetracosanoic (lignoceric) acid *[557-59-5]* **$C_{24}H_{48}O_2$, M 368.7, m 84°, 87.5-88°, pK_{Est} ~5.0.** Crystallise the acid from acetic acid, Me_2CO, toluene, petroleum ether/Me_2CO or$*C_6H_6$/Me_2CO. [*Beilstein* **2** IV 1301.]

Tetracyanoethylene (TCNE, ethylenetetracarbonitrile) *[670-54-2]* **C_6N_4, M 128.1, m 197-199°, 199-200°(sealed tube).** Recrystallise it from chlorobenzene, dichloroethane, or dichloromethane [Hall et al. *J Org Chem* **52** 5528 *1987*, DOI: 10.1021/jo00234a006]. Note that its solubility in dry chlorobenzene increases rapidly near the boiling point of the solvent. Therefore crystals should be extracted with boiling chlorobenzene which should be dry. Store it at 0° in a desiccator over NaOH pellets. (It slowly evolves HCN on exposure to moist air **CARE**.) Also purify it by repeated sublimation at 120-130°/0.5mm. Pure product with barely a trace of yellow colour is obtained by placing TCNE (35g) in a glass thimble and covering it with activated wood charcoal chips (4-8 mesh). The mouth of the thimble is covered with coarse grade filter paper which is held in place by wiring. The thimble is then placed in a sublimer, and sublimation is carried out at 1-2 mm with bath temperature at 175-200°. TCNE is recovered in 80-90% yield as a colourless, hard crystalline mass with **m 201-202°**(sealed tube). [Frey et al. *J Am Chem Soc* **107** 748 *1985*, DOI: 10.1021/ja00290a002; Traylor & Miksztal *J Am Chem Soc* **109** 2778 *1987*, DOI: 10.1021/ja00243a033; Fatiadi *Synthesis* 249 *1986*, DOI: 10.1055/s-1986-31584; Fatiadi *Synthesis* 749 *1987*, DOI: 10.1055/s-1987-28074; Fatiadi *Synthesis* 959 *1987*, DOI: 10.1055/s-1987-28140; Carboni *Org Synth* Coll Vol **4** 877 *1963*, DOI: 10.15227/orgsyn.039.0064; *Beilstein* **2** IV 2450.] It is a π-acid which forms π-complexes with polycyclic hydrocarbons, e.g. with pyrene where the π-complex has an equilibrium constant of 29.5 [Melby et al. *J Am Chem Soc* **84** 3374 *1962*, DOI: 10.1021/ja00876a029; Acker & Hertler *J Am Chem Soc* **84** 3370 *1962*, DOI: 10.1021/ja00876a028].

Tetradecane (C14) *[629-59-4]* **C_2H_{30}, M 198.4, m 6°, b 122°/10mm, 252-254°/atm, d_4^{20} 0.763, n_D^{20} 1.429.** Wash it successively with 4M H_2SO_4 and water. Dry it over $MgSO_4$ and distil it several times under reduced pressure [Poë et al. *J Am Chem Soc* **108** 5459 *1986*, DOI: 10.1021/ja00278a015]. It is used as a standard in gas chromatography. [*Beilstein* **1** H 171, **1** IV 520.]

1-Tetradecanol (myristyl alcohol) *[112-72-1]* **$C_{14}H_{30}O$, M 214.4, m 35-39°, 39-39.5°, b 160°/10mm, 170-173°/20mm, 289°/atm.** Crystallise the alcohol from aqueous EtOH or distil preferably in a vacuum. It has also been purified by zone melting. [*Beilstein* **1** IV 1864.]

Tetradecyl ether (di-tetradecyl ether) *[5412-98-6]* **$C_{28}H_{58}O$, M 410.7, m 43.5°, 45°, b 457°/760mm, d_4^{43} 0.8117.** Distil the ether under a vacuum and then crystallise it repeatedly from MeOH/*benzene. It also crystallises from MeOH alone (**m 31.2°, 33°,** and **44.4°** also reported), or Me_2CO (**m 43.5°**). [Di Giacomo & Smyth *J Am Chem Soc* **78** 2027 *1956*, DOI: 10.1021/ja01591a001; *Beilstein* **1** IV 1865.]

Tetradecyltrimethylammonium bromide (myristyl trimethylammonium bromide) *[1119-97-7]* **$C_{17}H_{38}N$. Br, M 336.4, m 244-245°, 244-249°, 245-250°.** Crystallise the bromide from Me_2CO or a mixture of Me_2CO and >5% MeOH or Me_2CO and EtOH. Wash it with diethyl ether and dry it in a vacuum oven at 60°. It is a cationic detergent with micellar average weight 27,000, aggregation number 80 and CMC 4-5mM at 20-25°. Its solubility is 1g/5g H_2O. [Dearden & Woolley *J Phys Chem* **91** 2404 *1987*, DOI: 10.1021/j100293a040; Shelton et al. *J Am Chem Soc* **68** 753 *1946*, DOI: 10.1021/ja01209a012; *Beilstein* **4** III 419, **4** IV 813.]

Tetraethoxymethane See tetraethyl orthocarbonate below.

Tetraethylammonium bromide (TEA bromide) *[71-91-0,]* **$C_8H_{20}N$. Br, M 210.2, m 269°(dec), 284°(dec), 285°(dec).** Recrystallise the bromide from EtOH, $CHCl_3$ or diethyl ether, or, recrystallise it from acetonitrile and dry it over P_2O_5 under reduced pressure for several days. It also recrystallises from EtOH/diethyl ether (1:2), EtOAc, water or boiling MeOH/acetone (1:3) or by adding an equal volume of acetone and allowing to cool. Dry it at 100° *in vacuo* for 12 days, and store over P_2O_5. [*Beilstein* **4** IV 332.]

Tetraethylammonium chloride hydrate (TEA chloride) *[68696-18-4 (H_2O), 56-34-8 (anhydrous)]* **$C_8H_{20}N$. Cl, M 165.7 (anhydrous), m dec >200°.** Crystallise the chloride from EtOH by adding diethyl ether, from warm water by adding EtOH and diethyl ether, from dimethylacetamide or from CH_2Cl_2 by addition of diethyl ether. Dry it over P_2O_5 in vacuum for several days. It also crystallises from acetone/CH_2Cl_2/hexane (2:2:1) [Blau & Espenson *J Am Chem Soc* **108** 1962 *1986*, DOI: 10.1021/ja00268a039; White & Murray *J Am Chem Soc* **109** 2576 *1987*, DOI: 10.1021/ja00243a005]. [*Beilstein* **4** IV 332.]

Tetraethylammonium hexafluorophosphate *[429-07-2]* **$C_8H_{20}N$. PF_6, M 275.2, m >300°, 331°(dec), pK_1^{25} ~ 0.5, pK_2^{25} 5.12 (for fluorophosphoric acid H_2PO_3F).** Dissolve the salt (0.8g) in hot H_2O (3.3ml) and cool to crystallise. Yield of prisms is 0.5g. Its solubility in H_2O is 8.1g/L at 19° [Lange & Müller *Chem Ber* **63** 1058 *1930*, DOI: 10.1002/cber.19300630510]. [*Beilstein* **4** III 199.]

Tetraethylammonium iodide *[68-05-3]* **$C_8H_{20}N$. I, M 257.2, m 302°, >300°(dec).** Crystallise the iodide from acetone/MeOH, EtOH/water, dimethylacetamide or ethyl acetate/EtOH (19:1). Dry it under a vacuum at 50° and store it over P_2O_5. [*Beilstein* **4** IV 332.]

Tetraethylammonium perchlorate *[2567-83-1]* **$C_8H_{20}N$. ClO_4, M 229.7, m 345°(dec).** Crystallise the perchlorate repeatedly from water, aqueous MeOH, acetonitrile or acetone, and dry it at 70° under a vacuum for 24 hours. [Cox et al. *J Am Chem Soc* **106** 5965 *1984*, DOI: 10.1021/ja00332a035; Liu et al. *J Am Chem Soc* **108** 1749 *1986*, DOI: 10.1021/ja00268a006; White & Murray *J Am Chem Soc* **109** 2576 *1987*, DOI: 10.1021/ja00243a005.] It has also been crystallised twice from ethyl acetate/95% EtOH (2:1) [Lexa et al. *J Am Chem Soc* **109** 6464 *1987*, DOI: 10.1021/ja00255a036]. [*Beilstein* **4** IV 332.]

Tetraethylammonium picrate *[741-03-7]* **$C_8H_{20}N$. $C_6H_2N_3O_7$, M 342.1, m >300°(dec).** Purify it by successive crystallisations from water or 95% EtOH followed by drying in vacuum at 70°. [*Beilstein* **4** IV 332.]

Tetraethylammonium tetrafluoroborate *[429-06-1]* **$C_8H_{20}N$. BF_4, M 217.1, m 235°, 356-367°, 275-277°, 289-291°, pK^{25} -4.9 (for HBF_4).** Dissolve the salt in hot MeOH, filter and add Et_2O. It is soluble in ethylene chloride [Thompson & Kraus *J Am Chem Soc* **69** 1016 *1947*, DOI: 10.1021/ja01197a012; Wheeler & Sandstedt *J Am Chem Soc* **77** 2025 *1955,* DOI: 10.1021/ja01612a103]. It has also been recrystallised three times from a mixture of ethyl acetate/hexane (5:1) or MeOH/petroleum ether, then stored at 95° for 48 hours under vacuum [Hartley & Faulkner *J Am Chem Soc* **107** 3436 *1985*, DOI: 10.1021/ja00298a007; Huang et al. *Anal Chem* **58** 2889 *1986*, DOI: 10.1021/ac00126a070]. It is used as a supporting electrolyte. [*Beilstein* **4** IV 333.]

Tetraethylammonium tetraphenylborate *[12099-10-4]* **$C_8H_{20}N.C_{24}H_{20}B$, M 449.4.** Recrystallise the borate from aqueous acetone. Dry it in a vacuum oven at 60° for several days. *Similarly for the propyl and butyl homologues*. [*Beilstein* **4** IV 333.]

Tetraethylene glycol dimethyl ether (tetraglyme) *[143-24-8]* **$C_{10}H_{22}O_5$, M 222.3, m -30°, b 105°/1mm, 275-276°/atm, d_4^{20} 1.010, n_D^{20} 1.435.** Stand the ether over CaH_2, $LiAlH_4$ or sodium, and distil it when required. [*Beilstein* **1** IV 2404.]

Tetraethylenepentamine (TEPA, tetrene) *[112-57-2]* **$C_8H_{23}O_5$, M 189.3, m -40°, b 169-171°/0.05mm, 340°/atm, d_4^{20} 0.999, n_D^{20} 1.506, pK_1^{25} 2.98, pK_2^{25} 4.72, pK_3^{25} 8.08, pK_4^{25} 9.10, pK_5^{25} 9.68.** Distil the amine under vacuum. Also purify *via* its ***penta hydrochloride***, ***nitrate*** or ***sulfate***. Jonassen, Frey and Schaafsma [*J Phys Chem* **61** 504 *1957*, DOI: 10.1021/j150550a033] cooled a solution of 150g of the base in 300ml of 95% EtOH, and added dropwise 180ml of concentrated HCl, keeping the temperature below 20°. The white precipitate was filtered off, crystallised three times from EtOH/water, then washed with diethyl ether and dried by suction. Reilley & Holloway [*J Am Chem Soc* **80** 2917 *1958*, DOI: 10.1021/ja01545a001], starting with a similar solution cooled to 0°, added slowly (keeping the temperature below 10°) a solution of 4.5g-moles of HNO_3 in 600ml of aqueous 50% EtOH (also cooled to 0°). The precipitate was filtered by suction, recrystallised five times from aqueous 5% HNO_3, then washed with acetone and absolute EtOH and dried at 50°. [For purification *via* the sulfate see Reilley and Vavoulis (*Anal Chem* **31** 243 *1959*, DOI: 10.1021/ac60146a026), and for an additional purification step using the Schiff base with benzaldehyde see Jonassen et al. *J Am Chem Soc* **79** 4279 *1957*, DOI: 10.1021/ja01573a011]. [*Beilstein* **4** IV 1244.] The **TEPA *pentahydrochloride*** *[4961-41-5]* **$C_8H_{23}O_5.5HCl$, M 371.6** has **m 280°(dec).**

Tetraethyl 1,1,2,2-ethanetetracarboxylate *[632-56-4]* **$C_{14}H_{22}O_8$, M 318.3, m 73-74°, 73-75°.** Recrystallise the ester twice from EtOH by cooling to 0°. [Mochizuki et al. *Bull Chem Soc Jpn* **64** 1750 *1991*, DOI: org/10.1246/bcsj.64.1750; Weinges et al. *Angew Chem Int Ed* **20** 960 *1981*, DOI: 10.1002/anie.198109601; *Beilstein* **2** IV 2415.]

Tetraethyl orthocarbonate (ethyl orthocarbonate, tetraethoxy ethane) *[78-09-1]* **$C_9H_{20}O_4$, M 192.3, b 59.6-60°/14mm, 158°/atm, 159°/atm, 160-161°/atm, d_4^{20} 0.9186, n_D^{20} 1.3932.** Likely impurities are hydrolysis products. Shake the orthocarbonate with brine (saturated NaCl, dilute with a little Et_2O if amount of material is small) and dry ($MgSO_4$). The organic layer is filtered, evaporated, and the residue is distilled through a helices packed fractionating column with a total reflux partial take-off head. All distillations can be done at atmospheric pressure in an inert atmosphere (e.g. N_2). [Roberts & McMahon *Org Synth* Coll Vol **4** 457 *1963*, DOI: 10.15227/orgsyn.032.0068; Connolly & Dyson *J Chem Soc* 828 *1937*, DOI: 10.1039/JR9370000827; Tieckelmann & Post *J Org Chem* **13** 265 *1948*, DOI: 10.1021/jo01160a014; for review see Kantlehner et al. *Justus Liebigs Ann Chem* 507 *1982*, DOI: 10.1002/ jlac.198219820313; *Beilstein* **3** IV 6.]

2,2,3,3-Tetrafluoropropan-1-ol *[76-37-9]* **$C_3H_4F_4O$, M 132.1, b 106-106.5°/~760mm, d^{25} 1.48 g/ml, n_D^{20} 1.321, pK^{25} 12.74.** Tetrafluoro-1-propanol (450ml) is added to a solution of $NaHSO_3$ (2.25g) in water (90ml), shaken vigorously and set aside for 24 hours. The fraction distilling at or above 99° is refluxed for 4 hours with 5-6g of KOH and rapidly distilled, followed by a final fractional distillation. [Kosower & Wu *J Am Chem Soc* **83** 3142 *1961*, DOI: 10.1021/ja01475a034.] *Alternatively*, shake the alcohol with alumina for 24 hours, dry it overnight with anhydrous K_2CO_3 and distil it, taking the middle fraction (**b** 107-108°). [*Beilstein* **1** IV 1438.]

Tetra-*n*-heptylammonium bromide *[4368-51-8]* **$C_{28}H_{60}N.Br$, M 490.7, m 88.9-89.1°.** Crystallise the bromide from *n*-hexane, then dry it in a vacuum oven at 70°. [Goodrich et al. *J Am Chem Soc* **72** 4411 *1950*, DOI: 10.1021/ja01166a020; *Beilstein* **4** IV 736.]

Tetra-*n*-heptylammonium iodide *[3535-83-9]* **$C_{28}H_{60}N.Cl$, M 537.7, m 102-103°.** Recrystallise the iodide from EtOH or aqueous EtOH. [Erikson et al. *J Org Chem* **25** 849 *1960*, DOI: 10.1021/jo01075a616; *Beilstein* **4** IV 736 for triheptylamine.]

Tetra-*n*-hexylammonium bromide *[4328-13-6]* **$C_{24}H_{52}N.Br$, M 434.6, m 99-100°.** Wash the bromide with

ether, and dry it in a vacuum at room temperature for 3 days.

Tetra-*n*-hexylammonium chloride *[5922-92-9]* **$C_{24}H_{52}N$. Cl, M 390.1, m 111-113°.** Crystallise the chloride from EtOH.

Tetra-*n*-hexylammonium iodide *[2138-24-1]* **$C_{24}H_{52}N$. I, M 481.6, m 99-101°, 102-103°.** Wash the iodide with diethyl ether and dry it at room temperature *in vacuo* for 3 days. It is soluble in CH_2Cl_2. [Eriksen et al. *J Org Chem* **25** 849 *1960*, DOI: 10.1021/jo01075a616; *Beilstein* **4** IV 711 for trihexylamine.]

Tetrahexylammonium perchlorate *[4656-81-9]* **$C_{24}H_{52}N$. ClO_4, M 454.1, m 104-106°.** Crystallise the salt from acetone and dry it *in vacuo* at 80° for 24 hours.

Tetrakis(dimethylamino)ethylene (TDAE) *[996-70-3]* **$C_{10}H_{24}N_4$, M 300.2, b 60°/1mm, d_4^{20} 0.861, n_D^{20} 1.4817, $pK_{Est(1)}$<0, $pK_{Est(2)}$<0, $pK_{Est(3)}$~1.5, $pK_{Est(4)}$ ~5.1.** Impurities include tetramethylurea, dimethylamine, tetramethylethane-diamine and tetramethyloxamide. It is washed with water while being flushed with nitrogen to remove dimethylamine, dried over molecular sieves, then passed through a silica gel column (previously activated at 400°) under nitrogen. De-gas it in a vacuum line by distillation from a trap at 50° to one at -70°. Finally, it is stirred over sodium-potassium alloy for several days. [Holroyd et al. *J Phys Chem* **89** 4244 *1985*, DOI: 10.1021/j100266a019; Wiberg *Angew Chem Int Ed* **7** 766 *1968*, DOI: 10.1002/anie.196807661; *Beilstein* **4** IV 167.]

Tetramethylammonium bromide *[64-20-0]* **$C_4H_{12}N$. Br, M 154.1, sublimes with dec >230°.** Crystallise the bromide from EtOH, EtOH/diethyl ether, MeOH/acetone, water or from acetone/MeOH (4:1) by adding an equal volume of acetone. It is dried at 110° under reduced pressure or at 140° for 24 hours. [*Beilstein* **4** IV 145.]

Tetramethylammonium chloride (TMA) *[75-57-0]* **$C_4H_{12}N$. Cl, M 109.6, m >230°(dec).** Crystallise the chloride from EtOH, EtOH/$CHCl_3$, EtOH/diethyl ether, acetone/EtOH (1:1), isopropanol or water. Traces of the free amine can be removed by washing with $CHCl_3$. [*Beilstein* **4** IV 145.]

Tetramethylammonium hexafluorophosphate *[558-32-7]* **$C_4H_{12}N$. PF_6, M 219.1, m >300°, d_4^{25} 1.617, pK_1^{25} ~ 0.5, pK_2^{25} 5.12 (for fluorophosphoric acid H_2PO_3F).** The salt (0.63g) is recrystallised from boiling H_2O (76ml), yielding pure (0.45) $Me_4N.PF_6$ after drying at 100°. It is a good supporting electrolyte. [Lange & Müller *Chem Ber* **63** 1058 *1930*, DOI: 10.1002/cber.19300630510; *Beilstein* **4** III 110.]

Tetramethylammonium hydroxide ($5H_2O$) *[10424-65-4 ($5H_2O$), 75-59-2 (aqueous solution)]* **$C_4H_{12}N$. OH, M 181.2, m 63°, 65-68°, 67-70°.** It is freed from chloride ions by passage through an ion-exchange column (e.g. Amberlite IRA-400, prepared in its OH^- form by passing 2M NaOH until the effluent is free from chloride ions, then washed with distilled H_2O until neutral). A modification, to obtain carbonate-free hydroxide, uses the method of Davies and Nancollas [*Nature* **165** 237 *1950*, DOI:10.1038/165237b0]. An aqueous solution (1.0 ±0.02 M in H_2O) and a methanolic solution (25% w/w) are also commercially available. [*Beilstein* **4** H 50, **4** IV 145.]

Tetramethylammonium iodide *[75-58-1]* **$C_4H_{12}N$. I, M 201.1, m >230°(dec), >300°(dec).** Crystallise the iodide from water or 50% EtOH, EtOH/diethyl ether, ethyl acetate, or from acetone/MeOH (4:1) by adding an equal volume of acetone. Dry it in a vacuum desiccator. [*Beilstein* **4** IV 146.]

Tetramethylammonium nitrate *[1941-24-8]* **$C_4H_{12}N$. NO_3, M 136.2, m >300°, 410°.** Recrystallise the nitrate from EtOH and dry at 110° in an air oven. [Coats & Taylor *J Chem Soc* 1495 *1936,* DOI: 10.1039/JR9360001495; *Beilstein* **4** III 113, **4** IV 147.]

Tetramethylammonium perchlorate *[2537-36-2]* **$C_4H_{12}N$. ClO_4, M 123.6, m>300°, pK^{25} -2.4 to -3.1 (for $HClO_4$).** Crystallise it twice from H_2O and dry it at 110° in an air oven. It is insoluble in most organic solvents. [Mead et al. *J Chem Soc* 1207 *1933*, DOI: 10.1039/JR9330001207; Coats & Taylor *J Chem Soc* 1495 *1936*, DOI: 10.1039/JR9360001495.]

Tetramethylammonium tetraphenylborate *[15525-13-0]* **$C_4H_{12}N$, $C_{24}H_{20}B$, M 393.3.** Recrystallise it from acetone, acetone/CCl_4 and from acetone/1,2-dichloroethane. Dry it over P_2O_5 in a vacuum, or in a vacuum oven at 60° for several days. [*Beilstein* **4** IV 145.]

N,N,N',N'*-Tetramethylethylenediamine (TMEDA, TMED)** *[110-18-9]* **$C_6H_{16}N_2$, M 116.2, m -55°, b 122°/atm, d_4^{20} 1.175, n_D^{25} 1.4153, pK_1^{25} 5.90, pK_2^{25} 9.14.** Dry TMEDA partially with molecular sieves (Linde type 4A), then distil it in a slight vacuum from butyl lithium. This treatment removes all traces of primary and secondary amines and water. [Hay et al. *JCS Faraday Trans 1* **68** 1 *1972*, DOI: 10.1039/F19726800001.] Or dry it with KOH pellets, reflux for 2 hours with one-sixth its weight of *n*-butyric anhydride (to remove primary and secondary amines) and fractionally distil it. Reflux it with fresh KOH, and distil it under nitrogen. [Cram & Wilson *J Am Chem Soc* **85** 1245 *1963*, DOI: 10.1021/ja00892a008.] It was also distilled from Na. Store it sealed under N_2. The ***dipicrate has **m 263°(dec)**. [*Beilstein* **4** H 250, **4** I 415, **4** II 690, **4** III 512, **4** IV 1172.]

Tetramethylethylenediamine dihydrochloride *[7677-21-8]* **$C_6H_{16}N_2$. 2HCl, M 198.2, m ~300°.** Crystallise the salt from 98% EtOH/concentrated HCl. It is *hygroscopic*. [Knorr *Chem Ber* **37** 3507 *1904*, DOI: 10.1002/cber.190403703177; *Beilstein* **4** IV 1172.]

1,1,3,3-Tetramethylguanidine *[80-70-6]* **$C_5H_{13}N_3$, M 115.2, b 52-54°/11mm, 159-160°/atm, 162-163°/atm, d_4^{20} 0.917 n_D^{20} 1.470, pK^{25} 13.6.** Reflux it over granulated BaO, then fractionally distil it. Protect it from CO_2 and H_2O as it is a strong base. [*Beilstein* **4** IV 227.]

Tetramethyl orthocarbonate (methyl orthocarbonate, tetramethoxy methane) *[1850-14-2]* **$C_5H_{12}O_4$, M 136.2, m -5.6°, -5°, -2°, b 113.5°/760mm, 113.5-114°/755mm, 112-114°/atm, d_4^{20} 1.0202, n_D^{20} 1.3860.** Purify it in the same way as for tetraethyl orthocarbonate. [Smith *Acta Chem Scand* **10** 1006 *1956*, DOI: 10.3891/acta.chem.scand.10-1006; Tieckelmann & Post *J Org Chem* **13** 265 *1948*, DOI: 10.1021/jo01160a014; Kantlehner et al. *Synthesis* 73 *1977*, DOI: 10.1055/s-1977-24283; Fatiadi *Synthesis* 749 *1987*, DOI: 10.1055/s-1987-28074; Fatiadi *Synthesis* 959 *1987*, DOI: 10.1055/s-1987-28140; *Beilstein* **3** IV 4.]

2,6,10,14-Tetramethylpentadecane (pristane, norphytane) *[1921-70-6]* **$C_{19}H_{40}$, M 268.5, b 68° (bath temp)/0.004mm, 158°/10mm, 296°/atm, d_4^{20} 0.7827, n_D^{20} 1.4385.** Purify pristane by shaking it with concentrated H_2SO_4 (**care**, if amount of pristane is too small then it should be diluted with petroleum ether *not* Et_2O which is quite soluble in H_2SO_4), then H_2O (**care,** as it may heat up in contact with concentrated H_2SO_4), dry ($MgSO_4$), evaporate and distil it over Na. It is a lubricant, which was isolated from shark liver oil, petroleum crude oils and wool wax; and was synthesised from phytol [7541-49-3] [Sörensen & Sörensen *Acta Chem Scand* **3** 939 *1949*, DOI: 10.3891/acta.chem.scand.03-0939]. [*Beilstein* **1** III 570.]

Tetramethylthiuram disulfide [bis-(dimethylthiocarbamyl)disulfide, Thiram] *[137-26-8]* **$C_6H_{12}N_2S_4$, M 240.4, m 146-148°, 155-156°.** Crystallise thiram (three times) from boiling $CHCl_3$, then recrystallise it from boiling $CHCl_3$ by adding EtOH dropwise to initiate crystallisation, and allow it to cool. Finally, it is precipitated from cold $CHCl_3$ by adding EtOH (which retains the monosulfide in solution). [Ferington & Tobolsky *J Am Chem Soc* **77** 4510 *1955*, DOI: 10.1021/ja01622a020; *Beilstein* **4** IV 242.]

1,1,3,3-Tetramethyl urea *[632-22-4]* **$C_5H_{12}N_2O$, M 116.2, m -1.2°, b 62-63°/12mm, 175.2°/760mm, d_4^{20} 0.969, n_D^{20} 1.453.** Dry it over BaO and distil it under nitrogen. It denatures proteins in H_2O. [Elbaum & Herskovits *Biochemistry* ***13*** *1268* 1974, DOI: 10.1021/bi00703a033; Kane *Anal Biochem* **53** 350 *1973*, DOI:10.1016/0003-2697(73)90081-X; *Beilstein* **4** IV 225.]

Tetranitromethane (TNM) *[509-14-8]* **CN_4O_8, M 196.0, m 14.2°, b 46°/36mm, 21-23°/23mm, 126°/760mm, d_4^{20} 1.640, n_D^{20} 1.438.** Shake tetranitromethane with dilute NaOH, wash (H_2O), steam distil, dry with Na_2SO_4 and fractionally crystallise it by partial freezing. The melted crystals are dried with $MgSO_4$ and fractionally distilled under reduced pressure. *Alternatively*, shake it with a large volume of dilute NaOH until no absorption attributable to the *aci*-nitro anion (from mono- di- and tri- nitromethanes) is observable in the water. Then wash it with distilled water, and distil it at room temperature by passing a stream of air or nitrogen through the liquid and condensing it in a trap at -80°. It can be dried with $MgSO_4$ or Na_2SO_4, fractionally recrystallised from the

melt, and fractionally distilled under reduced pressure. [Liang *Org Synth* Coll Vol **3** 803 *1955*, DOI: 10.15227/orgsyn.021.0105; *Beilstein* **4** H 80, **4** I 21, **4** II 45, **4** III 116, **4** IV 107.] **Potentially explosive (when impure e.g. with toluene), toxic, carcinogenic.**

Tetra-*n*-propylammonium bromide *[1941-30-6]* **$C_{12}H_{28}N.Br$, M 266.3, m >280°(dec).** Crystallise it from ethyl acetate/EtOH (9:1), acetone or MeOH. Dry it at 110° under reduced pressure. [*Beilstein* **4** IV 471.]

Tetra-*n*-propylammonium iodide *[631-40-3]* **$C_{12}H_{28}N.I$, M 313.3, m >280°(dec).** Purify the iodide by crystallising it from EtOH, EtOH/diethyl ether (1:1), EtOH/water or aqueous acetone. Dry it at 50° under a vacuum and store it over P_2O_5 in a vacuum desiccator. Keep it away from light. [*Beilstein* **4** IV 472.]

Tetra-*n*-propylammonium perchlorate *[15780-02-6]* **$C_{12}H_{28}N.ClO_4$, M 285.8, m 238-240°, 239-241°, pK^{25} -2.4 to -3.1 (for $HClO_4$).** Purify it by recrystallisation from H_2O or MeCN/H_2O (1:4.v/v), and dry it in an oven at 60° for several days, or in a vacuum over P_2O_5 at 100°. [Walden & Hilgert *Z Phys Chem* **165** 245 *1933*, Walden & Birr *Z Phys Chem* **144** 281 *1929*, Walden & Busch *Z Phys Chem* **140** 97 *1929*, *Beilstein* **4** II 628.]

Thioacetamide *[62-55-5]* **C_2H_5NS, M 75.1, m 112-113°, pK^{25} 13.4.** Crystallise the amide from absolute diethyl ether or *benzene. Dry it at 70° in a vacuum and store it over P_2O_5 at 0° under nitrogen. (*It develops an obnoxious odour on storage*, and the absorption at 269nm decreases, hence it should be freshly recrystallised before use). [*Beilstein* **2** IV 565.]

Thiodiglycollic acid (2,2'-dithioacetic acid) *[123-93-3]* **$C_4H_6O_4S$, M 150.2, m 129°, 128-131°, pK_1^{25} 3.15 (3.24), pK_2^{25} 4.13 (4.56).** Crystallise the acid from water. It forms Cu, Pb, Hg and Ag salts used for their detection. [*Beilstein* **3** IV 612.]

3,3'-Thiodipropionic acid (bis[2-carboxyethyl]sulfide) *[111-17-1]* **$C_6H_{10}O_4S$, M 178.2, m 134°, pK_1^{25} 3.84, pK_2^{25} 4.66.** Crystallise the sulfide from water (very soluble at 100°, but 3.7% at 26°). It is soluble in EtOH and Me_2CO. It is an antioxidant. [*Beilstein* **3** IV 735.]

Thioformamide *[115-08-2]* **CH_3NS, M 61.0, m 29°, 32.0-33.8°, pK_{Est} ~12.4.** Crystallise thioformamide from EtOAc, Et_2O or ether/petroleum ether. The ***monohydrate*** is a yellow oil soluble in many organic solvents. Its UV has λ_{max} at 263nm (ε 2500) in MeOH. [Erlenmeyer & Menzi *Helv Chim Acta* **31** 2065 *1948*, DOI: 10.1002/hlca.19480310722.] *Alternatively*, dissolve it in Et_2O to separate it from any formanide and/or polymers, filter, evaporate and recrystallise the residue from EtOAc at Dry-ice temperature [Londergan et al. *J Am Chem Soc* **75** 4456 *1953*, DOI: 10.1021/ja01114a018]. Store it in Et_2O solution over P_2O_5. [Cousineau & Secristill *J Org Chem* **44** 4351 *1979*, DOI: 10.1021/jo01338a023; *Beilstein* **2** H 95, **2** I 39, **2** III 128, **2** IV 92.]

Thioglycollic acid (mercaptoacetic acid) *[68-11-1]* **$C_2H_4O_2S$, M 92.1, m -16°, b 95-96°/8mm, d_4^{20} 1.326, n_D^{20} 1.505, pK_1^{25} 3.42, pK_2^{25} 10.20.** Mix the acid with an equal volume of *benzene; the *benzene is then distilled off to dehydrate the acid. After heating to 100° to remove most of the *benzene, the residue is distilled under vacuum and stored in sealed ampoules at 3°. [Eshelman et al. *Anal Chem* **32** 844 *1960*, DOI: 10.1021/ac60163a036; *Beilstein* **3** IV 1130.]

***RS*-Thiomalic (mercaptosuccinic) acid** *[70-49-5]* **$C_4H_6O_4S$, M 150.2, m 153-154°, 155-157°, pK_1^{25} 3.64 (3.17), pK_2^{25} 4.64 (4.67), pK_3^{25} 10.37 (10.52).** Dissolve the acid in water and extract it several times with diethyl ether to remove impurities. The aqueous solution gave the acid on freeze-drying. [*Beilstein* **3** IV 472.]

Thiosemicarbazide *[79-19-6]* **CH_5N_3S, M 91.1, m 181-183°, pK_1^{25} 1.88, pK_2^{25} 12.81.** Crystallise thiosemicarbazide from H_2O (solubility is 20.3% w/w at 80°). The ***hydrochloride*** has **m 190-191°**(dec, 184° also reported). It forms salts with heavy metals. [*Beilstein* **3** H 195, **3** I 79, **3** II 134, **3** III 315, **3** IV 374.]

Thiourea *[62-56-6]* **CH_4N_2O, M 76.1, m 179°, pK^{20} -1.19 (aqueous H_2SO_4).** Crystallise thiourea from absolute EtOH, MeOH, acetonitrile or water. Dry it under vacuum over H_2SO_4 at room temperature. [*Beilstein* **3** IV 342.]

Tiglic acid (*trans*-2,3-dimethylacrylic acid) *[80-59-1]* **$C_5H_8O_2$, M 100.1, m 63.5-64°, b 198.5°/atm, 95°/11mm, pK^{18} 4.96**. Crystallise it from water. It is steam volatile and is soluble in organic solvents. [*Beilstein* **2** IV 1552.]

trans*-Traumatic acid (2-dodecene-1,12-dioic acid)** *[6402-36-4]* **$C_{12}H_{20}O_4$, M 228.3, m 165-166°, 150-160°/0.001mm, $pK_{Est(1)}$~4.2, $pK_{Est(2)}$~4.6.** Crystallise the acid from EtOH, acetone or glyme. The ***bis-4-phenylphenacyl ester has **m** 144-145° (from EtOH). [*Beilstein* **2** III 1978, **2** IV 2279.]

1,2,3-Triaminopropane trihydrochloride *[free base 21291-99-6]* **$C_8H_{11}N_3$, M 198.7, m 250° (sintering at 100°), pK_1^{20} 3.72, pK_2^{20} 7.95, pK_3^{20} 9.59.** Crystallise the trihydrochloride from EtOH or H_2O. The ***free base*** decomposes at 190°/760mm, but has **b 92-93°/9mm** without decomposition. [*Beilstein* **4** H 274, **4** III 630.]

Tribromochloromethane *[594-15-0]* **CBr_3Cl, M 287.2, m 55°, b 158-159.5°/~760mm, 160°/~760mm.** Melt it, wash it with aqueous $Na_2S_2O_3$, dry it with BaO and fractionally crystallise from its melt. It also crystallises from EtOH and distils at atmospheric pressure. [Miller & Smyth *J Chem Phys* **24** 816 *1956*, DOI: 10.1063/1.17426; *Beilstein* **1** H 68, **1** II 35, **1** III 91, **1** IV 85.]

Tribromofluoromethane *[353-54-8]* **CBr_3F, M 270.7, m -73.6°, b 106-107°/~760mm, d_4^{25} 2.765, n_D^{20} 1.525.** It has been prepared from dry CBr_4 (1mole), SbF_3 (0.5 mole), and Br_2 (0.05 mole) by heating at 120-130° during 1 hr whereby CBr_3F distils out as it is formed. The reaction is completed by further heating at 150-160° for 0.5 hr. The crude product is washed with 5% aqueous tartaric acid, 10% aqueous sodium sulfite, 2% aqueous NaOH, then H_2O, dried (P_2O_5) and distilled to give CBr_3F (65-75%), b 106-107°/atm. Some CBr_2F_2 (~5-10%) with b 23.5°/atm is also formed and distils first. [Birchall & Haszeldine *J Chem Soc* 13 *1959*, DOI: 10.1039/JR9590000013.] Cu is added as a stabiliser [Hellmann et al. *J Am Chem Soc* **79** 5654 *1957*, DOI: 10.1021/ja01578a018; Beilstein **1** IV 87.]

Tri-*n*-butylamine (TBA) *[102-82-9]* **$C_{12}H_{27}N$, M 185.4, m -70°, b 68°/3mm, 120°/44mm, 216°/atm, d_4^{20} 0.7788, n_D^{20} 1.4294, pK^{25} 9.93.** Purify the amine by fractional distillation from sodium under reduced pressure. Pegolotti and Young [*J Am Chem Soc* **83** 3251 *1961*, DOI: 10.1021/ja01476a018] heated the amine overnight with an equal volume of acetic anhydride, in a steam bath. The amine layer was separated and heated with water for 2 hours on the steam bath (to hydrolyse any remaining acetic anhydride). The solution was cooled, solid K_2CO_3 was added to neutralise any acetic acid that had been formed, and the amine was separated, dried (K_2CO_3) and distilled at 44mm pressure. Davis and Nakshbendi [*J Am Chem Soc* **84** 2085 *1926*, DOI: 10.1021/ja00870a017] treated the amine with one-eighth of its weight of benzenesulfonyl chloride in aqueous 15% NaOH at 0-5°. The mixture was shaken intermittently and allowed to warm to room temperature. After a day, the amine layer was washed with aqueous NaOH, then water and dried with KOH. (This treatment removes primary and secondary amines.) It was further dried with CaH_2 and distilled under vacuum. [*Beilstein* **4** IV 554.]

Tri-*n*-butylammonium hydrobromide *[37026-85-0]* **$C_{12}H_{27}N.HBr$, M 308.3, m 75.2-75.9°.** Crystallise the hydrobromide from ethyl acetate. [*Beilstein* **4** H 157, **4** III 292, **4** IV 555.]

Tri-*n*-butylammonium nitrate *[33850-87-2]* **$C_{12}H_{27}N.HNO_3$, M 304.5.** Crystallise the nitrate from mixtures of *n*-hexane and acetone (95:5). Dry it over P_2O_5 in a vacuum. [*Beilstein* **4** H 157, **4** I 371, **4** II 633, **4** III 291, **4** IV 554.]

Tri-*n*-butylammonium perchlorate *[14999-66-7]* **$C_{12}H_{27}N.HClO_4$, M 285.5.** Recrystallise the perchlorate from *n*-hexane. (Potentially explosive.) [*Beilstein* **4** IV 554.]

Tricarballylic acid (propane-1,2,3-tricarboxylic acid) *[99-14-9]* **$C_6H_8O_6$, M 176.1, m 156-161°, 166°, pK_1^{25} 3.47, pK_2^{25} 4.54, pK_3^{25} 5.89.** Crystallise the acid from diethyl ether. [*Beilstein* **2** IV 2366.]

Trichloroacetamide *[594-65-0]* **$C_2H_2Cl_3NO$, M 162.4, m 139-141°, b 238-240°/atm.** Its solution in xylene is dried with P_2O_5, then fractionally distilled. [*Beilstein* **2** IV 520.]

Trichloroacetic acid (TCA) *[76-03-9]* **$C_2HCl_3O_2$, M 163.4, m 59.4-59.8°, b 196°/atm, pK^{25} 0.51.** Purify this strong acid (care) by fractional crystallisation from its melt, then crystallise it repeatedly from dry *benzene and store it over concentrated H_2SO_4 in a vacuum desiccator. It can also be crystallised from $CHCl_3$ or cyclohexane, and dried over P_2O_5 or $Mg(ClO_4)_2$ in a vacuum desiccator. Trichloroacetic acid can be fractionally distilled under reduced pressure from $MgSO_4$. Layne, Jaffé and Zimmer [*J Am Chem Soc* **85** 435 *1963*, DOI: 10.1021/ja00887a014] dried trichloroacetic acid in *benzene by distilling off the *benzene-water azeotrope, then crystallised the acid from the remaining *benzene solution. Manipulations should be carried out under N_2. [*Toxic vapours, use a well ventilated fume cupboard*.] [*Beilstein* **2** IV 508.]

Trichloroacetonitrile *[545-06-2]* **C_2Cl_3N, M 144.4, m -42°, -44°, b 84.6°/741mm, 85.8-86°/764mm, 85.7°/760mm, d_4^{20} 1.441, n_D^{25} 1.4409.** It is prepared by mixing trichloroacetamide (150g, obtained from ethyl trichloroacetate and ammonia) with an equal weight of P_2O_5 and heating at ~200° in an oil bath, and a further amount of P_2O_5 is added before distilling the nitrile off. The distillate is then carefully fractionated, and the fraction **b** 85.8-86°/764mm is collected (yield 70-75%), and should contain <0.02% of amide: cf. IR (film) has a nitrile band at 2250 cm^{-1}, and is almost free from bands at ~1735 (CO) and >2502 (NH) cm^{-1}. The liquid shows no signs of change after several months, even with traces of moisture, provided that it is kept in away from light. [Davies & Jenkin *J Chem Soc* 2374 *1954*, DOI: 10.1039/JR9540002374, and references therein, Carpenter *J Org Chem* **27** 2085 *1962*, DOI: 10.1021/jo01053a043; *Beilstein* **2** H 212, **2** I 95, **2** II 201, **2** III 477, **2** IV 524]. **It is lachrymatory, a skin and eye irritant, and has been used as a fumigant.**
It is a useful reagent for selectively esterifying phosphoric acid, e.g. with benzyl alcohol in the presence of Et_2N it gives monobenzylphosphate with H_2PO_4 [Cramer & Baldauf *Chem Ber* **92** 370 *1959*, DOI: 10.1002/cber.19590920219], and converts a monophosphoric ester into a symmetrical pyrophosphate in the presence of pyridine [Cramer et al. *Justus Liebigs Ann Chem* **654** 180 *1962*, DOI: 10.1002/jlac.19626540118]. It is readily converted into its trichloroacetimidate esters by reaction with allylic alcohols in CH_2Cl_2, in the presence of DBU at ~0° to ambient temperatures [Anderson & Overman *J Am Chem Soc* **125** 12412 *2003*, DOI: 10.1021/ja037086r; Kirsch et al. *Org Lett* **9** 911 *2007*, DOI: 10.1021/ol070110b]; similarly prepared trichloroacetimidates of allylic alcohols were shown to undergo ether-directed Pd(II)-catalysed aza-Claisen rearrangements [Jamieson & Sutherland *Tetrahedron* **63** 2132 *2007* DOI:10.1016/j.tet.2006.12.067], and bis-trichloroacetimidates from 2-aminopropane-1,3-diols yielded dihydro-oxazines through an acid catalysed cyclisation [Rondot et al. *Org Lett* **9** 247 *2007*, DOI: 10.1021/ol0627202].

1,1,1-Trichloroethane *[71-55-6]* **$C_2H_3Cl_3$, M 133.4, f -32.7°, b 74.0°/atm, d_4^{20} 1.337, n_D^{20} 1.4385.** Wash it successively with concentrated HCl (or concentrated H_2SO_4), aqueous 10% K_2CO_3 (Na_2CO_3), aqueous 10% NaCl, dry it with $CaCl_2$ or Na_2SO_4, and fractionally distil it. It can contain up to 3% dioxane as preservative. This is removed by washing successively with 10% aqueous HCl, 10% aqueous $NaHCO_3$ and 10% aqueous NaCl, and distilling over $CaCl_2$ before use. **TOXIC VAPOURS.** [*Beilstein* **1** IV 138.]

1,1,2-Trichloroethane *[79-00-5]* **$C_2H_3Cl_3$, M 133.4, f -36.3°, b 113.6°/atm, d_4^{20} 1.435, n_D^{20} 1.472.** Purify the chloroethane as for 1,1,1-trichloroethane above. **TOXIC VAPOURS.** [*Beilstein* **1** IV 139.]

Trichloroethylene (TCE) *[79-01-6]* **C_2HCl_3, M 131.4, m -84.8°, b -12.4°/10mm, 20°/60mm, 48°/200mm, 67°/400mm, 86.9°/760mm, 87.2°/atm, d_4^{20} 1.463, n_D^{21} 1.4767.** Tricloroethylene undergoes decomposition in a similar way as $CHCl_3$, giving HCl, CO, $COCl_2$ and organic products. It reacts with KOH, NaOH and 90% H_2SO_4, and forms azeotropes with water, MeOH, EtOH, and acetic acid. It is purified by washing successively with 2M HCl, water and 2M K_2CO_3, then dried with K_2CO_3 and $CaCl_2$, then fractionally distilled before use. It has also been steam distilled from 10% $Ca(OH)_2$ slurry, most of the water being removed from the distillate by cooling to -30° to -50° and filtering off the ice through chamois skin: the trichloroethylene is then fractionally distilled at 250mm pressure and collected in a blackened container. **ANAESTHETIC, TOXIC VAPOURS.** [Carlisle & Levine *Ind Eng Chem (Anal Ed)* **24** 1164 *1932*, DOI: 10.1021/ie50274a019; *Beilstein* **1** IV 712.]

1,1,2-Trichloro-1,2,2-trifluoroethane *[76-13-1]* **$C_2Cl_3F_3$, M 187.4, b 47.6°/760mm, d_4^{20} 1.576, n_D^{20} 1.360.** Wash it with water, then with weak alkali. Dry it with $CaCl_2$ or H_2SO_4 and distil it. [Locke et al. *J Am Chem Soc* **56** 1726 *1934*, DOI: 10.1021/ja01323a023; *Beilstein* **1** III 157, **1** IV 142.]

Tridecanoic acid *[638-53-9]* **$C_{13}H_{26}O_2$, M 214.4, m 41.8°, 44.5-45.5° (several forms), b 199-200°/24mm, 236°/100mm, pK_{Est} ~5.0.** Recrystallise the acid from acetone or distil it in a vacuum. [*Beilstein* **2** IV 1117.] The ***methyl ester [1731-88-0]*** **$C_{14}H_{24}O_2$, M 228.4** has **m 5.5°, b 131°/4mm.** [*Beilstein* **2** IV 1118.]

7-Tridecanone (dihexyl ketone) *[462-18-0]* **$C_{13}H_{26}O$, M 198.4, m 33°, b 255°/766mm, 264°/atm.** Crystallise the ketone from EtOH. [*Beilstein* **1** H 715.]

Tri-*n*-dodecylamine (Hydrogen ionophore I) *[102-87-4]* **$C_{36}H_{75}N$, M 522.0, m 15.7°, b 220-228°/0.03mm, d_4^{20} 0.833, n_D^{20} 1.4577, pK_{Est} ~11.0.** Distil tridodecylamine under high vacuum and N_2, and store it in the absence of CO_2. It can be recrystallised from 95%EtOH/*C_6H_6 at low temperature under vacuum. The ***hydrochloride*** has **m 78-79°**. [Ra et al. *J Org Chem* **09** 259 *1944*, DOI: 10.1021/jo01185a009; *Beilstein* **4** III 413, **4** IV 801.]

Tri-*n*-dodecylammonium nitrate *[2305-34-2]* **$C_{36}H_{75}N.HNO_3$, M 585.0.** Crystallise the salt from *n*-hexane/acetone (95:5) and keep it in a desiccator over P_2O_5 under vacuum. [*Beilstein* **4** IV 801 for tridodecylamine.]

Tri-*n*-dodecylammonium perchlorate *[5838-82-4]* **$C_{36}H_{75}N.HClO_4$, M 622.4.** Recrystallise the salt from *n*-hexane or acetone and keep it in a desiccator over P_2O_5. (Potentially explosive.)

Triethanolamine (2,2',2"-nitriloethanol) *[102-71-6]* **$C_6H_{15}NO_3$, M 149.2, m 20-22°, b 190-103°/5mm, 206-207°/15mm, 335.4°/760mm, d_4^{20} 1.124, n_D^{20} 1.485, pK^{25} 7.92.** Shake the amine gently with Linde type 4A molecular sieves for 24 hours, filter and fractionate it under a vacuum, and preferably in the presence of N_2. Store it in dark stoppered bottles under N_2 as it is *hygroscopic*, and turns brown in air and light. It has a strong ammoniacal odour (like diethanolamine). It is miscible with H_2O, MeOH and Me_2CO and its solubilities at 25° in *n*-heptane, Et_2O and *C_6H_6 are 0.4%, 1.6% and 4.2%, respectively. [See diethanolamine above, *Beilstein* **4** IV 1524.]

Triethanolamine hydrochloride *[637-39-8]* **$C_6H_{15}NO_3$.HCl, M 185.7, m 177°, 177-179°, pK^{25} 7.92 (free base).** Crystallise the salt from EtOH. Dry it at 80°. [*Beilstein* **4** IV 1525.]

1,1,2-Triethoxyethane *[4819-77-6]* **$C_8H_{18}NO_3$, M 162.2, b 74°/28mm, 164°/~760mm, 167.2°/760mm, d_4^{20} 0.897, n_D^{20} 1.401.** Dry it with Na_2SO_4, and distil it. [McElvain & Walters *J Am Chem Soc* **64** 1963 *1942*, DOI: 10.1021/ja01260a060; *Beilstein* **1** H 818, **1** I 418, **1** III 3184, **1** IV 3958.]

Triethylamine *[121-44-8]* **$C_6H_{15}N$, M 101.2, m -115°, b 88.8°/atm, 89.4°/atm, d_4^{20} 0.7280, n_D^{20} 1.4005, pK^{25} 10.82.** Dry triethylamine with $CaSO_4$, $LiAlH_4$, Linde type 4A molecular sieves, CaH_2, KOH, or K_2CO_3, then distil it, either alone or from BaO, sodium, P_2O_5 or CaH_2. It has also been distilled from zinc dust, under nitrogen. To remove traces of primary and secondary amines, triethylamine has been refluxed with acetic anhydride, benzoic anhydride, phthalic anhydride, then distilled, refluxed with CaH_2 (ammonia-free) or KOH (or dried with activated alumina), and again distilled. Another purification method involved refluxing for 2 hours with *p*-toluenesulfonyl chloride, then distilling. Grovenstein and Williams [*J Am Chem Soc* **83** 412 1961, DOI: 10.1021/ja01463a039] treated triethylamine (500ml) with benzoyl chloride (30ml), filtered off the precipitate, and refluxed the liquid for 1 hour with a further volume of benzoyl chloride (30ml). After cooling, the liquid was filtered, distilled, and allowed to stand for several hours with KOH pellets. It was then refluxed with, and distilled from, stirred molten potassium. Triethylamine has been converted to its *hydrochloride* (see below), crystallised from EtOH (to **m 254°**), then liberated with storng aqueous NaOH, dried with solid KOH and distilled from sodium under N_2. It is a strong base and should not be inhaled. [*Beilstein* **4** H 99, **4** I 348, **4** II 593, **4** III 194, **4** IV 322.]

Triethylammonium bromide *[636-70-4]* **$C_6H_{15}N.HBr$, M 229.1, m 248°.** Equimolar portions of triethylamine and aqueous solutions of HBr in acetone are mixed with cooling. The precipitated salt is washed with anhydrous acetone and dried in a vacuum for 1-2 hours. [Odinokov et al. *JCS Faraday Trans 2* **80** 899 *1984*, DOI: 10.1039/F29848000899.] Recrystallise it from $CHCl_3$ or EtOH. [*Beilstein* **4** IV 322.]

Triethylammonium chloride *[554-68-7]* **$C_6H_{15}N$. HCl, M 137.7, m 257-260°(dec), 261°(dec).** Purify it like the bromide above. [*Beilstein* **4** IV 327.]

Triethylammonium iodide *[4636-73-1]* **$C_6H_{15}N$. HI, M 229.1, m 181°.** Purify it as for triethylammonium bromide, except the solution for precipitation should be precooled in acetone at -10°, and the precipitate is twice recrystallised from a cooled acetone/hexane mixture at -10°. Store it in the dark. [*Beilstein* **4** IV 327.]

Triethylammonium trichloroacetate *[4113-06-8]* **$C_6H_{15}N$. $C_2Cl_3O_2H$, M 263.6.** Equimolar solutions of triethylamine and trichloroacetic acid in *n*-hexane are mixed at 10°. The solid so obtained is recrystallised from $CHCl_3$/*benzene. [Hoigné & Gäumann *Helv Chim Acta* **42** 437 *1959*, DOI: 10.1002/hlca.19590420206; *Beilstein* **4** IV 330.]

Triethylammonium trifluoroacetate *[454-49-9]* **$C_6H_{15}N$. $C_2F_3O_2H$, M 196.2.** Purify as for the corresponding trichloroacetate but in Et_2O. Evaporation of the Et_2O gives the salt as a colourless viscous liquid at ambient temperature. [Emmons et al. *J Am Chem Soc* **76** 3472 *1954*, DOI: 10.1021/ja01642a031; *Beilstein* **4** IV 330.]

Triethylene glycol *[112-27-6]* **$C_6H_{14}O_4$, M 150.2, m -7°, b 125-127°/0.1mm, 165°/14mm, 278°/760mm, d_4^{15} 1.1274, n_D^{15} 1.4578.** Dry the glycol with $CaSO_4$ for 1 week, then it is repeatedly and very slowly fractionally distilled under a vacuum. Store it in a vacuum desiccator over P_2O_5. It is very *hygroscopic*. [Matignon et al. *Bull Chem Soc Fr* **1** [5] 1308 *1934*, *Beilstein* **1** IV 2400.]

Triethylene glycol dimethyl ether (triglyme) $C_8H_{18}O_4$, *[112-49-2]* **M 178.2, m -45°, b 20°/0.9mm, 103.5°/10mm, 216°/atm, 225°, d_4^{20} 0.987, n_D^{20} 1.425.** Reflux it with, and distil it from sodium hydride or $LiAlH_4$. [*Beilstein* **1** IV 2401.]

Triethylenetetramine (TRIEN, TETA, trientine, $H_2NCH_2CH_2NHCH_2CH_2NHCH_2CH_2NHCH_2CH_2NH_2$) *[112-24-3]* **$C_6H_{18}N_4$, M 146.2, m 12°, b 157°/20mm, 266-267°/atm, d_4^{20} 0.971, n_D^{20} 1.497, pK_1^{25} 3.32, pK_2^{25} 6.67, pK_3^{25} 9.20, pK_4^{25} 9.92.** Dry the amine with sodium, then distil it under a vacuum. Further purification has been *via* the nitrate or the chloride salts. For example, Jonassen and Strickland [*J Am Chem Soc* **80** 312 *1958*, DOI: 10.1021/ja01535a015] separated TRIEN from admixture with TREN (38%) by solution in EtOH, cooling to approximately 5° in an ice-bath and adding concentrated HCl dropwise from a burette, keeping the temperature below 10°, until all of the white crystalline precipitate of TREN.HCl (see below) had formed and was removed. Further addition of HCl then precipitated thick, creamy white TRIEN.HCl (see following entry) which was crystallised several times from hot water by adding an excess of cold EtOH. The crystals were finally washed with Me_2CO, then Et_2O and dried in a vacuum desiccator. The ***hydrate*** *[305808-21-3, xH_2O]* has **m 45-48°, b 272°/atm.** [*Beilstein* **4** H 255, **4** II 695, **4** III 542, **4** IV 1242.]

Triethylenetetramine tetrahydrochloride (TRIEN HCl) *[4961-10-4]* **$C_6H_{18}N_4$. 4HCl, M 292.1, m 266-270°, 269-270°.** Crystallise the salt repeatedly from hot water by precipitation with cold EtOH or EtOH/HCl. Wash it with acetone and absolute EtOH and dry it in a vacuum oven at 80° (see TRIEN above). The ***tetrabenzoyl*** derivative has **m 230°** after recrystallisation from boiling EtOH. [Peacock *J Chem Soc* 1518 *1936*, DOI: 10.1039/JR9360001518; *Beilstein* **4** H 255, **4** II 695, **4** III 543.]

Triethyl orthoformate (ethyl orthoformate, 1,1,1-triethoxymethane) *[122-51-0]* **$C_7H_{16}N_3$, M 148.2, m -76°, b 60°/30mm, 144-146°/760mm, d_4^{20} 0.891, n_D^{20} 1.392.** Fractionate it first at atmospheric pressure, then in a vacuum. If impure, then shake it with aqueous 2% NaOH, dry it with solid KOH and distil it from sodium through a 20cm Vigreux column. *Alternatively*, wash it with H_2O, dry it over anhydrous K_2CO_3, filter and fractionate it through a Widmer column. [Sah & Ma *J Am Chem Soc* **54** 2964 *1932*, DOI: 10.1021/ja01346a048; Ohme & Schmitz *Justus Liebigs Ann Chem* **716** 207 *1968*, DOI: 10.1002/jlac.19687160130; *Beilstein* **2** IV 25.] **IRRITANT** and **FLAMMABLE**.

Triethyloxonium tetrafluoroborate *[368-39-8]* **$C_6H_{15}O$. BF_4, M 190.0, m 92-93°(dec).** Crystallise it from

diethyl ether. It is *very hygroscopic*, and must be handled in a dry box and stored at 0°. [Meerwein *Org Synth* Coll Vol **5** 1096 *1973*, DOI: 10.15227/orgsyn.046.0120.] Pure material should give a clear and colourless solution in dichloromethane (1 in 50, w/v is a 0.1M solution available commercially). [*Beilstein* **1** IV 1322.]

Trifluoroacetic acid (TFA) *[76-05-1]* **$C_2HF_3O_2$, M 114.0, m -15.5°, b 72.4°/atm, d_4^{20} 1.494, n_D^{20} 1.2850, pK^{25} 0.52.** Although an improved preparation of the acid (in 87% yield) involving the oxidation of 2,3-dichloro-1,1,1,4,4,4-hexafluorobut-2-ene (b 65-66°/745mm, [303-04-8], steam volatile, **d_4^{25} 1.605, n_D^{20} 1.3458)** *via* oxidation with $KMnO_4$/KOH/95°/8-10 hours has been reported [Henne & Trott *J Am Chem Soc* **69** 1820 *1947*, DOI: 10.1021/ja01199a076], the next purification procedure should be avoided. The purification of trifluoroacetic acid, reported in earlier editions of this work, by refluxing over $KMnO_4$ for 24 hours and slowly distilling has resulted in very **SERIOUS EXPLOSIONS** on various occasions, but not always. This apparently depends on the source and/or age of the acid. The method is **NOT RECOMMENDED**. It forms an azeotropic mixture of acid and H_2O (80:20) which boils at 103-105°/745mm. Water can be removed by adding trifluoroacetic anhydride (0.05%, to diminish water content) and distilling. [Conway & Novak *J Phys Chem* **81** 1459 *1977*, DOI: 10.1021/j100530a006]. It can be refluxed and distilled from P_2O_5, but do not use an excess of P_2O_5 as it produces the anhydride (see below and Schmidt & Staub *Chem Ber* **87** 388 *1954*, DOI:10.1002/cber.19540870317) which can be separated by fractional distillation because the anhydride distils about 30° lower than the acid at atmospheric pressure. It is further purified by fractional crystallisation by partial freezing and again distilled. It is a strong acid and attacks skin (wear gloves) and eyes (wear safety glasses). It is soluble in H_2O and most organic solvents. **Highly TOXIC vapour — do not inhale it. Work in an efficient fume hood.** [Roepke *Biotechnol Forum Eur* **7** 161 *1990*, *Beilstein* **2** II 186, **2** III 426, **2** IV 458.]

Trifluoroacetic anhydride (TFAA) *[407-25-0]* **$C_4F_6O_3$, M 210.0, m -65°, b 38-40°/760mm, d_4^{20} 1.508.** Purification by distilling over $KMnO_4$, as for the acid above, is **EXTREMELY DANGEROUS** due to the possiblility of **EXPLOSION** (see preceding acid). It is best purified by distilling from P_2O_5 slowly, and collecting the fraction boiling at 39.5°. Store it in a dry atmosphere. It is soluble in most organic solvents, but reacts with protic solvents. **Highly TOXIC vapour and attacks skin, work in an efficient fume hood — see previous entry. [**Tedder *Chem Rev* **55** 787.*1955*, DOI: 10.1021/cr50005a001; *Beilstein* **2** II 186, **2** III 427, **2** IV 469.]

1,1,1-Trifluoroacetone *[421-50-1]* **$C_3H_3F_3O$, M 112.1, b 21°/atm, 22°/atm, d_4^{25} 1.252, n_D^{20} 1.3.** The ketone was obtained by refluxing ethyl 4,4,4-trifluoroacetoacetate (see [372-31-6]) for 2 hours with 10% aqueous H_2SO_4 and collecting the distillate into a receiver containing P_2O_5, and redistilling it from P_2O_5. The ***2,4-dinitrophenylhydrazone*** has **m 139°** [Henne et al. *J Am Chem Soc* **69** 1820 1947, DOI: 10.1021/ja01199a076] synthesis in a few steps [Huguenot & Brigaud *J Org Chem* **71** 7075 *2006*, DOI: 10.1021/jo0607717]. It has also been used to synthesise 2-trifluoromethyl-7-azaindoles from 2,6-dihalopyridines [Schirok et al. *Synthesis* 251 *2007*,DOI: 10.1055/s-2006-958935].

2,2,2-Trifluoroethanol *[75-89-8]* **$C_2H_3F_3O$, M 100.0, m −44°, b 72.4°/738mm, 77-80°/atm, n_D^{20} 1.30, d_4^{20} 1.400, pK^{25} 12.8.** Dry it with $CaSO_4$ and a little $NaHCO_3$ (to remove traces of acid) and distil it. It is used as a calibration standard for NMR spectroscopy. **Highly TOXIC vapour. [***Beilstein* **1** IV 1370.]

Trifluoromethanesulfonic anhydride (triflic anhydride) *[358-23-6]* **$C_2F_6O_5S_2$, M 282.1, b 82-85°/atm, 84°/atm, d_4^{20} 1.71, n_D^{20} 1.322.** Distil it through a short Vigreux column. It can be freshly prepared from the anhydrous acid (11.5g) and P_2O_5 (11.5g, or half this weight) by setting aside at room temperature for 1 hour, distilling off volatile products then distil it through a short Vigreux column. It is readily hydrolysed by H_2O and decomposes appreciably after a few days to liberate SO_2 and produce a viscous liquid. Store it dry at low temperatures. [Burdon et al. *J Chem Soc* 2574 *1957*, DOI: 10.1039/JR9570002574; Beard et al. *J Org Chem* **38** 3673 *1973*, DOI: 10.1021/jo00961a003; *Beilstein* **3** IV 35.] **Highly TOXIC vapour.**

1,1,1-Trifluoro-2,4-pentanedione (α,α,α-trifluoroacetlyacetone, tfacac or facac) *[367-57-7]* **$C_5H_5F_3O_2$, M 154.1, b 105-107°/atm, 107°/760mm, d_4^{25} 1.27, n_D^{20} 1.3890.** The diketone was prepared from ethyl trifluoroacetate (74.5g) and Na wire (10g, or an equivalent of NaOEt) in Et_2O (5ml) at 0°, by adding Me_2CO (80ml) at a rate to maintain a steady reaction, kept at 0° for 2 hours, and then allowed to warm to room tempera-

ture. Ice-water (5ml) was added, the aqueous layer was acidified with AcOH, and the Cu complex was precipitated with a warm saturated solution of $Cu(OAc)_2$. The ***copper trifluoroacetylacetone*** crystallised in long blue needles from EtOH and had **m 189°**; its UV has λ_{max} at 240nm (ε 19,500) and 294nm (ε 31,000) in EtOH, and the effect of fluorine substitution on the complexing properties has been studied in detail by Calvin and coworkers [Belford et al. *J Inorg Nucl Chem* **2** 11 *1956,* DOI: 10.1016/0022-1902(56)80100-0].
An ethereal mixture of the complex (partly dissolved) was shaken with 2N H_2SO_4, then H_2O, the organic layer was separated, dried (Na_2SO_4), filtered and distilled to give a 62% yield of ***trifluoroacetylacetone***. *Alternatively*, the metal can be removed by bubbling H_2S through the ethereal mixture, the CuS was filtered off and the filtrate was distilled. [Reid & Calvin *J Am Chem Soc* **72** 2948 *1950*, DOI: 10.1021/ja01163a038; Henne et al. *J Am Chem Soc* **69** 1819 *1947*, DOI: 10.1021/ja01199a076; Haszeldine et al. *J Chem Soc* 609 *1951*, DOI: 10.1039/JR9510000609; Belford et al. *J Inorg Nucl Chem* **2** 11 *1956*, DOI:10.1016/0022-1902(56)80100-0].
Its UV has λ_{max} at 284nm (ε 10,500) in $CHCl_3$; the FT-IR (film) has ν_{max} at 1604.7, 1422.3, 1369.5, 1282.2, 1154.7, 887.4, 857.4, 795.2, 726.4 cm^{-1}; and the ^1H NMR (300MHz, $CDCl_3$, TMS) has δ at 2.36 (s), 4.60 (s, 3H, CH_3), 8.30 (s, CH); and the ^{13}C NMR (75MHz, $CDCl_3$, TMS) has δ at 193.47, 176.71, 176.22, 175.74, 175.25, 127.75, 119.00, 115.25, 111.50, 96.37, 96.35, 24.83. It enolises in aqueous solution, and rates of enolisation were determined by Ried and Calvin (*vide infra*) in H_2O, 0.1N and 0.5N HCl, and in aqueous EtOH of varying concentrations; and are temperature dependent. Thus at equilibrium, at 0.08-0.09M solution of *tfacac* and 25°, 16% aqueous EtOH contains 2.5% of enol+enolate, whereas at 95% it contains 20.7% of enol+enolate. This enolisation should be taken into account when measuring spectra and other physical parameters.
Complexation with Cu, Fe and Al can be used to extract the metals from aqueous medium (acetate buffered) by a 0.10M of the diketone in $CHCl_3$ [Scribner et al. *Anal Chem* **37** 1136 *1965*, DOI: 10.1021/ac60228a017], and Be into organic solvents [Scribner et al. *Anal Chem* **38** 1779 1966, DOI: 10.1021/ac60244a041]. The *oxime*, **m 86-87°**, crystallises from H_2O or aqueous EtOH. [*Beilstein* **1** III 3123, **1** IV 3680.]

Trimethylamine *[75-50-3]* **C_3H_9N, M 59.1, m –117°, b 3.5°/atm, pK^{25} 9.80.** Dry triethylamine by passing the gas through a tower filled with solid KOH. Water and impurities containing labile hydrogen were removed by treatment with freshly sublimed, ground, P_2O_5. It has been refluxed with acetic anhydride, and then distilled through a tube packed with HgO and BaO. [Comyns *J Chem Soc* 1557 *1955,* DOI: 10.1039/JR9550001557.] For more extensive purification, trimethylamine is converted to the hydrochloride, crystallised (see below), and regenerated by treating the hydrochloride with excess aqueous 50% KOH; the gas is passed through a $CaSO_4$ column into a steel cylinder containing sodium ribbon. After 1-2 days, the cylinder is cooled to -78° and hydrogen and air are removed by pumping. [Day & Felsing *J Am Chem Soc* **72** 1698 *1950*, DOI: 10.1021/ja01160a077.] Me_3N has been distilled using trap-to-trap methods and degassed by freeze-pump-thaw [Halpern et al. *J Am Chem Soc* **108** 3907 *1986*, DOI: 10.1021/ja00274a009]. It is commercially available under pressure in tin cylinders. It is available commercially as a ~ 4.2M (31-35 wt%) in EtOH, and as ~25 w% and ~45 w% solutions in H_2O. [Adams & Brown, *Org Synth* Coll Vol **I** 528 *1941*, DOI: 10.15227/orgsyn.001.0075; *Beilstein* **4** H 43, **4** I 322, **4** II 553, **4** III 99, **4** IV 134.]

Trimethylamine hydrochloride *[593-81-7]* **C_3H_9N. HCl, M 95.7, m >280°(dec), 283-284°(dec).** The salt crystallises from $CHCl_3$, EtOH or *n*-propanol, and is dried under vacuum. It also crystallises from *benzene/MeOH, MeOH/diethyl ether and is dried under vacuum over paraffin wax and H_2SO_4. It is kept over P_2O_5 as it is *hygroscopic*. [*Beilstein* **4** H 262, **4** I 419, **4** IV 138.]

Trimethylamine hydroiodide *[20230-89-1]* **C_3H_9N. HI, M 186.0, m 263°.** It crystallises from MeOH.

Trimethylolpropane (1,1,1-tris-hydroxymethylpropane, 2-ethyl-2-hydroxymethyl-1,3-propanediol) *[77-99-6]* **$C_6H_{11}O_3$, M 134.2, m 57-59°, 60-62°, b 159-161°/2mm.** Crystallise it from acetone and ether, and it distils at high vacuum. [*Beilstein* **1** III 2349, **1** IV 2786.]

2,2,3-Trimethylpentane *[564-02-3]* **C_8H_{18}, M 114.2, b 109.8°/atm, d_4^{20} 0.7161, n_D^{20} 1.40295, n_D^{25} 1.40064.** Purify it by azeotropic distillation with 2-methoxyethanol, which is subsequently washed out with water. The trimethylpentane is then dried and fractionally distilled. [Forziati et al. *J Res Nat Bur Stand* **36** 129 *1946*, DOI:org/10.6028/jres.036.005; *Beilstein* **1** IV 439.]

2,2,4-Trimethylpentane (isooctane) *[540-84-1]* **C_8H_{18}, M 114.2, m -107°, b 99.2°/atm, d_4^{20} 0.693, n_D^{20} 1.39145, n_D^{25} 1.38898.** Distil isooctane from sodium, pass it through a column of silica gel or activated alumina (to remove traces of olefins), and again distilled from sodium. Extract it repeatedly with concentrated H_2SO_4, then agitate it with aqueous $KMnO_4$, wash it with water, dry ($CaSO_4$) and distil it. Purify it also by azeotropic distillation with EtOH, which is subsequently washed out with water, and the trimethylpentane is dried and fractionally distilled. [Forziati et al. *J Res Nat Bur Stand* **36** 129 *1946*, DOI: org/10.6028/jres.036.005.] [*Beilstein* **1** IV 439.]

2,4,4-Trimethylpent-2-ene (β-diisobutylene) *[107-40-4]* **C_8H_{16}, M 112.2, m -106°, b 104°/atm, d_4^{20} 0.720, n_D^{20} 1.4160.** Fractionate it under N_2 as it is highly flammable. [*Beilstein* **1** III 848, **1** IV 891.]

Trimethylsulfonium iodide *[2181-42-2]* **C_3H_9S. I, M 204.1, m 211-212.5°(dec), 215-220°(dec).** Crystallise the iodide from EtOH. [Emeleus & Heal *J Chem Soc* 1126 *1946*, DOI: 10.1039/JR9460001126; Swain & Kaiser *J Am Chem Soc* **80** 4089 *1958*, DOI: 10.1021/ja01548a067; Borredon et al. *J Org Chem* **55** 501 *1990*, DOI: 10.1021/jo00289a022; Bouda et al. *Synth Commun* **17** 503 *1987*, DOI: 10.1080/00397918708056436; *Beilstein* **1** IV 1280.]

Trimyristin [glyceryl trimyristate, glyceryl tri(tetradecanoate)] *[555-45-3]* **$C_{45}H_{86}O_6$, M 723.2, m 56.5°, 56-57°, d^{60} 0.885.** Crystallise it from diethyl ether. [*Beilstein* **2** IV 1135.]

Tri-*n*-octylamine *[1116-76-3]* **$C_{24}H_{51}N$, M 353.7, b 164-168°/0.7mm, 365-367°/760mm, d_4^{20} 0.813, n_D^{20} 1.450, pK^{25} 10.65.** It is converted to the amine hydrochloride etherate which is recrystallised four times from diethyl ether at -30° (see below). Neutralisation of this salt regenerates the free amine which distil under high vacuum. [Wilson & Wogman *J Phys Chem* **66** 1552 *1962*, DOI: 10.1021/j100814a513.] Distil the strong base amine at <1-2mm pressure. [*Beilstein* **4** H 196, **4** III 382, **4** IV 754.]
Tri-n-octylammonium chloride *[1188-95-0]* **$C_{24}H_{51}N$. HCl, M 384.2, m 78-79°, pK^{25} 8.35 (in 70% aqueous EtOH).** Crystallise it from Et_2O, then *n*-hexane (see above). [Borrows et al. *J Chem Soc* 197 *1947*, DOI: 10.1039/JR9470000197; *Beilstein* **4** H 196.]

Tri-*n*-octylammonium perchlorate *[2861-99-6]]* **$C_{24}H_{51}N$. $HClO_4$, M 454.2, m >300°(dec).** Crystallise the perchlorate from *n*-hexane. (Possibly explosive.) [*Beilstein* **4** IV 754.]

Tripalmitin [glyceryl tripalmitate, glyceryl tri(hexadecanoate)] *[555-44-2]* **$C_{51}H_{98}O_6$, M 807.4, m 66.4°.** Crystallise it from acetone, diethyl ether or EtOH. It exists in an α-form (**m 56.0°**), a β'-form (**m 63.5°**) and a β-form (**m 65.5°**). [*Beilstein* **2** H 373, **2** I 167, **2** II 340, **2** III 971, **2** IV 1176.]

Tri-*n*-propylamine *[102-69-2]* **$C_9H_{21}N$, M 143.3, m -93.5°, b 40-42°/11mm, 155-158°/atm, 156.5°, d_4^{20} 0.757, n_D^{20} 1.419, pK^{25} 10.66.** Dry the amine with KOH and fractionally distil it. Also reflux it with toluene-*p*-sulfonyl chloride and with KOH, then fractionally distil it. The distillate, after additon of 2% phenyl isocyanate, was redistilled and the residue fractionally distilled from sodium. It is a strong base. [Takahashi et al. *J Org Chem* **52** 2666 *1987*, DOI: 10.1021/jo00389a007; *Beilstein* **4** IV 470.]

Tris(2-aminoethyl)amine (TREN) $C_6H_{18}N$, *[4097-89-6]* **M 146.2, b 114°/15mm, 263°/744mm, d_4^{20} 0.977, n_D^{20} 1.498, pK_1^{25} 8.42, pK_2^{25} 9.44, pK_3^{25} 10.13.** For a separation from a mixture containing 62% TRIEN, see entry under triethylenetetramine [112-24-3] above. Also purify it by conversion to the hydrochloride (see below), recrystallise it and regenerate the free base [Xie & Hendrickson *J Am Chem Soc* **109** 6981 *1987*, DOI: 10.1021/ja00257a013].

Tris(2-aminoethyl)amine trihydrochloride (TREN.HCl) *[14350-52-8]* **$C_6H_{18}N$. HCl, M 255.7, m 300°(dec).** Crystallise the salt several times by dissolving it in the minimum of hot water and precipitating it with excess of cold EtOH. The precipitate is washed with acetone, then diethyl ether and dried in a vacuum desiccator. [*Beilstein* **4** H 256, **4** II 695, **4** III 545, **4** IV 1250.]

Tris(dimethylamino)methane (*N,N,N',N',N",N"*-hexamethylmethanetriamine) *[5762-56-1]* **$C_7H_{19}N_3$, M**

145.3, b 42-43°/12mm, n_D^{20} 1.4349, pK_{Est} ~ 10. Dry it over KOH and distil it through a Vigreux column at water pump vacuum. Store it in the absence of CO_2. [Bredereck et al. *Chem Ber* **101** 1885 *1968*, DOI: 10.1002/cber.19681010541; and *Angew Chem Int Ed* **5** 132 *1966*, DOI: 10.1002/anie.196601321.]

1,1,1-Tris(hydroxymethyl)ethane (2-hydroxymethyl-2-methyl-1,3-propanediol) *[77-85-0]* **$C_5H_{12}NO_3$, M 120.2, m 193-195°, 200°.** Dissolve it in hot tetrahydrofuran, filter and precipitate it with hexane. It has also been crystallised from acetone/water (1:1). Dry it in a vacuum. [*Beilstein* **1** H 520, **1** IV 2780.]

Tris(hydroxymethyl)methylamine (TRIS, tris(hydroxymethyl)aminomethane, Trizma, trometamol) *[77-86-1]* **$C_4H_{11}NO_3$, M 121.1, m 172°, b 219-220°/10mm, pK^{25} 8.07.** TRIS can ordinarily be obtained in highly pure form suitable sources for use as an acidimetric standard. If only impure material is available, it should be crystallised from 20% EtOH, aqueous MeOH (**m** 171.1°) or isopropanol (**m** 172-173°). Dry it in a vacuum desiccator over P_2O_5 or $CaCl_2$. Its solubility in H_2O at 20° is 80% w/v, and the pH of a 0.1 M in H_2O is 10.36. *Alternatively*, it is dissolved in twice its weight of water at 55-60°, filtered, concentrated to half its volume and poured slowly, with stirring, into about twice its volume of EtOH. The crystals which separate on cooling to 3-4° are filtered off, washed with a little MeOH, air dried by suction, then finally ground and dried in a vacuum desiccator over P_2O_5. It has also been recrystallised from water, MeOH or aqueous MeOH, and vacuum dried at 80° for 2 days. The ***amidosulfate [NH_2SO_3H] salt*** has **m 103.5°**. [*Beilstein* **4** H 303, **4** III 857, **4** IV 1903.]
Tris(hydroxymethyl)methylammonium hydrochloride **(TRIS-HCl)** *[1185-53-1]* **$C_4H_{11}NO_3$. HCl, M 157.6, m 149-150°(dec).** Crystallise the salt from 50% EtOH, then from 70% EtOH. TRIS-hydrochloride is also available commercially in a highly pure state. Otherwise, recrystallise it from 50% EtOH, then 70% EtOH, and dry it below 40° to avoid risk of decomposition. [*Beilstein* **4** H 304.]

***N*-Tris(hydroxymethyl)methyl-2-aminomethanesulfonic acid (TES)** **$C_6H_5NO_6S$** *[7365-44-8]* **M 229.3, m 224-226°(dec), 231°(dec), pK^{37} 7.14, pK^{20} 7.50, pK^{0} 7.92.** Crystallise the acid from hot EtOH containing a little water. It is a useful buffer.

Tris(hydroxymethyl)nitromethane [2-(hydroxymethyl)-2-nitro-1,3-propanediol] *[126-11-4]* **$C_4H_9NO_5$, M 151.1, m 160°(dec), 174-175°(dec, tech. grade), 214°(pure).** Crystallise it from $CHCl_3$/ethyl acetate or ethyl acetate/*benzene. It is an acid and a 0.1M solution in H_2O has pH 4.5. **IRRITANT.** [*Beilstein* **1** H 520, **1** IV 2777.]

Tris[2-(methylamino)ethyl]amine *[65604-89-9]* **$C_9H_{24}N_4$, M 188.3, b 77-78°/0.1mm, d_4^{20} 0.896, $pK_{Est(1)}$ ~8.8, $pK_{Est(2)}$ ~9.4, $pK_{Est(3)}$ ~10.4.** If this strong base contains carbonate (check IR) it should be shaken with solid KOH, decanted and distilled at high vaccum to give a colourless oil with a strong amine odour. Store it in the dark under N_2 as it absorbs CO_2 in moist air. It is synthesised in two steps. Ethyl chloroformate (33.4g, 310mmol, lachrymatory, see [541-41-3]) is added dropwise to a mixture of TREN (29.2g, 200mmol, see [4097-89-6]) in *C_6H_6 (225ml) and H_2O (100ml), and cooled to 5°. Then a solution of KOH (36.4g, 650mmol) in H_2O (35ml) is added simultaneously with more ethyl chloroformate (33.4g, 310mmol), with stirring, while keeping the reaction mixture below 5° for 2 hours followed, still with stirring, by 8 hours at ~25°. The *C_6H_6 layer is separated, the aqueous layer is extracted with $CHCl_3$ (3 x 100ml), the combined organic layers are dried ($MgSO_4$), filtered and the filtrate is evaporated to leave *tris[2-(ethoxycarbonylamino)ethyl]amine* (~85%) as a thick oil which is used directly in the subsequent step. [The crude tri-ester has IR (film) bands with ν_{max} at 3300, 1720, 1530, and 1250 cm^{-1}; and the ^1H NMR (300MHz, $CDCl_3$, TMS) has δ at 1.27 (t, 9H, $^3J_{HH}$ = 7.1Hz), 2.60 (t, 6H, $^3J_{HH}$ = 5.7 Hz), 3.23 (br s, 6H), 4.10 (q, 6H, $^3J_{HH}$ = 7.1 Hz) and 5.50 (br s, 3H)].
In the second step the preceding crude tri-ester (61.3g, 170mmol) in THF (250ml) is added dropwise to a suspension of $LiAlH_4$ (30.0g, 790mmol) in THF (700ml), and the reaction mixture is refluxed overnight. Water (50ml), followed by a solution of KOH (50g) in H_2O (50ml) are very carefully added to it (cool if necessary), the solvent is decanted from the inorganic gel, evaporated *in vacuo*, and the residual yellow oil is fractionated in a vacuum to give the desired ***amine*** in 88% yield. It has ^1H NMR (300MHz, $CDCl_3$, TMS) with δ at 1.30 (br s, 3H, NH), 2.39 (s, 9H, CH_3), 2.48 (m, 6H, $^3J_{HH}$ = 6.1 Hz, $3CH_2$) and 2.52 (m, 6H, $^3J_{HH}$ = 6.1 Hz, $3CH_2$); the ^{13}C NMR (75MHz, $CDCl_3$, TMS) has δ at 54.1 (CH_2), 49.6 (CH_2) and 36.3 (CH_3); and HRMS has *m/z* 189.2082 (calc for M + H is 189.20793). [Schmidt et al. *Z Anorg Allg Chem* **578** 75 *1989*, DOI: 10.1002/zaac.19895780109.]

Triuret (1,3-dicarbamoylurea, carbonyldiurea) *[556-99-0]* **$C_3H_6N_4O_3$, M 146.1, m 233°(dec).** It crystallises from aqueous ammonia or H_2O (plates **m 232-234°**), and is soluble in liquid NH_3. It gives mono and dipotassium salts. [Haworth & Mann *J Chem Soc* 603 *1943*, DOI: 10.1039/JR9430000603; *Beilstein* **3** H 72, **3** I 35, **3** II 60, **3** III 142.]

Undecan-1-ol *[112-42-5]* **$C_{11}H_{24}O$, M 172.3, m 11°, 16.5°, 146°/30mm, d^{25} 0.830, n_D^{20} 1.440.** Purify the alcohol by repeated fractional crystallisation from its melt or by distillation in a vacuum. [*Beilstein* **1** H 427, **1** IV 1835.]

1,11-Undecanedicarboxylic acid (Brassylic acid, 1,13-tridecanedicarboxylic acid) *[505-52-2]* **$C_{13}H_{24}O_4$, M 244.3, m 103-107°, 113°, 112-114°, pK_{Est} ~5.0.** The dicarboxylic acid was prepared by Mislow and Steinberg from azelaic acid (see above) → 1,9-nonadiol (92.4%) →1,9-dibromononane (89.7%) → 1,9(bis-diethylmalonyl)nonane → 1,9-bis(carboxy)nonane (= 1,11-undecanedioic acid, 80%). Brassylic acid is purified by recrystallisation from $^*C_6H_6$, aqueous EtOH, EtOAc or 50% EtOH/CCl_4. The ***diethyl ester***, prepared in the usual way (76.6%), has **m 20°, b 162-163°/1.3mm, 204°/12mm, n_D^{25} 1.4408**. The ***monomethyl ester*** *[3927-59-1]* **$C_{14}H_{26}O_4$, M 258.3,** has **m 58°,** and the ***dimethyl ester*** *[1472-87-3]* **$C_{15}H_{28}O_4$, M 272.3,** has **m 32°(36°), 32.3°, b 192-194°/11mm, 326-328°/atm.** The ***diamide***, prepared from the acid *via* $SOCl_2$ then 25% NH_4OH, has **m 177°** (white fine needles from EtOH). [Chuit *Helv Chim Acta* **9** 264 *1926*, DOI: 10.1002/hlca.19260090131; Potter & Taylor *J Chem Soc* 3514 *1951*, within Note pp 3508-3514, DOI: 10.1039/JR9510003508; Mislow & Steinberg *J Am Chem Soc* **77** 3807 *1955*, DOI: 10.1021/ja01619a038; for synthesis from methylene-bis-dihydroresorcinol and conversion to the diamide see Stetter & Dietrichs *Chem Ber* **85** 290 *1952*, DOI: 10.1002/cber.19520850405; *Beilstein* **2** H 731.]

Undecanoic acid (C11, undecylic acid, hendecanoic acid) *[112-37-8]* **$C_{11}H_{22}O_2$, M 186.3, m 28.5°, b 164°/18mm, 228°/160mm, 248-250°/~760mm, d_4^{20} 0.8907, n_D^{25} 1.4294, pK_{Est} ~5.0.** Purify the acid by repeated fractional crystallisation from its melt or by distillation in a vacuum. [*Beilstein* **2** H 358, **2** IV 1068.]

Undec-10-enoic acid (undecylenic acid) *[112-38-9]* **$C_{11}H_{20}O_2$, M 184.3, m 24.5°, 25-25.5°, b 131°/1mm, 137°/2mm, 168°/15mm, 275°(dec)/atm, d_4^{20} 0.912, n_D^{25} 1.447, pK_{Est} ~5.0.** Purify the acid by repeated fractional crystallisation from its melt or by distillation preferably in a high vacuum as it decomposes at atmospheric pressure. It was originally isolated from castor oil by destructive distillation and gave **ω-bromo-undecylic acid** (**m 50.5°, 51°,** by recrystallisation from petroleum ether). The ***methyl ester*** has **b 124°/10mm, 148°/atm, n_D^{20} 1.43928.** The ***Zinc salt*** [557-08-4], prepared by dissolving ZnO in dilute undecylenic acid in MeOH and evaporated giving a white powder with **m ~115-116°**, and is sold commercially as a topical fungicide (Fungex). [Das et al. *J Am Oil Chem Soc* **66** 938 *1989*, DOI: 10.1007/BF02682613; Perkin & Cruz *J Am Chem Soc* **49** 1070 *1927*, DOI: 10.1021/ja01403a030; *Beilstein* **2** IV 1612.]

Urea (carbamide) *[57-13-6]* **CH_4N_2O, M 60.1, m 132.7-132.9°, 132-135°, pK^{25} 0.12.** Crystallise urea twice from conductivity water using centrifugal drainage and keeping the temperature below 60°. The crystals are dried under vacuum at 55° for 6 hours. Levy and Margoulas [*J Am Chem Soc* **84** 1345 *1962*, DOI: 10.1021/ja00867a003] prepared a 9M solution in conductivity water (keeping the temperature below 25°) and, after filtering through a medium-porosity glass sinter, added an equal volume of absolute EtOH. The mixture was set aside at -27° for 2-3 days and filtered cold. The precipitate was washed with a small amount of EtOH and dried in air. Crystallisation from 70% EtOH between 40° and -9° has also been used. Ionic impurities such as ammonium isocyanate have been removed by treating the concentrated aqueous solution at 50° with Amberlite MB-1 cation- and anion-exchange resin, and allowing it to crystallise on evaporation. [Benesch et al. *J Biol Chem* **216** 663 *1955*, PMID: 13271343, http://www.jbc.org/content/216/2/663.citation.] It can also be crystallised from MeOH or EtOH, and is dried under vacuum at room temperature. [*Beilstein* **3** H 42, **3** I 19, **3** II 35, **3** III 80, **3** IV 94.]

Urea nitrate *[124-47-0]* **$CH_3N_3O_4$, M 123.1, m 152°(dec), 157-158°, 163°.** Crystallise it from dilute HNO_3 or EtOH (**m** 157-158°), and dry it in a vacuum over P_2O_5. Its solubility (w/w%) in H_2O is 9.3 (at 0°) and 40 (at 65.3°); and in EtOH is 1.35 (at 0°) and 8.8 (at 65.3°). May **EXPLODE** if shocked or heated. [*Beilstein* **3** H 54,

3 I 25, **3** II 45, **3** III 105, **3** IV 94.]

Urethane (ethyl carbamate, ethyl urethane) *[51-79-6]* **$C_3H_7NO_2$, M 89.1, m 48-50°, b 182-184°/~760mm, d_4^{20} 0.986, n_D^{25} 1.4144.** Urethane is best purified by fractional distillation, but it can be sublimed at ~103°/~50mm. It has also been recrystallised from *benzene. Its solubilitiy at room temperature is 2g/ml in H_2O, 1.25g/ml in EtOH, 1.1g/ml in $CHCl_3$, 0.67g/ml in Et_2O and 0.03g/ml in olive oil. It is a suspected **human carcinogen**. [*Beilstein* **3** H 22, **3** IV 40.]

***cis*-Vaccenic acid (octadec-11-enoic acid)** *[506-17-2]* **$C_{18}H_{34}O_2$, M 282.5, m 14-15°, b 158-163°/0.4mm, d_4^{20} 0.880, n_D^{25} 1.4598, pK_{Est} ~ 4.9.** Purify the acid by fractional distillation under high vacuum or crystallisation form its melt in an inert atmosphere away from light. [*Beilstein* **2** I 198, **2** III 1384, **2** IV 1639.]

trans*-Vaccenic acid (octadec-11-enoic acid)** *[693-72-1]* **$C_{18}H_{34}O_2$, M 282.5, m 43-44°, n_D^{50} 1.4472, pK_{Est} ~ 4.9.** Crystallise the acid from acetone (**m** 45-45.5°) or aqueous MeOH (**m** 43.5-43.7°). The ***methyl ester **$C_{19}H_{36}O_2$** has **b 174-175°/5mm**. [Böeseken et al. *Recl Trav Chim Pays-Bas* **46** 619 *1927*, DOI: 10.1002/recl.19270460902; Ahmad et al. *J Am Chem Soc* **70** 3391 *1948*, DOI: 10.1021/ja01190a051; IR: Rao & Daubert *J Am Chem Soc* **70** 1102 *1948*, DOI: 10.1021/ja01183a069.]

n*-Valeraldehyde (pentanal)** *[110-62-3]* **$C_5H_{10}O$, M 86.1, m -92°, b 103°/atm, d_4^{20} 0.811, n_D^{25} 1.40233.** Purify pentanal *via* the bisulfite derivative (see 2-butanone above for the preparation and decomposition of the bisulfite derivative). [Birrell & Trotman-Dickenson *J Chem Soc* 2059 *1960*, DOI: 10.1039/JR9600002059; *Beilstein* **1** H 676, **1** IV 3268.] The ***2,4-dinitrophenylhydrazone [2057-84-3] **M** 266.3 has **m 103-105°** (from EtOH). [*Beilstein* **15** III/IV 429.]

***n*-Valeramide (pentanamide)** *[626-97-1]* **$C_5H_{11}NO$, M 101.1, m 115-116°.** Crystallise the amide from EtOH. It sublimes at 80°. [Philbrook *J Org Chem* **19** 623 *1954*, DOI: 10.1021/jo01369a022; *Beilstein* **2** H 301, 2 I 131, **2** II 266, **2** III 674, **2** IV 874.]

Valeric acid (*n*-pentanoic acid) *[109-52-4]* **$C_5H_{10}O_2$, M 102.1, m -20° to -18°, b 95°/22mm, 186.4°/~760mm, d_4^{20} 0.938, n_D^{20} 1.4080, pK^{25} 4.81.** Water is removed from the acid by distillation using a Vigreux column, until the boiling point reaches 183°. A few crystals of $KMnO_4$ are added, and after refluxing, the distillation is continued. [Andrews & Keefer *J Am Chem Soc* **83** 3708 *1961*, DOI: 10.1021/ja01478a032; *Beilstein* **2** H 299, 2 I 130, **2** II 263, **2** III 663, **2** IV 868.] The ***ethyl ester*** *[539-82-2]* **$C_7H_{14}O_2$, M 130.2,** has **b 145-146°/atm, d_4^{20} 0.877,** and **n_D^{20} 1.401.** It is used as a substrate for assaying the activities of some esterases, and as an intermediate in the preparation of perfumes. [*Beilstein* **2** IV 872.]

Valeronitrile (butyl cyanide) *[110-59-8]* **C_5H_9N, M 83.1, m -96°, b 45-47°/15mm, 142.3°/~760mm, d_4^{20} 0.799, n_D^{15} 1.39913, n_D^{30} 1.39037.** Wash the nitrile with half its volume of concentrated HCl (twice), then with saturated aqueous $NaHCO_3$, dry it with $MgSO_4$ and fractionally distil it from P_2O_5. [*Beilstein* **2** H 301, **2** I 131, **2** II 267, **2** III 675, **2** IV 875.]

Vinyl acetate *[108-05-4]* **$C_4H_6O_2$, M 86.1, m -93°, b 72.3°/atm, d_4^{20} 0.938, n_D^{20} 1.396.** Inhibitors such as hydroquinone and other impurities are removed by drying with $CaCl_2$ and fractionally distilling under nitrogen, then refluxing briefly with a small amount of benzoyl peroxide and redistilling it under nitrogen. Store it in the dark at 0°. Add inhibitor (~0.004%) for storage. [*Beilstein* **2** IV 176.]

Vinyl butoxyethyl ether (ethylene glycol butyl vinyl ether) *[4223-11-4]* **$C_8H_{16}O_2$, M 144.2, b 70-72°/20mm, d_4^{20} 0.866, n_D^{20} 1.4220.** Wash this ether with aqueous 1% NaOH, dry with CaH_2, then reflux with, and distil it from sodium. Stabilise it with 0.5% of 2,6-di-*tert*-butyl-*p*-cresol for storage. [*Beilstein* **1** IV 2387.] **IRRITANT.**

Vinyl chloroformate *[5130-24-5]* **$C_3H_3ClO_2$, M 106.5, b 46.5°/80mm, 67-69°/atm, 109-110°/760mm, d_4^{20} 1.136, n_D^{21} 1.420**. It has been fractionated through a Todd column (Model A with ~60 plates) under atmospheric pressure and the purity can be checked by gas chromatography. Stabilise it with 0.5% of 2,6-di-*tert*-butyl-*p*-

cresol. It has IR with ν_{max} at 3100 + 2870 (CH_2), 1780 (C=O), 1640 (C=C) and 940 (CH_2 out-of-plane) and 910 (CH_2 wagging) cm^{-1}. [IR: Lee *J Org Chem* **30** 3943 *1965*, DOI: 10.1021/jo01022a511; Levaillant *Ann Chim (Paris)* **6** 504 *1936*.] It is used for protecting NH_2 groups in peptide synthesis [Olofson et al. *Tetrahedron Lett* 1563 *1977*, DOI:10.1016/S0040-4039(01)93103-X]. [*Beilstein* **3** III 28.]

Vinyl stearate *[111-63-7]* **$C_{20}H_{38}O_2$, M 310.5, m 35°, 35-36°, b 166°/1.5mm, 167°/2mm, 187-188°/4.3mm, d_4^{40} 0.8517, n_D^{40} 1.4423.** Distil the ester in a vacuum under nitrogen, then crystallise it from acetone (3ml/g) or ethyl acetate at 0°. Store it under nitrogen in the dark. When polymerised with a small amount of benzoyl peroxide, a white wax-like polymer was formed. [Swern & Jordan *J Am Chem Soc* **70** 2334 *1948*, DOI: 10.1021/ja01187a008; Swern & Jordan *Org Synth* **30** 106 *1950*, DOI: 10.15227/orgsyn.030.0106; *Beilstein* **2** III 1019.]

ALICYCLIC COMPOUNDS

Abietic acid *[514-10-3]* **$C_{20}H_{30}O_2$, M 302.5, m 172-175°, $[\alpha]_D^{25}$ -116 (-106°)(c 1, EtOH), pK^{25} 5.27.** Crystallise it by dissolving 100g of acid in 95% EtOH (700ml), adding to H_2O (600ml) and cooling. Filter, dry it in a vacuum (over KOH or $CaSO_4$) and store it in an O_2-free atmosphere. It can also be purified *via* the anhydride, tritylabietate and the potassium, piperidine and brucine salts. It has λ_{max} : nm(log ε): 2343(4.3), 241(4.4), 2505(4.2), 235(4.34) and 240(4.36) in EtOH. [Harris & Sanderson *Org Synth* Coll Vol **4** 1 *1963*, DOI: 10.15227/orgsyn.032.0001; Lambard & Frey *Bull Soc Chim Fr* 1194 *1948*, Buchbauer et al. *Monatsh Chem* **116** 1345 *1985*, DOI: 10.1007/ BF00811105.] [*Beilstein* **9** IV 2175.]

***S*-Abscisic acid (natural; 2-*cis*-4-*trans*-5*S*-abscisic acid, Dormin)** *[S(+) 21293-29-8]* **$C_{15}H_{20}O_4$, M 264.3, m 160-161°, 161-163° (sublimation), $[\alpha]_D^{20}$ +411 (1, EtOH), $[\alpha]_{287}$ +24,000, $[\alpha]_{245}$ -69,000 (c 1-50μg/ml in acidified MeOH or EtOH), pK_{Est} ~3.9.** Crystallise the acid from CCl_4/petroleum ether, EtOH/hexane and sublime it at 120°. Also purify it by dissolving ~30g in 30ml of EtOAc, adding 100ml of hexane and allow to crystallise overnight (yield 8.4g), **m 156-158°, 161-163°, $[\alpha]_D^{20}$ +426 (c 1, 0.005M H_2SO_4 in MeOH).** [Cornforth et al. *Nature (London)* **206** 715 *1965*, DOI:10.1038/206715a0; Soukup et al. *Helv Chem Acta* **72** 361 *1989*, DOI: 10.1002/hlca.19890720222.] The **non-natural 2-*cis*-4-*trans*-5*R*-abscisic acid** *[R(-) 14398-53-9]* has **m 162-163°, $[\alpha]_D^{20}$ -426 (c 1, 0.005*N* H_2SO_4). Racemic 2-*cis*-4-*trans*-5*RS*-abscisic acid** *[RS(±) 14375-45-2]* was purified on a Kieselgel F_{254} plate with toluene/EtOAc/AcOH (50:50:3) and has **m 188-190°** [Cornforth et al. *Aust J Chem* **45** 179 *1992*, DOI: 10.1071/CH9920179]. [Absolute configuration: Ryback *JCS Chem Commun* 1190 *1972*, DOI: 10.1039/C39720001190.] [*Beilstein* **17/3** V 13.]

Acetylcyclohexane (cyclohexyl methylketone) *[823-76-7]* **$C_8H_{14}O$, M 126.2, b 64°/11mm, 76.2-77°/25mm, d_4^{20} 0.9178, n_D^{20} 1.4519.** Dissolve acetylcyclohexane in Et_2O, shake it with H_2O, dry, evaporate and fractionate it under reduced pressure. [UV: Mariella & Raube *J Am Chem Soc* **74** 518 *1952*, DOI: 10.1021/ja01122a069; enol content: Gero *J Org Chem* **19** 1960 *1954*, DOI: 10.1021/jo01377a013.] The ***semicarbazone*** has **m 174°** and the ***2,4-dinitrophenylhydrazone*** has **m 139-140°** [Theus & Schinz *Helv Chem Acta* **39** 1290 *1956*, DOI: 10.1002/hlca.19560390516].

2-Acetylcyclohexanone *[874-23-7]* **$C_8H_{12}O_2$, M 140.2, m -11°, b 62-64°/2.5mm, 95-98°/10mm, 111-112°/18mm, d_4^{20} 1.08, n_D^{20} 1.51.** Dissolve it in ligroin (b 30-60°), wash it with saturated aqueous $NaHCO_3$, dry over Drierite and fractionate in a vacuum. [Perfett & Levine *J Am Chem Soc* **75** 626 *1953*, DOI: 10.1021/ja01099a031; Manyik et al. *J Am Chem Soc* **75** 5030 *1953*, DOI: 10.1021/ja01116a042; Eistert & Reiss *Chem Ber* **87** 108 *1954*, DOI: 10.1002/cber.19540870116.] It forms a ***Cu salt*** which crystallises in green leaflets from EtOH, **m 162-163°** [UV: McEntee & Pinder *J Chem Soc* 4419 *1957*, DOI: 10.1039/JR9570004419]. [*Beilstein* **7** IV 1997.]

2-Acetylcyclopentanone *[1670-46-8]* **$C_7H_{10}O_2$, M 126.2, b. 72-75°/8mm, 82-86°/12mm, 88°/18mm, d_4^{20} 1.043, n_D^{20} 1.490.** Dissolve the ketone in petroleum ether (b 30-60°), wash it with saturated aqueous $NaHCO_3$, dry over Drierite and fractionate in a vacuum. It gives a violet colour with ethanolic $FeCl_3$ and is only slowly hydrolysed by 10% aqueous KOH, but rapidly on boiling to yield 6-oxoheptanoic acid. [Manyik et al. *J Am Chem Soc* **75** 5030 *1953*, DOI: 10.1021/ja01116a042; Acheson *J Chem Soc* 4232 *1956*, DOI: 10.1039/JR9560004232; UV: Martin & Fernelius *J Am Chem Soc* **81** 2342 *1959*, DOI: 10.1021/ja01519a017.] It gives a grey green ***Cu salt*** from Et_2O/pentane, **m 237-238°** [House & Wasson *J Am Chem Soc* **79** 1488 *1957*, DOI: 10.1021/ja01563a058]. [*Beilstein* **7** IV 1993.]

2-Acetyl-5,5-dimethylcyclohexane-1,3-dione (2-acetyldimedone) *[1755-15-3]* **$C_{10}H_{14}O_3$, M 182.2, m 36°, 36-40°, b 132-133°/20mm, 138°/23mm, pK ~4.5.** It can be purified by fractional distillation. *Alternatively*, convert it into the insoluble Cu salt in H_2O and recrystallise it from EtOH, **m ~260°**. The Cu salt is decomposed with N H_2SO_4, extracted into Et_2O, dried (Na_2SO_4), evaporated and distilled in a vacuum. The residual oil, which solidifies on cooling can be recrystallised from AcOH. It gives a red colour with Fe^{3+} ions. The ***oxime*** has **m 115°**(dec, from EtOH), and with concentrated NH_3 it forms the ***mono-imide*** which crystallises from H_2O

in needles with **m 133°**. Its UV in EtOH has $\lambda_{max}(\varepsilon)$ 231(10,620) and 273(10,800)nm. It is used as a protecting group for primary amines. [Dieckmann & Stein *Chem Ber* **37** 3370 *1904*, DOI: 10.1002/cber.190403703147; Birch *J Chem Soc* 3026 *1951*, DOI: 10.1039/JR9510003026; Crossley & Renouf *J Chem Soc* **101** 1524 *1912,* DOI: 10.1039/CT9120101524; Nash et al. *Tetrahedron Lett* **37** 2625 *1996*, DOI: 10.1016/0040-4039(96)00344-9; Kellam et al. *Tetrahedron Lett* **38** 4849 *1997*, DOI: 10.1016/S0040-4039(97)01010-1; *Beilstein* **7** H 860, **7** I 471, **7** IV 2756.]

4-Acetyl-1-methyl-1-cyclohexene *[6090-09-1]* **$C_9H_{14}O$, M 138.2, b 73-75°/7.5mm, 85-86°/13mm, 94-94.7°/20mm, 204.5-206°/747mm, d_4^{20} 1.0238, n_D^{20} 1.469.** Purify it by fractionation under reduced pressure *in vacuo*, and if it is almost pure it can be fractionated at atmospheric pressure, preferably in an inert atmosphere. It forms two ***semicarbazones*** one of which is more soluble in $*C_6H_6$, and both can be recrystallised from EtOH; the more soluble has **m 149°(151°)**, and the less soluble has **m 172-175°(191°)**. The ***4-nitrophenylhydrazone*** has **m** 166-167° and the ***2,4-dinitrophenylhydrazone*** has **m 114-115°**. [Pfau & Plattner *Helv Chem Acta* **17** 129, 142 *1934*, DOI: 10.1002/hlca.19340170118; Adler & Vogt *Justus Liebigs Ann Chem* **564** 109 *1949*, DOI: 10.1002/jlac.19495640204.]

2-Acetyl-1-methyl-3,5-dioxo-1-methylcyclohexanecarboxylic acid (ADCC-linker) *[181486-37-3]* **$C_{10}H_{12}O_5$, M 212.2, m 95-99°, pK_{est} ~4.5.** It is prepared from 3,5-dioxo-1-methylcyclohexane-1-carboxylic acid methyl ester (obtained from 3,5-dimethoxybenzoic acid [119-52-8] *via* Birch reduction, methylation with MeI and treatment with aqueous HCl) by acetylation to 3-acetoxy-5-oxo-1-methylcyclohex-3,4-ene-1-carboxylic acid methyl ester, rearrangement (heating with DMAP) to 4-acetyl-3,5-dioxo-1-methylcyclohexane carboxylic acid methyl ester (93% yield) followed by hydrolysis (LiOH/THF/MeOH/H_2O) and H^+ ion-exchange purification to give the ADCC-linker as a crystalline solid. It should be stored at ~5°. After attaching to a solid support through the carboxy function (e.g. to amino-modified polystyrene beads), it is used for linking to primary amines (including α-amino-acid esters) *via* enamine formation of the 4-acetyl group for combinatorial synthesis. The linker is stable to acids such as CF_3CO_2H, bases such as piperidine or BTU, and uronium type coupling agents; and by treatment with 2% hydrazine in DMF, the primary amine is released quantitatively from the support. Its ^1H NMR (250MHz, Me_2SO) has δ at 1.25 (s, Me-C1(1)), 2.50 (s, MeCO-C(4)), 2.50-3.00 (m, 2H-C(3), 2H-C(5)), 17.80 (2H, enol OH and COOH). [Bannwarth et al. *Bioorg Med Chem Lett* **6** 1525 *1966*, DOI: 10.1016/S0960-894X(96)00258-2.]

Adamantane (tricyclo[3.3.1.$1^{3,7}$]-decane) *[281-23-2]* **$C_{10}H_{16}$, M 136.2, m 269.6-270.8° (sublimes).** Crystallise adamantane from acetone or cyclohexane, and sublime it in a vacuum below its melting point [et al. *JCS Faraday Trans 2* **82** 535 *1986*, DOI: 10.1039/F29868200535]. Adamantane is also purified by dissolving it in *n*-heptane (*ca* 10ml/g of adamantane) on a hot plate, adding activated charcoal (2g/100g of adamantane), and boiling for 30 minutes, filtering the hot solution through a filter paper, concentrating the filtrate until crystallisation just starts, adding one quarter of the original volume of *n*-heptane, and allowing to cool slowly over a period of hours. The supernatant is decanted off and the crystals are dried *in vacuo* at 25°. [Prelog & Seiwerth *Chem Ber* **74** 1769 *1941*, DOI: 10.1002/cber.19410741110; Schleyer et al. *Org Synth* Coll Vol **5** 16 *1973*, DOI: 10.15227/orgsyn.042.0008; Walter et al. *J Am Chem Soc* **107** 793 *1985*, DOI: 10.1021/ja00290a010.] [*Beilstein* **5** III 393, **5** IV 469.]

1-Adamantane acetic acid *[4942-47-6]* **$C_{12}H_{18}O_2$, M 194.3, m 136°, pK_{Est} ~4.8.** Dissolve the acid in hot N NaOH, treat with charcoal, filter and acidify. Collect the solid, wash it with H_2O, dry and recrystallise it from MeOH. [Stetter et al. *Chem Ber* **92** 1629 *1959*, DOI: 10.1002/cber.19590920722.] The ***acid chloride*** [2094-72-6] has **M 168.7, m 51-54°,** and **b 135-136°**/1mm. [*Beilstein* **9** IV 256.] **LACHRYMATORY.**

1-Adamantane carboxylic acid *[828-51-3]* **$C_{11}H_{16}O_2$, M 180.3, m 175-176.5°, 177°, pK_{Est} ~4.9.** Possible impurities are trimethylacetic acid and C9 and C13 acids. Dissolve 15g of the acid in CCl_4 (300ml) and shake with 110ml of 15N aqueous NH_3 whereby the ammonium salt separates and is collected. Acid impurities form soluble ammonium salts. The salt is washed with cold Me_2CO (20ml) and suspended in H_2O (250mL). This is treated with 12N HCl and extracted with $CHCl_3$ (100ml). The dried (Na_2SO_4) extract is evaporated and the residue is recrystallised from a mixture of MeOH (30ml) and H_2O (*ca* 10ml) to give the pure acid (10-11g). [Koch & Haaf *Org Synth* Coll Vol **5** 20 *1973*, DOI: 10.15227/orgsyn.044.0001.] It was also recrystallised from

absolute EtOH and dried under vacuum at 100°. *Alternatively*, the acid (5g) is refluxed for 2 hours with 15ml of MeOH and 2ml of 98% H_2SO_4 (cool when mixing this solution). Pour into 10 volumes of H_2O and extract with the minimum volume of $CHCl_3$ to give clear separation of phases. The extract is washed with H_2O, dried ($CaCl_2$) and distilled. The ***methyl ester*** is collected at 77-79°/1mm, **m 38-39°**. The ester is hydrolysed with the calculated amount of N KOH and refluxed until clear. Acidification with HCl provides the pure acid with 90% recovery. The ***amide*** *[5511-18-3]* **$C_{11}H_{17}NO$, M 179.3,** crystallises from cyclohexane, and has **m 189-190°**. [Stetter et al. *Chem Ber* **92** 1629 *1959*, DOI: 10.1002/cber.19590920722.] [*Beilstein* **9** IV 253.]

1,3-Adamantane diamine dihydrochloride *[26562-81-2]* **M 239.2, m >310°, $pK_{Est(1)}$ ~8.1, $pK_{Est(2)}$ ~10.1.** Dissolve it in boiling concentrated HCl (400mg in 15ml) and evaporate to dryness. Dissolve it in absolute EtOH and add dry Et_2O to crystallise the *dihydrochloride*. [Stetter & Wulff *Chem Ber* **93** 1366 *1960*, DOI: 10.1002/cber.19600930619; *Beilstein* **13** III 27,]

1,3-Adamantane dicarboxylic acid *[39269-10-8]* **$C_{12}H_{16}O_4$, M 224.3, m 276°, 276-278°, 279°, $pK_{Est(1)}$ ~4.9. $pK_{Est(2)}$ ~5.9.** Dissolve the acid in aqueous NaOH, treat with charcoal, filter and acidify with dilute HCl. It crystallises from MeOH. [Stetter & Wulff *Chem Ber* **93** 1366 *1960*, DOI: 10.1002/cber.19600930619; *Beilstein* **9** III 4066, **9** IV 2997.]

1-Adamantane methylamine *[17768-41-1]* **$C_{11}H_{19}N$, M 165.3, b 83-85°/0.3mm, d_4^{20} 0.935, pK_{Est} ~10.2.** Dissolve the amine in Et_2O, dry over KOH and distil it. The ***N-Tosyl*** derivative has **m 134-135°** (from EtOH). [Stetter & Goebel *Chem Ber* **96** 550 *1963*, DOI: 10.1002/cber.19630960228.]

1-Adamantanol (1-hydroxyadamantane) *[768-95-6]* **$C_{10}H_{16}O$, M 152.4, m 288.5-290°.** If 2-adamantanol is a suspected impurity, then dissolve the substance (10g) in acetone (100ml) and add Jones's reagent [CrO_3 (10.3g) in H_2O (30ml)], then concentrated H_2SO_4 (8.7ml) is added dropwise (turns green in colour) until excess reagent is present (slight red colour). Stir overnight, decant the acetone solution from the Cr salts and adamantan-2-one, dry (Na_2SO_4) and evaporate to dryness. The residue (*ca* 7g) is chromatographed through Al_2O_3 (250g) and washed with 50% *benzene/petroleum ether (b 40-60°), then 100% Et_2O (to remove any adamantan-2-one present) and the 1-adamantanol is then eluted with 5% MeOH in Et_2O. The eluate is evaporated, and the residue is recrystallised from petroleum ether (b 30-60°) at -70°, **m 287.2-288.5°**. It also crystallises from MeOH and can be sublimed *in vacuo*. It has characteristic IR, with ν_{max} at 3640, 1114, 1086, 982 and 930 cm^{-1}. [Schleyer & Nicholas *J Am Chem Soc* **83** 182 *1961*, DOI: 10.1021/ja01462a036.] [*Beilstein* 6 IV 391.] *Alternatively*, if free from the 2-isomer, dissolve it in tetrahydrofuran, and dilute with H_2O to precipitate the alcohol. Collect, dry and sublime it in a vacuum at 130°. [Stetter et al. *Chem Ber* **92** 1629 *1959*, DOI: 10.1002/cber.19590920722.]

2-Adamantanol (2-hydroxyadamantane) *[700-57-2]* **$C_{10}H_{16}O$, M 152.4, m 296-299°, 296.2-297.7°.** Best obtained by reduction of adamantanone (30.0g) in Et_2O (300ml) and $LiAlH_4$ (7.3g,) in Et_2O (150ml) at ~25° for 2hrs, decomposed in the usual way, and extracted into CH_2Cl_2 to give the adamantan-2-ol (30g). It can be purified by chromatography as for the 1-isomer. It crystallises from cyclohexane and has characteristic IR with ν_{max} at 3600, 1053, 1029 and 992 cm^{-1} [Schleyer & Nicholas *J Am Chem Soc* **83** 182 *1961*, DOI: 10.1021/ja01462a036].

2-Adamantanone *[700-58-3]* **$C_{10}H_{14}O$, M 150.2, m 256-258°(sublimes).** Purify 2-admantanone by repeated sublimation *in vacuo*. [Butler et al. *JCS Faraday Trans 2* **82** 535 *1986*, DOI: 10.1039/F29868200535.]

***N*-(1-Adamantyl)acetamide** *[880-52-4]* **$C_{12}H_{19}NO$, M 193.3, m 149°.** Wash the amide well with H_2O, dry and recrystallise it from cyclohexane. *It is an* **irritant.** [Stetter et al. *Chem Ber* **92** 1629 *1959*, DOI: 10.1002/cber.19590920722.]

1-Adamantylamine (1-adamantanamine, Amantadine) *[768-94-5]* **$C_{10}H_{17}N$, M 151.2, m 160-190° (sealed tube), 180-192°, 208-210°, pK^{25} 10.58.** Dissolve the amine in Et_2O, dry it over KOH, evaporate and sublime it *in vacuo*. [Stetter et al. *Chem Ber* **93** 226 *1960*, DOI: 10.1002/cber.19600930133.] It is physiologically active (see next entry).

1-Adamantylamine hydrochloride (Amantadine hydrochloride, Amazolone, Mantadan, Mantadix, Virofral) *[665-66-7]* **$C_{10}H_{17}N$. HCl, M 187.7, m >360° (dec), pK^{25} 10.58.** Dissolve the salt in dry EtOH, add a few drops of dry EtOH saturated with HCl gas, followed by dry Et_2O to crystallise the hydrochloride out. Dry the salt in a vacuum. Its solubility in H_2O is >5%; and it is soluble in EtOH but insoluble Et_2O. [Stetter et al. *Chem Ber* **93** 226 *1960*, DOI: 10.1002/cber.19600930133.] It is an antiviral, and an anti-Parkinsonian agent [Kornhuber et al. *J Neural Transm* **46** (Suppl) 399 *1995*].

2-Adamantylamine hydrochloride *[10523-68-9]* **$C_{10}H_{17}N$. HCl, M 187.7, m >300°, pK_{Est} ~10.4.** The ***free amine*** in Et_2O, liberated by the action of alkali in H_2O, is dried over KOH, filtered, evaporated and sublimed at 110°/12torr, **m 230-236°**. The base is dissolved in EtOH, sufficient ethanolic HCl is added dropwise and crystallised by the addition of Et_2O. Dry it *in vacuo*. [Stetter et al. *Justus Liebigs Ann Chem* **658** 151 *1962*, DOI: 10.1002/jlac.19626580113].

1-Adamantyl bromide *[768-90-1]* **$C_{10}H_{15}Br$, M 215.1, m 117-119°, 118°, 119.5-120°.** If coloured, dissolve it in CCl_4, wash with H_2O, treat with charcoal, dry ($CaCl_2$), filter and evaporate to dryness. Dissolve the residue in a small volume of MeOH and cool in a CO_2/trichloroethylene bath and collect the crystals. Sublime it at 90-100°/water pump vacuum. [Stetter et al. *Chem Ber* **92** 1629 *1959*, DOI: 10.1002/cber.19590920722; Schleyer & Nicholas *J Am Chem Soc* **83** 2700 *1961*, DOI: 10.1021/ja01473a024; *Beilstein* **5** IV 469.] ***2-Adamantyl bromide*** *[7314-85-4]* **$C_{10}H_{15}Br$, M 215.1,** has **m 138-140°.** Purify as for the 1-isomer.

1-Adamantyl bromomethylketone *[5122-82-7]* **$C_{12}H_{17}BrO$, M 257.2, m 76-79°, 78-79°.** Dissolve the ketone in Et_2O, wash it with H_2O, dry ($MgSO_4$), evaporate and crystallise the residue from small volumes of MeOH. **LACHRYMATORY.** [Stetter & Rauscher *Chem Ber* **93** 2054 *1960*, DOI: 10.1002/cber.19600930922.] Also recrystallise it from aqueous MeOH and sublime it at 100°/12torr. It crystallises from MeOH at -70°. Do not keep in contact with MeOH for too long. [Stetter et al. *Chem Ber* **92** 1629 *1959*, DOI: 10.1002/cber.19590920722.]

1-Adamantyl chloride *[935-56-8]* **$C_{10}H_{15}Cl$, M 170.7, m 164.3-165.6°.** It has been prepared by refluxing 1-acetamidoadamantane (3g, m 148° from dry cyclohexane, and obtained by hydrolysis of 1-cyanoadamantane with H_2SO_4) in concentrated HCl (100ml) for 2 hours during which time some 1-chloroadamantane sublimed in the condenser. 1-chloroadamantane was collected (on evaporation and addition of H_2O), recrystallised from aqueous MeOH, and sublimed to provide pure 1-adamantyl chloride (3.3g, 98%), **m 165°**. [Stetter et al. *Chem Ber* **92** 1269 *1959*, DOI: 10.1002/cber.19590920722; Schleyer & Nicholas *J Am Chem Soc* **83** 2700 *1961*, DOI: 10.1021/ja01473a024; *Beilstein* **5** IV 469.]

1-Adamantyl chloroformate *[5854-52-4]* **$C_{11}H_{15}ClO_2$, M 214.6, m 46-47°.** Crystallise it from petroleum ether (b 30-60°) at -20°. Also purify it as for 1-adamantyl fluoroformate below. Its IR has ν_{max} at 4.2, 5.6 and 8.4μ (2380, 1786 and 1190 cm^{-1}). [Haas et al. *J Am Chem Soc* **88** 1988 *1966*, DOI: 10.1021/ja00961a024; cf. Moroder et al. *Hoppe-Seyler's Z Physiol Chem* **357** 1647 *1976*.]

***RS*-1-(1-Adamantyl)ethylamine hydrochloride (Rimantadine hydrochloride, Flumadine, Roflual)** *[1501-84-4]* **$C_{12}H_{21}N$. HCl, M 215.8, m >300° , 373-375°(sealed tube), pK_{Est} ~10.4.** It is prepared by adding the oxime of 1-adamantyl methyl ketone (6 parts, see [1660-04-4] below) in dry THF (200 parts) to a cold suspension of excess of $LiAlH_4$ in Et_2O, refluxing for 1 hour, decomposing with cold brine, making strongly alkaline and extracting thoroughly with Et_2O. The dried (Na_2CO_3) extract, is filtered, concentrated, and saturated with dry HCl. The hydrochloride (~5.25 parts) is collected, dried and recrystallised as for 2-adamantylamine hydrochloride above. [US patent to du Pont de Nemours 1069563 (1969, Brit amended), *Chem Abstr* **75** 140372w *1971*.] It is an antiviral agent [Burkinskaya et al. *J Gen Virol* **60** 49 *1982*, DOI: 10.1099/0022-1317-60-1-49].

1-Adamantyl fluoride (1-fluoroadamantane) *[768-92-3]* **$C_{10}H_{15}F$, M 154.2, m 210-212°(dec, sealed tube), 259-260°(dec).** Dissolve it in Et_2O, dry over Na_2SO_4, evaporate to dryness and sublime the residue at 90-100°/12mm. Recrystallise the sublimate from MeOH, **m 259-260°**. To remove 1-hydroxyadamantane impurity, dissolve it in cyclohexane, cool for many hours, filter off the hydroxyadamantane, and evaporate to dryness, or

by passage through an Al_2O_5 column in dry cyclohexane. Recrystallise the residue from petroleum ether at -77° and sublime it in vacuum, **m 210-212°dec** (sealed tube). [Bhandari & Pinock *Synthesis* 655 *1974*, DOI: 10.1055/s-1974-23391; NMR: Fort et al. *J Org Chem* **30** 789 *1965*, DOI: 10.1021/jo01014a033.]

1-Adamantyl fluoroformate *[62087-82-5]* **$C_{11}H_{15}FO_2$, M 198.2, m 31-32°.** Dissolve it in *n*-hexane (*ca* 10g in 150 ml) and keep at 0° for 24 hours. Any 1-adamantanol present will separate. Filter and evaporate to dryness. The crystalline residue has **m 31-32°** and is recrystallised from *n*-hexane (90g/500ml), (IR (KBr): ν_{max} 1242, 1824 and 2340 cm^{-1}). There should be no OH str band above 2500 cm^{-1}. [Moroder et al. *Hoppe-Seyler's Z Physiol Chem* **357** 1647 *1976*, cf. Haas et al. *J Am Chem Soc* **88** 1988 *1966*, DOI: 10.1021/ja00961a024.]

1-Adamantyl iodide (1-iodoadamantane) *[768-93-4]* **$C_{10}H_{15}I$, M 262.1, m 75.3-76.4°.** The iodide was prepared by heating 1-adamantanol (5g) in 47% hydroiodic acid (75ml) in a sealed glass tube at 100°/1hr, then poured into H_2O and extracted with Et_2O, shaken with aqueous $NaHSO_3$, aqueous K_2CO_3, and H_2O, dried (Na_2SO_4), evaporated and recrystallised from MeOH at -70° (to avoid alcoholysis) to give white crystals of the iodide (3.56g) **m 75.3-76.4°**. [Schleyer & Nicholas *J Am Chem Soc* **83** 2700 *1961*, DOI: 10.1021/ja01473a024; Literature **m** of **151-152.5°** (Landa & Hála *Coll Czech Chem Commun* **24** 93 *1959*, DOI: 10.1135/cccc19590093) is incorrect.] Also purify by recrystallisation from petroleum ether (40-60°C) followed by rigorous drying and repeated sublimation. [*Beilstein* **5** IV 470.]

1-Adamantyl isocyanate *[4411-25-0]* **$C_{11}H_{15}NO$, M 177.3, m 144-145°.** Recrystallise the isocyanate from *n*-hexane and sublime it. **Irritant.** [Stetter & Wulff *Chem Ber* **95** 2302 *1962*, DOI: 10.1002/cber.19620950932.]

1-Adamantyl isothiocyanate *[4411-26-1]* **$C_{11}H_{15}NS$, M 193.3, m 168-169°.** Dissolve it in Et_2O, wash with H_2O, dry (Na_2SO_4), evaporate and sublime the residue in a vacuum at 140°, then recrystallise it from MeOH. **Irritant.** [Stetter & Wulff *Chem Ber* **95** 2302 *1962*, DOI: 10.1002/cber.19620950932.]

1-Adamantyl methyl ketone *[1660-04-4]* **$C_{12}H_{18}O$, M 178.3, m 53-55°, 54-55°.** The ketone is prepared by bubbling acetylene through a vigorously stirred solution of 1-adamantylbromide (1g, see [769-90-1]) in 96% H_2SO_4 (40ml) at 5° for 5 hours with evolution of HBr. The mixture is poured onto ice, extracted with Et_2O, the extract is dried (Na_2SO_4), filtered and evaporated to give an ~80% yield of ketone. This was purified *via* the ***2,4-dinitrophenylhydrazine derivative*** (by passage of a solution through silica gel/*C_6H_6) which gave orange needles from AcOH/EtOH or EtOH with **m 221° (219-222°** and **220-222°** also reported). The ***ketone*** has an IR (KBr) peak at ν_{max} 1690 cm^{-1} (C=O); its ^{1}HNMR has τ at 7.96 (s, 3H), 7.90 and 8.30 (15H); and its MS has *m/z* at 178 (M^+). [Kell & McQuillin *JCS Perkin Trans I* 2100 *1972*, DOI: 10.1039/P19720002100; Sasaki et al. *Chem Commun (London)* 780 *1968*, DOI: 10.1039/C19680000780.]
Alternatively, 1-(ethoxycarbonylmethylcarbonyl)adamantane [1-(EtOCOCH$_2$CO)-Ad), **b 108-115°/0.06mm**, prepared from 1-adamantylcarbonyl chloride and diethyl malonate] (~25g) was hydrolysed and decarboxylated by boiling in AcOH (50ml), H_2O (30ml) and concentrated H_2SO_4 (5.5ml) until evolution of CO_2 ceased, poured into ice-water (~300ml), the oily *ketone* solidified (94-96% yield), and was recrystallised from MeOH or aqueous MeOH. It sublimes at 40°/0.1mm. ***1-Adamantyl methyl ketone oxime***, **m 182-184°**, (used for the preparation of *Rimantadine hydrochloride* see [1501-84-4] above) is obtained by shaking hydroxylamine hydrochloride (2.5g) and recrystallised NaOAc (4g) in H_2O (10ml) in a glass test tube, then warming to 40° and adding the *ketone* (2.5g), replacing the stopper and shaking vigorously for a few minutes. The crystalline oxime that soon separates is filtered off, washed with H_2O, and gives colourless plates in high yield upon recrystallising from aqueous dioxane. [Stetter & Rauscher *Chem Ber* **93** 2054 *1960*, DOI: 10.1002/cber.19600930922; see also Hála & Landa *Coll Czech Chem Commun* **25** 2692 *1960*, DOI: 10.1135/cccc19602692.]

3-Bromoadamantane-1-carboxylic acid *[21816-08-0]* **$C_{11}H_{15}BrO_2$, M 259.1, m 145-146°, 146.5°, 147-150°, pK^{25} 6.28 (50% aqueous EtOH).** Purify the acid by recrystallising it from cyclohexane and/or subliming at 130°/10mm. It can be converted to the ***methyl ester*** (diazomethane) with **m 32°** (from petroleum ether at -10°). [Stetter & Mayer *Chem Ber* **95** 667 *1962*, DOI: 10.1002/cber.19620950314; Stetter & Wulff *Chem Ber* **93** 1366 *1960*, DOI: 10.1002/cber.19600930619; Bayal & Lantvoev *J Org Chem USSR (Engl Trans)* **9** 291 *1973*.]

1-Bromoadamantan-4-one (5-bromo-2-adamantanone, 1-bromotricyclo[3.3.1.13.7]decan-4-one) *[20098-20-8]* **$C_{10}H_{13}BrO$, M 229.1, m 149-153°, 150-152°, 153°, 151-155°.** Brinker and coworkers [Wagner et al. *Org Lett* **12** 332 *2010*, DOI: 10.1021/ol902667a] prepared it by dissolving 1-hydroxyadamantan-4-one (1g, 6.02mmol, 20098-14-0) in 48% aqueous HBr (20ml) solution and boiling under reflux for 16 hours, then adding H_2O (15ml) and extracting with Et_2O. The Et_2O extract is washed with brine, dried ($MgSO_4$) and evaporated to dryness *in vacuo* to give the bromo-ketone (0.8g, 3.49mmol, 58%) which has m 150-152°, and is recrystallised from hexane. It has ^1H NMR (400 MHz $CDCl_3$) δ: 1.97-2.10 (m 4H, 4 peaks), 2.24 (bs, 1H), 2.49-2.63 (m, 8H, four peaks); ^{13}C NMR (150 MHz $CDCl_3$) δ: 31.2, 37.5, 47.8, 49.0, 59.9 and 214.3; and HRMS (EI) has *m/z* 228.0144, calc for $C_{10}H_{13}BrO$ (M^+) 228.0150. The bromoketone is then converted into ***1-bromo-4-aziadamantane*** as follows: Anhydrous NH_3 was bubbled through a solution of 1-bromoandamantan-4-one (1.9g, 8.29mmol) in dry MeOH (30ml) at 0° for 75min while keeping the temperature between 0° and ~10°; then the solution is cooled to -12° and hydroxylamine-*O*-sulfonic acid (1.13g, 9.99mmol) is added in small amounts under stirring during 2.5hrs, and the mixture is kept at +7° overnight. The MeOH and NH_3 of this solution are removed *in vacuo* at 40°, the solid residue is suspended in Me_2CO (50ml) and CrO_3 (1.25g, 12.50mmol) in 20% H_2SO_4 (14ml) is added dropwise over 20min at 0°, then stirred for 1hr at ~25° and then poured onto ice (300g). The aqueous phase is extracted with CH_2Cl_2, the organic layer is dried ($MgSO_4$), filtered, evaporated to dryness and the residue is subjected to chromatography on SiO_2 and eluting with hexane. The eluent gave ***1-bromo-4-aziadamantane*** (0.96g, 3.98mmol, 48%) with **m 85-90°**, and IR (KBr) with ν_{max} at 2934, 2858, 1577, 1451 1079, 1014, 809, 789 and 716 cm^{-1}; UV (cyclohexane) has λ_{max} nm(ε) at 344(165), 349(141) and 362(226); ^1H NMR (400MHz, $CDCl_3$) with δ at 0.81 (bs, 2H), 1.77 (dm, 2H), 2.07 (bd, 2H, *J* = 12.9Hz), 2.24-2.27 (m, 1H),

2.33 (dm, 2H), 2.41 (*s*, 2H), 2.68 (dm, 2H); ^{13}C NMR (150MHz, $CDCl_3$) with δ at 31.6, 33.4, 37.9, 46.5, 62.5; HRMS (ESI) found *m/z* 455.0532 and calcd for $C_{20}H_{27}Br_2N_2$ (corresponding azine) $M+H^+$ 455.0521: and elemental analysis found C 49.46, H 5.11, N 11.50, calcd for $C_{10}H_{13}BrN_2$ C 49.81, H 5.43, N 11.62. [see also Geluk & Schlatmann *Tetrahedron* **24** 5369 *1968*, DOI: 10.1016/S0040-4020(01)96330-6.]

2-*tert*-Butyl-1-cyclohexanol *[13491-79-7 isomeric mixture]* **$C_{10}H_{20}O$, M 156.2, m 43-46°, 52-53°, d_4^{25} 0.902.** This is a mixture of geometric isomers obtained by the catalytic reduction of *o-tert*-butylphenol with a Ni-kieselguhr catalyst. The liquid residue deposited white rhombs **m 52-53°** of the isomeric mixture. However, upon oxidation with CrO_3 in AcOH-H_2O (10:75) at 30-35° (overnight) all isomers yield the same racemic *2-tert-butyl-1-cyclohexanone* described below. [Schmerling *J Am Chem Soc* **69** 1121 *1947,* DOI: 10.1021/ja01197a040; *Beilstein* **7** IV 82.]
When the urine of rabbits fed with (±)-2-*tert*-butyl-1-cyclohexanone (see next entry) is acidified (+)-***cis-2-tert-butylcyclohexyl-β-D-glucosiduronic acid***, **$C_{16}H_{28}O_7$. H_2O**, separates and can be obtained pure after two recrystallisations from 10% aqueous EtOH. It has **m 167-168°**, **$[\alpha]_D^{18}$ +3.4 (c 2.6, MeOH)**. By boiling a solution of this *glycosiduronic acid* under reflux in N HCl for 15 minutes, neutralising with $NaHCO_3$, steam distilling, extracting the distillate with Et_2O, drying (Na_2SO_4), filtering, evaporating then distilling the residue under high vacuum, *S-(+)-2-tert-butyl-1-cyclohexanol* is obtained. This *S*-(+)-alcohol gave ***S*-(-)-2-*tert*-Butyl-1-cyclohexanone** upon oxidation with CrO_3 (see below). [Cheo et al. *J Chem Soc (C)* 1988 *1966*, DOI: 10.1039/J39660001988.]

(±)-2-*tert*-Butyl-1-cyclohexanone *[1728-46-7, racemate, also for (±) 13495-19-7]* **$C_{10}H_{18}O$, M 154.2, b 62.5°/4mm, d_4^{25} 0.896, n_D^{20} 1.4579.** This ketone is obtained when the CrO_3 oxidation mixture from the preceding entry is diluted with MeOH-H_2O ((1:10) and steam distilled. The distillate is washed to remove any formaldehyde and AcOH present and then distilled under high vacuum. The **(±)-*semicarbazone*, m 182-183°,** separates slowly after the ketone is added to a mixture of $NH_2CONHNH_2$.HCl-NaOAc-H_2O (1:1.5:10 w/w). [Schmerling *J Am Chem Soc* **69** 1121 *1947,* DOI: 10.1021/ja01197a040; *Beilstein* **7** IV 82.] ***S*-(-)-2-*tert*-Butyl-1-cyclohexanone** *[14123-21-9]* **$C_{10}H_{18}O$, M 154.2,** has **b 40°/4x10^{-5}mm, $[\alpha]_D^{22}$ -45.5 (c 2.75, $CHCl_3$).** Optical resolution of the *trans*-2-*tert*-butyl-1-cyclohexyl 3β-acetoxy-Δ^5-etienate {see (-)-3β-acetoxy-5-etienic acid [51424-66-9] in 'Steroids' in Chapter 6} diastereoisomers by chromatographic separation on neutral Al_2O_3 (grade II) is achieved by eluting with *C_6H_6/hexane whereby the (-)-acid-(-)-alcohol (m 181-182° from MeOH/CH_2Cl_2, $[\alpha]_D^{20}$ -45) elutes before the (-)-acid-(+)-alcohol [m 171-174° from MeOH/CH_2Cl_2, $[\alpha]_D^{20}$ -9] which comes through on further elution with *C_6H_6. $LiAlH_4$ in Et_2O cleaves the respective diastereomeric esters to provide *R-(-)-2-tert-butyl-1-cyclohexanol [trans-1R,2S- 98104-30-4]* {m 50-52° $[\alpha]_D^{20}$ +44.4 (c 0.76, $CHCl_3$)} from the ester with m 181-182°, and *S-(+)-2-tert-butyl-1-cyclohexanol [trans-1S,2R- 13492-07-4]* {m 50-52° $[\alpha]_D^{20}$ +44.2 (c 0.79, $CHCl_3$)} from the ester with m 171-174°. These have been used as chiral auxiliaries. [Djerassi et al. *J Am Chem Soc* **86** 78 *1964*, DOI: 10.1021/ja01055a019; *Beilstein* **6** III 126.]
Oxidation of the enantiomeric cyclohexanols by titration with a standardised solution of CrO_3 [Bowden, Heilbron, Jones and Weedon *J Chem Soc* 39 *1946*, DOI: 10.1039/JR9460000039] with occasional addition of small portions of anhydrous $MgSO_4$, furnished ***S*-(-)-2-tert-butyl-1-cyclohexanone** [from the (+)-alcohol] and ***R*-(+)-2-tert-butyl-1-cyclohexanone** [from the (-)-alcohol], which are purified by distilling in a vacuum system at 3 x 10^{-5}mm using cooled receivers. Distillation can also be carried out in distilling equipment at high vacuum. The ORD for the *S- enantiomer* in MeOH at 22° exhibited Cotton extrema (λ_{max}) at [ϕ] -1650° (317nm) and +1670° (275nm) with amplitude (*a*) equal to -33. The ORD of the *R- enantiomer* is [ϕ] +1690° (317nm) and -1720° (275nm) with amplitude (*a*) equal to +34. These rotatory dispersions in MeOH were unchanged during 64 days at room temperature. Also in *iso*propanol solution containing one drop of concentrated HCl did not affect the amplitude of its Cotton effect at room temperature, however this decreased rapidly on heating at 65°: e.g. $[\alpha]_{317}$ -1089 (25°) → $[\alpha]_{317}$ -447 (6 min at 65°) → $[\alpha]_{317}$ -102 (14 min at 65°). The IR and the retention times with g.l.c. were identical with those of the racemic ketone. [Djerassi et al. *J Am Chem Soc* **86** 78 *1964*, DOI: 10.1021/ja01055a019; *Beilstein* **7** IV 82.]

It is estimated colorimetrically with H_3PO_4 in EtOH followed by vanillin and HCl [Hayward & Seymour *Anal Chem* **20** 572 *1948*, DOI: 10.1021/ac60018a022]. The ***3,5-dinitrobenzoyl*** derivative has **m 92-93°**. [Stork & Clarke *J Am Chem Soc* **83** 3114 *1961,* DOI: 10.1021/ja01475a030; *Beilstein* **6** III 424.] The synthetic *racemic* (±)-**Cedrol** *[22567-44-8]* also crystallises nicely from aqueous MeOH and has **m 94-96°** and ^1H NMR (360 MHz CCl_4, TMS) with δ at 0.82 (3H, d, *J* = 6Hz, CH_3COH), 0.97 (3H, s, *endo*- CH_3), 1.18 (3H, s, *exo*- CH_3), 1.26 (3H, s, CH_3COH) [Breitholle & Fallis *J Org Chem* **43** 1964 *1978*, DOI: 10.1021/jo00404a025].

S*(+)-Chaulmoogric acid [13(cyclopent-2-enyl-1(*S*)-yl)tridecanoic acid]** *[29106-32-9]* **$C_{18}H_{32}O_2$, M 280.4, m 68.5°, b 247-248°/20mm, $[\alpha]_D^{20}$ +62.1 (c 4, $CHCl_3$), pK_{Est} ~5.0.** The acid was isolated from the oil of Chaulmoogra seeds *Taraktogenos kurzii* (King) [Power & Gornall *J Chem Soc* **85** 838, 851 *1904*, DOI: 10.1039/CT9048500838]. Crystallise the acid from petroleum ether or EtOH. Mislow and Steinberg prepared it electrolytically from *S*(+)-2-cyclopentene-1-acetic acid and ethyl hydrogen brassylate, after determining the absolute configuration of cyclopenteneacetic acid by two different methods. The ***Me ester *[24828-59-9]* **$C_{19}H_{34}O_2$, M 294.4,** prepared by bubbling HCl gas through a methanolic solution of the acid, has **m 22°**, **b 227°/20mm** and $[\alpha]_D^{15}$ +50 (c 5, $CHCl_3$). The ***amide***, prepared from the acid chloride and NH_3, has **m 106°**, $[\alpha]_D^{27}$ +57.3 (c 4.3, $CHCl_3$) after recrystallisation from EtOH. [Barrowcliff & Power *J Chem Soc* **91** 557 *1907*, DOI:10.1039/CT9079100557; Mislow & Steinberg *J Am Chem Soc* **77** 3807 *1955*, DOI: 10.1021/ja01619a038.] ***S*(+)-*Chaulmoogric ethyl ester*** **(Moogrol, Chaulmestrol, ethyl 13-cyclopent-2-enylyl)tridecanoate)** *[623-32-5]* **$C_{20}H_{36}O_2$, M 308.5,** has **b 230°/20mm, d_{20}^{20} 0.90456, $[\alpha]_D^{20}$ +50.7 (neat)**, prepared as for the methyl ester (previous entry) with EtOH instead of MeOH, is a light yellow liquid with a fruity odour and nasty taste. It is active against *Mycobacterium leprae* and largely used to treat leprosy and various skin disorders [see Power & Gornall *J Chem Soc* **85** 838 *1904*, DOI: 10.1039/CT9048500838; Levy *Am Rev Respir Dis* **111** 703 *1975*, PMID: 1093460]. The ethyl ester is used in the treatment of leprosy and sarcoidosis [Levy *Am Rev Respir Dis* **111** 703 *1975*, PMID: 1093460].

Chlorendic anhydride (1,4,5,6,7,7-hexachloro-5-norbornene-2,3-dicarboxylic anhydride) *[115-27-5]* **$C_9H_2Cl_6O_3$, M 370.9, m 234-236°. 235-237°, 238°.** Steam distil the anhydride or recrystallise it from H_2O to yield pure diacid. The pure diacid yields the anhydride with Ac_2O. [Prill *J Am Chem Soc* **69** 62 *1947*, DOI: 10.1021/ja01193a015.]

1-Chloroadamantan-4-one (5-chloro-2-adamantanone, 1-chlorotricyclo[3.3.1.13.7]decan-4-one) *[20098-17-3]* **$C_{10}H_{13}BrO$, M 229.1, m 197-200°, 199-200°.** Brinker and coworkers [Wagner et al. *Org Lett* **12** 332 *2010*, DOI: 10.1021/ol902667a] prepared it by adding $SOCl_2$ (38ml, 0.52mol, CARE lachrymmatory) to 4-hydroxyadamantan-1-one (6.16g, 37.1mmol, see [20098-14-0] below) and boiling under reflux for 2 hours, evaporating to dryness *in vacuo*, and dissolving the residue in CH_2Cl_2. The solution CH_2Cl_2 is washed twice with aqueous 0.1N NaOH, twice with brine, dried (Na_2SO_4), filtered and evaporated to dryness. The residue is recrystallised from hexane or petroleum ether to give the 1-chloroadamantan-4-one (4.2g, 61% yield) with **m** 199-200°, and has IR (KBr) with ν_{max} at 2935s and 2860m (C-H), 1725vs (C=O, + 5 peaks as in adamantanone), 1289m, 1060s, 1024s, 829s, 664m and 473m cm^{-1}; the ^1H NMR (400 MHz $CDCl_3$) has δ at 1.92-2.04 (m 4H, 4 peaks), 2.27-2.31 (m, 2H), 2.32-2.35 (*s*, 3H), 2.42 (d, 2H, *J* = 12.3Hz), 2.61 (s, 2H); ^{13}C NMR (150 MHz $CDCl_3$) with δ at 30.6, 37.6, 46.5, 47.5, 48.0, 64.5 and 214.6; and HRMS (EI) has *m/z* 184.0653, calc for $C_{10}H_{13}ClO$ (M^+) 184.0655. [See also Geluk & Schlatmann *Tetrahedron* **24** 5369 *1968*, DOI: 10.1016/S0040-4020(01)96330-6.] ***1-chloro-4-aziadamantane*** is prepared in the same way as for *1-bromo-4-aziadamantane* above but in 27% yield, and after recrystallisation from hexane it started to decompose at *ca* 80-90°, and has IR (KBr) with ν_{max} at 2934, 2859, 1577, 1453, 1079, 1020, 828 and 587 cm^{-1}; UV (pentane) has λ_{max} nm(ε) at 348(134), 353(114) and 367(207); ^1H NMR (400MHz, $CDCl_3$) with δ at 0.84 (bs, 2H), 1.73 (dm, 2H), 2.01 (bd, 2H, *J* = 12.9Hz), 2.11 (dm, 2H), 2.20 (brs, 2H), 2.28-2.32 (m, 1H), 2.48 (m, 2H, *J* = 11.3Hz); ^{13}C NMR (150MHz, $CDCl_3$) with δ at 30.9, 33.5, 37.1, 45.0, 47.0 and 66.4; HRMS (ESI) found *m/z* 365.1558 and calcd for $C_{20}H_{27}Cl_2N_2$ (corresponding azine) $M+H^+$ 365.1551: and elemental analysis found C 61.07, H 6.07, Cl 18.17, N 14.13, calculated for $C_{10}H_{13}ClN_2$ C 61.07, H 6.66, Cl 18.03, N 14.24. [see also Geluk & Schlatmann *Tetrahedron* **24** 5369 *1968*, DOI: 10.1016/S0040-4020(01)96330-6.]

Chlorocyclohexane (cyclohexyl chloride) *[542-18-7]* **$C_6H_{11}Cl$, M 118.6, b 46-48°/26mm, 142.5°/atm, d_4^{20} 1.00, n_D^{25} 1.46265.** It has been prepared using the general procedure of Norris and coworkers by refluxing the alcohol with 5 volumes of 'constant boiling HCl' for 2-4 hours [Norris et al. *J Am Chem Soc* **38** 1071 (1077) *1916*, DOI: 10.1021/ja02262a014]. It has also been prepared in 76% yield by the '$CaCl_2$' procedure described for chlorocyclopentane (see below [930-28-9]). Wash the chlorocyclohexane several times with dilute $NaHCO_3$, then repeatedly with distilled water. Dry it with $CaCl_2$ and fractionally distil it slowly at atmospheric pressure or better under vacuum. [Perlman et al. *J Org Chem* **1** 288 (294) *1936*, DOI: 10.1021/jo01232a008; IR: Roberts & Chambers *J Am Chem Soc* **73** 5030 1951, DOI: 10.1021/ja01155a004; *Beilstein* **5** H 21, **5** I 8, **5** II 11, **5** III 37, **5** IV 48.]

2-Chlorocyclohexanone *[822-87-7]* **C_6H_9ClO, M 132.6, m 23°, b 82-83°/10mm, 98-99°/14-15mm, d_4^{25} 1.161, n_D^{20} 1.484.** The chlorocyclohexanone is prepared in a well ventilated fume cupboard by bubbling chlorine (215g, ~3moles, use mercury traps) rapidly through a mixture of cyclohexanone (284g, 3moles) and H_2O (900ml) while being stirred in an ice bath at a reaction temperature between 20° and 50°. After about 45 minutes all the chlorocyclohexanone separates as a heavy oil which is combined with the Et_2O (3 x 150ml) extract of the upper aqueous layer, washed with H_2O (150ml), saturated aqueous NaCl (200ml), filtered (by gravity) through anhydrous Na_2SO_4, the solvent is evaporated, the residue is distilled in a Claisen flask, and the fraction boiling below 110° (300-340g, b 110°/13mm, 92°/4mm) is collected. This is then carefully fractionated through a heated 42-inch Vigreux column with a variable take-off head to give pure *2-chlorocyclohexanone* (240-265g, 61-66%, **b 90-91°/14-15mm**) with 5-13% recovery of cyclohexanone b 52°/14-15mm. [Newman et al. *Org Synth* Coll Vol **3** 188 *1855*, DOI: 10.15227/orgsyn.025.0022; *Beilstein* **7** H 10, **7** I 8, **7** II 11, **7** III 36, **7** IV 32.]

Chlorocyclopentane (cyclopentyl chloride) *[930-28-9]* **C_5H_9Cl, M 104.6, b 113-115°/atm, 114°/atm, d_4^{20} 1.005, n_D^{20} 1.4512.** It is prepared by mixing cyclopentanol (43g) with concentrated HCl (125ml) and anhydrous $CaCl_2$ (50g), and stirring under reflux on a steam bath for 10 hours. [As HCl gas evolves continuously, the reaction should be carried out in an sufficient fume cupboard.] After cooling, the upper layer is collected, washed wih brine, saturated aqueous $NaHCO_3$ (CARE, as evolution of CO_2 will occur), brine again and dried over anhydrous $CaCl_2$ for at least 24 hours. Filter off the solid and fractionate through an efficient column at atmospheric pressure to obtain a ~ 58% yield of *cyclopentyl chloride* (30g). Bubbling dry HCl gas through the reaction mixture does not appear to increase the yield. See preparation and purification of chlorocyclohexane above. [*Beilstein* **5** IV 18.]

(-)-α-Copaene (*1R,2S,6S,7S,8S*-8-isopropyl-1,3-dimethyltricyclo[4.4.0.0^{2,7}]dec-3-ene) *[3856-25-5]* **$C_{15}H_{24}$, M 204.4, b 119-120°/10mm, 246-251°, d_4^{20} 0.908, n_D^{20} 1.489, $[\alpha]_D^{20}$ -6.3 (c 1.2, $CHCl_3$).** It is a naturally occurring liquid tricyclic sesquiterpene [Simonen & Barton *The Terpenes* **Vol III**, pp 88-91 *1952*, University Press, Cambridge]. Purify it by distillation, preferably under vacuum. Other purifications involved a Varian Aerograph A-700 gas chromatograph (He carrier gas with thermal conductivity detection) and Hewlett-Packard Model 810 and 5750 gas chromatographs (N_2 carrier gas, 30 mL/min, flame ionisation detection) which separated the copaene from the isomeric *ylangene* which also occur naturally. The racemate has been synthesised. [Heathcock *J Am Chem Soc* **88** 4110 *1966*, DOI: 10.1021/ja00969a051; Heathcock et al. *J Am Chem Soc* **89** 4133 *1967*, DOI: 10.1021/ja00992a032; Corey & Watt *J Am Chem Soc* **95** 2303 *1973*, DOI: 10.1021/ja00788a034; *Beilstein* **5** IV 1189.]

Cyclobutane *[287-23-0]* **C_4H_8, M 56.1, m -50°, -80°, b 13°/740mm, 12°/atm, d_4^{20} 0.721, n_D^{20} 1.426.** This easily liquefiable gas is dried over Na at melting ice temperature for 4 days and distilled at low temperature through a Podbielniak precision still. A dry sample has been prepared by passage through P_2O_5 and distilled repeatedly until all fractions had similar vapour pressures at 0°. [Cason & Way *J Org Chem* **14** 31 *1949*, DOI: 10.1021/jo01153a006; Heisig *J Am Chem Soc* **63** 1698 *1941*, DOI: 10.1021/ja01851a055; Heisig & Stodola *Org Synth* Coll Vol **3** 213 *1955*, DOI: 10.15227/orgsyn.023.0016.]

Cyclobutanone *[1191-95-3]* **C_4H_6O, M 70.1, b 96-97°, 99-100°/atm, d_4^{20} 0.931, n_D^{20} 1.4210, n_D^{52} 1.4189.** Treat cyclobutanone with dilute aqueous $KMnO_4$, dry it with molecular sieves and fractionally distil it. Purify it *via* the semicarbazone, then regenerate the ketone, dry it ($CaSO_4$), and distil it in a stainless steel spinning-band (or Vigreux column). *Alternatively*, purify it by preparative gas chromatography using a Carbowax 20-M column at 80° (this treatment also removes acetone). It has FT-IR (NaCl) with ν_{max} at 3543.3, 2970.3 (CH), 1783.2 (C=O), 1392.5 (OH enol ?), 1208.9, 1136.4, 1080.8, 724.9, and 461.4 cm^{-1}; ^1H NMR (60MHz, $CDCl_3$,

TMS) with δ at 2.01 (q, 2H, C-3 methylene), 3.09 (t, 4H, C-2 and C-4 methylenes); ^{13}C NMR (15MHz, $CDCl_3$, TMS) with δ at 9.74 (C-3), 47.73 (C-2,4) and 208.90 (C-1). The ***oxime*** has **m** 84-85° (from petroleum ether) and the ***semicarbazone*** has **m 212-212-5°** (**220-221°** from MeOH or H_2O, Buchman et al. *J Am Chem Soc* **64** 2701 *1942*, DOI: 10.1021/ja01263a049). [Salaun et al. *Org Synth* **57** 36 *1977*, DOI: 10.15227/orgsyn.057.0036, Fitjer & Quabeck *Synthesis* 299 1987, DOI: 10.1055/s-1987-27926; *Beilstein* **7** IV 3.]

Cyclobutylamine *[2516-34-9]* **C_4H_9N, M 71.1, b 82-83°/atm, 83.2-84.2°/760mm, d $_4^{20}$ 0.839, n $_D^{20}$ 1.437, pK^{25} 10.04 (9.34 in 50% aqueous EtOH).** It has been purified by steam distillation. The aqueous distillate (e.g. 2L) is acidified with 3N HCl (90ml) and evaporated to dryness in a vacuum. The *hydrochloride* is treated with a few ml of H_2O, cooled in ice and a slush of KOH pellets ground in a little H_2O is added slowly in portions and keeping the solution very cold. The amine separates as an oil from the strongly alkaline solution. The oil is collected, dried over solid KOH and distilled using a vacuum jacketed Vigreux column and protected from CO_2 using a soda lime tube. The fraction boiling at 79-83° is collected, dried over solid KOH for 2 days and redistilled over a few pellets of KOH (**b** 80.5-81.5°). Best distil in a dry N_2 atmosphere. The purity can be checked by GLC using a polyethylene glycol on Teflon column at 72°, 15 psi, flow rate of 102 ml/min of He. The sample can appear homogeneous but because of tailing it is not possible to tell if H_2O is present. The NMR in CCl_4 should shows no signals less than 1 ppm from TMS. The *hydrochloride* has a multiplet at *ca* 1.5-2.6ppm (H 2,2,4,3,3,4,4), a quintet at 3.8 ppm (H 1) and a singlet at 4.75 for NH_2 [Roberts & Mazur *J Am Chem Soc* **73** 2509 *1951*, DOI: 10.1021/ja01112a048]. The ***benzenesulfonamide*** has **m 85-86°** (from aqueous MeOH) and the ***benzoyl*** derivative has **m 120.6-121.6°**. [Roberts & Mazur *J Am Chem Soc* **73** 2509 *1951*, DOI: 10.1021/ja01150a029; Iffland et al. *J Am Chem Soc* **75** 4044 *1953*, DOI: 10.1021/ja01112a048; Werner & Casanova Jr *Org Synth* Coll Vol **5** 273 *1973*, DOI: 10.15227/orgsyn.047.0028; *Beilstein* **12** IV 3.]

(±)-Cyclobutyrol (α-ethyl-1-hydroxycyclohexaneacetic acid) *[512-16-3]* **$C_{10}H_{18}O_3$, M 186.25, m 81-81°, b 167-170°/16mm, 164°/24mm, d $_4^{20}$ 1.001, n $_D^{20}$ 1.4680.** It forms colourless crystals from petroleum ether, and can be distilled *in vacuo* without decomposition. It is obtained by hydrolysis of ethyl α-ethyl-1-hydroxycyclohexaneacetate [b 125-127°/12mm, 135-136°/20mm, Wallach *Justus Liebigs Ann Chem* **360** 26 *1908*, DOI: 10.1002/jlac.19083600104] which is better performed as follows, otherwise decomposition to butyric acid and cyclohexanone occurs. The ester (100g) is added to a hot solution of KOH (100g) in H_2O (100ml), then MeOH (100ml) is added gradually and the mixture is refluxed for 2-3hrs. The solution is freed from MeOH under a vacuum, diluted with H_2O, extracted with Et_2O, and the aqueous solution is acidified with ice-cold 30% H_2SO_4, the free hydroxyl-acid is extracted into Et_2O, the extract is dried (Na_2SO_4), filtered, evaporated and the residue is distilled under reduced pressure. It is very soluble in organic solvents, sparingly in petroleum ether and acidic aqueous solution but very soluble in aqueous alkaline solutions. [Kon and Narayanan *J Chem Soc* 1536 *1927*, DOI: 10.1039/JR9270001536; Kandiah & Linstead *J Chem Soc* 2139 *1929*, DOI: 10.1039/JR9290002139; Maillard et al. *Bull Soc Chim Fr* 244 *1958*, *Beilstein* **10** III 38.]
The ***sodium salt (Trade names: Colepan, Dimene, Hebucol, Bilimix)*** *[1130-2300]* **$C_{10}H_{17}O_3Na$, M 208.2,** has **m 299-300°.** It is a white crystalline powder which should be stored in sealed containers as it is slightly hygroscopic. It is a choleretic agent which inhibits biliary secretions.

Cyclodecanone *[1502-06-3]* **$C_{10}H_{18}O$, M 154.2, m 21-24°, b 100-102°/12mm.** Purify the ketone *via* the ***semicarbazone*** (**m** 205-207°, from EtOH) and distil it through an efficient column. It sublimes in a vacuum. The ***oxime*** has **m** 80°, from MeOH or by sublimation in a high vacuum. [Cope et al. *Org Synth* Coll Vol **4** 218 *1963*, DOI: 10.15227/orgsyn.036.0014; Prelog et al. *Helv Chim Acta* **30** 1741 *1947*, DOI: 10.1002/hlca.19470300637; Ruzicka et al. *Helv Chim Acta* **11** 670 1928, DOI: 10.1002/hlca.19280110178; *Beilstein* **7** III 134, **7** IV 76.]

***cis*-Cyclodecene** *[935-31-9]* **$C_{10}H_{18}$, M 138.3, m -3°, -1°, b 73°/15mm, 90.3°/33mm, 194-195°/740mm, 197-199°/atm, d $_4^{20}$ 0.8770, n $_D^{20}$ 1.4854.** *cis-Cyclodecene* has been prepared by the Pd-catalysed hydrogenation of cyclododecyne, and by dechlorination of 1-chlorocyclodecene using Na and liquid NH_3. Purify it by fractional distillation preferably after chromatographing three times through silica gel. The IR has ν_{max} (film) at 1656m, 1684m, 1715w (C=C), 2680w, 2915vs (C-H) cm^{-1}. It forms an $AgNO_3$ complex which crystallises from MeOH, **m** 167-187°. Attempted thermal isomerisation of pure *cis*-isomer (sealed tube, under N_2 with hydroquinone and 2-naphthalenesulfonic acid, at 170-180°/1.5 h) gave a *cis/trans* mixture. [Cope et al. *J Am*

Chem Soc **77** 1628 *1955*, DOI: 10.1021/ja01611a066; IR: Blomquist et al. *J Am Chem Soc* **74** 3636 *1952*, DOI: 10.1021/ja01134a051; Prelog et al. *Helv Chim Acta* **35** 1598 *1952*, DOI: 10.1002/hlca.19520350526; *Beilstein* **5** IV 295.]

trans*-Cyclodecene** *[2198-20-1]* **$C_{10}H_{18}$, M 138.3, b 68-70°/10mm, 70.5-71.5°/11mm, 78°/18mm, 194°/740mm, d_4^{20} 0.8681, n_D^{20} 1.4846.** It has been prepared by shaking cyclodecyl-trimethylammonium iodide with Ag_2O in MeOH (2 h) then filtered, the fitrate was evaporated and the residual oil (free base) was decomposed by heating (in a bath at 100°) at 150mm. The distillate was extracted with Et_2O, the extract was washed with dilute HCl, followed by aqueous Na_2CO_3 solution, H_2O, then was distilled through a short Vigreux column to provide ***trans-cyclodecene in 50% yield. Chromatography through silica gel prior to distillation has been used. Final purification was by distillation over Na *in vacuo*. The IR has ν_{max} (film) at 1667m (C=C), 2675w, 2915vs (C-H) cm^{-1}. [Cope et al. *J Am Chem Soc* **77** 1628 *1955*, DOI: 10.1021/ja01611a066; IR: Blomqvist et al. *J Am Chem Soc* **74** 3636 *1952*, DOI: 10.1021/ja01134a051; Prelog et al. *Helv Chim Acta* **35** 1598 *1952*, DOI: 10.1002/hlca.19520350526; *Beilstein* **5** IV 295.]

***cis-cis-trans*-1,5,9-Cyclododecatriene (cyclododec-1c,5c,9t-triene)** *[2765-29-9]* **$C_{10}H_{18}$, M 162.3, m -9°, -8°, b 117.5°/2mm, 237-239°/atm, 244°/760mm, d_4^{20} 0.907, n_D^{20} 1.5129.** Purify the triene by fractional distillation, preferably in a vacuum under N_2, and it forms an insoluble $AgNO_3$ complex. [IR: Breil et al. *Makromol Chemie* **69** 18 *1963*, DOI: 10.1002/macp.1963.020690102; *Beilstein* **5** IV 1114.]

Cyclododecylamine *[1502-03-0]* **$C_{12}H_{25}N$, M 183.3, m 27-29°, b 122-124°/7mm, 140-150°/*ca* 18mm, 280°/atm, pK 9.62 (in 80% methyl cellosolve).** It can be purified *via* the ***HCl salt*** **m 274-275°** (from EtOH) or the ***picrate*** **m 232-234°**, and the free base is distilled preferably at water-pump vacuum. It is a strong base and should be stored away from moisture and CO_2. [Prelog et al. *Helv Chim Acta* **33** 365 *1950*, DOI: 10.1002/hlca.19500330220; *Beilstein* **12** IV 164.]

1,3-Cycloheptadiene *[4054-38-0]* **C_7H_{10}, M 94.2, b 55°/75mm, 71.5°/150mm, 120-121°/atm, d_4^{20} 0.868, n_D^{20} 1.4972.** Purify the diene by dissolving it in Et_2O, washing with 5% HCl, H_2O, drying ($MgSO_4$), evaporating, and the residue is distilled under dry N_2 through a semi-micro column (some foaming occurs) [Cope et al. *J Am Chem Soc* **79** 6287 *1957,* DOI: 10.1021/ja01580a047; UV: Pesch & Friess *J Am Chem Soc* **72** 5756 *1950* DOI: 10.1021/ja01168a512]. Stabilise it with ~0.1% hydroquinone. It is highly flammable. [Marvel & Martzell, *J Am Chem Soc* **81** 448 *1959*, DOI: 10.1021/ja01511a047; for use see Feng et al. *Organometallics* **25** 5456 *2006*, DOI: 10.1021/om0606385; *Beilstein* **5** IV 382.] ***1,4-Cyclohexadiene (1,4-dihydrobenzene)*** *[628-41-1]* **C_6H_8, M 80.1,** has **b 83-86°/714mm, 88.3°/741mm, 86-88°/atm, 88.7-89°/760mm, d_4^{20} 0.8573, n_D^{20} 1.4725.** Dry the diene over $CaCl_2$ and distil it in a vacuum under N_2. Stabilise it with ~0.1% hydroquinone. [Hückel & Wörffel *Chem Ber* **88** 338 *1955*, DOI: 10.1002/cber.19550880305; Giovannini & Wegmüller *Helv Chim Acta* **42** 1142 *1959*, DOI: 10.1002/hlca.19590420403; for use see Feng et al. *Organometallics* **25** 5456 *2006*, DOI: 10.1021/om0606385; *Beilstein* **5** IV 385.]

Cyclohexane *[110-82-7]* **C_6H_{12}, M 84.2, m 6.47°, 6.6°, 4-7°, b 6.7°/40mm, 14.7°/60mm, 25.5°/100mm, 42°/200mm, 60.8°/400mm, 80.7°/760mm, d_4^{24} 0.77410, n_D^{20} 1.42623, n_D^{25} 1.42354.** It is best to purify it by washing with concentrated H_2SO_4 until the washings are colourless, followed by water, aqueous Na_2CO_3 or 5% NaOH, and again water until neutral. It is then dried with P_2O_5, Linde type 4A molecular sieves, $CaCl_2$, or $MgSO_4$, then Na and distilled. Cyclohexane has been refluxed with, and distilled from Na, CaH_2, $LiAlH_4$ (which also removes peroxides), sodium/potassium alloy, or P_2O_5. Traces of *benzene can be removed by passage through a column of silica gel that has been freshly heated: this gives material suitable for ultraviolet and infrared spectroscopy. If there is much *benzene in the cyclohexane, most of it can be removed by a preliminary treatment with **nitrating acid** (a cold mixture of 30ml concentrated HNO_3 and 70ml of concentrated H_2SO_4) which converts *benzene into nitrobenzene. The impure cyclohexane and the nitrating acid are placed in an ice bath and stirred vigorously for 15 minutes, after which the mixture is allowed to warm to 25° during 1 hour. The cyclohexane is decanted, washed several times with 25% NaOH, then water, dried with $CaCl_2$, and distilled from sodium. Carbonyl-containing impurities can be removed as described for chloroform. Other purification procedures include passage through columns of activated alumina and repeated crystallisation by partial freezing. Small quantities may be purified by chromatography on a Dowex 710-Chromosorb W gas-liquid chromatographic column. It is very soluble in most organic solvents, but less so in MeOH (57% w/v at 20°), and is difficultly soluble in H_2O (~0.0052% w/w at 24°). **Flammable liquid.** [Sabatier *Ind Eng Chem* **18** 1005 *1926*, Schefland & Jacobs *The Handbook of Organic Solvents* (Van Nostrand) p592 *1953, Beilstein* **5** IV 27.] It is **TOXIC** at relatively low concentrations causing irritation of the eyes, skin (can cause dermatitis), respiratory tract and can cause nercosis and coma at high concentrations. It is highly volatile with *vapour pressures ca* 77mm at 20° and 169mm at 38°.
Rapid purification: Distil, discarding the forerun. Stand distillate over Grade I alumina (5% w/v) or 4A molecular sieves.

Cyclohexane butyric acid *[4441-63-8]* **$C_{10}H_{18}O_2$, M 170.3, m 31°, 26.5-28.5°, b 136-139°/4mm. 169°/20mm, 188.8°/46mm, pK^{25} 4.95.** Distil the acid through a Vigreux column, and the crystalline distillate is recrystallised from petroleum ether at low temperatures. The **S-*benzylisothiuronium salt*** has **m 154-155°** (from EtOH) [Friediger & Pedersen *Acta Chem Scand* **9** 1425 *1955*, DOI: 10.3891/acta.chem.scand.09-1425; English & Dayan *J Am Chem Soc* **72** 4187 *1950*, DOI: 10.1021/ja01165a099]. 1,4-Cyclohexanedione monoethylene acetal (1,4-dioxa-spiro[4.5]decan-8-one) *[4746-97-8]* **$C_8H_{12}O_3$, M 156.2, m 70-73°, 73.5-74.5°.** Recrystallise it from petroleum ether. It sublimes slowly on attempted distillation. Also purify it by dissolving it in Et_2O and adding petroleum ether (b 60-80°) until turbid, and cooling. [Gardner et al. *J Org Chem Soc* **22** 1206 *19 57*, DOI: 10.1021/jo01361a021; Britten & Lockwood *JCS Perkin Trans 1* 1824 *1974*, DOI: 10.1039/P19740001824; cf: Revial et al. *J Org Chem* **67** 2252 *2002*, DOI: 10.1021/jo0110597.] [*Beilstein* **19/4** V 93.]

cis,cis*-1,3,5-Cyclohexane tricarboxylic acid** *[16526-68-4]* **$C_9H_{12}O_6$, M 216.2, m 216-218°, $pK_{Est(1)}$ ~4.1, $pK_{Est(2)}$ ~5.4, $pK_{Est(3)}$ ~6.8.** Purify the acid by recrystallisation from toluene/EtOH or H_2O. It forms a ***1.5 hydrate with **m 216-218°**, and a ***dihydrate*** **m 110°**. Purify it also by conversion to the ***triethyl ester*** **b 217-218°/10mm, 151°/1mm**, the distillate solidifies on cooling, **m 36-37°**, which is hydrolysed by boiling in aqueous HCl. The ***trimethyl ester*** can be distilled and recrystallised from Et_2O, **m 48-49°**. [Newman & Lowrie *J Am Chem Soc* **76** 4598 *1954*, DOI: 10.1021/ja01647a028; Lukes &S Galik *Coll Czech Chem Comm* **19** 712 *1954*, DOI: 10.1135/cccc19540712; *Beilstein* **9** III 4749, **9** IV 3723.]

Cyclohexanol *[108-93-0]* **$C_6H_{12}O$, M 100.2, m 20-22°, 25.2°, b 161.1°/atm, d^{25} 0.946g/ml, n_D^{20} 1.466, n_D^{25} 1.437, n_D^{30} 1.462.** Reflux it with freshly ignited CaO, or dry it with Na_2CO_3, then fractionally distil it. Redistil it from a very small amount of sodium, about 0.5-2% depending on the amount of H_2O estimated to be present. It is further purified by fractional crystallisation from the melt in dry air. Peroxides and aldehydes can be re-

moved by prior washing with ferrous sulfate and water, followed by distillation under nitrogen from 2,4-dinitrophenylhydrazine, using a short fractionating column: water distils as the azeotrope. Dry cyclohexanol is *very hygroscopic*, store in a dry atmosphere. The ***3,4-dinitrobenzoate*** has **m 111-112°** (EtOH or aqueous EtOH). It has **TOXIC** vapours. [*Beilstein* **6** III 10, **6** IV 20.]

Cyclohexanone *[108-94-1]* **$C_6H_{10}O$, M 98.2, m -32.1°, -47°, b 1.4°/1.0mm, 26.4°/5mm, 38.7°/10mm, 52.5°/20mm, 67.8°/40mm, 77.5°/60mm, 90.4°/100mm, 110.3°/400mm, 132.5°/400mm, 155.7°/atm, d_4^{20} 0.947, n_D^{15} 1.452. n_D^{20} 1.451, pK^{25} -6.8 (aqueous H_2SO_4), pK^{25} 11.3 (enol), 16.6 (keto).** Dry cyclohexanone over $MgSO_4$, $CaSO_4$, Na_2SO_4 or Linde type 13X molecular sieves, then distil it. Cyclohexanol and other oxidisable impurities can be removed by treatment with chromic acid or dilute $KMnO_4$. More thorough purification is possible by conversion to the bisulfite addition compound, or the semicarbazone, followed by decomposition with Na_2CO_3 and steam distillation. [For example, equal weights of the bisulfite adduct (crystallised from water) and Na_2CO_3 are dissolved in hot water and, after steam distillation, the distillate is saturated with NaCl and extracted with Et_2O which is then dried (anhydrous $MgSO_4$ or Na_2SO_4), filtered, and the solvent evaporated prior to further distillation.] Its solubility in H_2O is 15%w/v (at 10°) and 5%w/v (at 30°). Conversely the solubility of H_2O in cyclohexanone is 7.8% at 20°. **FLAMMABLE.** The ***semicarbazone*** has **m 167°**, the ***4-nitrophenylhydrazone*** has **m 147°**, the ***2,4-dinitrophenylhydrazone*** has **m 162°**, and the ***benzal derivative*** has **m 118°**. [*Beilstein* **7** III 14, **7** IV 15.] ***Cyclohexanone cyanohydrin*** *[931-97-5]* **$C_7H_{11}NO$, M 125.2,** has **m 32-35°**, **b 132°/19mm**, and should be stored in a tight container as it may slowly liberate HCN [*Beilstein* **10** H 5]. ***Cyclohexanone dimethyl ketal (1,1-dimethoxycyclohexane)*** *[933-40-4]* **$C_8H_{16}O_2$, M 144.2,** has **b 83°/50mm**, **d_4^{25} 0.948, n_D^{20} 1.4360,** and is purified by fractional distillation after washing with dilute aqueous acid and drying ($MgSO_4$). Should not have a C=O frequency in the IR spectrum. [*Beilstein* **7** IV 19.] ***Cyclohexanone oxime*** *[100-64-1]* **$C_6H_{11}NO$, M 113.2,** has **m 91°, b 100-105°/10-12mm, 206-210°/atm.** Crystallise the oxime from water or petroleum ether (b 60-80°). [Bousquet *Org Synth* Coll Vol **2** 313 *1943*, DOI: 10.15227/orgsyn.011.0054; *Beilstein* **7** III 32, **7** IV 21.] ***Cyclohexanone phenylhydrazone*** *[946-82-7]* **$C_{12}H_{15}N_2$, M 187.3,** has **m 77°, 81°.** Crystallise it from EtOH.

Cyclohexanone-2-carboxylic acid (2-oxocyclohexane carboxylic acid) *[18709-01-8]* **$C_7H_{10}O_3$, M 142.1, decarboxylates at 81-82°.** A preparation which is reproducible on a large scale involves adding cyclohexanone (49g, 52ml, 0.5mole) to a stirred suspension of $NaNH_2$ in Et_2O [obtained by dissolving Na (14g, 0.61g atom) in liquid NH_3 (500ml), and then replacing the NH_3 by Et_2O (500ml) carefully]. The mixture is boiled for 30 minutes, kept at ~35° while dry CO_2 is bubbled through for 3 hours, then poured into a slurry of ice and excess of 2M aqueous HCl, extracted with Et_2O (5 x 300ml), and the Et_2O is extracted with excess of saturated aqueous Na_2CO_3. The ice cold Na_2CO_3 solution is acidified with 2M aqueous HCl and again extracted with Et_2O (5 x 300ml). The combined extracts are dried ($MgSO_4$), filtered and evaporated *in vacuo* to give the carboxylic acid (29g, 41%) which can be recrystallised from Et_2O to form colourless needles. [Christie & Reid *JCS Perkin Trans I* 880 *1976*, DOI: 10.1039/P19760000880; Gardner et al. *J Chem Soc* 1910 *1764*, cf. Chiba et al. *Chem Lett* 1387 *1978*, DOI: 10.1246/cl.1978.1387.] The ***methyl ester (methoxycarbonyl cyclohexanone)*** *[41302-34-5]* **$C_8H_{12}O_3$, M 156.2,** has **b 50°/0.2mm, d_4^{20} 1.10,** and is purified by distillation through a short column if a film shows no OH bands in the IR spectrum; however if these bands are present then treat it with diazomethane in dry Et_2O until the yellow colour persists, and then distil under *in vacuo*. [*Beilstein* **10** IV 2606.]

Cyclohexene (tetrahydrobenzene) *[110-83-8]* **C_6H_{10}, M 82.2, m -104°, b 83°/atm d_4^{20} 0.810, n_D^{20} 1.4464, n_D^{25} 1.4437.** Free cyclohexene from peroxides by washing with successive portions of dilute acidified ferrous sulfate, or with $NaHSO_3$ solution, then with distilled water, drying with $CaCl_2$ or $CaSO_4$, and distilling under N_2. Alternative methods for removing peroxides include passage through a column of alumina, refluxing with sodium wire or cupric stearate (then distilling from sodium). The diene is removed by refluxing with maleic anhydride before distilling under vacuum. Treatment with 0.1moles of MeMgI in 40ml of diethyl ether removes traces of oxygenated impurities. Other purification procedures include washing with aqueous NaOH, drying and distilling under N_2 through a spinning band column, redistilling from CaH_2, storing under sodium wire, and passing through a column of alumina, under N_2, immediately before use. Store it at <0° under argon. [Coleman & Johnstone *Org Synth* Coll Vol **I** 183 *1941*, DOI: 10.15227/orgsyn.005.0033; Corson & Ipatieff *Org Synth* Coll Vol **2** 151 *1943*, DOI: 10.15227/orgsyn.019.0036; Woon et al. *J Am Chem Soc* **108** 7990 *1986*, DOI:

After removing excess HBr, the sample is dried and fractionally distilled. [IR: Roberts & Chambers *J Am Chem Soc* **73** 5030 *1951*, DOI: 10.1021/ja01155a004; *Beilstein* **5** III 48, **5** IV 67.]

1-Cyclohexylethylamine *[S-(+)- 17430-98-7, R-(-)- 5913-13-3]* **$C_8H_{17}N$, M 127.2, b 177-178°/atm, d_4^{20} 0.866, n_D^{20} 1.446, $[\alpha]_D^{20}$ (-) and (+) 3.8(4.0) (neat), pK_{Est} ~10.6.** Purify it by conversion to the ***bitartrate salt*** (**m** 172°), then decomposing with strong alkali and extracting into Et_2O, drying (KOH), filtering, evaporating and distilling. The ***hydrochloride*** has **m 242°** (from EtOH/Et_2O), $[\alpha]_D^{15}$ -5.0 (c 10 H_2O, from (+) amine). The ***oxalate salt*** has **m** 132° (from H_2O). The ***(±)-base*** has **b 176-178°/760mm**, and its ***hydrochloride*** has **m 237-238°**. [Reihlen et al. *Justus Liebigs Ann Chem* **534** 247 *1938*, DOI: 10.1002/jlac.19385340115; Leithe *Chem Ber* **65** 660 *1932*, DOI: 10.1002/cber.19320650432; *Beilstein* **12** III 95.]

Cyclohexylidene fulvene (6,6-pentamethylene fulvene) *[3141-04-6]* **$C_{11}H_{14}$, M 146.2.** Purify the fulvene by column chromatography and eluting with *n*-hexane [Abboud et al. *J Am Chem Soc* **109** 1332 *1987*, DOI: 10.1021/ja00239a008].

Cyclohexyl methacrylate *[101-43-9]* **$C_{10}H_{16}O_2$, M 168.2, b 81-86°/0.1mm, d_4^{20} 0.964, n_D^{20} 1.458.** Purify it as for methyl methacrylate (see [80-62-6]). [Tong & Kenyon *J Am Chem Soc* **68** 1355 *1946*, DOI: 10.1021/ja01211a078; *Beilstein* **6** III 25, **6** IV 39.]

Cyclononanone *[3350-30-9]* **$C_9H_{16}O$, M 140.2, m 142.0-142.8°, b 220-222°, 100-101.5°/15mm.** Purify it *via* the ***semicarbazone*** (**m** 179.5-180.5° from 90% MeOH) and regenerate it by steam distilling a mixture of 13.1g of semicarbazone, 22g of phthalic anhydride and 45ml of H_2O. After collecting 300ml of distillate, the latter is extracted with Et_2O. The dried extract ($MgSO_4$) gives on evaporation 8.4g of ketone **b 100-101.5°/15mm**. The ***oxime*** has **m 76.5-77.5°** (**79°** from MeOH) and the ***iso-oxime*** has **m 138-139°**. [Ruzicka et al. *Helv Chim Acta* **32** 544 *1949*, DOI: 10.1002/hlca.19490320224.] It has also been repeatedly sublimed at 0.05-0.1mm pressure. [Blomquist et al. *J Am Chem Soc* **74** 3639, 3645 *1952*, *Beilstein* **7** III 110, **7** IV 62.]

***cis,cis*-1,3-Cyclooctadiene** *[3806-59-5]* **C_8H_{12}, M 108.2, m -5°, -49°, -53 to -51°, b 55°/34mm, 142-144°/760mm, d_4^{20} 0.8690, n_D^{20} 1.48921.** Purify the diene by GLC. Fractional distillation through a Widmer column gives a mobile liquid, and redistil it with a Claisen flask or through a semi-micro column [Gould, et al. *Anal Chem* **20** 361 *1948*, DOI: 10.1021/ac60016a027]. **NB:** It has a strong characteristic disagreeable odour detectable at low concentrations and causes headaches on prolonged exposure. *Do not breath it internally*. [IR: Cope & Estes *J Am Chem Soc* **72** 1128 *1950*, DOI: 10.1021/ja01159a016; UV: Cope & Bumgardner *J Am*

Chem Soc **78** 2812 *1956* DOI: 10.1021/ja01593a045.] [*Beilstein* **5** IV 401.]

***cis-cis*-1,5-cyclooctadiene (COD)** *[111-78-4, 1552-12-1]* **C_8H_{12}, M 108.2, m -69.5°, -70°, b 51-52°/25mm, 97°/144mm, 150.8°/757mm, 149-150°/atm, d_4^{20} 0.880, n_D^{20} 1.4935.** Purify it by GLC. It has been purified *via* the $AgNO_3$ salt. This is prepared by shaking with a solution of 50% aqueous $AgNO_3$ w/w several times (e.g. 3 x 50 ml and 4 x 50 ml) at 70° for *ca* 20 minutes to get a good separation of layers. The upper layers are combined and further extracted with $AgNO_3$ at 40° (2 x 20 ml). The upper layer (19 ml) of original hydrocarbon mixture gives colourless needles of the $AgNO_3$ complex on cooling. The adduct is recrystallised from MeOH (and cooling to 0°). The hydrocarbon is recovered by steam distilling the complex. The distillate is extracted with Et_2O, dried ($MgSO_4$), filtered, evaporated and re-distilled. [Jones *J Chem Soc* 312 *1954*, DOI: 10.1039/JR9540000312.] [*Beilstein* **5** H 116, **5** IV 403.]

Cyclooctanone *[502-49-8]* **$C_8H_{14}O$, M 126.2, m 32-41°, 42°, 43.8°, b 115-115.5°/60mm, 195-197°/atm, d^{25} 0.958.** Purify the ketone by sublimation after drying an ethereal solution over Linde type 13X molecular sieves, filtering and evaporating. The ***semicarbazone*** has **m 168-169°** (from dioxane) [Kohler et al. *J Am Chem Soc* **61** 1057 *1939*, DOI: 10.1021/ja01874a021]. The ***oxime*** has **m 36-37°** after subliming at high vacuum, or distillation, and has **b** 128-129° /14mm. The ***iso-oxime*** has **m 72-73°** [Ruzicka et al. *Helv Chim Acta* **32** 544 *1949*, DOI: 10.1002/hlca.19490320224]. [*Beilstein* **7** III 77, **7** IV 49.]

1,3,5,7-Cyclooctatetraene *[629-20-9]* **C_8H_8, M 104.2, m -5° to -3°, b 141-141.5°/atm, 142-143°/atm, d_4^{20} 1.537, n_D^{25} 1.5350.** Purify the triene by shaking 3ml with 20ml of 10% aqueous $AgNO_3$ for 15 minutes, then filtering off the $AgNO_3$ complex which precipitates. The precipitate is dissolved in water and added to cold concentrated ammonia to regenerate the cyclooctatetraene which is fractionally distilled under vacuum onto molecular sieves and stored at 0°. Add ~0.1% of hydroquinone as stabiliser. It is passed through a dry alumina column before use [Broadley et al. *JCS Dalton Trans* 373 *1986*, DOI: 10.1039/DT9860000373]. [*Beilstein* **5** I 228, **5** IV 1331.]

***cis*-Cyclooctene** *[931-87-3; 931-88-4]* **C_8H_{14}, M 110.2, m -16°, b 32-34°/12mm, 66.5-67°/60mm, 88°/141mm, 140°/170mm, 143°/760mm, 145-146°/760mm, d_4^{20} 0.84843, n_D^{20} 1.4702.** The *cis*-isomer is freed from the *trans*-isomer by fractional distillation through a spinning-band column, followed by preparative gas chromatography on a Dowex 710-Chromosorb W GLC column. It is passed through a short alumina column immediately before use [Collman et al. *J Am Chem Soc* **108** 2588 *1986*, DOI: 10.1021/ja00270a016]. It has also been distilled in a dry N_2 glove box from powdered fused NaOH through a Vigreux column, then passed through activated neutral alumina before use [Wolf et al. *J Am Chem Soc* **109** 4328 *1987*, DOI: 10.1021/ja00248a031]. *Alternatively*, it can be purified *via* the $AgNO_3$ salt. This salt is obtained from crude cyclooctene (40 ml) by shaking at 70-80° with 50% w/w $AgNO_3$ (2 x 15 ml) to remove cyclooctadienes (aqueous layer). Extraction is repeated at 40° (4 x 20 ml, of 50% $AgNO_3$). Three layers are formed each time. The middle layer contains the $AgNO_3$ adduct of cyclooctene which crystallises on cooling the layer to room temperature. The adduct (complex 2:1) is highly soluble in MeOH (at least 1g/ml) from which it crystallises in large flat needles when cooled at 0°. It is dried under slight vacuum for 1 week in the presence of $CaCl_2$ and paraffin wax soaked in cyclooctene. It has **m** 51° and loses hydrocarbon on exposure to air. *cis*-Cyclooctene can be recovered by steam distillation of the salt, collected, dried ($CaCl_2$) and distilled in a vacuum. [Braude et al. *J Chem Soc* 4711 *1957*, DOI: 10.1039/JR9570004711; $AgNO_3$: Jones *J Chem Soc* 1808 *1954*, DOI: 10.1039/JR9540001808; Cope & Estes *J Am Chem Soc* **72** 1128 *1950*, DOI: 10.1021/ja01159a016; *Beilstein* **5** I 35, **5** IV 263.] **FLAMMABLE LIQUID.**

Cyclopentadecanone (Exaltone) *[502-72-7]* **$C_{15}H_{28}O$, M 224.4, m 63°, 65°, 65-66°, b 120°/0.3mm, 155-157°/5mm.** Subliming Exaltone is better than crystallising it from aqueous EtOH for purification. The *semicarbazone* has **m** 186-187°. [Stevens & Erickson *J Am Chem Soc* **64** 144 1942, DOI: 10.1021/ja01253a038; Mathur et al. *J Chem Soc* 3505 *1963*, DOI: 10.1039/JR9630003505; Bienz & Hesse *Helv Chim Acta* **71** 1704 *1988*, DOI: 10.1002/hlca.19880710717; *Beilstein* **7** III 203, **7** IV 113.]

Cyclopentadiene *[542-92-7]* **C_5H_6, M 66.1, b 41-42°/atm, pK^{25} 15.** Dry the diene with $Mg(ClO_4)_2$ and distil it rapidly as it dimerises readily at room temperature. It should be used immediately or stored in a Dry Ice or an

ice-salt bath. **HIGHLY FLAMMABLE.** [Moffett *Org Synth* Coll Vol **4** 238 *1963*, DOI: 10.15227/orgsyn.032.0041.] ***Cyclopentadiene Dimer (dicyclopentadiene) (4,7-methano-3a,4,7,7a-tetrahydroindene)*** has [77-73-6], **$C_{10}H_{12}$, M 132.3, m 33°, b 170°/atm, and d^{25} 0.986**; add ~0.05% of 2,6-di-*tert*-butyl-4-methylphenol as stabiliser. Cyclopentadiene is prepared when required by ***de-polymerising*** the technical grade dimer by heating (and distilling) it carefully under a fractionating column [Wilkinson *Org Synth* Coll Vol **4** 473 *1963*, DOI: 10.15227/orgsyn.036.0031], as described by Moffett (above reference), or by adding the dimer at a steady rate onto mineral oil heated at 240-270° when it distils off. [Korach et al. *Org Synth* **42** 50 *1962*, DOI: 10.15227/orgsyn.042.0050]. [*Beilstein* **5** II 391.]

Cyclopentane *[287-92-3]* **C_5H_{10}, M 70.1, m -94°, b 49.3°/atm, 50°/atm, d_4^{20} 0.745, n_D^{20} 1.40645, n_D^{25} 1.4340.** Free it from cyclopentene by two passages through a column of dried and degassed activated silica gel. It occurs in petroleum and is **HIGHLY FLAMMABLE.** [NMR: Christl *Chem Ber* **108** 2781 *1975*, DOI: 10.1002/cber.19751080836; Whitesides & Gutowski *J Org Chem* **41** 2882 *1976,* DOI: 10.1021/jo00879a019; *Beilstein* **5** III 10, **5** IV 4.]

Cyclopentane carbonitrile *[4254-02-8]* **C_6H_9N, M 95.2, m -75.2°, -76°, b 43-44°/7mm, 50-62°/10mm, 67-68°/14mm, 74.5-75°/30mm, d_4^{20} 0.912, n_D^{20} 1.441.** Dissolve the nitrile in Et_2O, wash it thoroughly with saturated aqueous K_2CO_3, dry ($MgSO_4$) and distil it through a 10 cm Vigreux column. [McElvain & Starn *J Am Chem Soc* **77** 4571 *1955*, DOI: 10.1021/ja01622a040; Bailey & Daly *J Am Chem Soc* **81** 5397 *1959*, DOI: 10.1021/ja01529a036; *Beilstein* **9** IV 14.]

Cyclopentanecarboxaldehyde *[872-53-7]* **$C_6H_{10}O$, M 98.1, b 36°/12mm, 74-78°/100mm, 140-141°/atm, d^{25} 0.919, n_D^{20} 1.4420-1.4428.** Several preparations of this aldehyde have been described but only two will be briefly mentioned here, and both start from cyclohexene. The ***first*** requires decomposition of the mercuric sulfate complex where, under N_2, concentrated H_2SO_4 (43.5ml, 80.0g, 0.82mole) in H_2O (3L) and $HgSO_4$ (740.0g, 2.49moles, CARE **POISONOUS**) are stirred to form the deep-yellow basic salt. To this stirred mixture, under N_2 at 55°, is added all at once cyclohexene (101ml, 82.0g, 1mole, freshly distilled b 82-84°/atm [110-83-8]), and the temperature kept at 55-65° for 1 hour (optimal conditions for decomposition of complex). The colour of the mixture turns from deep-yellow to cream. The equipment is altered for distillation at the end of the hour, and the temperature is raised, stirring and the N_2 flow are continued as the crude *aldehyde* and H_2O distil over during *ca* 2 hours. The layers are separated, the H_2O layer is extracted with Et_2O (3 x 50ml) which is combined with the product, dried (Na_2SO_4), filtered, and distilled rapidly (b 74-78°/100mm) to give the *aldehyde* (46-52g, 46-53%), which if not used immediately should be stored in a brown bottle at 0° for under N_2, after 0.1g of hydroquinone is added as stabiliser. The *aldehyde* readily forms a *trimer*, and does so on prolonged storage. [Grummit et al. *Org Synth* Coll Vol **5** 320 *1973*, DOI: 10.15227/orgsyn.044.0026; English et al. *J Am Chem Soc* **73** 615 *1951*, DOI: 10.1021/ja01146a036.] When the distillation residue is cooled a solid may be formed which can be distilled above 78°/100mm to give a clear liquid that solidifies, and can be recrystallised from 95% EtOH to give a white solid **m 122-124°**, identical with ***cyclopentanecarboxaldehyde trimer*** obtained from the *aldehyde* and 85% H_3PO_4 [Brook & Wright *Can J Chem* **29** 308 *1951*, DOI: 10.1139/v51-036]. In the ***second*** procedure, $Tl(III)(NO_3)_3$ $3H_2O$ (4.4g, 10mmol, TTN [13453-38-8]) is dissolved in MeOH (50ml), cyclohexene (10mmol) is added, and the mixture is stirred at room temperature or heated until a starch-iodide paper indicates complete reduction of Tl(III) to Tl(I) (usually within a few minutes). The mixture is filtered, and an alcoholic solution containing 10mmol of 2,4-dinitrophenylhydrazine is added. This is evaporated to 1/3 its volume and after addition of H_2O (10ml) the mixture is heated on a steam bath for 10 minutes. On cooling to 0°, the ***2,4-dinitrophenylhydrazone*** *[20956-07-4]* crystallises out and is recrystallised from EtOH to **m 195.5-196°** (85% yield). Hydrolysis of the hydrazone in the usual way provides the free *aldehyde*. On a preparative scale the precipitated $Tl(I)(NO_3)$ salt is filtered off, the filtrate is evaporated to a small volume, the mixture of aldehyde and its methyl acetal formed is heated on a steam bath with excess of 5% H_2SO_4 for 30 minutes, and *cyclopentanecarboxaldehyde* is isolated by ether extraction followed by distillation as in the first preparation above. [McKillop et al. *J Am Chem Soc* **95** 3635 *1973*, DOI: 10.1021/ja00792a028.] It should be stabilised with 0.1% of hydroquinone as before.

Cyclopentane carboxylic acid *[3400-45-1]* **$C_6H_9O_2$, M 114.1, m 3-5°, b 87-89°/2-3mm, 106.5-107°/10mm, 120-123°/27mm, 216°/atm, d^{25} 1.053, n_D^{20} 1.4530, n_D^{25} 1.4522, pK^{25} 4.98.** If it is discoloured, shake it with

saturated aqueous NaCl, extract it with Et_2O, dry the extract ($MgSO_4$), filter, evaporate and distil the residue preferably under a vacuum. The **lachrymatory *acid chloride*** *[4524-93-0]* has **C_6H_9ClO, M 132.6, m 4° and b 161-162°/atm, d_4^{20} 1.091, n_D^{20} 1.4622.** [*Beilstein* **9** H 6, **9** IV 11.] The ***amide*** *[3217-94-5]* **$C_6H_{11}NO$,** has **m 179°**. Like the methyl ester below, the acid can also be prepared *via* a Favorskii reaction, but by using a little over 2 moles of alkoxide (1mol provides the ester). Thus, to sodium (83g, 3.61mol) in absolute EtOH (2.3L) is added dropwise 2-chlorocyclohexanone (240.5g, 1.82mol, [822-87-7]) during several hours, left overnight, the EtOH is distilled off, replaced by an equal volume of H_2O, acidified to pH 3, and the oily acid that separates is extracted with Et_2O. The extract is washed with H_2O, dried (Na_2SO_4), filtered, and distilled to give the pure *acid* (110g, 53%). [Jackman et al. *J Am Chem Soc* **70** 497 *1948*, DOI: 10.1021/ja01182a019; Mourisson et al. *Bull Soc Chim Fr* 767 *1952*.] [*Beilstein* **6** H 6, **6** I 4, **6** II 6, **6** III 11, **6** IV 9.]

Methyl cyclopentanecarboxylate *[4630-80-2]* **$C_7H_{12}O_2$, M 128.1, b 70-73°/48mm, 38-39°/7mm, 158.2°/760mm, n_D^{25} 1.4341**, can be obtained by reacting the acid chloride with MeOH and distilling; but it can also be obtained in ~55% yield directly from 2-chlorocyclohexanone and NaOMe (1mol) in dry Et_2O, *via* a Favorskii reaction, and purified by fractional distillation, using a Podbielniak column filled with tantalium wire spirals and a partial reflux head, under reduced pressure [Goheen & Vaughan *Org Synth* Coll Vol **4** 594 *1963* DOI: 10.15227/orgsyn.039.0037]. The *methyl ester* has also been prepared in 98% yield by direct esterification of cyclopentane carboxylic acid with MeOH in CH_2Cl_2 in the presence of catalytic amounts of H_2SO_4. The acid has FTIR (CCl_4) with ν_{max} at 2952(s), 2873 (m), 1734 (s), 1436 (w), 1165 (s) and 1140 (s) cm^{-1}; ^1H NMR (75MHz, $CDCl_3$, TMS) with δ at 1.5-2.0 (m, 8H, 4-methylenes), 2.7 (pentet, 1H, *J* = 9.0Hz), 3.7 (s, 3H, Me); ^{13}C NMR (300MHz, $CDCl_3$, TMS) with δ at 25.7, 29.9, 43.6, 51.5, 177.2, and the GCMS has *m/z* at 128 (M^+) [Davis et al. *J Org Chem* **58** 6843 *1993*, DOI: 10.1021/jo00076a055].

1,1-Cyclopentanediacetic acid (3,3-tetramethyleneglutaric acid) *[16713-66-9]* **$C_9H_{14}O_4$, M 186.2, m 176-177°, 180-181°, pK_1^{25} 3.80, pK_2^{25} 6.77.** Purify it by recrystallisation from H_2O and dry it in air, *in vacuo* or over $CaCl_2$. However, if it is suspect it is better to convert the acid to the **anhydride (8-oxaspiro[4.5]decane-7,8-dione** [5662-95-3] **$C_9H_{12}O_3$, M 168.2**, **m 64-66° (68°** also reported), **b 186°/15mm**) by refluxing it for 7 hours in excess of Ac_2O, evaporating to dryness, and distilling the residue in a vacuum or recrystallising it from light petroleum. [Kon & Thorpe *J Chem Soc* **115** 686 *1919*, DOI: 10.1039/CT9191500686.] The anhydride (e.g. 30g) is then hydrolysed by refluxing it for 2.5 hours (i.e. until it dissolves) in aqueous KOH (35g, 3mols in 55ml of H_2O), then acidified with concentrated HCl, extracted with Et_2O (3 x 50ml) after saturating the aqueous solution with $(NH_4)_2SO_4$, drying the extract (Na_2SO_4), filtering, evaporating the Et_2O and recrystallising the *di-acid* from hot H_2O. The ***dimethyl ester*** *[70179-60-3]* has **b 141°/17mm** [Vogel *J Chem Soc* 1758 *1934*, DOI: 10.1039/JR9340001758; Dickins et al. *J Chem Soc* 1496 *1922*, DOI: 10.1039/CT9222101496], and the ***diethyl ester*** has **b 153°/14mm** [Kon *J Chem Soc* 513 *1922*, DOI: 10.1039/JR9340001758]. [*Beilstein* **9** I 319, and anhydride *Beilstein* **17/11** V 80.]

Cyclopentane-1,1-dicarboxylic acid *[5802-65-3]* **$C_7H_{10}O_4$, M 158.1, m 183°, 184°, (176-178°), pK_1 3.23, pK_2 4.08.** The dicarboxylic acid can be prepared in 71% yield by using the nickel(0) catalyst *2-{2-[2-(dicyclohexyl-phosphino)ethyl]pyridine}-4-oxo-2-nickela-3-oxa-cis-bicyclo[3.3.0]octane* which promotes the di-carbonylation of cyclopentene (1.16g, 2.44mmol) in THF (30ml)/pyridine (30ml), in the presence of BeCl (0.2g, 2.50mmol), by CO_2 (10 bar pressure) in an autoclave, and stirring at 60° for 24 hours. The solvent is evaporated off *in vacuo*, the residue is treated with Et_2O/HCl and the solid is collected, dried and recrystallised from pentane/Et_2O (10:1), or H_2O. The pure *dicarboxylic acid* melts at 183° with decarboxylation to *cyclopentanecarboxylic acid* (see preceding acid), and has FTIR (KBr) with ν_{max} at 3200-2500 (CO**OH**) and 1700 (C=O) cm^{-1}; ^1H NMR (200MHz, THF-d_8/TMS) with δ at 1.6 (m, 4H, 2-methylenes), 2.1 (m, 4H, 2-methylenes), 9.6 (br, 2H, 2-COO***H***) ppm; ^{13}C NMR (50MHz, THF-d_8/TMS) with δ at 26.3 (t), 35.2 (t), 60.6 (s), 174.2 ppm; and the MS (70 eV) has *m/z* at 158 (M^+). [Hoberg et al. *Synthesis* 395 *1991*, DOI: 10.1055/s-1991-26475]. ***Dimethyl 1,1-cyclopentanedicarboxylate*** *[74090-15-6]* **M 186.2, b 102°/10mm,** can be prepared in 76% yield from the preceding *methyl cyclopentanecarboxylate* (40mmol, [*4630-80-2*]) in THF (60ml), with $(^iPr)_2NH$ (60mmol) and *n*-BuLi (60mmol) followed by MeOCOCl (60mmol), and finally distilling. The *dimethyl ester* has FTIR (CCl_4) with ν_{max} at 2953(s), 2928 (w), 2876 (w), 1736 (s), 1434 (w), 1266 (s), 1165 (s) and 1159 (m) cm^{-1}; ^1H NMR (300MHz, $CDCl_3$, TMS) with δ at 1.7 (m, 4H, 2-methylenes), 2.1 (m, 4H, 2-methylenes), 3.7 (s, 6H, 2-Me) ppm; ^{13}C NMR (75MHz, $CDCl_3$, TMS) with δ at 25.3, 34.5, 52.4, 60.2, 173.0 ppm, and the GCMS has *m/z* at 187 (M^++1) [Davis et al. *J Org Chem* **58** 6843 *1993*, DOI: 10.1021/

jo00076a055].

1RS,2SR*-(meso)-*cis*-1,2-Cyclopentanedicarboxylic acid** *[1461-96-7]* **$C_7H_{10}O_4$, M 158.2, m 139°, 140°, 141°, pK_1^{20} 4.42, p K_2^{20} 6.57.** The *cis*-acid has been prepared by hydrogenation of cyclopent-1-ene-1,2-dicarboxylic acid with Pt as catalyst [Peters *J Chem Soc* 1757 *1959*, DOI: 10.1039/JR9590001757], heating diethyl 1-cyanocyclopentane-1,2-dicarboxylate (b 135-136°/3.5mm) with aqueous HCl and isolating the anhydride [Fuson & Cole *J Am Chem Soc* **60** 1237 *1938*, DOI: 10.1021/ja01272a066; Dutta *J Indian Chem Soc* **17** 611, 617 *1940*], but is best prepared by boiling the *trans*-acid with excess of acetic anhydride for at least 2 hours (which provides the *cis-anhydride*), dissolving this in boiling H_2O or aqueous KOH with cooling (**care**, may be exothermic), and acidifying to pH ~2 in order to precipitate the *cis*-acid. The *cis*-acid crystallises from hot H_2O as colourless needles melting at **140°**, and is rapidly converted to the ***cis-anhydride at **150-160°**. The *cis*-acid is also obtained from the *trans*-acid by heating at 300 ° [Perkin Jnr *J Chem Soc* **51** 240 *1887*, DOI: 10.1039/CT8875100240]. It is more soluble in H_2O than the (±)-*trans*-acid. It had not been possible to prepare *trans*-cyclopentane-1,2-dicarboxylic anhydride because all attempts gave the ***cis-anhydride*** (*cis*-**tetrahydro-*1H*-cyclopent[*c*]furan-1,3(*3aH*)-dione**, **m 73.5-74°, b 100-102°/1.5mm,** *[5763-49-5]*). [Perkin Jnr *J Chem Soc* **65** 572 *1894*, DOI: 10.1039/CT8946500572; cf. Fuson & Cole *J Am Chem Soc* **60** 1237 *1938*, DOI: 10.1021/ja01272a066; Goldsworthy & Perkin Jnr *J Chem Soc* **105** 2639 *1914*, DOI: 10.1039/CT9140502639.]. The nickel(0) catalyst *2-{2-[2-(dicyclohexyl-phosphino)ethyl]pyridine}-4-oxo-2-nickela-3-oxa-cis-bicyclo-[3.3.0]octane* promotes the carbonylation of cyclopentene in THF by CO at 1bar pressure and -40°, then at ~25°/10 hours followed by treatment with 2N H_2SO_4 and recrystallisation from pentane/Et_2O (10:1), which provides cyclopentane-1,2-dicarboxylic acid (78% yield) presumed to be mainly the *cis-isomer*. However, its melting point of 124-125° suggests that it must be contaminated with some of the *trans*-isomer [Hoberg et al. *Synthesis* 395 *1991*, DOI: 10.1055/s-1991-26475]. Its FT-IR (KBr) has ν_{max} at 3300-2500 (CO**OH**) and 1710 (C=O) cm^{-1}; its ^1H NMR (200MHz, THF-d_8/TMS) has δ_H at 10.4 (br s, 2H, OH), 2.9 (m, 2H, 2CH), 1.51-2.1 (m, 6H, $3CH_2$), 1.69 (m, 4H); its ^{13}C NMR (200MHz, THF-d_8/TMS) has δ_C at 176.10 (s, carboxylic C), 47.5 (d, C1 and C2), 29.4 (t, C-3 and C-5) and 24.4 (t, C-4); and its MS (70 eV) has m/z = 158 (M^+), see GC-MS [below, Lu et al. *J Org Chem* **55** 2503, 2507 *1990*, DOI: 10.1021/jo00295a048]. ***Dimethyl cis-cyclopentane-1,2-dicarboxylate*, b 129°/20mm, n_D^{21} 1.4528** *[4841-91-2]*, is obtained by treating the acid with diazomethane in Et_2O, evaporating and distilling the residue [Owen & Peto *J Chem Soc* 2383, 2386 *1955*, DOI: 10.1039/JR9550002383]. The ***cis-imide*** (*cis*-**tetrahydrocyclopent[*c*]pyrrole-1,3(*2H,3aH*)-dione**, *[5763-44-0]*) has **m 85-87°** (also **90°** reported) after recrystallisation from H_2O or petroleum ether (b 40-60°) [Menon & Simonsen *J Chem Soc* 302 *1929*, DOI: 10.1039/JR9290000302; Rice et al. *J Org Chem* **24** 7 *1959*, DOI: 10.1021/jo01083a002], and *cis-**cyclopentane-1,2-dicarboxylic acid dihydrazide***, prepared from the dimethyl ester and $NH_2NH_2.H_2O$ in EtOH and recrystallised from MeOH/Et_2O, has **m 125-126°** [Müller et al. *J Am Chem Soc* **73** 2487 *1951*, DOI: 10.1021/ja01150a023]. [*Beilstein* **9** H 728, **9** III 3807, **9** IV 3793.]

***1RS,2RS*-(±)-*trans*-1,2-Cyclopentanedicarboxylic acid** *[1461-97-8]* **$C_7H_{10}O_4$, M 158.2, m 160-161°, 161.5°, 162°, 162-163°, 163°, 163-165°, 164-165°, pK_1^{20} 4.14, p K_2^{20} 5.99.** Several syntheses of the (±)-*trans*-acid have been described. The first preparation involved tetraethyl cyclopentane-1,2,3,4-tetracarboxylate [b 185-190°/1mm, from trimethylene-1,3-dibromide (96g), Na (22g) and diethyl malonate (150g) in absolute EtOH (300ml)] which was refluxed with 2-3 volumes of AcOH, 1 volume of concentrated H_2SO_4 and 1 volume of H_2O for 2 days, and the AcOH and H_2O were distilled off to give *trans*-cyclopentane-1,2-dicarboxylic acid [Perkin Jnr *J Chem Soc* **65** 572 *1894*, DOI: 10.1039/CT8946500572; Wassermann *Helv Chim Acta* **13** 207 *1930*, DOI: 10.1002/hlca.19300130212; Perkin Jnr & Prentice *J Chem Soc* **59** 818 *1891*, DOI: 10.1039/CT8915900818]. Other preparations include heating the *cis*-acid with concentrated HCl at 180° [Perkin Jnr *J Chem Soc* **65** 572, 590 *1894*, DOI: 10.1039/CT8946500572], refluxing diethyl 1-cyanocyclopentane-1,2-dicarboxylate with concentrated aqueous HCl for 4 days which provided a 92% yield of the *trans*-acid [Fuson et al. *J Org Chem* **10** 121, 126 *1945*, DOI: 10.1021/jo01178a005; Fuson & Cole *J Am Chem Soc* **60** 1237 *1938*, DOI: 10.1021/ja01272a066], and electrochemical coupling between 1,3-dibromopropane and dimethyl maleate which gave a 10/1 ratio of *trans*/*cis* dimethyl esters in 42% yield [Lu et al. *J Org Chem* **55** 2503, 2507 *1990*, DOI: 10.1021/jo00295a048]. Invariably the crude *trans*-diesters formed are contaminated with some *cis*-isomer and it was found that hydrolysing the ester mixture by refluxing the acidic solution for 4 to 5 days provided only the *trans*-acid in ~95% yields. The *trans*-acid crystallises (charcoal) from hot H_2O, and it is easily soluble in AcOH, and EtOH, but very soluble in Et_2O, $CHCl_3$, $*C_6H_6$

and petroleum ether. Its FT-IR (Nujol)) has ν_{max} at 3008.3, 2653.8, 1692.6, 1419.2, 1311.1, 1253.5, 1199.3, 935.7 and 689.4 cm^{-1}; its ^1H NMR (60MHz, $CDCl_3$) has δ_H at 12.2 (br s, 2H, OH), 2.96 (m, 2H, C1 and C2 methines), 1.99 (m, 2H,), 1.69 (m, 4H); its ^{13}C NMR (75MHz, $CDCl_3$) has δ_C at 176.10 (s, carboxylic C), 46.77 (s, C1 and C2), 30.03 (s, C3 and C5) and 25.01 (s, C-4); and its GC-MS has *m/z* (relative intensity) *trans*-isomer: 157(37, M^+-2), 155(15), 126(67), 113(29), and 67(100), and *cis*-isomer: 157(6, M^+-2), 155(40), 126(32), 113(56), and 67(100) [Lu et al. *J Org Chem* **55** 2503, 2507 *1990* DOI: 10.1021/jo00295a048]. ***Dimethyl** trans-**cyclopentane-1,2-dicarboxylate*, **b 118.5-119°/17mm, n_D^{20} 1.4491** *[941-75-3]*, is obtained by treating the acid with diazomethane in Et_2O, evaporating and distilling the residue [Owen & Peto *J Chem Soc* 2383 *1955*, DOI: 10.1039/JR9550002383]. *trans-**Cyclopentane-1,2-dicarbonyl dichloride***, has **b 98-100°/2mm** [Aspinall & Baker *J Chem Soc* 743 *1950* DOI: 10.1039/JR9500000743], and *trans-**cyclo-pentane-1,2-dicarboxylic acid dihydrazide***, prepared from the dimethyl ester and NH_2NH_2. H_2O in EtOH, and recrystallised from EtOH, has **m 224-225°** [Müller et al. *J Am Chem Soc* **73** 2487 *1951*, DOI: 10.1021/ ja01150a023]. [*Beilstein* **9** H 728, **9** I 316, **9** III 3807, **9** IV 2793.]

1S,2S*-(+)-*trans*-1,2-Cyclopentanedicarboxylic acid** *[21917-20-4]* **$C_7H_{10}O_4$, M 158.2, m 181°, $[\alpha]_D$ +87.6 (c 0.88, H_2O)** and ***1R,2R*-(-)-*trans*-1,2-cyclopentanedicarboxylic acid** *[17224-73-6]* **m 180-181°, $[\alpha]_D$ -85.9 (c 1.2, H_2O).** Optical resolution of the (±)-acid (above) is readily achieved *via* separation of the diastereoisomeric brucine salts (the base being *l*-brucine). Thus pure (±)-acid (15g, ~0.1mole) is dissolved in hot H_2O, and while stirring, the finely powdered brucine tetrahydrate (90g, 0.2 moles, [5892-11-5], care **POISONOUS**) that is added gradually dissolves. At the end of the addition, the mixture is stirred for ~10 minutes and filtered hot from a small amount of undissolved brucine. The brucine is washed well with hot H_2O, and the combined filtrate and washings are concentrated on a boiling water bath until crystals commence to form on the surface. When the liquid is cooled and vigorously stirred, copious crystals of the *d*-acid (*l*-base)$_2$ separate, and the whole mixture sets into a mass of crystals. These are filtered off and recrystallised from hot H_2O to constant specific rotation. An analytical sample of the *d*-acid (*l*-base)$_2$ is obtained by dissolving it in hot H_2O and allowing it to crystallise slowly in a desiccator over concentrated H_2SO_4. The decahydrate is obtained on drying the crystalline plates in air but they effloresce in a vacuum desiccator or on heating at 125° for 1 hour to give *anhydrous* ***d*-acid (*l*-base)$_2$** that has **$[\alpha]_D$ -19.9 (c 1.3, H_2O).** The *d*-acid (*l*-base)$_2$ is then decomposed by dissolving it in hot H_2O, adding aqueous ammonia, filtering off the solid brucine, washing it well with aqueous ammonia, and the combined hot filtrate and washings are cooled and acidified with hydrochloric acid. On cooling the ***(+)-acid (m 178-180°) separates and is recrystallised from hot H_2O as plates with m 180°. ***Diethyl 1S,2S-(+)-trans-1,2-cyclopentanedicarboxylate*** **b 170°/100mm, $[\alpha]_D$ +70.3 (c 1.3, Me_2CO)**, is prepared by boiling the (+)-acid with 5 times its weight of 10% ethanolic H_2SO_4 for 6 hours, cooling, adding H_2O, the ester is extracted into Et_2O which is washed with dilute Na_2CO_3, dried (Na_2SO_4), filtered, evaporated and the residue is distilled in a vacuum. The ***1S,2S-(+)-trans-dianilide*, m 245-247°, $[\alpha]_D$ +110.1 (c 0.85, Me_2CO)** is prepared by heating the (+)-acid with $SOCl_2$ in a sealed tube at 100° for 1 hour, evaporating, the di-acid chloride formed is then dissolved in $*C_6H_6$, treated with excess of aniline, evaporated again, the residue is stirred with dilute aqueous HCl, the precipitate is collected and recrystallised twice from large volumes of MeOH.

1R,2R-(-)-trans-1,2-cyclopentanedicarboxylic acid is obtained by concentrating the mother liquors from the first crystallisation of the *d*-acid (*l*-base)$_2$ above, which provides copious crystals of the more soluble ***diastereoisomeric l*-acid (*l*-base)$_2$**. Treatment of this salt with aqueous ammonia as above followed by recrystallisation from H_2O gives the pure ***(-)-acid*** with **m 180-181°**. ***Diethyl 1R,2R-(-)-trans-1,2-cyclo-pentanedicarboxylate*,** prepared in the same way as its enantiomer above has similar properties except for the optical rotation which is **$[\alpha]_D$ -69.8 (c 1.7, Me_2CO)**. [Goldsworthy & Perkin Jnr *J Chem Soc* **105** 2639 *1914*, DOI: 10.1039/CT9140502639]. [*Beilstein* **9** I 316] The absolute configuration of the ***(-)-acid*** was determined as ***1R,2R*** by comparing the ORD spectra of the respective 1,2-bis(N-methylthionamide) [1,2-(CSNHMe)$_2$] with those of the corresponding 1,2-disubstituted cyclopropane, cyclobutane and cyclohexane homologues [Inouye et al. *Tetrahedron* **23** 3237 *1967*, DOI :10.1016/S0040-4020(01)92293-8]. [*Beilstein* **9** III 3807.]

***1RS,2SR-cis*-1,2-Cyclopentanediol (*meso-cis*-cyclopentane-1,2-diol)** *[5057-98-7]* **$C_5H_{10}O_2$, M 102.1, m 24-28°, 30°, b 88-92°/2mm, 108-109°/20mm, 123.5°/29mm, n_D^{21} 1.4770.** The *cis*-diol can be obtained by treating cyclopentene (21.8g, [142-29-0]) in EtOH (600ml) at -40° with a solution of $KMnO_4$ (40g) and anhydrous $MgSO_4$ (30g) in H_2O (800ml) dropwise, with vigorous stirring, during 2 hours. The MnO_2 is filtered off, washed with hot H_2O, the combined aqueous filtrates are evaporated *in vacuo* to 100ml and continuously extr-

acted with Et_2O (liquid-liquid extractor) for 48 hours. The dried ($MgSO_4$) Et_2O extract is evaporated and the residual oil is distilled to give the *cis*-diol (11.1g, 34%). The ***cis-di-p-nitrobenzoate*** has **m 117° (117-118°)** (from EtOH) the ***cis-di-methanesulfonate*** has **m 82°** (needles from MeOH), and the ***cis-di-toluene-p-sulfonate*** has **m 92°** (prisms from EtOH) are obtained in the usual way in pyridine. The ***cis-monoacetate*** has **b 104-106°/20mm, n_D^{17} 1.4576**, the ***cis-monoacetate-mono-p-nitrobenzoate*** has **m 93-94°** (nodules from EtOH), and the ***cis-diacetate*** has **m -5°, b 80°/2mm**. The ***cis-dibenzoate*** has **m 47°**. [Owen & Smith *J Chem Soc* 4026 *1952*, DOI: 10.1039/JR9520004026; *Beilstein* **6** I 369, **6** II 742, **6** III 4053, **6** IV 5187.]

1RS,2RS*-(±)-*trans*-1,2-Cyclopentanediol [*trans*-(±)-cyclopentane-1,2-diol]** *[5057-99-8, (±) 86703-52-8]* **$C_5H_{10}O_2$, M 102.1, m 50°, 55°, b 93°/2mm, 122°/10mm, 136°/22mm.** The *cis*-diol can been prepared in a seven step synthesis from *racemic* diethyl tartrate [Cunningham & Küendig *J Org Chem* **53** 1823 *1988*, DOI: 10.1021/jo00243a048], from *trans*-2-tri-methylsilylcyclopentan-1-ol and MeOH [Kono & Ngai *Org Prep Proced Int* **6** 19 *1974*], and by performate oxidation of cyclopentene which is described herein. A mixture of 30% aqueous H_2O_2 (13g) and formic acid (105g) is added to cyclopentene (6.6g, b 44-45°/atm [142-29-0]) under a reflux condenser, when much heat is generated, the temperature is allowed to fall to 40° and is so maintained for 4 hours. The solvent is removed *in vacuo*, the residue is dissolved in 10% aqueous NaOH (50ml), boiled under reflux for 45 minutes, the solvent is distilled off, and the residue is twice distilled under reduced pressure to give pure *trans*-pentane-1,2-diol (6g, 60%) which solidified in the distillate. The ***trans-dibenzoate has **m 63°**, and the ***trans-(±)-di-p-nitrobenzoate*** **(m 145°**, from EtOH), the ***trans-(±)-di-methanesulfonate*** **(m 82°,** small needles from EtOH), and the ***trans-(±)-di-p-toluenesulfonate*** **(m 109°**, colourless plates from MeOH) are prepared in the usual way in pyridine. [Owen & Smith *J Chem Soc* 4026 *1952*, DOI: 10.1039/JR9520004026; Englund *J Prakt Chem* **129** 1, 10 *1931*, DOI: 10.1002/prac.19311290101; *Beilstein* **6** H 739, **6** I 369, **6** II 743, **6** III 4053, **6** IV 5187.]

1R,2R*-(-)-*trans*-1,2-Cyclopentanediol [*trans-(-)*-cyclopentane-1,2-diol]** *[(-) 930-46-1, (-) 86703-52-8]* **$C_5H_{10}O_2$, M 102.1, m 48-48.5°, $[\alpha]_D^{20}$ −24.88 (c 6, EtOH)** and ***1S,2S-trans*-1,2-cyclopentanediol [*trans*-(+)-cyclopentane-1,2-diol]** *[(+)107492-82-0], m 47-48°, $[\alpha]_D^{20}$ +24.54 (c 5.4, EtOH).** The *1R,2R-enantiomer* is obtained optically pure in a seven step synthesis from diethyl D(-)tartrate by benzylation (TlOEt/$PhCH_2Br$, 81%), reduction (LAH/Et_2O, 94%) to *2R,3R-(-)-2,3-bis(benzyloxy)-1,4-butanediol*, ditosylation (TsCl/py, 87%), dibromination (with LiBr/DMSO, 94%) to *2R,3R-(-)-2,3-bis(benzyloxy)-1,4-butanedibromide*, and formation of the cyclopentane ring ($PhSO_2CH_2SO_2Ph/K_2CO_3$/DMF, 92%) to give *1R,2R-(-)-1,2-bis(benzyloxy)-4,4-bis(phenylsulfonyl)cyclopentane*. Removal of the bis-sulfonyl groups (Mg/MeOH, 82%) provides *1R,2R-(-)-1,2-bis(benzyloxy)cyclopentane*, and finally debenzylation (H_2/10% Pd/C, 99%) gives pure 1*R*,2*R*-(-)-cyclopentane-1,2-diol in 47% overall yield. The final step only is detailed here. The mixture of *trans-(-)*-1,2-bisbenzyloxycyclopentane (5.11g, 18.1mmol) in EtOH (35ml) containing 10% Pd/C (1.35g) is degassed three times, H_2 gas is introduced into the flask at a pressure of 6 atmospheres for 5 hours, the catalyst is filtered off, and the filtrate is evaporated to provide the **1*R*,2*R*-*trans*-(-)-diol** (8.2g, 99%) as a white hygroscopic solid **m 47-48°** which should be stored under dry N_2 in a sealed vessel. The enantiomeric **1*S*,2*S*-*trans*-(-)-diol** can be prepared in 40% overall yield from diethyl L(+)-tartrate *via* the same high yielding steps. Its IR (CH_2Cl_2) has ν_{max} at 3600, 3390br, 2920, 1450, 1280, 1075, 1040 and 970 cm^{-1}; and its ^1H NMR (200MHz, $CDCl_3$, TMS) with δ at 3.93-4.06 (m, 2H), 2.24 (s, 2H, exchanges with D_2O), 1.86-2.12 (m, 2H), 1.63-1.80 (m, 2H) and 1.42-1.62 (m, 2H). The enantiomers are >96% enantiomerically pure. The **1*R*,2*R*-*(-) [113350-86-0]*** and **1*S*,2*S*-*(+) [113303-27-8]* 1,2-bis(dimethoxyphosphinoxy)cyclopentane** derivatives, prepared from the respective diols ($2NEt_3/2(MeO)_2PCl$, in 80% and 73% yields respectively), are yellow oils with **b 120°/0.1mm** and **$[\alpha]_D^{20}$ -41.39** and **+41.78 (c 4.8, CH_2Cl_2)**. The **1*R*,2*R*-*(-) [113303-35-8]*** and **1*S*,2*S*-*(+) [113303-28-9]* 1,2-bis(difluorophosphinoxy)cyclopentane** derivatives, prepared from the respective diols (PCl_3 in CH_2Cl_2/SbF_3 in pentane, 49% and 48% respectively) are mobile oils with **b 58°/80mm** and **$[\alpha]_D^{20}$ -12.22** and **+12.96 (c 4.8, CH_2Cl_2)**. [Cunningham & Küendig *J Org Chem* **53** 1823 *1988*, DOI: 10.1021/jo00243a048].

1,2-Cyclopentanedione *[3008-40-0]* **$C_5H_6O_2$, M 98.1, m 55-56°, 56°, b 67-69°/1.4mm, 87-88°/16mm, 97°/20mm, 105°/20mm, pK^{20} 9.14 (H_2O).** The dione has a weak amine-like odour and is soluble in H_2O, EtOH, and Et_2O, but poorly soluble in petroleum ether and CS_2, and is steam volatile. It has been prepared by various routes from cyclopentanone *via* oxidation by SeO_2 (23%) [Goto et al. *Bull Chem Soc, Jpn* **52** 2589 *1952*, DOI: 10.1246/bcsj.52.2589.], conversion to the α-methylthio ether then oxidation with $CuCl_2/CuO$ (42%)

[Gregoire et al. *J Org Chem* **51** 1419 *1986,* DOI: 10.1021/jo00359a008], and autooxidation with O_2/*t*-BuOK/DME-*t*-BuOH (35.7%). Only the first is described because of its simplicity. *The following procedure should be carried out in a well-ventilated fume cupboard as selenium compounds have foul odours*. To cyclopentanone (1.5L) warmed at 30° is added dropwise, with stirring, a solution of selenium dioxide (361g, 3.25ml) in dioxane (420ml) and H_2O (155ml) during 24 hours, and stirring is continued for a further 18 hours at 35°. The red selenium that is formed is filtered off (Buchner) and extracted with EtOH (500ml) by boiling for 3 hours. The liquids are combined and distilled through a 60cm Vigreaux column at 20mm, the lower boiling portion (b 35-90°) is removed, and the remainder is distilled at 10mm until a thick brown residue is left in the distilling flask. This distillate is redistilled, and the fraction with **b 86-88°/16mm** is collected to give pure ***1,2-dione*** (74g, 23% based on SeO_2 used) which solidifies (**m 56-58°**). It should be stored at -30° under N_2, in the dark. Cyclopentane-1,2-dione has IR (NaCl) with ν_{max} at 1650 (C=C), 1700 (C=O), 3300 (OH enol) cm^{-1}; ^1H NMR (400MHz, CCl_4, TMS) with δ at 2.20-2.67 (m, 4H, 2-methylenes), 6.47-6.62 (m, 1H, C=C*H*), 6.93-7.36 (m, 1H, C=CO*H*); ^{13}C NMR (100MHz, $CDCl_3$, TMS) with δ 22.01, 32.58, 131.36, 153.62, 187.53.
In ethanolic solution the '*dione*' is almost entirely in the ***mono-enol***-form which slowly tautomerises to a mixture containing ~9% of the ***diketo-***form after 36 hours at 50°. The UV in hexane has λ_{max} (log ε) at 246nm (4.003) and 300nm (1.900) due mostly to the ***diketo***–form, whereas in 0.05N aqueous NaOH it has λ_{max} (log ε) at 288nm (3.383) due to the ***enol***-form [Hesse & Bücking *Justus Liebigs Ann Chem* **563** 31 *1949*, DOI: 10.1002/jlac.19495630105]. ***Cyclopentane-1,2-dione dioxime*** (see above [66,35-29-6]) decomposes at ~210° after recrystallisation from H_2O, and a 0.01M aqueous solution of it is used for the gravimetric determination of Ni. [Voter et al. *Anal Chem* **21** 1320 *1949*, DOI: 10.1021/ac60035a004.] The ***bis-phenylhydrazone*** has **m 146°**.

1,3-Cyclopentanedione *[3859-41-4]* **$C_5H_6O_2$, M 98.1, m 149-150°, 151-152.5°, 151-154°, 151-153°, pKa 4.5.** Purify the dione by Soxhlet extraction with $CHCl_3$. The $CHCl_3$ is evaporated and the residue is recrystallised from EtOAc and/or sublimed at 120°/4mm. [IR: Boothe et al. *J Am Chem Soc* **75** 1732 *1953*, DOI: 10.1021/ja01103a505; DePuy & Zaweski *J Am Chem Soc* **81** 4920 *1959*, DOI: 10.1021/ja01527a040; *Beilstein* **7** IV 1981.]

Cyclopentanol *[96-41-3]* **$C_5H_{10}O$, M 86.1, m -20°, -19.5°, b 53°/10mm, 56.9-57.4°/34mm, 139.5°/752mm, 140.85°/760mm, d_4^{20} 0.9478, n_D^{20} 1.4531.** Cyclopentanol has been prepared by hydration of cyclopentene, or from cyclopentanone (see next entry) by catalytic reduction with H_2 (Ni/MeOH, Ra-Ni/EtOH, PtO_2, Pt-black in EtOH or AcOH, Cu-chromite), $Al(isoPrO)_3$/NaOH, LAH/Et_2O or $NaBH_4$ in MeOH or H_2O. The last named has many advantages in ease of use and efficiency. Thus cyclohexanone in H_2O (solubility is 15% at 10°, 8.7% at 20°, 5% 30°) is stirred with excess of $NaBH_4$ (theoretically 0.25 mol/mol ketone) at room temperature until the reaction is complete (addition of a drop of dilute HCl causes effervescence). The pH of the solution is adjusted to ~3-4, NaCl is added to almost saturation and the alcohol is extracted several times with Et_2O, dried (K_2CO_3), filtered, and the filtrate is distilled to give cyclopentanol in ~90% yield. [Chaikin & Brown *J Am Chem Soc* **71** 122 *1949*, DOI: 10.1021/ja01169a033]. Its FT-IR (neat) has ν_{max} at 3334.9 (br OH), 2959.6 (CH), 1437.2 (OH ?), 1341.3, 1282.9, 1174.3, 1073.7, 994.3, and 837.1 cm^{-1}; the ^1H NMR (60MHz, $CDCl_3$, TMS) has δ at 1.55 (m, 4H, C-3 and C-4 -methylenes), 1.75 (m, 4H, C-2 and C-5 -methylenes), 2.30 (s, 1H, H-1) and 4.30 (brs, 1H, OH); and its ^{13}C NMR (15MHz, $CDCl_3$, TMS) has δ at 23.32 (C-3,4), 35.51 (C-2,5) and 73.86 (C-1). At atmospheric pressure cyclopentanol forms azeotropes with H_2O (96.3°, 42%), tetrachloroethylene (118.8°, 8%), chlorobenzene, *m*-xylene (132.8°, 40%), *p*-xylene (132.8°, 38%), *n*-Bu_2O (139.0°, 75%), among other solvents. It can be characterised as the ***4-nitrobenzoate*** (**m 56°**), ***3,5-dinitrobenzoate*** (**m 123°**), and ***phenylcarbamate*** (**m 137-138°**). [*Beilstein* **6** H 5, **6** I 3, **6** II 3, **6** III 4, **6** IV 5.]

Cyclopentanone (dumasine, adipic ketone) *[keto-form 120-92-3, enol-form 59557-02-7]* **C_5H_8O, M 84.1, m -58°, -51°, b 23-24°/10mm, 130°/atm, d_4^{20} 0.947, n_D^{20} 1.4366, n_D^{25} 1.4340. pK^{25} 16.7.** This is a flammable liquid (flash point 26-31°) with a pleasant odour, but which is a strong **SKIN** and **EYE IRRITANT**, and should be used in a well ventilated fume cupboard. It is sparingly soluble in H_2O, and forms explosive mixtures with HNO_3 and H_2O_2. It is volatile with Et_2O and care should be taken that careful fractionation is require when it is extracted with Et_2O. It is prepared by heating, in a distilling flask, a powdered mixture of adipic acid (200g, 1.34moles) and ground $Ba(OH)_2$ (10g) in a metal bath (e.g. Wood's metal) to 285-295° during 1-1.5 hours. [The temperature is best controlled with the thermometer within 5mm above the bottom of the flask and the temperature held as near as 290° as possible to minimising the amount of adipic acid which distils off.] During

the heating period, the *cyclopentanone* distils slowly with small quantities of adipic acid, and after a further 2 hours of heating a very small amount of dry residue remains in the flask. The distillate is separated from some H_2O and adipic acid by salting out with K_2CO_3, washed with H_2O, dried over $CaCl_2$ or anhydrous K_2CO_3, filtered and fractionated through an efficient column; fraction with b 128-131°/atm of the pure *ketone* (86-92g, 75-80%) is collected. [Thorpe & Kon *Org Synth* Coll Vol **1** 192 *1932*, DOI: 10.15227/orgsyn.005.0037.] If cyclopentanone has been standing for a while, it can be purified by shaking it with aqueous $KMnO_4$ to remove materials absorbing around 230 to 240nm. Dry it over Linde-type 13X molecular sieves and fractionally distil it. It has also been purified by conversion to the $NaHSO_3$ adduct which, after crystallising four times from EtOH/water (4:1), is decomposed by adding to an equal weight of Na_2CO_3 in hot H_2O. The free cyclopentanone is steam distilled from the solution. The distillate is saturated with NaCl and extracted with *benzene (do not use H_2O, see above) which is then dried (anhydrous K_2CO_3), filtered and evaporated. The residue is then distilled [Allen et al. *J Chem Soc* 1909 *1960*, DOI: 10.1039/JR9600001909]. Its FT-IR (NaCl) has ν_{max} at 2966 (CH), 1746.4 (C=O), 1407.6 (OH enol ?), 1278.2, 1153.0, 959.2, 834.2, 582.2 and 471.7 cm^{-1}; the ^1H NMR (15MHz, $CDCl_3$, TMS) has δ at 1.97 (t, 4H, C-3 and C-4 -methylenes), 2.17 (t, 4H, C-2 and C-5 -methylenes); and its ^{13}C NMR (60MHz, $CDCl_3$, TMS) has δ at 23.24 (C-3,4), 38.30 (C-2,5) and 220.16 (C-1). The ***oxime*** *[1192-28-5]* **C_5H_9NO, M 99.1** forms prisms with **m 56.5°, b 120-121°/45mm**, **196°/atm** [*Beilstein* **7** H 7], the ***semicarbazone*** *[5459-00-7]* has **m 224°**, the ***2,4-dinitrophenylhydrazone*** *[2057-87-6]* has **m 145.5, 146.5°**, and the ***ethylene ketal (1,4-dioxaspiro[4.4]nonane*** *[176-32-9]* has **m 153°**. The ***enol***-form is present to the extent of 2.5 x 10^{-7}% in the gas phase.

(±)-2-Cyclopentene-1-acetic acid *[13668-61-6, 75247-34-6]* **$C_7H_{10}O_2$, M 126.2, M 419°, b 93-94°/2.5mm, 95-100°/4mm, 109-114°/16mm, d^{25} 1.047g/ml, n_D^{20} 1.4688, 1.4682, pK_{Est} ~4.8.** Prepared from the sequence cyclopentadiene → 3-chlorocyclopentene → ethyl-2-cyclopentene-1-malonate → 2-cyclopentene-1-malonic acid → 2-cyclopentene-1-acetic acid and purified by redistillation under reduced pressure. Optical resolution *via* the brucine salt gave pure diastereoisomeric salt with $[\alpha]_D^{28}$ +1.54 (c 7.1, H_2O) that was basified with NH_3 to provide chiral ***S*(+)-2-cyclopentene-1-acetic acid** *[67886-21-9]* **b 105°/8mm, n_D^{25} 1.4673** and **$[\alpha]_D^{30}$ +109.2 (c 5.9, $CHCl_3$).** This dextro acid was shown to have the ***S*** (D) configuration, and on standing at ~25° for eight months it became yellow and viscous with $[\alpha]_D^{30}$ +66.0 (c 5.7, $CHCl_3$) and n_D^{25} 1.4673; and when distilled gave a 55% recovery of pure (+)-acid with b 122-123°/30mm, n_D^{25} 1.4678, and $[\alpha]_D^{30}$ +107.8 (c 5.9, $CHCl_3$); and a red glassy residue. The ***S*(+)-*methyl ester*** *[769820-82-5]* has **$[\alpha]_D^{25}$ +45 (c 0.94, $CHCl_3$).** The ***S(+)-acid*** was used to prepare **Chaulmoogric acid** [*29106-32-9*] see above by electrolysis with ethyl hydrogen brassylate. [Mislow & Steinberg *J Am Chem Soc* **77** 3807 *1955*, DOI: 10.1021/ja01619a038; *Beilstein* **9** III 152.] ***R*(-)-2-cyclopentene-1-acetic acid** *[696-67-3]* and the ***S*(-)-*methyl ester*** *[67920-83-6]* have properties similar to those of their enantiomers except with negative optical rotations. The *racemic* ***RS*(±)-*methyl ester*** *[20006-85-3]* has **b 77-78°/20mm**. [For reduction to the respective 1-hydroxyethylcyclopent-2-enes see Irwin & Jones *J Am Chem Soc* **99** 1625 *1977*, DOI: 10.1021/ja00447a057; for alternative synthesis from 1-chlorocyclopent-2-ene see Chapman et al. *J Am Chem Soc* **100** 4878 *1978*, DOI: 10.1021/ja00483a039; for preparations using phenylseleno-cyclisations see Nicolaou et al. *JCS Chem Commun* 83 *1979*, DOI: 10.1039/C39790000083].

Cyclopentyl methyl ether (CPME) *[5614-37-9]* **$C_6H_{12}N$, M 100.2, fp -134.8°, b 105.44°/760mm 105-106.5°/760mm 106°/760mm, d_4^{20} 0.8627, n_D^{20} 1.4206.** This ether has the advantage of having a high resistance to hydroperoxide formation. It is an 'environmentally friendly' solvent and is an alternative to ether solvents like THF, Et_2O and methyl *tert*-butyl ether. Two methods after Williamson's synthesis have been reported. In the ***first*** Na (370g, 16g. atoms) is dissolved in MeOH (2370g, 74moles) and excess of MeOH is distilled off until NaOMe starts to separate. The solution is cooled to 60° and cyclopentyl chloride (1254g, 12moles, b 114°/atm [930-28-9]) is added slowly and kept at 60° for 100 hours. The mixture is then fractionated to give recovered cyclopentyl chloride (21%), cyclopentyl methyl ether (278g, 29% based on reacted cyclopentyl chloride) and cyclopentene [31% which distils as an azeotrope with MeOH (b 37-38°/atm)]. [Olson et al. *J Am Chem Soc* **69** 2451 *1947*, DOI: 10.1021/ja01202a060.] In the ***second***, Na (15g) is dispersed under hot xylene, cooled, the xylene is replaced with anhydrous Et_2O (150ml), and a solution of cyclopentanol (57g, b 141-142°/769mm, see [96-41-3]) in dry Et_2O (~100ml) is added with stirring during 3 hours and allowed to stand for 12 hours. Methyl iodide (103g) is then added during 2 hours to the preceding sodio compound as the Et_2O boils gently, allowed to stand overnight, the Et_2O is distilled off, the crude CPME is then distilled out and redistilled under N_2 at 105°/763mm to give pure ***cyclopentyl methyl ether*** (21g, 32%). It can be stabilised with 50ppm of

BHT. [Vogel *J Chem Soc* 1809 *1948*, DOI: 10.1039/JR9480001809; *Beilstein* **6** III 5, **6** IV 6.]

Cyclotetradecane *[295-17-0]* **$C_{14}H_{28}$, M 196.4, m 56°.** Recrystallise it twice from aqueous EtOH, then sublime it *in vacuo* [Drotloff et al. *J Am Chem Soc* **109** 7797 *1987*, DOI: 10.1021/ja00259a031]. It also crystallises from MeOH (**m 54.2°**) and has **m 55°** after sublimation. [Prelog & Polyák *Helv Chim Acta* **40** 816 *1957*, DOI: 10.1002/hlca.19570400332; *Beilstein* **5** III 152, **5** IV 177.]

Cyclotetradecanone *[3603-99-4]* **$C_{14}H_{26}O$, M 210.4, m 53°, b 145°/10mm, 158-160°/12mm, d_4^{20} 0.926, n_D^{20} 1.480.** It is converted to the ***semicarbazone*, $C_{15}H_{29}N_3O$, m 201-202°** (198° and 198-199° also reported) which is recrystallised from EtOH. It is converted to cyclotetradecanone by hydrolysis [Drotloff et al. *J Am Chem Soc* **109** 7797 *1987*, DOI: 10.1021/ja00259a031]. The ketone crystallises from EtOH (**m 52-53°**) and can be fractionated in a vacuum. The ***oxime*, m 113-114°**, crystallises from MeOH and sublimes at high vacuum. [Ruzicka et al. *Helv Chim Acta* **13** 1152 *1930*, DOI: 10.1002/hlca.19300130540]. [*Beilstein* **7** IV 109.]

Decahydronaphthalene (decalin, mixed isomers) *[91-17-8]* **$C_{10}H_{18}$, M 138.2, m -125°, b 191.7°/760mm, d_4^{20} 0.886, n_D^{20} 1.476.** Stir decalin with concentrated H_2SO_4 for several hours. Then the organic phase is separated, washed with water, saturated aqueous Na_2CO_3, again with water, dried with $CaSO_4$ or CaH_2 (and perhaps dried further with Na), filtered and distilled under reduced pressure (**b 63-70°/10mm**). It has also been purified by repeated passage through long columns of silica gel previously activated at 200-250°, followed by distillation from $LiAlH_4$ and storage under N_2. Type 4A molecular sieves can be used as drying agent. Storage over silica gel removes water and other polar substances. [For the separation of *cis* and *trans* isomers see Seyer & Walker *J Am Chem Soc* **60** 2125 *1938*, DOI: 10.1021/ja01276a028; and Baker & Schuetz *J Am Chem Soc* **69** 1250 *1947*, DOI: 10.1021/ja01198a005; *Beilstein* **5** III 245.]

cis*-Decahydronaphthalene (decalin)** *[493-01-6]* **$C_{10}H_{18}$, M 138.2, m -43.2°, b 67.0°/9mm, 81-83°/19mm, 195.7°/atm, d_4^{20} 0.897, n_D^{20} 1.48113.** Purification methods described for the mixed isomers are applicable here. The individual isomers can be separated by very efficient fractional distillation, followed by fractional crystallisation by partial freezing. The *cis*-isomer reacts preferentially with $AlCl_3$ and can be removed from the *trans*-isomer by stirring the mixture with a limited amount of $AlCl_3$ for 48 hours at room temperature, filtering and distilling. *Note*: the boiling points of the *cis* isomer are higher than those of the *trans* isomer. [Seyer & Walker *J Am Chem Soc* **60** 2125 *1938*, DOI: 10.1021/ja01276a028; Baker & Schuetz *J Am Chem Soc* **69** 1250 *1947*, DOI: 10.1021/ja01198a005.] A very pure authentic sample is best obtained by synthesis from *cis*-1,2-bis-chloroethylcyclohexane [Whitesides & Gutowski *J Org Chem* **41** 2882 *1976*, DOI: 10.1021/jo00879a019]. *cis*-Decalin is a flexible molecule (relative to the *trans*-isomer) and its ^{1}H NMR signals are more grouped together, i.e. the axial and equatorial H signals coalesce being time averaged because of the flexibility of the rings. This is not so in the *trans*-isomer where the rings are rigid and axial and equatorial H signals are more spread out. [Musher & Richards *Proc Chem Soc* 205 (p 230) *1958*, DOI: 10.1039/PS9580000205; Gerig & Roberts *J Am Chem Soc* **88** 2791 *1966*, DOI: 10.1021/ja00964a031; see also *cis*- and *trans*- decahydronaphthyridines Armarego *J Chem Soc (C)* 377 *1967*, DOI: 10.1039/J39670000377]. [*Beilstein* **5** IV 310.] ***trans*-Decahydronaphthalene** *[493-02-7]* has **m -32°, -30.6°, b 62.0°/9mm, 187.3°/atm, d_4^{20} 0.870, n_D^{20} 1.46968.** See purification of *cis*-isomer above. ***Note: the boiling points of the *cis* isomer are higher than those of the *trans* isomer. [Seyer & Walker *J Am Chem Soc* **60** 2125 *1938*, DOI: 10.1021/ja01276a028; Baker & Schuetz *J Am Chem Soc* **69** 1250 *1949*, DOI: 10.1021/ja01198a005; *Beilstein* **5** IV 311.] See *cis*-decahydronaphthalene above for ^{1}H NMR spectra.

(+)-Dehydroabietylamine (abieta-8,11,13-triene-18-ylamine) *[1446-61-3]* **$C_{20}H_{31}N$, M 285.5, m 41°, 42.5-45°, b 192-193°/1mm, 250°/12mm, n_D^{40} 1.546, $[\alpha]_D^{20}$ +56.1 (c 2.4, pyridine), $[\alpha]_{546}^{20}$ +51 (c 1, EtOH), pK_{Est} ~10.3.** The crude base is purified by converting 2g of base in toluene (3.3ml) into the *acetate salt* by heating at 65-70° with 0.46g of AcOH, and the crystals are collected and dried (0.96g from two crops, **m 141-143°**). The ***acetate salt*** *[2026-24-6]* **$C_{22}H_{35}NO_2$, M 345.5,** has **m 139-141°** and **$[\alpha]_D^{20}$ +50 (c 2.4, pyridine)** [*Beilstein* **12** IV 3006]. The acetate salt is then dissolved in warm H_2O, basified with aqueous NaOH and extracted with $*C_6H_6$. The dried extract ($MgSO_4$) is evaporated in vacuum leaving a viscous oil which crystallises and can be distilled. It is a useful base for optical resolutions. [Gottstein & Cheney *J Org Chem*

30 2072 *1965*, DOI: 10.1021/jo01017a518.] The ***picrate*** has **m** 234-236° (from aqueous MeOH), and the ***formate salt*** has **m 147-148°** (from heptane). [*Beilstein* **12** IV 3005.]

Diamantane (congressane, pentacyclo[7.3.1.1^{4,12}.0^{2,7}.0^{6,11}]tetradecane, decahydro-3,5,1,7-[1,2,3,4]-butanetetraylnaphthalene) *[2292-79-7]* **$C_{14}H_{20}$, M 188.3, m 234-235°, 236-237°, 243-245°.** Purify diamantane by repeated crystallisation from MeOH or pentane. *Alternatively*, purify it by dissolving it in CH_2Cl_2, washing with 5% aqueous NaOH and water, and drying ($MgSO_4$). The solution is filtered, concentrated to a small volume, an equal weight of alumina is added, and the solvent evaporated. The residue is placed on an activated alumina column (*ca* 4 x weight of diamantane) and eluted with petroleum ether (b 40-60°). Eight sublimations and twenty zone refining experiments gave material **m** 251° of 99.99% purity by differential analysis [Gund et al. *Tetrahedron Lett* 3877 *1970*, DOI: 10.1016/S0040-4039(01)98613-7; Courtney et al. *JCS Perkin Trans I* 2691 *1972*, DOI: 10.1039/P19720002691]. [For spectra see Cupas et al. *J Am Chem Soc* **87** 917 *1965*, DOI: 10.1021/ja01082a042.] It has been isolated from petroleum [Hala et al. *Angew Chem Int Ed* **5** 1045 *1966*, DOI: 10.1002/anie.196610451].

1.3-Diaminoadamantane *[10303-95-4]* **$C_{10}H_{18}N_2$, M 166.2, m 52°, $pK_{Est(1)}$ ~8.6, $pK_{Est(2)}$ ~10.6.** Purify it by zone refining. The ***dibenzoyl*** derivative has **m** 248° (from EtOH), and the ***dihydrochloride salt*** has **m 310°** (360°) after recrystallisation from aqueous EtOH or EtOH/Et_2O. The ***dipicrate*** has **m 290-295°** (yellow crystals from EtOH), and the ***H_2PtCl_6 salt*** does not decompose at 360°. [Prelog & Seiwerth *Chem Ber* **74** 1769 *1941*, DOI: 10.1002/cber.19410741109; Stetter & Wulff *Chem Ber* **93** 1366 *1960*, DOI: 10.1002/cber.19600930619.] [*Beilstein* **13** III 27.]

cis*-1,2-Diaminocyclohexane (*meso*-chxn)** *[1436-59-5]* **$C_6H_{14}N_2$, M 114.2, b 92-93°/8mm, 170°/atm, d_4^{25} 0.952, n_D^{20} 1.493, pK_1^{20} 6.13 (6.41), pK_2^{20} 9.93(9.91).** It is prepared by reduction of the cis-1,2-dioxime with boiling Na/EtOH, or from *cis*-1,2-dihydrazinocarbonylcyclohexane with $NaNO_2$/HCl [Jaeger & Blumendal *Z Anorg Chem* **175** 161 *1928*, DOI: 10.1002/zaac.19281750112]. Dry the diamine over solid KOH and distil it in a vacuum. It is a strong base, keep it away from CO_2, and store it in the dark under N_2. The ***dihydrochloride has **m 307-310°**, and the ***dipicrate*** (from H_2O) has **m 260°(dec)**. This cis-diamine is a ***meso*** form because its mirror image is identical to it, and is superimposable over it (see below) [*Beilstein* **13** II 3, **13** IV 15.] ***(±)-trans-1,2-Diaminocyclohexane* [(±)-chxn)]** *[1121-22-8]* **$C_6H_{14}N_2$, M 114.2,** has **m 14-15°, b 78-81°/15mm, 85-88°/25mm, d_4^{25} 0.951, n_D^{20} 1.489, pK_1^{20} 6.47(6.72), pK_2^{20} 9.94(9.86).** Purify this ***racemic base***, and store it as for the *cis*-isomer above since it is a strong base, and becomes yellow on storage. [*Beilstein* **13** H 1, **13** III 8, **13** IV 1,5.]

***cis*/*trans*-1,2-Diaminocyclohexane *resolution*.** **[*Note that the* trans- *isomer is a racemic mixture, whereas the* cis- *isomer has a* meso *configuration and it mirror image is identical and superimposable over it*.]** A solution of L(+)-tartaric acid (150g, 0.99mol) in distilled H_2O (400ml) in a 1L beaker is stirred until clear, and a mixture of *cis*- and *trans*- 1,2-diaminocylohexane (240ml, 1.94mol, of ~60/40 trans/cis mixture which is commercially available and is cheaper than the pure *trans* compound for which the same procedure applies) is added at a rate whereby the temperature rises to 70°. Glacial acetic acid (100ml, 1.75mol) is then added at such a rate that the temperature rises to 90°. A white precipitate immediately separates as the acid is added, and the slurry is stirred vigorously until the temperature cools slowly to 25°(~2 hours), and then is cooled further to ~5° in an ice bath for 2 hours, and is collected by filtration. The filter cake is washed with H_2O (100ml at ~5°), then EtOH (5 x 100ml), and dried by sucking air through it for 1 hour and analysed for enantiomeric purity *via* the bis-*m*-toluoyl amide*. The salt is then dried *in vacuo* at ~40° to give *R,R*-1,2-diamoniumcyclohexane mono-(+)-tartrate as a white solid (160g, 99%) in ≥99% enantiomeric excess (ee). If the optical purity is not as expected then recrystallise the salt in two crops from Me_2CO (1:20 w/v with ~60-70% recovery). The *S,S*-diastereomeric tartrate salt is obtained by using D(-)-tartaric acid. If the 'ee' is <99%, or if the difference between the top and the bottom of the cake is >0.2%, then the cake should be washed with more MeOH. If product of ≥99% 'ee' is required then recrystallisation of the tartrate salt by dissolving it in H_2O (≈ 1:10 w/v) with heating to 90°, followed by cooling to 5° overnight, gives ~60-70% recovery.

* The diammonium salt (25mg) is mixed with 4N NaOH (0.5ml), CH_2Cl_2 (1.5ml) and *m*-toluoyl chloride (50µl) with vigorous mixing. The lower (organic layer) is diluted with 10µl of *iso*-propanol, and 10µl of this is analysed by HPLC using *iso*-propanol/hexane (1:9) mixture at 1ml/minute flow rate. [Larrow et al. *J Org Chem* **59** 1939 *1994*, DOI: 10.1021/jo00086a062; Gasbøl et al. *Acta Chem Scand* **26** 3605 *1972*, DOI:

10.3891/acta.chem.scand.26-3605.]

***1R,2R*(-)-*trans*-1,2-Diaminocyclohexane [(-)-chxn)]** *[20439-47-8]* **$C_6H_{14}N_2$, M 114.2, m 41-45°, $[\alpha]_D^{20}$ -25.5 (c 5 M HCl). m 14-15°.** Distil or recrystallise the diamine from petroleum ether under N_2 or argon. It is a useful chiral synthon. [Takahashi et al. *Tetrahedron Lett* **30** 7095 *1989*, DOI: 10.1016/S0040-4039(01)93432-X; Hanessian et al. *J Org Chem* **58** 1991 *1993*, DOI: 10.1021/jo00060a004; for absolute configuration see Gillard *Tetrahedron* **21** 503 *1965*, DOI: 10.1016/S0040-4020(01)82221-3; *Beilstein* **13** III 7.]

***trans*-1,4-Diaminocyclohexane** *[2615-25-0]* **$C_6H_{14}N_2$, M 114.2, m 69-72°, b 197°/760mm, $pK_{est(1)}$ ~9.4, $pK_{est(2)}$ 10.8.** Recrystallise the diamine from petroleum ether under N_2 or argon as it should be an even stronger base than the above 1,2-diamine isomers. It distils under N_2. Store it in the dark under N_2. [*Beistein* **13** I 3, **13** III 11.]

(1*RS*,2*SR*)-*cis*-1,2-Diaminocyclopentane (1*RS*,2*SR*-*cis*-1,2-cyclopentanediamine, *meso*-1,2-cyclo-pentane-diamine, (*meso*)-cptn) *[40535-45-3; no configuration 41330-23-8]* **$C_5H_{12}N_2$, M 100.1, b 62-65°/13.5mm, 99°/60mm.** Whereas reduction of ***anti*-*cyclopentane-1,2-dione dioxime*** (see below, and from reaction of cyclopentane-1,2-dione and NH_2OH) with Na/EtOH yields predominantly *trans-(±)-diamine,* the reaction of *cyclopentane-1,2-dione monooxime* [31597-37-0] with NH_2OH gives a 2:1 mixture of *anti-* and *amphi-*dioximes which provide the less water soluble red bis-*anti*-dioximatoNi(II) complex and the more water soluble yellow-brown bis-*amphi*-dioximatoNi(II) complex respectively. When this mixture of Ni(II) complexes, or the *amphi*-complex, is reduced with KBH_4 in 'diglyme', the base finally isolated is pure *cis-1,2-cyclopentanediamine*.

Thus, ***bis(amphi*-cyclopentane-1,2-dione dioximato)nickel(II)** (79g, 90.5mol, dried over H_2SO_4 *in vacuo*) is added to a solution of KBH_4 (30g) dissolved in dry diglyme [600ml, bis(2-methoxyethyl) ether, [111-96-6]) in 2L flask. N_2 is bubbled through the solution, then during 1 hour anhydrous $AlCl_3$ (25g) in dry diglyme (100ml) is added dropwise carefully as vigorous evolution of H_2 ensues; the temperature being kept below 35° by cooling in ice-water. When evolution of H_2 ceases, the mixture is heated at 70° for 18 hours. Then a solution of KOH (100g) in H_2O (150ml) is added carefully, and the ***cis-diamine*** is steam distilled off; 6L of distillate are collected, acidified with 12M HCl (to pH 3), and the dry ***cis-1,2-cyclopentanediamine dihydrochloride*** (23g, 27% based on the Ni complex) is isolated as for the *trans-(±)-isomer* below. The free base, ***cis-1,2-cyclopentanediamine*** **b 62-65°/13.5mm** (83%, based on the dihydrochloride) is stored under N_2 at -20°. [Toftlund & Pedersen *Acta Chim Scand* **26** 4019 *1972*, DOI: 10.3891/acta.chem.scand.26-4019]. This *cis-diamine* has been fractionated through a vacuum-jacketed distillation column as described by Ray et al. [*Rev Sci Instr* **28** 200 *1957*, DOI: org/10.1063/1.1746483] and the fraction with **b 99°/60mm** contained pure *cis*-isomer [Phillips & Royer *Inorg Chem* **4** 616 *1965*, DOI: 10.1021/ic50027a004].

The ^1H NMR in D_2O (TMS as external standard) can be used to distinguish between *trans-(±)-1,2-diamine* and and the preceding *cis-(meso)-1,2-diamine* because the triplets from carbon atoms 1 + 2 occur at δ 2.72 and δ 2.77 respectively [Phillips & Royer *Inorg Chem* **4** 616 *1965*, DOI: 10.1021/ic50027a004].

Distinct bis- and tris- *cis*-cptn complexes such as $[Ni(cis\text{-cptn})_2](ClO_4)_2.6H_2O$, $[Ni(cis\text{-cptn})_3](ClO_4)_2$ and $[Co(cis\text{-cptn})_3]Br_2.3H_2O$ are readily formed [Toftlund & Pedersen *Acta Chem Scand* **26** 4019 *1972*, DOI: 10.3891/acta.chem.scand.26-4019]. [*Beilstein* **4** II 3.]

(1*RS*,2*RS*)-(±)-*trans*-1,2-Diaminocyclopentane [(1*RS*,2*RS*)-*trans*-1,2-cyclopentanediamine, (±)-*trans*-1,2-cyclopentanediamine, (±)-cptn] *[3145-88-8]* **$C_6H_{14}N_2$, M 100.1, b 65-67°/13.5mm, 103°/60mm, 170°/atm,**

$pK_{Est\ 1}$ ~7.0 , $pK_{Est\ 2}$ ~10.0. This diamine is a strong base and is best kept as its salts which are not greatly affected by moisture and CO_2. It is prepared by reduction of **anti-*cyclopentan-1,2-dione dioxime*** *[6635-29-6]* **M 128.1, m 210° (215° dec; 210-225° dec, darkening at 192-205°** also reported for an analytically pure sample) which is obtained by adding *2-ethoxycarbonylcyclopentanone* (31.2g, b 102-104°/12mm, [611-10-9]) to a solution of NaOH (8.8g) in H_2O (160ml) whereby a heavy white precipitate separates. A solution of $NaNO_2$ (13.8g) in H_2O (32ml) is then added to it and the mixture, under N_2, is shaken mechanically for 44 hours at ~25°. The resulting clear yellow solution is cooled to 0°, and at this temperature 6N H_2SO_4 is added carefully while CO_2, and oxides of nitrogen evolve. The solution is extracted with Et_2O (in a continuous liquid-liquid extractor) for 5.5 hours, the extract is evaporated under N_2 and reduced pressure to a small volume of ~20ml. This suspension of crude cyclopentane-1,2-dione monooximes is treated with a solution of hydroxylamine hydrochloride (13.9g) and NaOH (8.0g) in H_2O (50ml) when heat is evolved and a precipitate separates immediately. The mixture is allowed to stand overnight at 5°, the light tan crude ***anti-cyclopentane-1,2-dione dioxime*** (16.8g, 66%, decomposes at 230-240°) is filtered off and is dried *in vacuo*, leaving the more soluble ***amphi****-cyclopentane-1,2-dione dioxime* in the filtrate. The analytically pure ***anti-dioxime*** (dec at 210-225° without melting, 83% recovery, [6635-29-6]) can be obtained by dissolving the crude material (1g) in 2% aqueous NaOH (25ml) at ~25° (slightly turbid), stirring with Norit, filtering, neutralising the filtrate with 1 N HCl (to phenolphthalein), filtering off the solid, washing it twice with H_2O, once with Me_2CO and it drying *in vacuo*. [Cope et al. *J Am Chem Soc* **73** 1199 *1951*, DOI: 10.1021/ja01147a096; Lloyd & Marshall *J Chem Soc* 2597 *1956*, DOI: 10.1039/JR9560002597.]

Alternatively, to a stirred mixture of granulated Na (38g) and $*C_6H_6$ (900ml, dried over Na) is added diethyl adipate (225ml, 1.11mole, [141-28-6]) rapidly followed by absolute EtOH (5ml), and is boiled under reflux with stirring for 18 hours then cooled to 0°. The white solid that separated is filtered off, washed with a little $*C_6H_6$ and dried *in vacuo* over shredded paraffin wax to give ***sodium cyclopentanone-2-carboxylate*** (180g). This salt (1mol) is partly dissolved in ice-water (600ml), N_2 is bubbled through for 15 minutes to remove O_2; and a mixture of a solution of NaOH (4g, 0.1mol) and $NaNO_2$ (70g, 1.03mol) in H_2O (160ml) is added dropwise to it. The mixture is then heated under N_2 with vigorous stirring at 40° for 30 hours. After cooling to 0°, 6M H_2SO_4 (200ml, 1.2mol) is added in one hour; and when evolution of CO_2 has ceased the solution is neutralised with 12M ammonia. A solution of NH_2OH HCl (70g, 1.0mol) in H_2O (160ml), neutralised with K_2CO_3 (70g, 0.5mol), is immediately added. After 1 hour, the precipitation of crude *anti-****cyclopentane-1,2-dione dioxime*** as light tanned needle-like crystals is complete; it is filtered off, washed with a little H_2O and dried *in vacuo* over H_2SO_4 for 48 hours (yield 90g, 62% calculated on diethyl adipate used). The filtrate contains the *amphi-****cyclopentane-1,2-dione dioxime*** which is isolated as the yellow-brown ***bis(****amphi****-cyclopentane-1,2-dione dioximato)nickel(II) complex*** (30g) by slowly adding Ni(II)SO_4 7H_2O (20g) in H_2O (60ml) to this filtrate, and washing the complex with H_2O and drying in air. [Toftlund & Pedersen *Acta Chim Scand* **26** 4019 *1972*. DOI: 10.3891/acta.chem.scand.26-4019.] ***Bis(****amphi****-cyclopentane-1,2-dione dioximato)nickel(II) complex*** is obtained analytically pure, as a red precipitate in 70% yield, from ***anti-****cyclopentane-1,2-dione dioxime* (12.8g, 0.1mol) in 4M ammonia (15ml), by adding slowly Ni(II)Cl_2 6H_2O (12g, 0.05mol) in H_2O (40ml) to it, filtering off the solid, washing it with H_2O and drying it in air. [Toftlund & Pedersen *Acta Chim Scand* **26** 4019 *1972,* DOI: 10.3891/acta.chem.scand.26-4019.]

Reduction to (±)-diamine*:** The ***anti*-cyclopentane-1,2-dione dioxime* (10g) in absolute EtOH (2L) is reduced by addition of freshly cut small pieces of Na metal (180g) over a period of several hours. The solution is refluxed until all the metal has dissolved. The EtOH is distilled off *in vacuo*, the residue is basified strongly with 10N NaOH, and the base is steam distilled. The distillate is made strongly alkaline with aqueous NaOH, extracted with trichloroethylene, the solvent is evaporated and ***trans-1,2-cyclopenanediamine*** then distils at **65°/13.5mm, n_D^{25} 1.4850-1.4858** in 29% yield. When the fractional distillation is carried out using a column (90cm x 1 cm) packed with glass helices and the reflux ratio is kept at >40:1, the first 25% of distillate contains a significant amount of lower boiling *cis-diamine*, **99°/60mm**; the remaining 75% of material then boils at a constant temperature, **103°/60mm**, and is the ***trans-(±)-diamine***. *Alternatively*, the steam distillate is acidified with concentrated HCl, the solution is evaporated to dryness *in vacuo*, and the residue is recrystallised from EtOH/Et_2O to provide ***trans-(±)-1,2-cyclopentanediamine dihydrochloride*** in 77% yield, which **decomposes at 287-290°** (darkening gradually >230°), and forms a ***dihydrate*** on exposure to air. The ***trans-(±)-dipicrate*** has **m 233-233.5° (dec)** after recrystallisation from aqueous EtOH or H_2O, and the ***trans-(±)-diacetyl derivative*** has **m 226.5-227.5° (dec)** after recrystallisation from EtOH by addition of Et_2O. [Cope et al. *J Am Chem Soc* **73** 1199 *1951*, DOI: 10.1021/ja01147a096; Phillips & Royer *Inorg Chem* **4** 616 *1965*, DOI: 10.1021/ic50027a004;

Lloyd & Marshall *J Chem Soc* 2597 *1956*, DOI: 10.1039/JR9560002597; Jaeger & Blumendal *Z Anorg Allgem Chem* **175** 161 *1928*, DOI: 10.1002/zaac.19281750112.]

Alternative reduction to (±)-diamine*:** The ***anti*-cyclopentane-1,2-dione dioxime* (20g, 156mmol) in absolute EtOH (1.5L) is reduced by heating to 40° (internal temperature), and stirring under a reflux condenser, with Mg powder (8g) and Hg(II)Cl_2 (0.1g) while Na metal (150g, 6.5mol, in 5g pieces) is added *via* the top of the condenser and keeping the temperature below 50° (internal temperature). The mixture is finally heated to boiling in order to dissolve all the Na. The *(±)-diamine* is isolated by steam distillation (external heating being necessary so as to maintain a small volume in the flask) until the pH of the distillate is below 8 (*ca* 4L). This is acidified (pH 3) with 12M HCl, evaporated almost to dryness *in vacuo* (at ~25°), excess HCl is removed by washing with EtOH/Et_2O (2:1v/v, 20ml), and the hygroscopic salt is dried over KOH in a desiccator to give the ***(±)-diamine dihydrochloride*** (5g, 18% based on dioxime). The free base is obtained by adding the dihydrochloride (5g, 29mmol) in small portions with stirring to a 1:1v/v mixture of MeOH/Et_2O (50ml) into which is dissolved Na (1.7g, 74mmol, cooling). After stirring for 1 hour, the precipitated NaCl is filtered off, extracted with MeOH/Et_2O (1:1v/v, 5ml), the combined extract and filtrate are evaporated to ~3ml and this residue is distilled in a N_2 atmosphere to give ***(±)-trans-cyclopentane-1,2-diamine***, **b 65-67°/13.5mm** (2.5g, 89%, based on the dihydrochloride) which is stored under N_2 at -20°. Distinct *trans*-(±)-cptn complexes of Ni, Co, Rh and Pt have been prepared; some are enantiomorphic and others are structural isomers [Phillips & Royer *Inorg Chem* **4** 616 *1965*, DOI: 10.1021/ic50027a004; Jaeger & Blumendal *Z Anorg Allgem Chem* **175** 161 *1928*, DOI: 10.1002/zaac.19281750112; Toftlund & Pedersen *Acta Chim Scand* **26** 4019 *1972*, DOI: 10.3891/acta.chem.scand.26-4019]. The ^1H NMR in D_2O (TMS as external standard) can be used to distinguish between *trans-(±)-1,2-diamine* and and the preceding *cis-(meso)-1,2-diamine* because the triplets from carbon atoms 1 + 2 occur at δ 2.72 and δ 2.77 respectively [Phillips & Royer *Inorg Chem* **4** 616 *1965*, DOI: 10.1021/ic50027a004].

(1*R*,2*R*)-(-)-*trans*-1,2-Diaminocyclopentane dihydrochloride [(-)-cptn HCl] *[1030390-38-5]* **$C_6H_{14}N_2$. 2HCl, M 173.1, dec on melting, $[\alpha]_D^{25}$ -23.5 (c 2, 1M HCl)** and **(1*S*,2*S*)-(+)-*trans*-1,2-Diaminocyclopentane dihydrochloride [(+)-cptn HCl]** *[477873-22-6]* **M 173.1, dec on melting, $[\alpha]_D^{25}$ +23 (c 2, 1M HCl).** ***Optical resolution*:** (±)-Cptn (2g, 20mmol) is resolved by adding it to a solution of D-(+)-tartaric acid (7g, 47mmol) in MeOH (1ml) and H_2O (7ml), and at 40° MeOH (12ml) is added dropwise. The mixture is then kept at 3° for 18 hours, the crystalline solid is filtered off, washed with MeOH (10ml) to give the less soluble hydrogen tartrate salt [5.2g, 65% based on (±)-cptn]. After two recrystallisations, the **(-)-cptn—(+)-tartrate salt** [2.5g, 31.4% based on (±)-cptn] has **m 134-135°** (143-144° also reported), **$[\alpha]_D^{25}$ +10.1 (c 2,** H_2O). When this salt (2.4g, 6mmol) in H_2O (8ml) is treated with a solution of KCl (0.9g, 12mmol) in H_2O (4ml), the highly insoluble potassium hydrogen tartrate separates and is filtered off after standing for 1 hour. Addition of solid KOH (8g, with cooling) allowed solid (-)-cptn hydrate to separate, but the mixture is extracted thoroughly with Et_2O (5 x 10ml), the extract is dried (KOH or $MgSO_4$), filtered, and evaporated to give **(-)-*trans*-cptn** (0.55g, 92% based on tartrate salt). When carried out on a larger scale the ***(-)-base*** can be distilled, **b 166°/atm, d^{25} 0.9463**, and has **$[\alpha]_D$ -54.7 (neat)**, **$[\alpha]_D$ -42 (*C_6H_6)**, **$[\alpha]_D$ -39 (H_2O)**, and a plain-negative ORD curve. **(-)-*trans*-Cptn sulfate** has **$[\alpha]_D$ -12 (H_2O)**. [Toftlund & Pedersen *Acta Chim Scand* **26** 4019 *1972*, DOI: 10.3891/acta.chem.scand.26-4019; Jaeger & Blumendal *Z Anorg Allgem Chem* **175** 161 *1928*, DOI: 10.1002/zaac.19281750112; Phillips & Royer *Inorg Chem* **4** 616 *1965*, DOI: 10.1021/ic50027a004]. **(+)-Cptn—(+)-tartrate** can be obtained from the mother liquors of the above resolution in order to isolate the (+)-base; but it is advisable to collect all the mother liquors, liberate the free base with KOH, isolate it and repeat the process using L-(-)-tartaric acid to form the less soluble diasterioisomeric **(+)-cptn—(-)-tartrate salt.** Pure **(+)-*trans*-cptn** can then be isolated as above and will have the same physical properties except for the optical rotations that will be of opposite sign and has a plain-positive ORD curve [Dunlop et al. *J Chem Soc* 3160 *1964*, Gillard *Tetrahedron* **21** 503 *1965*, DOI:10.1016/S0040-4020(01)82221-3; O'Brien & Toole *J Am Chem Soc* **77** 1368 *1955*, DOI: 10.1021/ja01610a089]. [*Beilstein* **4** II 3, **4** III 5]

Complexes of optically active cptn with Rh, Co, Ni and Pt have been prepared, and in some cases enantiomeric and geometrical isomers have been identified. One has been used to obtain pure enantiomeric diamine, for example, the complex **$[Co_2(±\text{-cptn})_7\ (H_2O)_2]^{6+}$** has been resolved into three bands on Amberlite CG-50 carboxylic acid resin 400-400 by elution with aqueous HCl (pH 2, flow rate 5ml/hour) and collecting 40ml fractions. Bands I, II and III are probably geometrical isomers because when the isolated complexes are decomposed with concentrated aqueous NaOH, extracted with *C_6H_6, the extract dried and evaporated, the free

base **(+)-*cptn*** with **$[\alpha]_D$ +42 ±1 (*C_6H_6)** is obtained (compare with above) [Phillips & Royer *Inorg Chem* **4** 616 *1965*, DOI: 10.1021/ic50027a004].
The optical properties (ORD, CD) of several cptn-transition metal complexes have been thoroughly investigated and used to determine and confirm the absolute configuration of cptn [Dunlop et al. *J Chem Soc* 3160 *1964*, DOI: 10.1039/JR9640003160; Gillard *Tetrahedron* **21** 503 *1965*, DOI: 10.1016/S0040-4020(01)82221-3]. The crystal structure of **$(-)_{587}$-[Co(+*trans*-cptn)$_3$]Cl_3. $4H_2O$** confirms the *1S,2S-configuration* for the dextro-enantiomer [Ito et al. *Acta Cryst* **B 27** 2187 *1971*, DOI: 10.1107/S0567740871005545].

***trans*-1,2-Dibromocyclopentane** *[10230-26-9]* **$C_5H_8Br_2$, M 227.9, b 72.5°/15mm, 74°/17mm, d_4^{20} 1.857, n_D^{25} 1.5460.** It is prepared by addition of bromine to cyclopentene at -20° followed by fractional distillation. The ^{1}H NMR (60MHz, CCl_4) has a complex multiplet centered at ~2.5 ppm (3 x CH_2), and two triplets centered at 4.58ppm (J = 7.4Hz, for 2 x CHBr) from TMS. [Altona et al. *Recl Trav Chim, Pays-Bas* **85** 983 *1966*, DOI: 10.1002/recl.19660851003; cf. Abell et al. *J Am Chem Soc* **82** 3610 *1960*, DOI: 10.1021/ja01499a034.]

***cis*-3,4-Dichlorocyclobutene (3*RS*,4*SR*)** *[2957-95-1]* **$C_4H_4Cl_2$, M 123.0, b 70-71°/55mm, 74-76°/55mm, d_4^{20} 1.297, n_D^{20} 1.499.** Distil the cyclobutene at 55mm through a 36-in platinum spinning band column, a fore-run b 58-62°/55mm is mainly 1,4-dichlorobutadiene. When the reaction temperature reaches 70° the reflux ratio is reduced to 10:1 and the product is collected quickly. It is usually necessary to apply heat frequently with a sun lamp to prevent any dichlorobutadiene from clogging the exit in the early part of the distillation [Pettit & Henery *Org Synth* **50** 36 *1970*, DOI: 10.15227/orgsyn.050.0036; Warrener et al. *Aust J Chem* **26** 389 *1973*, DOI: 10.1071/CH9730389]. **(±)-((3*RS*,4*RS*)-3,4-Dichlorocyclobutene (3*RS*,4*SR*)** *[41326-64-1]*, **m -4°**, **b 28°/20mm**, is the more stable isomer formed by catalytic ($AlCl_3$) isomerisation of the *cis*-isomer and purified by gas preparative chromatography on a TCP-on-Fluoropak column at 50-75° and dried by distillation through P_2O_5. [Prepn and IR, Raman and NMR spectra of *cis*- and *trans*- isomers: Craig et al. *Spectrochimica Acta Part A,* **47A** 881 *1991*, DOI: 10.1016/0584-8539(91)80275-N.]

Dicyclohexylamine (Cy_2NH_2) *[101-83-7]* **$C_{12}H_{23}N$, M 181.3, m -1°, -2°, b 83°/1mm, 99.3°/4mm, 113.5°/9mm, 117-120°/10mm, 135.4°/30mm, 154.3°/50mm, 199°/200mm, 255.8°/atm, 256°/atm, d_4^{20} 0.912, n_D^{20} 1.4845, pK^{25} 11.25.** It is a strong base, has a fishy odour, is soluble in H_2O, and organic solvents and forms adducts with some of them. It can be purified by fractional distillation at atmospheric pressure, but if the distillate is coloured (e.g. green) then distillation under reduced pressure gives a clear colourless liquid [Vogel *J Chem Soc* 1825 *1948*, DOI: 10.1039/JR9480001825]. The ***hydrochloride*** *[4693-92-9]* crystallises from H_2O or EtOH and has **m 334-335°** (sealed tube), and the ***acetyl derivative*** *[1563-91-3]* has **m 103°** (from Et_2O). [Diwoky & Adkins *J Am Chem Soc* **53** 1868 *1931*, DOI: 10.1021/ja01356a035; *Beilstein* **12** H 6, **12** I 114, **12** II 7, **12** III 19, **12** IV 22.] **SKIN and EYE IRRITANT**.

1,3-Dicyclohexylcarbodimide (DCC) *[538-75-0]* **$C_{13}H_{22}N_2$, M 206.3, m 34-35°, b 95-97°/0.2mm, 122-124°/6mm, 155°/11mm.** It is sampled as a liquid after melting in warm H_2O. It is sensitive to air, and *it is a potent* ***skin irritant*****.** It can be distilled in a vacuum, and is best stored in a tightly stoppered bottle in a freezer. It dissolves readily in CH_2Cl_2 and pyridine where the reaction product with H_2O, after condensation, is dicyclohexyl urea which is insoluble and can be filtered off. *Alternatively*, dissolve it in CH_2Cl_2, add powdered anhydrous $MgSO_4$, shake for 4 hours, filter, evaporate and distil the residue at 0.6mm pressure and oil bath temperature of 145°. Possible SKIN ALLERGEN, handle with gloves, and do not breathe it in. [Bodansky et al. *Biochemical Preparations* **10**, 122 *1963*, Schmidt & Seefelder *Justus Liebigs Ann Chem* **571** 83 *1951*, DOI: 10.1002/jlac.19515710110; Schmidt et al. *Justus Liebigs Ann Chem* **612** 11 *1958*, DOI: 10.1002/jlac.19586120103; *Beilstein* **12** IV 72.]

***N*,*N*-Dicyclohexylmethylamine (Cy_2NMe, *N*-methyldicyclohexylamine)** *[7560-83-0]* **$C_{13}H_{25}N$, M 195.3, b 131-133°/13mm, 135-137°/15mm, 150°/50mm, 265°/atm, d_4^{25} 0.912, n_D^{25} 1.4900, pK 8.2.** When dicyclohexylamine (90.5g, 0.5mol, see 101-83-7) and 55% aqueous formic acid (121.1ml, 2.5mol) are heated at ~100° and 35% aqueous formaldehyde (97.5g, 11.25mol) is added dropwise over an hour, CO_2 evolution occurs. After gas evolution is complete, ~15 hours, concentrated HCl (1mol) is added and the mixture is evaporated *in vacuo*. The free base is liberated from the residue with strong aqueous NaOH and the oil is extracted with Et_2O, dried (solid KOH), filtered, the filtrate is evaporated *in vacuo* and the residue is fract-

ionally distilled to give Cy_2NMe in 51% yield. It was also obtained by alkylating Cy_2NH with dimethylsulfate. [Hünig & Kiessel *J Prakt Chem* **5** 224 *1958*, DOI: 10.1002/prac.19580050504.] The ***hydrochloride*** has **m 154-154°** (from EtOAc), and the ***methiodide*** has m **228-229°** (from EtOH/Et_2O). [*Beilstein* **12** I 115, **12** II 8, **12** III 21, **12** IV 23.]

Ethyl 2-oxocyclohexanecarboxylate (2-ethoxycarbonylcyclohexanone, 2-carbethoxycyclohexanone, ethyl 2-ketohexahydrobenzoate) *[1655-07-8]* **$C_9H_{14}O_3$, M 170.2, b 86-88°/3.2mm, 106°/11mm, d^{25} 1.064, n_D^{20} 1.47940, pK^{25} 10.94 (12.87).** The ester is obtained by the decarbonylation of *ethyl 2-ketocyclohexylglyoxalate* (which in turn is prepared from cyclohexanone and diethyl oxalate in the presence of NaOEt). The *ethyl glyoxalate* (~250-265g, boiling at 105° to 165°/10-15mm) is mixed with Fe powder (1-3mg) and finely ground soft glass 0.5-1.0g) in a Claisen flask (~500ml), and heated in a 40mm vacuum (bath temperature at 165-175°, not higher, to avoid unreacted ester from distilling) while CO [TOXIC] evolves and decarbonylated ester distils between 125-140°, requiring 1.5 to 2 hours for pyrolysis. The desired ester obtained (200-210g, 85.8%) has n_D^{25} 1.476 to 1.479. [Snyder et al. *Org Synth* Coll Vol **2** 531 *1943*, DOI: 10.15227/orgsyn.011.0042.] The ester has FT-IR (neat) with ν_{max} at 2939.5 (CH), 1716.2 (C=O), 1658.3 (C=O ester), 1442.5 (OH enol ?), 1365.2, 1299.3, 1219.0, 1082.9 and 832.9 cm^{-1}; ^1H NMR (60MHz, $CDCl_2$, TMS) with δ at 1.30 (t, 3H, ester C*H*$_3$), 1.65 (m, ~4H, 2-methylenes), 2.25 (m, 4H 2-methylenes), 3.35 (t, 1H, partly enolised), 4.20 (q, 2H, ester C*H*$_2$) and ~12.0 (s, enolic O*H*); and ^{13}C NMR (15MHz, $CDCl_3$, TMS) with δ at 14.17, 14.33, 21.97, 22.42, 23.31, 27.13, 29.10, 29.98, 41.55, 57.22, 60.12, 61.04, 97.72, 169.93, 171.93, 172.71, 206.19. [*Beilstein* **10** IV 2606.]
The *enol* content of *ethyl 2-oxocyclohexanecarboxylate* is higher than that of the *ethyl 2-oxocyclopentanecarboxylate* below ([611-10-9]) and varies with polarity of solvent, *viz*: 67% aqueous MeOH (22.2%), MeOH (45.1%), EtOH (61.7%), $CHCl_3$ (54.5%), $*C_6H_6$ (74.8%) [Kabachnik et al. *Tetrahedron* **1** 317 *1957*, DOI:10.1016/0040-4020(57)88007-7; Gero *J Org Chem* **19** 1960 *1954,* DOI: 10.1021/jo01377a013, see also Schreck *J Am Chem Soc* **71** 1881 *1949*, DOI: 10.1021/ja01173a523; Buu-Hoi & Cagniant *Bull Soc Chim Fr* **10 [5]** 251 *1943*, Lewin *Izv Akad S.S.S.R Ser fiz* **11** 413 *1947*, *Chem Abstr* **42** 3261 *1948*]. [*Beilstein* **10** H 601, **10** II 420, **10** III 2813, **10** IV 2606.]

Ethyl 2-oxocyclopentanecarboxylate (2-ethoxycarbonylcyclopentanone, 2-carbethoxycyclopentanone, Dieckmann Ester) *[611-10-9, ± 53229-92-8]* **$C_8H_{12}O_3$, M 156.2, b 79-81°/3mm**, **86-87°/6mm**, **102-104°/11mm, 108-111°/15mm**. The ester is prepared in a dry N_2 atmosphere by adding ethyl adipate (202g, 1mole), during 2 hours, to a stirred (important to use a Hershberg stirrer, Hershberg *Ind Eng Chem, Anal Ed* **8** 313 *1936* DOI: 10.1021/ac50102a041) suspension of Na metal (23g, 1g.atom) in dry toluene (250ml). The reaction starts immediately and the temperature is maintained at 100-115° (oil bath) during the 2 hours and for 5 hours longer, while dry toluene is added (~750ml to 1L) so as to keep the mixture fluid and efficiently stirred, and to avoid 'caking'. The mixture is cooled to 0° and slowly added with stirring to 10% aqueous KOH (below 1°), cold H_2O being added to keep the potassium salt in solution; the toluene layer is separated, washed with cold H_2O (2 x 150ml), cold 10% aqueous KOH (adding cold H_2O to dissolve separated potassium salt), the yellow toluene solution is finally washed with cold H_2O (2 x 150ml). The combined aqueous layers, after extraction with Et_2O (250ml), are run slowly, with stirring at 0°, into cold 10% AcOH. The oily ester which separates is extracted into Et_2O (400ml), the aqueous layer is extracted with Et_2O (4 x 250ml). The combined Et_2O extracts are washed with 7% aqueous Na_2CO_3, dried (Na_2SO_4), filtered, evaporated and the residue is distilled (**b 79-81°/4mm**) to give the *keto-ester* (100-115g, 64-74%) free from ethyl adipate. An alternative synthesis in $*C_6H_6$ with slight modification provided 79-82% yield of ester. [Pinkney *Org Synth* Coll Vol **2** 116 *1943*, DOI: 10 15227/orgsyn.017.0030; Cornubert & Borrel *Bull Soc Chim Fr* **47** 301 *1930*.]
The *enol* content of *ethyl 2-oxocyclopentanecarboxylate* is low and varies little with polarity of solvent, *viz*: MeOH (4.0%), EtOH (3.9%), $CHCl_3$ (3.7%), $*C_6H_6$ (8.2%) [Kabachnik et al. *Tetrahedron* **1** 317 *1957*, DOI: 10.1016/0040-4020(57)88007-7; Lewin *Izv Akad S.S.S.R Ser fiz* **11** 413 *1947*, *Chem Abstr* **42** 3261 *1948*]. The

ester has FT-IR (neat) with ν_{max} at 2979.9 (CH), 1725.6 (C=O), 1678.8 (C=O ester), 1454.5 (OH enol ?), 1370.0, 1255.0, 1190.7, 1111.9 and 1026.3 cm^{-1}; ^1H NMR (60MHz, $CDCl_3$, TMS) with δ at 1.29 (t, *J* = ~7Hz, 3H, ester Me), 1.89 (m, 1H, C-3 H_{eq}), 2.24 (m, 1H, C-3 H_{ax}), 2.31 (m, 4H, C-4,5 methylenes), 3.15 (t, 1H, *J* = ~8Hz, C-1 H), 4.20 (q, *J* = ~7Hz, ester CH_2); ^{13}C NMR (15MHz, $CDCl_3$, TMS) with δ at 14.18, 20.98, 27.43, 38.04, 54.77, 61.26, 169.37 and 212.25.

N-Phenyl 2-oxocyclopentanecarboxamide *[4874-65-1]* **M 203.2, m 104°** is obtained by boiling aniline (25mmol) with ethyl 2-oxocyclopentanecarboxylate (100mmol) and pyridine (0.5ml) for 2 minutes, cooling and the solid that separates is filtered off, washed with cold EtOH, then with 4% aqueous NaOH to free it from any anil formed. The solution is filtered and acidified with dilute AcOH, the precipitate is filtered off, dried and the *anilide* is recrystallised from EtOH. [Barany & Pianka *J Chem Soc* 1420 *1947*, DOI: 10.1039/JR9470001418.] It is soluble hot EtOH and in Me_2CO. A 0.3% solution of the anilide in EtOH is used for the gravimetric determination of Be, Hg V and U [Chaudhuri & Das *Anal Chim Acta* **57** 193 *1971*, DOI: 10.1016/S0003-2670(01)80144-6]. [*Beilstein* **10** IV 2602.]

1-Ethynyl-1-cyclohexanol *[78-27-3]* **$C_8H_{12}O$, M 124.2, m 30-33°, 32-33°, b 74°/12mm, 76-78°/17mm, 171-172°/694mm, 180°/atm, d_4^{25} 0.9734, n_D^{25} 1.4801.** Dissolve it in Et_2O, wash it with H_2O, dilute $NaHCO_3$, H_2O again, dry (Na_2SO_4), filter, evaporate and distil the residue. The IR (CCl_4) has ν_{max} at 3448 (OH), 2941 (CH), 1449-1123 and 956 cm^{-1}, and the ^1H NMR (CCl_4) has δ at 3.2 (OH), 2.5 (≡ CH), 1.70 (m 10H, CH_2) [Hasbrouck & Anderson *J Org Chem* **38** 2103 *1972*, DOI: 10.1021/jo00951a037]. 5*S*-(-)-Gabaculine [5*S*-(-)-5-aminocyclohexa-1,3-diene-1-carboxylic acid, 5-amino-2,3-dihydrobenzoic acid] *[S- 59556-29-5; 87980-11-8 unspecified stereochemistry]* **$C_7H_9NO_2$, M 139.2, amorphous white powder, $pK_{Est(1)}$ ~3.75, $pK_{Est(2)}$ ~8.86, $[\alpha]_D$ - 454 (c 1, H_2O).** The 5-*S*-aminoacid has been isolated from the culture filtrates of *Streptomyces toyocaensis* subsp 1039, and purified by chromatography through a cellulose column and eluted with *n*-BuOH/H_2O (100:7); the physiologically active fractions are concentrated to a small volume, the precipitate is collected, dissolved in a little H_2O and lyophilised. The white powder is homogeneous on silica gel TLC plates (60 F-254, Merck, eluting with *n*-BuOH/880 NH_3/H_2O::6:2:1) with R_F 0.65, and on cellulose plates (F, Merck, eluting with *n*-BuOH/AcOH/H_2O::3:1:1) with R_F 0.53. It has UV (H_2O) with λ_{max} at 275nm (ε 8600); the IR has ν_{max} at 1650cm^{-1} (C=C-C=O); ^1H NMR has δ at 6.82 (2-H, d, A of ABX), 6.47 (3-H, q, X of ABX), 6.06 (4-H, q, B of ABX) J_{cis} for BX = 9.5Hz, 4.11 (5-H, d, coupled with 4-H and 6-H), and 2.77 (geminal 6-H, 6-H, q), assignments are deduced by decoupling technique, i.e. irradiating 2-H, 5-H and 6-H respectively, and MS showed abundant peaks as those of benzoic acid except for the molecular ion and base peak at m/e 94 (M^+—COOH). [Kobayashi et al. *Tetrahedron Lett 537 1976,* DOI: 10.1016/S0040-4039(00)77904-4; *FEBS Lett* **76** 207 *1977*, DOI: 10.1016/0014-5793(77)80153-1.] It is a conformationally restricted analogue of γ-aminobutyric acid (GABA), an irreversible and potent inhibitor of γ-aminobutyrate (GABA) aminotransferase [EC 2.6.1.19] at sub μM concentrations, a GABA reuptake inhibitor, and as a drug it increases GABA levels in the brain. [Allan, Johnston and Twitchin *Neuroscience Lett* **4** 51 *1977*, DOI: 10.1016/0304-3940(77)90124-0.] It inhibits the formation of chlorophyll in plants [Gardner & Gordon *Plant Physiol* **77** 540 *1985*, http://www.jstor.org.virtual.anu.edu.au/stable/4269178].

(±)-Gabaculine *[59556-18-2]* has been synthesised using mild reagents and reaction conditions as well as judicious protection and deprotection of the NH_2 and CO_2H groups to avoid aromatisation of the cyclohexane ring. Final purification is achieved by dissolving the final product in the minimum volume of H_2O applying onto a column of Bio-Rad AG 11 A8 ion-retardation resin and eluting with H_2O. *Alternatively*, chromatography through an ion-exchange column (SP Sephadex C-25) and eluting with aqueous NH_4OH gave pure amino-acid. The eluent is visualised with UV light and the fractions which gave positive ninhydrin tests are collected, lyophilised and should have all the above spectroscopic (IR, UV NMR, MS), TLC and amino acid analysis properties. The (±)-amino-acid can be recrystallised by dissolving it in the minimum volume of H_2O, adding 1 to 2 drops of H_2O and placing in a closed chamber over Me_2CO (whereby H_2O distils into the Me_2CO) and after 24 hours crystals appear, and are recrystallised in the same manner to give pure crystals with **m 196-197°** (identical with that from other syntheses). Store it below 5°. Its ^{13}C NMR (in D_2O + Na_2HPO_4, and proton decoupled) has δ 176.0, 133.0, 128.8, 128.3, 128.1, 54.4 and 29.9, and HRMS has *m/z* 139.0635 (calc for $C_7H_9NO_2$ is 139.0635). ***(±)-Gabaculine hydrochloride*** *[59556-17-1]* **$C_7H_9NO_2$. HCl, M 175.6,** has **m 203° (dec), 203-306° (dec), 198-200° (dec)**, (***note***: not very different from the free amino-acid), can be purified by recrystallising from dilute HCl (in needles m 198-200°), by dissolving the amino-acid in ice cold MeOH (saturated with dry HCl gas), the solvent is removed under high vacuum, and the white solid is recrystallised from Me_2CO containing a little MeOH [**m 195-199°(dec)**]. *Alternatively*, the (±)-*hydrochloride* is prepared in MeOH by adding dry HCl and recrystallising by dissolving in the least volume of H_2O, adding 1 to 2 drops of H_2O, evaporating over Me_2CO in a closed chamber and collecting the crystals and drying them *in vacuo* [m 197-199°]. Store it below 5°. All salts were undepressed with authentic material. [Kobayashi et al. *Tetrahedron Lett 537 1976,* DOI: 10.1016/S0040-4039(00)77904-4; Singer & Sharpless *J Org Chem* **43** 1448 *1978*, DOI: 10.1021/jo00401a034; Trost & Keinen *J Org Chem* **44** 3451 *1979*, DOI: 10.1021/jo01334a001.] ***Note*** that the synthetic (±)-amino-acid has half the inhibitory GABA-aminotransferase activity compared with the natural (-)-amino-acid [Kobayashi et al.].

Gibberillic acid A_3 (gibberillin A_3, GA_3) *[77-06-5]* **$C_{19}H_{22}O_6$, M 346.4, m 233-235°(dec), $[\alpha]_{546}^{20}$ +92 (c 1, MeOH), $[\alpha]_D^{20}$ +93 (c 0.5, MeOH), pK 4.0.** It crystallises from EtOAc, EtOAc/petroleum ether, MeOH/petroleum ether or Me_2CO/petroleum ether. Hexamethyldewarbenzene (HMDB, 1,2,3,4,5,6-hexamethyl-bicyclo[2.2.0]hexa-2,5-diene) *[7641-77-2]* **$C_{12}H_{18}$, M 162.3, m 7.5°, b 60°/20mm, ~152°/760mm, d_4^{20} 0.8125, n_D^{20} 1.4480.** HMDB is obtained in ~80% yield when 2-butyne (dimethylacetylene, flammable gas b 27°/atm, [503-17-3]) in $*C_6H_6$ or CH_2Cl_2 containing anhydrous $AlCl_3$ is stirred at 35° for 5-7 hours. The brown reaction mixture is poured onto crushed ice, washed with dilute aqueous NaOH, and HMDB is isolated from the organic phase by fractional vacuum distillation. ***Hexamethylbenzene*** (**m 165-166°**, [87-85-4]) is a by-product (~12-18%) together with a mixture (~2%) of *syn*- (m 127°) and *anti*- (m 196°) octamethyltricyclo[4.2.0.$0^{2,5}$]octa-3,7-diene, and octamethylcyclooctatetraene (m 113°). Although longer reaction times increase the conversion of 2-butyne, they lower the yields of HMDB in favour of the other by-products. It is fairly thermally stable with half-life time conversions to hexamethylbenzene of 105 hours/120°, 5.5 hours/140°, and 2.1 hours/150°. It is best to store it at low temperature and away from light as radiation from a low pressure UV lamp converts it mainly to hexamethylbenzene with ~20-25% of the valence isomer hexamethylprismane (m 91°). The UV spectrum exhibits tail end absorption from 220 to 250nm; the FT-IR (neat) has ν_{max} at 2950.0, 1683.5, 1439.5, 1368.8, 1275.4, 1222.2, 1064.8, 736.2 and 490.7 cm^{-1}; the ^{1}H NMR (60MHz, $CDCl_3$, TMS) has δ at 1.08 (s, 6H, 1,4-$(CH_3)_2$) and 1.69 (s, 12H, 2,3,5,6-$(CH_3)_4$), and the ^{13}C NMR (15MHz, $CDCl_3$, TMS) has δ at 10.06 (1,4-Me carbons) and 11.22 (2,3,5,6-Me carbons), 55.68 (2 saturated carbons) and 144.09 (4 olefinic carbons). [Schäfer & Hellmann *Angew Chem Int Ed* **6** 518 *1967*, DOI: 10.1002/anie.196705181.] Purify it also by passing it neat through alumina or in $*C_6H_6$ or CH_2Cl_2 solution. [Traylor & Miksztal *J Am Chem Soc* **109** 2770 *1987*, DOI: 10.1021/ja00243a033].

α-Humulene [α-caryophyllene (*now an obsolete name*, *see above*), *trans-trans-trans*-2,6,6,9-tetramethyl-1,4,8-cycloundecatriene = 1,1,4,8-tetramethylcycloundeca- *trans-trans-trans*-3,7,10-triene] *[6753-98-6]* **$C_{15}H_{24}$, M 204.4, b 106-107°/5mm, 123°/10mm, 166-168°/atm, d_4^{20} 0.967, d_4^{25} 0.8883, n_D^{20} 1.4956, n_D^{35}**

1.5017, n_D^{30} 1.5004. It is a large component of the *mono-cyclic* sesquiterpenes in the essential oils of hops [Chapman *J Chem Soc* 54, 780 *1895*, DOI: 10.1039/CT8956700054; DOI: 10.1039/CT8956700780 and 785 *1928*, DOI: 10.1039/JR9280000785], is present in clove oil, Egyptian Hashish [Simonsen & Todd *J Chem Soc* 188 *1942*, DOI: 10.1039/JR9420000188], and subsequently found in many other sources [Duessen *J prakt Chem* **83** 483 *1911*, DOI: 10.1002/prac.19110830134]. Originally isolated by steam distillation of hops and the oil fractionated preferably *in vacuo*. Later purification was further carried out by column chromatography on Al_2O_3 or silica gel (hexane or petroleum ether) to remove polar by-products [Kitigawa et al. *J Am Chem Soc* **99** 3864 *1977*, DOI: 10.1021/ja00453a069]. It is best to purify it first by fractionation using a Podbielniak still and at a reflux ratio of ~50, or a 1.25 m Dixon ring-packed still under a reflux ratio of ~35. The sesquiterpene should be optically inactive (most purified samples from natural sources have a very small optical rotation due to small amounts of bicyclic impurities, e.g. caryophyllenes — see above). Pure optically inactive material is best obtained *via* its $AgNO_3$ adduct. After distillation, it is diluted with light petroleum (b 40°-60°) and stirred with an equal volume of 50% aqueous $AgNO_3$ (w/w). Colourless needles of the ***adduct*** separate almost immediately with evolution of heat. The solid is filtered after standing, washed with light petroleum and dried *in vacuo*. Upon recrystallisation from aqueous EtOH, the ***adduct*** has **m 175-175.5°(dec,** capillary tube), **179°(**copper block) and analyses for $\mathbf{C_{15}H_{24}.\ 2\ AgNO_3}$. It is stable on storage in the dark at 5°. X-ray crystallography confirmed the humulene structure and demonstrated that the two Ag+ ions are each complexed to the 7-8 and 10-11 double bonds [McPhail & Sims *J Chem Soc (B)* 112 *1966*, DOI: 10.1039/J29660000112].

Regeneration of the hydrocarbon is achieved by refluxing the adduct (e.g. 21.4g) with H_2O (e.g. 300 mL) under an oil trap (to avoid loss of hydrocarbon through the top of the condenser), cool, extract with Et_2O, dry over $CaCl_2$, or Na_2SO_4, filter, evaporate and fractionate through a still containing 1 m of Bower-Cooke packing (reflux ratio ~10) collecting the fraction with b 123°/10mm. *Alternatively*, regenerate by dissolving the adduct (e.g. 5g) in excess saturated NH_3 which liberates the hydrocarbon that is extracted with Et_2O as previously to yield pure α-caryophyllene (2g). The UV shows end absorption with ε 3050 at λ = 220 nm. FTIR (film cm^{-1}) ν_{max} : 2956, 2925, 2866, 2853, 1684, 1446, 1384, 1362, 1210, 1176, 966 and 822; ^{1}H NMR ($CDCl_3$, 500 MHz) δ: 5.57 (dt, *J* = 15.9. 7.4 Hz, 1H), 5.14 (d, *J* = 15.9 Hz, 1H), 4.93 (br t, *J* = 6.3Hz, 1H), 4.85 (br t, *J* = 7.5Hz, 1H), 2.49 (d, *J* = 7.4Hz, 2H), 2.05-2.11 (m, 4H), 1.89 (d, *J* = 7.4Hz, 2H), 1.62 (s, 3H), 1.41 (s, 3H), 1.04 (s, 6H); ^{13}C NMR ($CDCl_3$, 100 MHz) δ: 141.0, 139.2, 133.2, 127.7, 125.8, 125.0, 42.0, 40.4, 39.7, 37.3, 23.3, 17.9 and 15.1. This $AgNO_3$ procedure can be used to obtain pure hydrocarbon from '*commercial caryophyllene*' which contains ~13% of the hydrocarbon.

The white ***nitrosochloride*****, $\mathbf{C_{15}H_{24}ClNO}$, [-C(NO)—C(Cl)-]** (2.56g), prepared from α-caryophyllene (1.99g) and ethyl nitrite and concentrated HCl in MeOH-AcOH, crystallises from $CHCl_3$-EtOH with **m 172°(dec)** [also reported: 173-174°, 176°, 177°]. The ***nitrolpiperidide***, $\mathbf{C_{15}H_{24}NONC_5H_{10}}$, is prepared from the *nitroso-chloride* and piperidine at ~100° and crystallises from EtOH, to form colourless prisms with **m 148-149°** [also reported: 153°, 154-155°]. The ***nitrolbenzylamine***, $\mathbf{C_{15}H_{24}NONHCH_2C_6H_5}$, is similarly prepared from the *nitrosochloride* and benzylamine, has **m 136-137°** [also reported: 136°]. [Hildebrand & Sutherland *Aust J Chem* **14** 272 *1961*, DOI: 10.1071/CH9610272; Chapman *J Chem Soc* 785 *1928*, DOI: 10.1039/JR9280000785; Clemo & Harris *J Chem Soc* 22 *1951*, DOI: 10.1039/JR9510000022; *synthesis* Kitigawa et al. *J Am Chem Soc* **99** 3864 *1977*, DOI: 10.1021/ja00453a069; *biomimetic synthesis* Corey et al. *Tetrahedron Lett* **34** 3675 *1993*, DOI:10.1016/S0040-4039(00)79198-2; for *X-ray structure of $AgNO_3$ adduct* see McPhail & Sim *J Chem Soc (B)* 112 *1966,* DOI: 10.1039/J29660000112; *Beilstein* **5** III 1070.]

The ***nitrosate*****, $\mathbf{C_{15}H_{24}N_2O_4}$, [-C(NO)—C(ONO$_2$)-]** prepared from amyl nitrite and AcOH, then HNO_3-AcOH, crystallises from $*C_6H_6$, and has **m 161°** to **m 165°** depending on heating rate [reported also: 163°]. The ***nitrosite*****, $\mathbf{C_{15}H_{24}N_2O_3}$, [-C(NO)—C(ONO)-]** separates as blue crystals when equal volumes of α-humulene and light petroleum are shaken with concentrated aqueous $NaNO_2$ with cooling, followed by slow addition of glacial acetic acid (volume equal to humulene used) with shaking. The organic green-blue layer is separated, and the blue crystals of the nitrosite are collected and crystallised from EtOH to give blue needles of the ***dinitrosite compound*** (dimer ?) with **m 120-121°**. Boiling a solution of the blue nitrosite in EtOH for several hours slowly caused loss of colour which on cooling deposited almost colourless needles with a blue tinge of the isomeric (tautomeric) ***bis-oxime*** with **m 165-168°**. [Deussen *J Prakt Chem* **83** 483 *1911*, DOI: 10.1002/prac.19110830134; Chapman *J Chem Soc* 785 *1928*, DOI: 10.1039/JR9280000785.]

Humulene trioxide, $\mathbf{C_{15}H_{24}O_3}$, MW 252.3, prepared by oxidation of humulene (3g) in $CHCl_3$ (220 ml) for 3 days at room temperature with perbenzoic acid (1 ml of $CHCl_3$ containing 64mg of the acid), followed by shaking with cold 5% aqueous NaOH, H_2O to neutrality, drying, evaporating, and distilling to give a viscous oil

which formed crystals on trituration with EtOH-hexane. Recrystallisation from the same solvent gives pure ***trioxide*** with **m 122.5°** [Sorm et al. *Coll Czech Chem Commun* **14** 699 *1949*, DOI: 10.1135/cccc19490693]. *Alternatively*, a sample of humulene, extracted with other terpenes in the turpentine oil from *Araucaria cunnunghamii*, and purified by gas chromatography on 'Apiezon M on Embecel' at 170° with N_2 as carried gas, and the fraction from relevant peak converted into the $AgNO_3$ complex from which pure *humulene* was recovered, was oxidised with monoperphthalic acid to *humulene trioxide*, **m 121-122°** (hexane-EtOH) [Gallagher & Sutherland *Aust J Chem* **13** 367 *1960*, DOI: 10.1071/CH9600367; *Beilstein* **19** IV 4748].
Catalytic reduction of *α-humulene* in glacial acetic acid using Adam's Pt results in the absorption of 3 mols of H_2 (at 19°/747.6mm) to produce ***Humulane (hexahydrohumulene, 1,1,4,8-tetramethyl*** **cyclo*undecane*) $C_{15}H_{30}$, M 210.5**, which has **b 120-122°/13mm, d_4^{20} 0.8637, n_D^{20} 1.4723** [Sorm et al. *Coll Czech Chem Commun* **14** 669 *1949*, DOI: 10.1135/cccc19490693].

β-Humulene (*trans,trans*-8-methylene-1,4,4-trimethylcycloundeca-1,5-diene) *[116-04-1]* **$C_{15}H_{24}$, M 204.4, d_4^{20} 0.8905, n_D^{20} 1.5014.** The *mono-cyclic* sesquiterpenic fractions from hops, oil of cloves or other sources (see preceding entry) contain a high proportion of α-humulene which cannot be cleanly separated by fractional distillation from the smaller amounts of the isomeric β-humulene. The oil from the leaves of *Lindera strychnifolia* (F.) WILL gave very pure humulene. Column chromatography on alkaline Al_2O_3 (grade I, according to Brockmann) and eluting with light petroleum afforded better separation of the isomers than fractional distillation. The *α-isomer* elutes first followed by a mixture of α- and β-*isomers* followed by enriched β-*isomer*. The fractionation can be followed by evaporating aliquots and examining the IR spectra (film) of the residues. Unlike the *α-isomer*, the β-*isomer* has a medium-intense deformation vibration band characteristic of an exocyclic double bond at ν_{max} 888-889 cm^{-1}. A band at 968 cm^{-1} characteristic of *trans* —CH=CH— double bonds is present in both isomers. The exocyclic methylene double bond is further confirmed by bands at 1645 and 3075 cm^{-1}. Mixtures of isomers have the two sets of bands of varying intensities according to their ratios. Repeated chromatography of fractions can improve separation. However, pure α-humulene isolated *via* its $AgNO_3$ adduct and regenerated, did not possess an exocyclic double but repeated chromatography on Al_2O_3 as above caused isomerisation and enriched it in the β-*isomer* with the exocyclic methylene group. Catalytic reduction of the isomers provided the same ***humulane*** (see preceding entry). [Benesová, Herout and Sorm et al. *Coll Czech Chem Commun* **26** 1832 *1961*, DOI: 10.1135/cccc19611832, Sorm et al. *Coll Czech Chem Commun* **14** 669 *1949*, DOI: 10.1135/cccc19490693.] [*Beilstein* **5** III 1070.] **γ-Humulene (isohumulene, 5-methylene-1,8,8-trimethylcycloundeca-*cis*-1-, *trans*-6-diene)** *[26259-79-0]* **$C_{15}H_{24}$, M 204.4, d_4^{20} 0.9,** is a second humulene with an exocyclic methylene group. [*Beilstein* **5** III 1070.]

Humulon [α-lupulic acid, 6*R*-3,5,6-trihydroxy-4,6-bis(3-methyl-2-butenyl)-2-(3-methyl-1-oxobutyl)-2,4-cyclo-hexadien1-one *[26472-41-3]* **$C_{21}H_{30}O_5$, M 362.5, m 65-66.5°, $[\alpha]_D^{20}$ -232 (*C_6H_6), $[\alpha]_D^{26}$ -212 (c 6.5, 95% EtOH), -124 (abs EtOH), -162 (dioxane).** Originally, it was isolated from the mother liquors of the petroleum ether extract of hop cones, after crystallisation of *lupulone* (see below) as its *o*-phenylenediamine complex. After evaporation of the filtrate, the residue was recrystallised three times from *C_6H_6-petroleum ether (1:2) to constant optical rotation. Also recrystallise *humulon* from Et_2O. It dissolves slightly in hot H_2O but precipitates on cooling. It has λ_{max} nm (ε) at 237 (13,760) and 282 (8,330) in EtOH. It is an antimicrobial agent in commercial hops. ***Note***: variations in the specific rotations may well be caused by slight variation in keto-enol tautomeric ratios. [Wöllmer *Chem Ber* **49** 780 *1916*, DOI: 10.1002/cber.19160490185; Carson *J Am Chem Soc* **73** 4652 *1951*, DOI: 10.1021/ja01154a046; *Beilstein* **8** II 537, **8** III 4034, **8** IV 3410.]

(±)-1-Hydroxyadamantan-4-one (Kemantone, 5-hydroxy-2-adamantanone, 1-hydroxytricycl[3.3.1.13.7]-decan-4-one) *[20098-14-0]* **$C_{10}H_{14}O_2$, M 166.2, m 319-322°.** The hydroxyketone crystallises from CCl_4 and sublimes unchanged. It can be obtained by stirring 2-hydroxyadamantane (6.1g, see [700-57-2] above) in 70% H_2SO_4 (50ml) at 90° for 2 hours followed by neutralising with 50% NaOH to give a mixture of adamantane (44.5%) and adamantanone (17.5%), and from the aqueous solution a mixture of 1,4-dihydroxyadamantane and 1-hydroxyadamantan-4-one that are combined and oxidised with CrO_3 in 0.5N H_2SO_4/Me_2CO to give 1-hydroxyadamantan-4-one (0.86g, m 315-321°, 98% purity by GLC,), which after recrystallisation from CCl_4 (recovery 76%) has **m 319-322°**, *m/z* found 166.0994, $C_{10}H_{14}O_2$ requires M =166.0994; ^1H NMR has δ at 2.62 (2H, protons α to the C=O), 2.35 (1H, tertiary proton at C-7), 1.98 (10H, secondary protons), 1.89 (1H, -OH); and IR (CH_2Cl_2) has ν_{max} at 3590 (m, free OH), 2920 (s) and 2855 (m, CH), 1720 (vs, C=O), 1110 (s), 1090

(m), 1066 (m), 1055 (s), 971 (m) and 926 (s) cm^{-1}. ***1-Hydroxyadamantan-4-one oxime***, obtained in the usual way, crystallises from EtOAc in colourless crystals with **m 157-160°**; IR (KBr) with ν_{max} at 3300 (vs, OH), 2925 (s) and 2855 (m) (CH), 1660 (w, C=N), 1115 (s), 1095 (s), 1067 (m), 925 (s) and 848 (m) cm^{-1}. Reduction with $LiAlH_4$/THF/65°/20hrs provided the amine which was converted to the ***4-aminoadamantan-1-ol hydrochloride*** *[trans: 62075-23-4]* **$C_{10}H_{17}NO$. HCl, M 203.7, m 356-358°**, on treatment with HCl and recrystallising twice from MeOH (and addition of Et_2O) [Geluk & Schlatmann *Tetrahedron* **24** 5369 *1968*, DOI: 10.1016/S0040-4020(01)96330-6.]. ***Alternatively***, adamantanone (12.0g, 80mmol) is stirred into 100% HNO_3 (100ml) in an ice-water bath where the solid dissolves immediately, the temperature rises to 13-15°, and the colour changes to orange-brown. The mixture is allowed to stand for 70 hours, then is heated at 60° for 90min, the acid is distilled off under vacuum on a steam bath and the yellow oil solidified as the HNO_3-adduct. Water (40ml) and 96% H_2SO_4 (15ml) is added and the resultant clear solution is heated on a steam bath for 1 hour when all the nitrous fumes evolved (FUME HOOD). The cooled solution is extracted with 2:1 petroleum ether (b 40-60)/Et_2O (50ml x 2) to remove unreacted adamantone (0.07g), the acid layer is neutralised with 30% aqueous NaOH and while warm is extracted with CH_2Cl_2 (50ml x 2). The extract is washed with brine (25ml) and evaporated *in vacuo*, the crude residue (10.75g) is dissolved in CH_2Cl_2 (15-20ml) and petroleum ether (b 40-60) is added until no further precipitation occurs. The hydroxyadmantanone is collected and dried (**m 315-318°**, 9.65g, 77% yield, and has 3% of adamantane-2.6-dione by GLC). Recrystallisation from CCl_4 gave pure product with **m 319-312°.** [Geluk *Synthesis* 374 *1972*, DOI: 10.1055/s-1972-21884; Noble et al. *J Org Chem*. **48** 1099, *1983*, DOI: 10.1021/jo00155a034.] For a rapid conversion of adamantanone to 5-hydroxyadamantan-4-one in 60% yield on a multigram scale see Srivastava & le Noble *Synth Commun* 14 65 *1984*, DOI:10.1080/00397918408060865]. The (±)-form is a T-cell suppressor, and a lymphocyte and antibody stimulant in mice.
1-Acetoxyadamantan-4-one *[63382-10-5]* $C_{12}H_{16}O_3$, M 208.2, **m 60°,** is obtained by CrO_3/Ac_2O oxidation of adamantanone for 10 days at 20°, and purified through an Al_2O_3 column (neutral, activity III) and eluting with petroleum ether. It has IR (melt) with ν_{max} at 2870, 1730, 1235 and 1060 cm^{-1}; ^1H NMR ($CDCl_3$) has δ at 2.46 (2H α to C=O), 2.40 (7H), 2.00 (4H + 3H of OAc) ppm; and the ^{13}C NMR (C_6D_6) has δ at 212.9 (C=O) 169.4 (OAc), 77.5 (a), 47.2 (b), 41.3 (c), 40.0 (d), 38.0 (e), 30.2 (f), 22.0 (OAc) ppm [Morat & Rassat *Tetrahedron Lett* **20** 4409 *1979*, DOI: 10.1016/S0040-4039(01)86603-X].

1-Hydroxymethyladamantane (1-adamantanemethanol) *[770-71-8]* **$C_{11}H_{18}O$, M 166.3, m 115°, 114-117°.** Dissolve the adamantane in Et_2O, wash it with aqueous 0.1N NaOH and H_2O, dry over $CaCl_2$, evaporate and recrystallise the residue from aqueous MeOH. [Stetter et al. *Chem Ber* **92** 1629 *1959*, DOI: 10.1002/cber.19590920722; *Beilstein* **6** IV 400.]

The ***free base*** has **m 75-80°**, **b 156-157°/atm** and the ***picrate*** has **m 179-180°** (from aqueous MeOH). [*Beilstein* **12** III 160.]

Norbornylene (bicyclo[2.2.1]hept-2-ene) *[498-66-8]* **C_7H_{10}, M 94.2, m 44-46°, b 96°/atm.** Reflux it over Na, and distil it [Gilliom & Grubbs *J Am Chem Soc* **108** 733 *1986*, DOI: 10.1021/ja00264a027]. It has also been purified by sublimation *in vacuo* onto an ice-cold finger. [Woon et al. *J Am Chem Soc* **108** 7990 *1986*, DOI: 10.1021/ja00285a018; *Beilstein* **5** IV 394.]

(±)-*exo*-2-Norbornylformate *[41498-71-9]* **$C_8H_{12}O_2$, M 140.2, b 65-67°/16mm, 80-81°/25mm, d_4^{20} 1.048, n_D^{20} 1.4620.** Shake with $NaHCO_3$ and distil it *in vacuo* (*exo*-borneol has **m** 124-126°). *Alternatively*, mix the ester with formic acetic anhydride overnight and fractionate, particularly if the sample contains much *exo*-borneol as evidenced by strong OH bands in the IR spectrum. [*Beilstein* **6** III 219.]

Norcamphor (bicyclo[2.2.1]heptan-2-one, ± norbornan-2-one) *[497-38-1]* **$C_7H_{10}O$, M 110.2, m 94-95°, 95.5-96.5°, b 89-94°/60mm.** Crystallise it from water and sublime it *in vacuo*. It has λ_{max} at 287nm (EtOH). The ***semicarbazone*** has **m 196-196.5°** (from EtOH/H_2O). The ***2,4-dinitrophenylhydrazone*** has **m 137-138°** (from EtOH). [Wildman & Hemminger *J Org Chem* **17** 1641 *1952*, DOI: 10.1021/jo50012a011; Wood &

Roberts *J Org Chem* **23** 1124 *1957*, Bixler & Niemann *J Org Chem* **23** 742 *1958,* DOI: 10.1021/jo01099a600; *Beilstein* **7** III 243, **7** IV 139.]

1,2,3,4,5-Pentamethylcyclopentadiene (Cp') *[4045-44-7]* **$C_{10}H_{16}$, M 136.2, b 55-60°/13mm, 58°/13mm, 58.3°/13.5mm**, **d^{25} 0.870, n_D^{20} 1.4740.** Of the many syntheses of this useful ligand, the following is the most economical on materials and can be scaled up. Strictly anhydrous and anaerobic conditions should be used and reagents should be dried appropriately, degassed, and precaution against fire should be exercised. Three steps are involved: ***Step 1:*** Under argon, lithium (58g, 8.36moles, with 0.02%Na, of ~3.2mm diameter cut into the flask in ~5mm lengths) is covered with Et_2O (1600ml, freshly distilled from ~3:1w/w K/Na benzophenone), and 2-bromo-2-butene (120g, 0.88mole, 90.4ml of a molecular sieves 4Å dried commercial *cis*- and *trans*- mixture or prepared according to Bordwell & Landis *J Am Chem Soc* **79** 1593 *1957*, DOI: 10.1021/ja01564a020) is added slowly with stirring (10ml aliquots slowly at first until the reaction begins; with evolution of bubbles and cloudiness due to separation of LiBr), and at such a rate as to maintain gentle reflux of the Et_2O. ***Step 2:*** After addition is complete (~1.5 hours), still under argon, a mixture of ethyl acetate (166g, 1.88mole, 184ml, dried over molecular sieves 4Å) and 2-bromo-2-butene (430g, 3.18mole, 324ml as above) are then added dropwise with stirring, while carefully maintaining gentle reflux over a period of 4-5 hours. When this addition is completed, a further volume of dry EtOAc (50g, 55.4ml) and a further portion of 2-bromo-2-butene (~10-20g, 7.5-15ml) are added, while stirring is continued, until refluxing of Et_2O ceases. The mixture is allowed to cool over 4 hours, saturated aqueous NH_4Cl solution is added dropwise to hydrolyse unreacted Li, the Et_2O layer is collected, the aqueous layer is extracted with Et_2O (3 x 200ml), and the combined Et_2O solutions are evaporated to ~350ml. ***Step 3:*** The Et_2O concentrate is added, with stirring, to a slurry of *p*-toluenesulfonic acid monohydrate (26g) in Et_2O (500ml) under a reflux condenser, at such a rate that the solvent refluxes gently. The mixture is then stirred for 5 minutes after refluxing ceases, and poured into saturated aqueous $NaHCO_3$ (1200ml) containing Na_2CO_3 (19g). The yellow aqueous phase is removed, extracted with Et_2O (3 x 200ml), and the combined Et_2O solutions are dried (Na_2SO_4), filtered, evaporated to 250-300ml (rotavap), then trap-to-trap distilled *in vacuo* (bath temperature at 35-40°) to give a yellow liquid (85% pure by GC) which is fractionally distilled in a vacuum under N_2 using a 50cm vigreux column. The fraction with **b 65-70°/20mm** collected (142g, 53% yield based on EtOAc used) as pale-yellow liquid is ***1,2,3,4,5-pentamethylcyclopentadiene*** (92% pure by GC). An additional fraction (15g, 5%) with b 70-75°/20mm is 85% pure by GC. The liquids are colourless to pale-yellow in colour with a sweet olefinic odour, and are pure enough for use as ligands. They should be stored in a freezer under N_2 or argon. In **comparison with the unsubstituted *cyclopentadiene*** it is a stronger donor of electron density, exerting considerably enhanced thermal stability, and the metal complexes that it forms are generally more soluble and easier to crystallise. The *pentamethylpentadiene* has FT-IR (neat) with ν_{max} at 2960 (vs), 2915 (vs), 2855 (vs), 2735 (w), 1660 (m), 1640 (w), 1390 (s), 1355 (m), 1150 (w), 1105 (mw), 1048 (w), 840 (mw) and 668 (w) cm^{-1}; ^1H NMR (60MHz, CCl_4, TMS) with δ at 2.4 (m, 1H), 1.75 (br s, 13H, 2,3,4,5-Me), 0.95 (d, $^3J_{H\text{-}H}$ = 8Hz, 3H, 1-Me); ^{13}C NMR (15MHz, $CDCl_3$, TMS) with δ at 14.18, 20.98, 27.43, 38.04, 54.77, 61.26, 169.37 and 212.25. [Manriquez et al. *Inorg Synth* **XXI** 181 *1982*, Feitler et al. *Inorg Chem* **15** 466 *1976*, DOI: 10.1021/ic50156a046; Threlkel et al. *Org Synth* **65** 42 *1987*, DOI: 10.15227/orgsyn.065.0042.]

Perfluorocyclobutane (octafluorocyclobutane) *[115-25-3]* **C_4F_8, M 200.0, m -40°, b -5°/atm, d^{-20} 1.654, d^{o} 1.72.** Purify octafluorocyclobutane by trap-to-trap distillation, retaining the middle portion. [Danus *Ind Eng Chem* **47** 144 *1955*, Claasen *J Chem Phys* **18** 543 *1950*, DOI: org.virtual.anu.edu.au/10.1063/1.1747681; *Beilstein* **5** III 8, **5** IV 8.]

Perfluorocyclohexane (dodecafluorocyclohexane) *[355-68-0]* **C_6F_{12}, M 300.1, m 51° (sublimes), sublimes on melting at 52°, m 58.2° (sealed tube), d_4^{25} 1.720, n_D^{30} 1.269.** Extract it repeatedly with MeOH, then pass it through a column of silica gel (previously activated by heating at 250°). Sublime it *in vacuo*. [Haszeldine & Smith *J Chem Soc* 2689 *1950*, DOI: 10.1039/JR9500002689; IR: Thompson & Temple *J Chem Soc* 1432 *1948*, DOI: 10.1039/JR9480001432; *Beilstein* **5** III 37, **5** IV 48.]

Perfluoro-1,3-dimethylcyclohexane *[335-27-3]* **C_8F_{16}, M 400.1, m -55°, b 101-102°/atm, d_4^{20} 1.829, n_D^{20} 1.300.** Fractionally distil it, then 35ml are sealed with about 7g KOH pellets in a borosilicate glass ampoule and

heated at 135° for 48 hours. The ampoule is cooled, opened, and the liquid is resealed with fresh KOH in another ampoule and heated as before. This process is repeated until no further decomposition is observed. The substance is then washed with distilled water, dried ($CaSO_4$) and distilled. [Grafstein *Anal Chem* **26** 523 *1954*, DOI: 10.1021/ac60087a029, *Beilstein* **5** III 378.] **IRRITANT, avoid breathing its vapours.**

Perfluoro(methylcyclohexane) *[355-02-2]* **C_7F_{14}, M 350.1, b 76.3°/atm, d^{25} 1.7878.** Reflux it for 24 hours with saturated acid $KMnO_4$ (to oxidise and remove hydrocarbons), then neutralise, steam distil, dry with P_2O_5 and pass slowly through a column of dry silica gel. [Glew & Reeves *J Phys Chem* **60** 615 *1956*, DOI: 10.1021/j150539a026.] It can also be purified by percolation through a 1 metre neutral activated alumina column, and the impurities are checked by ^{1}H NMR. [*Beilstein* **5** IV 102.] **IRRITANT, avoid breathing its vapours.**

***R*(-)-α-Phellandrene (*p*-menta-1,5-diene)** *[4221-98-1]* **$C_{10}H_{16}$, M 136.2, b 61°/11mm, 171-174°/atm, 175-176°/760mm, d_4^{20} 0.838, n_D^{20} 1.471, $[\alpha]_D^{20}$ -230 (c 10, Et_2O), -153 to -183 (neat).** Purify it by gas chromatography using an Apiezon column. Also purify it by steam distillation (with 0.5% hydroquinone), then re-distil it through a 50 plate bubble cap column and collecting the fraction with **b 72-72.5°/22mm** [Pines & Eschinazi *J Am Chem Soc* **77** 6314 *1955*, DOI: 10.1021/ja01628a072]. UV: λ_{max} at 263nm (ε 3,345) in octane. [Read & Storey *J Chem Soc* 2770 1930, DOI: 10.1039/JR9300002770; *Beilstein* **5** III 341, **5** IV 436.]

Picrotoxin (cocculin) *[124-87-8]* **$C_{30}H_{34}O_{13}$, [$C_{15}H_{16}O_6$, $C_{15}H_{18}O_7$], M 602.6, m 203°, 203-204°, $[\alpha]_{546}^{20}$ -40 (c 1, EtOH), $[\alpha]_D^{16}$ -29.3 (c 4, EtOH).** It is the toxic and bitter principle in the seeds of *Anamirta cocculus*, and is *very poisonous* (use CARE when working with it). Crystallise picrotoxin from H_2O or Me_2CO/H_2O. It is sparingly soluble in Et_2O and $CHCl_3$. Its solubility (w/v) in H_2O is 0.3% (~20°) and 20% (100°); in 95% EtOH it is 7.4% (~20°) and 33% (78°). It is freely soluble in aqueous NaOH and 880 NH_3. The ***monoacetate*** has **m 244-245°** (*C_6H_6). [Meyer & Bruger *Chem Ber* **31** 2958 *1898*, DOI: 10.1002/cber.18980310366; Johns et al. *J Chem Soc* 4715 *1956*, DOI: 10.1039/JR9560004715; *Beilstein* **19** III/IV 5245.] **HIGHLY TOXIC**, stimulates the CNS and respiration [For toxicity see Setnikar et al. *J Pharmacol Exp Ther* **128** 176 *1960*, PMID: 14445192; and for the crystal and molecular structure see Dupont et al. *Acta Crystallographica B* **32** S. 2987 *1976*, DOI: 10.1107/S0567740876009424].

(±)−α-Pinene (2,6,6,-trimethylbicyclo[3.1.1.]hept-2-ene) *[80-56-8]* **$C_{10}H_{16}$, M 136.2, b 52.5°/20mm, 155-156°/760mm, d_4^{20} 0.8592, n_D^{20} 1.4664.** Racemic synthetic material can be purified like the chiral forms below. It forms a ***hydrochloride*, $C_{10}H_{17}Cl$,** with **m 132°**. Upon per-acid oxidation it forms the epoxide **(±)−α-pinene oxide** *[1686-14-2]* **$C_{10}H_{16}O$, M 152.3,** which distils at **102-103°/50mm** and has **d_4^{25} 0.964, n_D^{20} 1.469** [*Beilstein* **5** H 152]. It occurs naturally in optically active forms (see below) in turpentine oil (~ 60% of α-pinene and ~ 30% of β-pinene) where the pinene from most European sources are *laevo-rotatory* whereas those from North America are *dextro-rotatory*. [Simonsen *The Terpenes* **Vol II** pp 105-191 *1949*, Cambridge University Press.]

***1R,5S*-α-Pinene** *[7785-70-8]* **$C_{10}H_{16}$, M 136.2, b 61°/30mm, 156.2°/760mm, d_4^{20} 0.858, n_D^{15} 1.4634, n_D^{20} 1.4658, $[\alpha]_D^{20}$ +51 (neat).** It is isomerised by heat, acids and certain solvents. It should be distilled under reduced pressure under N_2 and stored in the dark. It has been purified *via* the nitrosochloride [Waterman et al. *Recl Trav Chim Pays-Bas* **48** 1191 *1929*, DOI: 10.1002/recl.19290481202]. For purification of optically active forms see Lynn [*J Am Chem Soc* **91** 361 *1919*, DOI: 10.1021/ja01460a010]. It forms a ***hydrochloride*, $C_{10}H_{17}Cl$,** with **m 132°**, **$[\alpha]_D^{20}$ +33.5 (EtOH).** Small quantities (0.5ml) have been purified by GLC using helium as carrier gas and a column at 90° packed with 20 wt% of polypropylene sebacate on a Chromosorb support. Larger quantities are fractionally distilled under reduced pressure through a column packed with stainless steel gauze spirals. The material can be dried over CaH_2 or sodium, and stored in a refrigerator: $CaSO_4$ and silica gel are not satisfactory because they induce spontaneous isomerisation. [Bates et al. *J Chem Soc* 1521 *1962*, DOI: 10.1039/JR9560004715; *Beilstein* **5** III 366, **5** IV 452.]

***1S,5S*−α-Pinene** *[7785-26-4]* **$C_{10}H_{16}$, M 136.2, b 155-156°/760mm, d_4^{20} 0.858, n_D^{20} 1.4634, $[\alpha]_D^{20}$ -47.2 and $[\alpha]_D^{20}$ -51.28 (neat).** Purify as for *1R,5S*-α-Pinene above. It forms a ***hydrochloride*, $C_{10}H_{17}Cl$,** with **m 132°**, **$[\alpha]_D^{20}$ -33.5 (EtOH).** [*Beilstein* **5** III 366, **5** IV 455.]

1S,5S*−β-Pinene (*1S,5S*−6,6-dimethyl-2-methylenebicyclo[3.1.1]heptane)** *[18172-67-3]* **$C_{10}H_{16}$, M 136.2, m -61°**, **b 162-163°/atm, 165-167°/atm, d_4^{20} 0.858, n_D^{15} 1.4872, n_D^{20} 1.478, $[\alpha]_D^{20}$ -47.2 and $[\alpha]_D^{20}$ -22.4 (neat).** Purification is as for the previous isomer, i.e. by fractional distillation. ***Note that it differs from the isomeric α-pinene (above) in that the 2-Me group is replaced by a 2-methylene group, and it isomerises irreversibly to α-pinene when shaken with Pt black that had been saturated with hydrogen [Richter & Wolff *Chem Ber* **59** 1733 *1926*, DOI: 10.1002/cber.19260590816]. [For synthesis see Harwood & Julia *Synthesis* 456 *1980*, DOI: 10.1055/s-1980-29049 and Crowley *Proc Chem Soc (London)* 237 (p 245) *1962*, DOI: 10.1039/PS9620000237.] [*Beilstein* **5** IV 457.]

Xanthatin **(3-methylene-7-methyl-6-[3-oxo-1-buten-1-yl]cyclohept-5-ene-[10,11-*b*]furan-2-one, (-)-2-[(*1R*)-7*t*-hydroxy-5*c*-methyl-4-(3-oxobut-1-en-ξ-yl)cyclohept-3-en-*r*-yl)-acrylic acid lactone** *[26791-73-1]* **$C_{15}H_{18}O_3$, M 246.3, m 114.5-115°, 114.5-115.2°, $[\alpha]_D^{20}$ -20 (c 2, $CHCl_3$, or EtOH).** Xanthatin was first isolated from *Xanthium pensylvanicum* [Little, Foote and Johnstone *Arch Biochem* **27** 247 *1950*, PMID: 14771893], found in several *Xanthium* species, and its structure was firmly established by Geissman and co-workers [Geissman et al.* *J Am Chem Soc* **76** 685 *1954*, DOI: 10.1021/ja01632a014; Deuel & Geissman* *J Am Chem Soc* **79** 3778 *1957*, DOI: 10.1021/ja01571a044]. It is a potent antibacterial against *Staphylococcus aureus*, including MRSA [Sato et al. *J Pharm Pharmacol* **49** 1042 *1997*, PMID: 9364417], and its total synthesis has been achieved by Shishido and coworkers [Hiromasa et al. *Tetrahedron Lett* **49** 3504 *2008*, DOI: 10.1016/j.tetlet.2008.03.081]. It can be purified by recrystallisation from MeOH, aqueous MeOH, absolute EtOH or aqueous EtOH. It is soluble in Et_2O, Me_2CO and EtOH, slightly soluble in H_2O at neutral pH, but almost insoluble in aqueous N NaOH and N HCl. Its UV has $\lambda_{max}(\varepsilon)$ at 213 (22800) and 275nm (7300) in H_2O; and IR (film) with ν_{max} at 1766 (C=O), 1660, 1609, 1590 (C=O, C=C) and 812 (R_2C=CCHR) cm^{-1}. The ***2,4-dinitrophenylhydrazone*** has **m 240°(dec)** (twice recrystallised from $CHCl_3$/MeOH as garnet-red crystals). *Beilstein* **17** III/IV 6221, **17/1** V 305.]

*Geissman and coworkers extracted the dried, ground young leaves of the Cocklebur *X Pennsylvanicum* (from the daisy family of the sunflower group of plants) (50g) with Me_2CO (800ml) at ~25° with shaking for 2 hours, filtered with suction, and the filtrate was evaporated to dryness. Water (5L) was added to the dry residue and set aside for 24 hours, then filtered and the filtrate was extracted with Et_2O (1L x 3) and the combined extracts were placed in the freezer to freeze out any H_2O present. After filtration, the filtrate was evaporated down to 15ml and this Et_2O concentrate gave crystals on cooling. These were filtered off washed with cold Et_2O and twice recrystallised from the minimum volume of dilute EtOH to give 0.5-0.6g of ***xanthinin*** [580-49-4, 64047-79-6] (representing 1-1.2% of dry leaves). *Xanthinin* crystallises as colourless plates from Et_2O, EtOH or aqueous EtOH with **m 121-122°**, is odourless, insoluble in cold but not hot H_2O, soluble in pyridine, EtOH, Me_2CO, and *C_6H_6, slightly soluble in Et_2O but insoluble in petroleum ether. It analyses for **$C_{17}H_{22}O_5$**, and its UV has $\lambda_{max}(\varepsilon)$ at 215 (9037) and 220nm (5974) in 95% EtOH, and 215 (12193) and 220nm (8823) in H_2O; has IR (film) with ν_{max} at 1765 (C=O), 1720 (C=O, C=C) and 814 (R_2C=CCHR) cm^{-1}; and has **$[\alpha]_D^{25}$ -53.0 (c 0.119g in 5ml $CHCl_3$).** Its ***p-bromophenylhydrazone*** forms yellow crystals from EtOH with **m 138-138.5°**.

Xanthatin (desacetylxanthinin) was best obtained by deacetylation of ***xanthinin*** (e.g. 1.24g) with NaOAc (2.3g) solution in EtOH (20ml) by refluxing (40 minutes) while some EtOH (10ml) was allowed to distil off. The solution was made alkaline (to litmus) with HCl, H_2O was added until the precipitated NaCl had just dissolved, and cooled whereby **xanthatin** crystallised out (0.96g, 96%). It had **m 114.5-115.5°** upon recrystallisation from absolute EtOH.

AROMATIC COMPOUNDS

Acenaphthene *[83-32-9]* **$C_{12}H_{10}$, M 154.2, m 94.0°, 95.0°, b 279°/atm.** It is a coal tar component with an odour of naphthalene and is used as a vermicide and insecticide. Crystallise acenaphthene from EtOH. It has also been purified by chromatography from CCl_4 on alumina with *benzene as eluent [McLaughlin & Zainal *J Chem Soc* 2485 *1960*, DOI: 10.1039/JR9600002485]. Acenaphthalene is almost insoluble in H_2O, but is soluble at ~ 25° (w/v) in EtOH (3.2%), MeOH (1.7%), PrOH (4.0%), $CHCl_4$ (40.0%), *C_6H_6 (20.0%) and AcOH (3.2%) and forms 1:2 complexes with bile acids in EtOH or dioxane. [*Beilstein* **5** IV 1834.]

Acenaphthenequinone *[82-86-0]* **$C_{12}H_6O_2$, M 182.2, m 249-252°(dec), 260-261°.** Extract it with, then recrystallise it twice from *C_6H_6. Dry it *in vacuo*. [LeFevre et al. *J Chem Soc* 974 *1963*, DOI: 10.1039/JR9630000974; *Beilstein* **7** IV 2498.] It has heen prepared by the oxidation of acenaphthene with $Na_2Cr_2O_7$/$Ce(OAc)_3$ in AcOH [Allen & VanAllan *Org Synth* 28.4.*2003*, DOI: 10.1002/0471264180.os024.01].

RS*-1-Acenaphthenol** *[6306-07-6]* **$C_{12}H_{10}O$, M 170.2, m 144.5-145.5°, 146°, 148°**. If highly coloured (yellow), dissolve it in boiling *benzene (14g in 200ml), add charcoal (0.5g), filter it through a heated funnel, concentrate to 100ml and cool to give almost colourless needles. **Benzene vapour is* **TOXIC**; *use an efficient fume cupboard*. The ***acetate has **b 166-168°/5mm** (bath temperature 180-185°). [Cason *Org Synth* Coll Vol **3** 3 *1955*, DOI: 10.15227/orgsyn.021.0001.] It can also be recrystallised from EtOH [Fieser & Cason *J Am Chem Soc* **62** 432 *1940*, DOI: 10.1021/ja01859a053]. It forms a brick-red crystalline ***complex*** with 2,4,5,7-tetranitrofluoren-9-one which is recrystallised from AcOH and is dried in a vacuum over KOH and P_2O_5 at room temperature, **m 170-172°** [Newman & Lutz *J Am Chem Soc* **78** 2469 *1956*, DOI: 10.1021/ja01592a034]. [*Beilstein* **6** IV 4623.]

Acenaphthylene *[208-96-8]* **$C_{12}H_8$, M 152.2, m 92-93°, b 280°/~760mm.** Dissolve acenaphthylene in warm redistilled MeOH, filter through a sintered glass funnel and cool to -78° to precipitate the material as yellow plates [Dainton et al. *Trans Faraday Soc* **56** 1784 *1960*, DOI: 10.1039/TF9605601784]. *Alternatively* it can be sublimed *in vacuo*. [*Beilstein* **5** H 625, **5** IV 2138.]

4-Acetamidobenzaldehyde (4'-formylacetanilide) *[122-85-0]* **$C_9H_9NO_2$, M 163.2, m 155°, 156°, 160°.** Recrystallise it from water. The ***4-nitrophenylhydrazone***, **m 264-265°**, crystallises as orange needles from EtOH [Hodgson & Beard *J Chem Soc* 21 *1927,* DOI: 10.1039/JR9270000020; *Beilstein* **14** H 38, **14** II 25, **14** III 75, **14** IV 71.]

***p*-Acetamidobenzenesulfonyl chloride (*N*-acetylsulfanilyl chloride)** *[121-60-8]* **$C_8H_8ClNO_3S$, M 233.7, m 149°(dec).** Crystallise the chloride from dry toluene, $CHCl_3$, or ethylene dichloride. Although difficultly soluble in *C_6H_6, it does however form thick, light tan, crystals from it. It is insoluble in Et_2O. It is useful for making sulfonamides. **IRRITANT**, do not breath it in, and use protective gloves and eye protection. [Smiles & Stewart *Org Synth* Coll Col **I** 8 *1941*, DOI: 10.15227/orgsyn.005.0003; *Beilstein* **14** IV 2703.]

α-Acetamidocinnamic acid *[5469-45-4]* **$C_{11}H_{11}NO_3$, M 205.2, m 185-186° ($2H_2O$), 190-191°(anhydrous), 193-195°, pK_{Est} ~3.2.** It crystallises from H_2O as the *dihydrate,* and on drying at 100° it forms the *anhydrous* compound which is *hygroscopic*. Alkaline hydrolysis yields NH_3 and phenylpyruvic acid. [Erlenmeyer & Früstück *Justus Liebigs Ann Chem* **284** 47 *1895*, DOI: 10.1002/jlac.18952840105; *Beilstein* **14** IV 1769.]

2-Acetamidofluorene (*N*-[2-fluorenyl)acetamide) *[53-96-3]* **$C_{15}H_{13}NO$, M 223.3, m 194°, 196-198°**. Recrystallise it from toluene (1.3mg in 100ml). Its solubility in H_2O is 1.3mg/l at 25°, its UV has λ_{max} at nm(log ε) : 288(4.43), 313(4.13). [Sawicki *J Org Chem* **21** 271 *1956*, DOI: 10.1021/jo01109a002.] It can also be recrystallised from 50% AcOH. [Diels et al. *Chem Ber* **35** 3284 *1902*, DOI: 10.1002/cber.190203503136]. 9-^{14}C and ω-^{14}C 2-acetamidofluorene were recrystallised from aqueous EtOH and had **m** 194-195° and 194° respectively. ***Potent* CARCINOGEN and handle with care.** It is used as a positive control for measuring carcinogenic activity. [Miller et al. *Cancer Res* **9** 504 *1949*, http://cancerres.aacrjournals.org/content/9/8/504; for ^{14}C labeling see Ray & Geiser *Cancer Res* **10** 616 *1950*, http://cancerres.aacrjournals.org/content/10/10/616;

Sandin et al. *J Am Chem Soc* **74** 5073 *1952*, DOI: 10.1021/ja01140a023; *Beilstein* **12** H 3287, **12** IV 3373.]

2-Acetamidophenol *[614-80-2]* **$C_8H_{13}NO$, M 151.2, m. 209°, pK_{Est} ~9.4.** Recrystallise it from water, EtOH or aqueous EtOH. [*Beilstein* **13** H 370, **13** I 113, **13** II 171, **13** III 778.] ***3-Acetamidophenol*** **(Metacetamol)** *[621-42-1]* **$C_8H_{13}NO$, M 151.2,** has **m 148-149°, pK^{25} ~9.59.** Recrystallise the phenol from water. The ***3,5-dinitrobenzamide complex*** gives orange-yellow crystals from hot H_2O and has **m 212°**. [*Beilstein* **13** IV 977.]

4-Acetamidophenol (Paracetamol, Acetaminophen, 4'-hydroxyacetanilide) *[103-90-2]* **$C_8H_{13}NO$, M 151.2,** has **m 169-170.5°, pK_{Est} ~10.0.** Recrystallise *Paracetamol* from water or EtOH. It is a highly used *analgesic* and is a febrifuge. The ***3,5-dinitrobenzamide complex*** gives orange crystals from hot H_2O and has **m 171.5°**. [*Beilstein* **13** II 243, **13** III 1056, **13** IV 1091.]

p*-Acetamidophenylacetic acid (Actarit)** *[18699-02-0]* **$C_{10}H_{11}NO_3$, M 193.2, m 167°, 168-170°, 173-175°, 174-175°, pK^{25} 3.49.** Crystallise the acid from MeOH/Me_2CO, aqueous EtOH or H_2O. The ***amide has **m 231°** (from 50% aqueous EtOH). [Gabriel *Chem Ber* **15** 834 *1882*, DOI: 10.1002/cber.188201501180; Cerecedo & Sherwin *J Biol Chem* **42** 217 *1924*; Tramontano et al. *J Am Chem Soc* **110** 2282 *1988*, DOI: 10.1021/ja00215a045; *Beilstein* **14** II 281.]

Acetanilide *[103-84-4]* **C_8H_9NO, M 135.2, m 114°, pK^{25} 0.5.** Recrystallise acetanilide from water, aqueous EtOH, *benzene or toluene. [*Beilstein* **12** IV 373.]

Acetoacetanilide *[102-01-2]* **$C_{10}H_{11}NO_2$, M 177.2, m 85°, 86°, pK^{25} 10.68.** Crystallise the anilide from H_2O, aqueous EtOH or petroleum ether (b 60-80°). [Williams & Krynitsky *Org Synth* Coll Vol **3** 10 *1955*, DOI: 10.15227/orgsyn.021.0004.]

4-Acetophenetidide (Phenacetin, *p*-methoxyacetanilide) *[62-44-2]* **$C_{10}H_{13}NO_2$, M 179.2, m 136°.** Crystallise it from H_2O or EtOH, and its solubility in H_2O is 0.08% (at ~10°) and 1.2% (at ~100°), and in EtOH it is 6.7% (at ~10°) and 36% (at ~100°). *Alternatively*, it can be purified by solution in cold dilute alkali and re-precipitating by addition of acid to neutralisation point. Dry it in air. It is an analgesic and a febrifuge. [*Beilstein* **13** H 461, **13** IV 1092.]

Acetophenone *[98-86-2]* **C_8H_8O, M 120.2, m 19.6°, 20.5°, b 54°/2.5mm, 202°/760mm, d_4^{25} 1.0238, n_D^{25} 1.5322, pK^{26} -7.6(basic), pK^{25} 19.2(acidic).** Dry it by fractional distillation or by standing with anhydrous $CaSO_4$ or $CaCl_2$ for several days, followed by fractional distillation under reduced pressure (from P_2O_5, optional), and careful, slow and repeated partial crystallisations from the liquid at 0° excluding light and moisture. It can also be crystallised at low temperatures from isopentane. Distillation can be followed by purification using gas-liquid chromatography [Earls & Jones *JCS Faraday Trans 1* **71** 2186 *1975*, DOI: 10.1039/F19757102186.] [*Beilstein* **7** H 271, **7** I 146, **7** II 208, **7** III 936, **7** IV 619.] It has hypnotic properties.
§ A commercial polystyrene supported version is available — scavenger resin (for diol substrates).

Aceto-*o*-toluidide (2-methylacetanilide) *[120-66-1]* **$C_9H_{11}NO$, M 149.2, m 110°, 112°, b 176°/14mm, 296°/760mm.** Crystallise the toluidide from hot H_2O (solubility 1g/210ml), EtOH or aqueous EtOH. Its UV has λ_{max} at 230 and 280nm (EtOH). [*Beilstein* **12** H 792, **12** I 376, **12** II 439, **12** III 1853, **12** IV 1755.] ***Aceto-m-toluidide*** **(3-methylacetanilide)** *[537-92-8]* has **m 65.5°, b 182-183°/14mm, 303°/760mm, 303°/760mm.** Crystallise the toluidide from H_2O, EtOH, aqueous EtOH or Et_2O/petroleum ether (**m** 66°). Its UV has λ_{max} at 245nm (EtOH). [*Beilstein* **12** H 860, **12** I 400, **12** II 468, **12** III 1962, **12** IV 1823.] ***Aceto-p-toluidide*** **(4-methylacetanilide)** *[103-89-9]* has **m 146°, b 307°/760mm.** Crystallise it from aqueous EtOH. [*Beilstein* **12** H 920, **12** I 420, **12** II 501, **12** III 2051, **12** IV 1902.]

***R*-(-)-α-Acetoxyphenylacetic (acetyl mandelic) acid** *[51019-43-3]* **$C_{10}H_{10}O_4$, M 194.2, m 96-98°, 97-99°, $[\alpha]_D^{20}$ -153.7 (c 2.06, Me_2CO), $[\alpha]_{546}^{20}$ -194 (c 2.4, Me_2CO), pK_{Est} ~2.9.** It crystallises from H_2O with 1mol of solvent which is removed on drying, or from other solvents as for the *S*-isomer below. [Angus & Owen *J Chem Soc* 227 *1943*, DOI: 10.1039/JR9430000227; Parker *Chem Rev* **91** 1441 *1991*, DOI: 10.1021/cr00007a009; *Beilstein* **10** III 453.] ***S*-(+)-α-Acetoxyphenylacetic** **(acetyl mandelic) acid** *[7322-88-*

5] has **m 80-81°, 95-97.5°, $[\alpha]_D^{27}$ +158 (c 1.78, Me_2CO), $[\alpha]_{546}^{20}$ +186 (c 2, Me_2CO).** Recrystallise it from *benzene/hexane or toluene. It has characteristic NMR and IR spectra. [Pracejus *Justus Liebigs Ann Chem* **622** 10 *1959*, DOI: 10.1002/jlac.19596220104; Breitholle & Stammer *J Org Chem* **39** 1311 *1974*, DOI: 10.1021/jo00923a033; *Beilstein* **10** IV 567.]

1-Acetylanthracene *[7396-21-6]* **$C_{16}H_{12}O$, M 220.3, m 109.4-109.8°, 110.5-111°** (uncorrected)**, 115.5-116°** (corrected)**, pK_{Est} 19.0.** Recrystallise from EtOAc. Most likely impurities are the 2-isomer, to a lesser extent the 9-isomer and to a yet lesser extent traces of diacetylanthracenes. These can be checked by TLC on silica gel G (Merck) and one dimensional multiple development with *C_6H_6/$CHCl_3$ and visualising under a UV lamp. On a larger scale chromatography through a column of activated Al_2O_3 (e.g. Spence, Type H) and the mono-acylanthracenes are eluted with *C_6H_6. Further elution with *C_6H_6/$CHCl_3$ affords diacetylanthracenes. The fractions are checked by TLC. [Gore & Thadani *J Chem Soc (C)* 1729 *1966*, DOI: 10.1039/J39660001729; 1498 *1967*, DOI: 10.1039/J39670001498.] Also obtained in almost equal proportion with the 9-isomer by acylation with Ac_2O/I_2 in CH_2Cl_2 (7 hours reflux, 43% yield) and purified by TLC. The UV has λ_{max} (EtOH) 2410, 2550, 3640, 3850nm and *3490sh*nm (ε 61,600, 68,900, 5,500, 6,050 and *4,300* resp.) [Gore & Hoskins *J Chem Soc* 5737 *1965*, DOI: 10.1039/JR9650005737], and the IR has ν_{max} (CCl_4) at 1686cm^{-1} (C=O). [Gore & Thadani *J Chem Soc (C)* 1729 *1966*, DOI: 10.1039/J39660001729]. The ***oxime*** has **m 162-163°** (from EtOH) [Bergmann & Katz *J Chem Soc* 3216 *1958*, DOI: 10.1039/JR9580003214], and the ***2,4-dinitrophenylhydrazone*** has **m 260°** (red crystals from pyridine/EtOH). [For crystallography see Langer & Becker *Z Krist* **206** 155 *1993*.] 1-Acetylanthracene dimerises in CH_2Cl_2 upon irradiation with light at 400nm [Becker et al. *J Photochem Photobiol* **97** 25 *1996*, DOI: 10.1016/1010-6030(96)04318-3].

2-Acetylanthracene *[10210-32-9]* **$C_{16}H_{12}O$, M 220.3, m 190-192°, 195.5-196°** (uncorrected)**, 205.5-206°** (corrected)**, pK_{Est} 19.2.** This is the thermodynamically stable isomer in the Friedel-Crafts reaction and is obtained, together with a smaller amount of 1-acetylanthracene (m 107.5-109°) by the $AlCl_3$-catalysed rearrangement of 9-acetylanthracene (see below) in nitrobenzene [Hawkins *J Chem Soc* 3858 *1957*, DOI: 10.1039/JR9570003858]. Similarly the 1- and 9-isomers are rearranged to the 2-isomer completely when heated with polyphosphoric acid (PPA) at 80-120°. [Mala'bi et al. *Letters in Organic Chemistry* **6** 237 *2009*, DOI: 10.2174/157017809787893118.] Purify 2-acetylanthracene by recrystallisation from boiling EtOAc (charcoal) then light petroleum (b 80-100°). It also crystallises from EtOH (**m 183-185°**), *C_6H_6 (yellow plates, **m 189-189.5°**) or light petroleum (**m 190-192°**). Important impurities are the 1-isomer and to a lesser extent the 9-isomer and diacetylanthracenes. For purification from these see 1-acetylanthracene above. the IR has ν_{max} ($CHCl_3$) at 1676cm^{-1} (C=O). [Gore & Thadani *J Chem Soc (C)* 1729 *1966*, DOI: 10.1039/J39660001729]. The ***oxime*** has **m 247-248** (from EtOH) [Bergmann & Katz *J Chem Soc* 3214 p3216 *1958*, DOI: 10.1039/JR9580003214], the ***phenylhydrazone*** has **m 262°** (from EtOH), and the ***2,4-dinitrophenylhydrazone*** has **m 297°** (bright red crystals from pyridine) [Gore & Thadani *J Chem Soc (C)* 1729 *1966*, DOI: 10.1039/J39660001729]. The ***semicarbazone*** has **m 316°** (from EtOH or AcOH). [*Beilstein* **7** H 450, **7** III 2538, **7** IV 1743.]

9-Acetylanthracene *[784-04-3]* **$C_{16}H_{12}O$, M 220.3, m 75-76°, 80°, 76.5-77.3°** (uncorrected)**, 79.6-80.4°** (corrected)**, pK_{Est} 18.9.** The 9-position (*meso*) in anthracene is the most reactive position in the Friedel-Crafts reaction and 9-acylation is kinetically favoured, thus forming 9-acetylanthracene under the mildest conditions [Gore & Thadani *J Chem Soc (C)* 1729 *1966*, DOI: 10.1039/J39660001729]. Dry 9-acetylanthracene *in vacuo*, then recrystallise it from EtOH (**m 80°**), from EtOH then EtOAc (charcoal, **m 74-76°**), or cyclohexane (**m 82°**). Its UV has λ_{max} (EtOH) 2530, 3300, 3480, 3630 and 3800nm (ε 128,000, 2,650, 5,950, 7,900 and 6,800 resp.) [Gore & Hoskins *J Chem Soc* 5737 p 5744 *1965*, DOI: 10.1039/JR9650005737], and the IR has ν_{max} (CCl_4) at 1705cm^{-1} (C=O). [Gore & Thadani *J Chem Soc (C)* 1729 *1966*, DOI: 10.1039/J39660001729]. The ***oxime*** has **m 185-186°** (from EtOH) [Bergmann & Katz *J Chem Soc*, 3214 p 3216 *1958*, DOI: 10.1039/JR9580003214], and the ***2,4-dinitrophenylhydrazone*** has **m 258°** (dark red crystals from pyridine/EtOH), prepared under forcing conditions because of steric hindrance: i.e. by refluxing the ketone (1g) and 2,4-dinitrophenylhydrazine (1g), conc HCl (5ml), H_2O (5ml) and EtOH (40ml), cool, (seed if necessary), collect the crystals, wash thoroughly with hot 10% aqueous HCl, then H_2O, dry *in vacuo* and recrystallise [Pearson & Greer *J Am Chem Soc* **77** 1294 *1955*, DOI: 10.1021/ja01610a068]. The ***semicarbazone*** forms yellow crystals **m 265°** (from EtOH). [Merritt Jr & Braun *Org Synth* Coll Vol **4** 8 *1943*, DOI: 10.15227/orgsyn.030.0001; *Beilstein* **7** III 2539, **7** IV 1743.]

N*-Acetylanthranilic acid (2-acetamidobenzoic acid)** *[89-52-1]* **$C_9H_9NO_3$, M 179.1, m 182-184°, 185-186°, 184-187°, 190°(dec), pK^{20} 3.61.** Wash the acid with distilled H_2O and recrystallise it from aqueous AcOH, dry it and recrystallise again from EtOAc. Also recrystallise it from water or EtOH. Its UV has λ_{max} at 221, 252 and 305nm (EtOH). The ***amide crystallises from aqueous EtOH and has **m 186-187°** and λ_{max} 218, 252 and 301nm. [Chattaway *J Chem Soc* 2495 *1931*, DOI: 10.1039/JR9310002495; Walker *J Am Chem Soc* **77** 6698 *1955*, DOI: 10.1021/ja01629a120; *Beilstein* **14** H 337, **14** I 540, **14** II 219, **14** III 922, **14** IV 1041.]

2-Acetylbenzoic acid *[577-56-0]* **$C_9H_8O_3$, M 164.2, m 115-116°, 115-117°, 116-118°, pK^{20} 4.14, pK^{25} 4.10.** It crystallises from $*C_6H_6$ and H_2O (15g/100ml). The ***oxime*** has **m 156-157°**, and the ***2,4-dinitrophenylhydrazone*** has **m 185-186°**(needles from EtOH). [Yale *J Am Chem Soc* **69** 1547 *1947*, DOI: 10.1021/ja01198a519; Panetta & Miller *Synthesis* 43 *1977*, DOI: 10.1055/s-1977-24269; *Beilstein* **10** H 690, **10** I 330, **10** II 479, **10** III 3025, **10** IV2766.] ***3-Acetylbenzoic acid*** *[586-42-5]* has **m 161-172°**, **169-171°**, **172°**, **pK^{25} 3.827, (5.21 in 50% aqueous EtOH).** It was synthesised from *m*-nitroacetophenone *via m*-amino- to the *m*-cyano- [*6136-68-1*, see below] intermediate which was hydrolysed (reflux with concentrated HCl/6hrs) to the acid, and recrystallised from conductivity H_2O or aqueous Me_2CO, and dried in a vacuum desiccator over silica gel. It is slightly soluble in H_2O, EtOH or Et_2O but very soluble in $CHCl_3$ and $*C_6H_6$. [Bray et al. *J Chem Soc* 265 *1957*, DOI: 10.1039/JR9570000265; *Beilstein* **10** H 694, **10** IV2769.] ***4-Acetylbenzoic acid*** *[586-89-0]* has **m 207.5-209.5°, 208.6-209.4°, 208-210°, pK^{25} 3.70, (5.10 in 50% aqueous EtOH).** Dissolve the acid in 5% aqueous NaOH, extract it with Et_2O, and acidify the aqueous solution. Collect the precipitate, and recrystallise it from boiling H_2O (100 parts) using decolorising charcoal [Pearson et al. *J Org Chem* **24** 504 *1959*, DOI: 10.1021/jo01086a015; Bray et al. *J Chem Soc* 265 *1957*, DOI: 10.1039/JR9570000265; Detweiler & Amstutz *J Am Chem Soc* **72** 2882 *1950*, DOI: 10.1021/ja01163a021; pKa: Bordwell & Cooper *J Am Chem Soc* **74** 1058 *1952*, DOI: 10.1021/ja01124a057]. [*Beilstein* **10** IV 2769.]

3-Acetylbenzonitrile (*m*-cyanoacetophenone) *[6136-68-1]* **C_9H_7NO, M 145.2, m 98-99°. 98-100°.** It was prepared by a Sandmeyer reaction on the corresponding 3-aminoacetophenone below. Recrystallise the nitrile from hot EtOH (**m** 98°) and using decolourising charcoal. UV (hexane) has λ_{max} (log ε) 3420 (2.66) and 3518 (3.70) nm. [Prepn. and UV spectra: Pestemer et al. *Monatsh Chem* **68** 326 *1936*, DOI: 10.1007/BF01518872]. [*Beilstein* **10** H 694, **10** III 3028.] ***4-Acetylbenzonitrile* (*p*-cyanoacetophenone)** *[1443-80-7]* has **m 57-58°, 56-59°.** Recrystallise the nitrile (prepared from the corresponding 4-aminoacetophenone below using a Sandmeyer reaction) from EtOH (charcoal). After two sublimations (bath temperature 130°) colourless needles, **m 56.8°**, are obtained. UV (hexane) has λ_{max} (log ε) 3382 (3.18), 3472 (3.28), 3504 (3.28) and 4078 (4.47) nm. [Prepn. and UV spectra: Pestemer et al. *Monatsh Chem* **68** 326 *1936*, DOI: 10.1007/BF01518872; Wagner et al. *J Am Chem Soc* **108** 7727 *1986*, DOI: 10.1021/ja00284a041]. [*Beilstein* **10** H 695, **10** III 3030.]

Acetyl-5-bromosalicylic acid *[1503-53-3]* **$C_9H_7BrO_4$, M 259.1, m (156°), 168°, 168-169°, pK_{Est} ~3.0.** Crystallise the acid from EtOH. [Robertson *J Chem Soc* **81** 1475 *1902*, DOI: 10.1039/CT9028101475; *Beilstein* **10** H 108, **10** II 64.]

2-Acetylfluorene *[781-73-7]* **$C_{15}H_{12}O$, M 208.3, m 128-129°, 130-131°, 132°.** Crystallise 2-acetylfluorene from EtOH (solubility is 60g/800ml) or Me_2CO (solubility is 60g/400ml). The ***oxime*** [110827-07-1] has **m 192-193.5°** and the ***2,4-dinitrophenylhydrazone*** [109682-26-0] has **m 261-262°**. [Ray & Rieveschl *Org Synth* Coll Vol **3** 23 *1973*, DOI: 10.15227/orgsyn.028.0003.]

5(3)-Acetyl-2(6)-methoxybenzaldehyde *[531-99-7]* **$C_{10}H_{10}O_3$, M 178.2, m 141-143°, 143-144°, 144°.** Extract a solution of the aldehyde in $*C_6H_6$ with 20% aqueous sodium bisulfite, and the bisulfite adduct in the aqueous solution is decomposed by acidifying and heating, whereby the aldehyde separates. It is collected, washed with H_2O, and dried in a vacuum. It is recrystallised from EtOH and then from Et_2O. It sublimes *in vacuo*. The ***2,4-dinitrophenylhydrazone*** (prepared by adding a cold saturated solution of 2,4-diphenylhydrazine in 95% EtOH to 5mg of aldehyde in 1ml of EtOH followed by a drop of concentrated HCl, whereby the orange derivative separates immediately) has **m 258-161°** after two crystallisations from EtOH and dried. The derivative is insoluble in most organic solvents but can be recrystallised from nitrobenzene. [Gray & Bonner *J Am Chem Soc* **70** *1249 1948*, DOI: 10.1021/ja01183a114; *Angyal* et al. *J Chem Soc* 2141 *1950*, DOI: 10.1039/JR9500002141; *Beilstein* **8** III 2339, **8** IV 1984.]

4-Acetyl-*N*-methylaniline (4-methylaminoacetophenone) *[17687-47-7]* **$C_9H_{11}NO$, M 149.2, m 102-106°, 103-107°.** This herbicide crystallises from H_2O. The ***4-acetyl-N,N-dimethylaniline*** derivative forms colourless plates also from H_2O with **m 58-59°**. [Klingel *Chem Ber* **18** 2687 *1885*, DOI: 10.1002/cber.188501802177; Staudinger & Kon *Justus Liebigs Ann Chem* **384** 111 *1911*, DOI: 10.1002/jlac.19113840103; *Beilstein* **14** H 47, **14** I 366.]

1-Acetylnaphthalene (1-acetonaphthenone) *[941-98-0]* **$C_{12}H_{10}NO$, M 170.1, m 10.5°, b 93-95°/0.1mm, 167°/12mm, 302°/760mm, d_4^{20} 1.12, pK^{25} -6.22 (H_o scale, aqueous H_2SO_4).** If the NMR spectrum indicates the presence of impurities, probably 2-acetylnaphthalene, convert the substance to its ***picrate*** by dissolving in *benzene or EtOH and adding excess of saturated picric acid in these solvents until separation of picrates is complete. Recrystallise the picrate till the melting point is **118°**. Decompose the picrate with dilute NaOH and extract with Et_2O. Dry the extract (Na_2SO_4), filter, evaporate and distil the residue. The ***2,4-dinitrophenylhydrazone*** crystallises from EtOH and has **m 259°**. [Stobbe et al. *Justus Liebigs Ann Chem* **380** 93 *1911*, DOI: 10.1002/jlac.19113800114; Williams & Osborne *J Am Chem Soc* **61** 3438 *1939*, DOI: 10.1021/ja01267a061; *Beilstein* **7** IV 1292.] ***2-Acetylnaphthalene* (2-acetonaphthenone, β-acetonaphthone, 2-acetonaphthalene, methyl-2-naphthylketone)** *[93-08-3]* has **m 52-53°, 55°, 55.8°, b 164-166°/8mm, 171-173°/17mm, 301-303°/760mm, pK^{25} -6.16 (H_o scale, aqueous H_2SO_4).** Separate it from the 1-isomer by fractional crystallisation of the ***picrate*** in EtOH (see entry for the 1-isomer above) to **m 82°**. Decomposition of the picrate with dilute NaOH and extraction with Et_2O, then evaporation, gives purer 2-acetylnaphthalene. If this residue solidifies, it can be recrystallised from petroleum ether, EtOH or acetic acid; otherwise it should be distilled in a vacuum and the solid distillate recrystallised [Gorman & Rodgers *J Am Chem Soc* **108** 5074 *1986*, DOI: 10.1021/ja00277a005; Levanon et al. *J Phys Chem* **91** 14 *1987*, DOI: 10.1021/j100285a006]. Purity should be checked by high field NMR spectroscopy. Its ***oxime*** has **m 145°(dec)**, and the ***semicarbazone*** has **m 235°**. [Stobbe et al. *Justus Liebigs Ann Chem* **380** 93 *1911*, DOI: 10.1002/jlac.19113800114; Raffauf *J Am Chem Soc* **72** 753 *1950,* DOI: 10.1021/ja01158a028; Hunsberger *J Am Chem Soc* **72** 5626 *1950*, DOI: 10.1021/ja01168a074; Immediata & Day *J Org Chem* **05** 512 *1940*, DOI: 10.1021/jo01211a005; *Beilstein* **7** IV 1294.]

1-Acetyl-2-phenylhydrazine *[114-83-0]* **$C_8H_{10}N_2O$, M 150.2, m 128.5°, pK^{25} 1.3.** Crystallise the hydrazine from aqueous EtOH. [*Beilstein* **15** H 241.]

Acetylsalicylic acid (Aspirin) *[50-78-2]* **$C_9H_8O_4$, M 180.2, m 133.5-135°, 134-136° (and various), pK^{25} 3.38, (pK^{17} 3.56).** Crystallise aspirin twice from toluene, wash it with cyclohexane and dry it at 60° under vacuum for several hours [Davis & Hetzer *J Res Nat Bur Stand* **60** 569 *1958*, DOI:org/10.6028/jres.060.057]. It has been recrystallised from isopropanol and from diethyl ether/petroleum ether (b 40-60°). It crystallises from EtOH (**m 143-144°**), *C_6H_6 (**m 143°**), hexane (**m 115°** and **128°**), octane (**m 121°**), and has **m 110°** after sublimation. It has pK^{26} 3.69(H_2O), 4.15(20% aqueous EtOH), 4.47(30% aqueous EtOH) and 4.94(40% aqueous EtOH). It is a commonly used analgesic. [*Beilstein* **10** H 67, **10** II 41, **10** III 102, **10** IV 138.] The anhydride, ***O*-acetylsalicylic anhydride** *[1466-82-6]* **$C_{18}H_{14}O_7$, M 342.3,** has **m 80-83°** (*C_6H_6-petroleum ether). [*Beilstein* **10** IV 165.]

***O*-Acetylsalicyloyl chloride** *[5538-51-2]* **$C_9H_7ClO_3$, M 198.6, m 45°, 46-49°, 48-52°, b 107-110°/0.1mm, 115°/5mm, 135°/12mm, n_D^{20} 1.536.** Check first the IR to see if an OH frequency is present. If so, some free acid is present. Then reflux with acetyl chloride for 2-3 hours and fractionate at high vacuum. The distillate should crystallise on cooling. It can be recrystallised from hexane or *C_6H_6 (**m 60°**, sintering at 52°). [Riegel & Wittcoff *J Am Chem Soc* **64** 1486 *1942*, DOI: 10.1021/ja01213a038; *Beilstein* **10** H 86, **10** I 43, **10** II 55, **10** III 151, **10** IV 169.]

***O*-Acetylsalicylsalicylic acid (Salsalate acetate)** *[530-75-6]* **$C_{16}H_{12}O_6$, M 300.3, m 152°, 159°.** Crystallise the acetate from dilute AcOH or EtOH (**m** 161-162°), MeOH (**m** 165-168°), and *C_6H_6/EtOH (**m** 163-165°). Its solubilities in boiling Et_2O, *C_6H_6 and EtOH are 1.4%, 2.2% and 33%, respectively. It has analgesic properties. [Baker et al. *J Chem Soc* 201 *1951* DOI: 10.1039/JR9510000201; Garrett et al. *J Am Pharm Soc* **48** 684 *1959*, *Beilstein* **10** I 41, **10** II 54, **10** IV 165.]

N*-(4)-Acetylsulfanilamide (Sulfacetamide)** *[144-80-9]* **$C_8H_{10}N_2O_3S$, M 214.2, m 182-184°, 216°, pK_1 1.8 (amino, basic), pK_2 5.4 (sulfonamide NH, acidic).** Crystallise the amide from aqueous EtOH (colourless or pale yellow prisms). Its solubility (w/v) at 20° in H_2O is 067%, in EtOH it is 6.7% and in Me_2CO it is 14.3 %. Its UV has λ_{max} at 258nm (ε 17,700) in H_2O; 217nm (ε 18,900) in 0.1M HCl; 270nm (ε 8,900) in 1M HCl and 257nm (ε 17,300) in 0.1M NaOH. The ***sodium salt *[127-56-0* ***anhydrous]*** **M 236.2, $C_8H_9N_2NaO_3S$,** *[6029-17-2* ***monohydrate]*** **M 253.3, $C_8H_{11}N_2NaO_4S$,** crystallises in very small prisms from aqueous EtOH with **m 257°.** It is sparingly soluble in 96% EtOH, and mostly insoluble in other organic solvents, but is 67% (w/v) soluble in H_2O. [*Beilstein* **14** IV 2662.]

Acetyl *p*-toluenesulfonate *[26908-82-7]* **$C_8H_{10}O_5S$, M 230.2, m 54-56°, b 186-188°/20mm.** The most likely impurity is *p*-toluenesulfonic acid (could be up to 10%). This can be removed by dissolving it in dry Et_2O and cooling until the anhydride crystallises out. It decomposes on heating; below ~130° it gives the disulfonic anhydride and above ~130° polymers are formed, but it can be distilled in a vacuum if it is free of acid. It is used for cleaving ethers [Prep, IR, NMR: Mazur & Karger *J Org Chem* **36** 528, DOI: 10.1021/ja01213a038; Mazur & Karger *J Org Chem* **36** 532 *1971*, DOI: 10.1021/jo00803a010]. [*Beilstein* **11** III 255.]

Alizarin (1,2-dihydroxyanthraquinone, Mordant Red 11) *[72-48-0]* **$C_{14}H_8O_4$, M 240.2, m 279-283°, 290°, d_4^{20} 0.884, CI 58000, pK_1^{25} 7.45, pK_2^{25} 11.80.** Alizarin crystallises from glacial acetic acid or 95% EtOH. It sublimes at 110°/2mm as orange needles (m 290°). It is an indicator with λ_{max} at 452nm (pH 5.8) and 520nm (pH 7.2,), and colour changes at 5.5-6.8, yellow to red (acidic) and 10.1 to 12.1, red to violet (alkaline); and stains biological materials. [*Beilstein* **8** IV 3256.]

Alizarin-3-methyliminodiacetic acid (Alizarin Complexone) ($2H_2O$) *[3952-78-1]* **$C_{19}H_{15}NO_8$, M 385.3, m 189°(dec), $pK_{Est(1)}$~4.9, $pK_{Est(2)}$~7.5.** It is purified by suspending it in 0.1M NaOH (1g in 50ml), filtering the solution and extracting alizarin with 5 successive portions of CH_2Cl_2. Then add HCl dropwise to precipitate the reagent, stirring the solution in an ice bath. Filter the precipitate onto a glass filter, wash it with cold water and dry it in a vacuum desiccator over KOH [Ingman *Talanta* **20** 135 *1973*, DOI: 10.1016/0039-9140(73)80243-7; *Beilstein* **14** IV 931].

Alizarin Yellow R [5-(4-nitrophenylazosalicylic acid), Mordant Orange I] *[2243-76-7]* **$C_{13}H_9N_3O_5$, M 287.2, m 253-254°(dec), >300°, CI 14030, pK^{25} 11.17.** The free acid is precipitated by adding HCl to an aqueous solution of the Na salt. After 2 recrystallisations from aqueous AcOH, it has **m 255°(dec)**; [**m 253-254°(dec)** was reported by Hewitt & Fox *J Chem Soc* **79** 49 *1901*, DOI: 10.1039/CT9017900049]. The free acid recrystallises from dilute AcOH as orange brown needles. The Na salt changes colour from yellow to red when the pH is increased from 10.2 to 12.0. [Woodland et al. *J Am Chem Soc* **75** 5835 *1953*, DOI: 10.1021/ja01119a018; *Beilstein* **16** IV 372.]

Allyl phenyl sulfide *[5296-64-0]* **$C_9H_{10}S$, M 150.2, b 59-60°/1.5mm, 79-80°/3mm, 114-114.3°/23.5mm, 225-226°/740mm, 215-218°/750mm, d_4^{20} 1.0275, n_D^{20} 1.5760.** Dissolve the sulfide in Et_2O, wash with alkali, H_2O, dry over $CaCl_2$, evaporate and fractionally distil it, preferably under vacuum. It should **not** give a precipitate with an alcoholic solution of $Pb(OAc)_2$. [Hurd & Greengard *J Am Chem Soc* **52** 3356 *1930*, DOI: 10.1021/ja01371a054; Tarbell & McCall *J Am Chem Soc* **74** 48 *1952*, DOI: 10.1021/ja01121a013; *Beilstein* **6** IV 1479.]

Amberlite IRA-904 Anion exchange resin (Rohm and Haas) *[9050-98-0]***.** Wash with 1M HCl, CH_3OH (1:10) and then rinse it with distilled water until the washings are neutral to litmus paper. Finally extract successively for 24 hours in a Soxhlet apparatus with MeOH, *benzene and cyclohexane [Shue & Yen *Anal Chem* **53** 2081 *1981*, DOI: 10.1021/ac00236a030]. It is a strong basic resin also used for base catalysis [Fieser **1** 511].

p-**Aminoacetanilide** *[122-80-5]* **$C_8H_{10}N_2O$, M 150.2, m 162-163°, 163°, 165-167°, 166-167°, pK^{15} 4.46, pK^{40} 3.94.** Crystallise the anilide from water. It has an unstable crystalline form with **m 141°**. It has IR with ν_{max} (CCl_4) at 1681cm^{-1}. [Atkinson et al. *J Chem Soc* 2023 *1954*, DOI: 10.1039/JR9540002023; *Beilstein* **13** H 94, **13** I 28, **13** II 50, **13** III 166, **13** IV 137.] The *ortho*-isomer, *o*-**aminoacetanilide** *[34801-09-7]* has **m 133-**

137°, pK_{Est} ~4.0, and the *meta*-isomer, *m*-**aminoacetanilide** *[102-28-3]* has **m 86-88°, pK_{Est} ~4.2**. [*Beilstein* **13** H 86.]

o*-Aminoacetophenone (2-acetylaniline)** *[551-93-9]* **C_8H_9NO, M 135.2, m 20°, b 85-90°/0.5mm, 103-105°/1mm, 113°/6mm, 124°/10mm, 130-131°/14mm, 250-255°/atm, d_4^{25} 1.123, $n_D^{25.1}$ 1.6632, pK^{25} 2.22.** It can be purified by conversion into the ***hydrochloride *[25384-14-9]* **C_8H_9NO. HCl, M171.6, m 264-265°** (**285-290°**, also reported) which can be recrystallised from EtOH or H_2O, then the *free base* is liberated with ammonia, collected, dried and distilled. It is steam volatile. *Alternatively*, it can be purified *via* the ***picrate***, **m 127°**, which recrystallises from H_2O, and from which the free base can be recovered. Its UV (Et_2O) has λ_{max} at 2764 (log ε 3.80) and 3965 (log ε 3.87)nm [Prepn. and UV spectra: Pestemer et al. *Monatsh Chem* **68** 326 *1936,* DOI: 10.1007/BF01518872]. The ***N-acetyl derivative*** has **m 74-75°**. The ***semicarbazone*, m 290°**, crystallises from EtOH (plates). The ***oxime*** [4964-49-2] crystallises from H_2O in needles with **m 111-112°**. Parks et al. have identified this ketone in the flavor of stale milk [*Nature* **202** 185 *1964*, DOI:10.1038/202185b0]. Also found in the mandibular secretion of ants. [Synth: Leonard & Boyd *J Org Chem* **11** 405 *1946*, DOI: 10.1021/jo01174a018; *Beilstein* **14** H 42, **14** II 29, **14** III 80, **14** IV 91.]

m*-Aminoacetophenone (3-acetylaniline)** *[99-03-6]* **C_8H_9NO, M 135.2, m 98-99°, 99.5°, b 189-290°/760mm, pK^{25} 3.59.** Recrystallise it from EtOH, aqueous EtOH (**m 99.5°**) or *C_6H_6/petroleum ether/EtOH (**m 98-99°**). Its UV (Et_2O) has λ_{max} at 2965 (log ε 3.40)nm and (hexane) 3704 (log ε 3.36)nm [Prepn. and UV spectra: Pestemer et al. *Monatsh Chem* **68** 326 *1936*, DOI: 10.1007/BF01518872]. The ***hydrochloride has **m 173°** (from EtOH); the ***oxime*** has **m 129-130°** (from H_2O), **132°** (from Et_2O/ petroleum ether); the ***semicarbazone*** has **m 196°(dec)** (from H_2O); the ***thiosemicarbazone*** has **m 152-154°** (**202-204°** also reported) (from aqueous EtOH or MeOH), and the ***benzenesulfonamide*** has **m 163-164°** (yellow crystals from MeOH). The ***N-acetyl derivative*** has **m 127-128°**. [Synth: Leonard & Boyd *J Org Chem* **11** 405 *1946*, DOI: 10.1021/jo01174a018; *Beilstein* **14** III 88, **14** IV 96.]

p*-Aminoacetophenone (4-acetylaniline)** *[99-92-3]* **C_8H_9NO, M 135.2, m 104-106°, 105-107°, b 293°/atm, pK^{25} 2.19.** Recrystallise it from $CHCl_3$, *C_6H_6 or H_2O. It is soluble in hot H_2O. Its UV (Et_2O) has λ_{max} at 3356nm (log ε 4.40) [Prepn. and UV spectra: Pestemer et al. *Monatsh Chem* **68** 326 *1936*, DOI: 10.1007/BF01518872]. Vandenbelt et al. *Anal Chem* **26** 726 *1954*, DOI: 10.1021/ac60088a031.] The ***2,4-dinitrophenylhydrazone has **m 266-267°** (from $CHCl_3$ or EtOH) with λ_{max} at 403nm (logε 4.42) [Johnson *J Am Chem Soc* **75** 2720 *1953*, DOI: 10.1021/ja01107a051] and the ***semicarbazone*** has **m 193-194°**(dec)(from MeOH). The ***hydrochloride*** has **m 98°**(**dec**)(from H_2O). [*Beilstein* **14** IV 100.]

ω-Aminoacetophenone hydrochloride (phenacylamine hydrochloride, 2-aminoacetophenone HCl) *[5468-37-1]* **C_8H_9NO. HCl, M 171.6, m 188°(dec), 194°(dec), pK^{25} 5.34.** Crystallise the salt from Me_2CO /EtOH, EtOH/ Et_2O, 2-propanol or 2-propanol and a little HCl (slowly after a few days). The ***oxime*** of the free base has **m 140°**, and the ***picrate*** of the free base has **m 182°** (from EtOH). [Castro *J Am Chem Soc* **108** 4179 *1986*, DOI: 10.1021/ja00274a055; Baumgarten & Petersen *Org Synth* Coll Vol **5** 909 *1973*, DOI: 10.15227/orgsyn.041.0082; cf. *Beilstein* **14** H 49, **14** III 105.]

1-Aminoanthraquinone-2-carboxylic acid *[82-24-6]* **$C_{15}H_9NO_4$, M 276.2, m 295-296°.** Crystallise the acid from nitrobenzene (red needles). It is used for the detection of Al, Mg Cd, Zn, Mn, Cu, Hg, Fe, Co, Ni and Pb. The ***methyl ester*** gives red needles from AcOH, **m 228°**. The ***phenyl ester*, m 198°**, crystallises as golden-red needles from AcOH. [Locher & Fierz *Helv Chim Acta* **10** 642 *1927*, DOI: 10.1002/hlca.19270100183; *Beilstein* **14** II 419, **14** III 168.]

***p*-Aminoazobenzene (*p*-phenylazoaniline, Aniline yellow)** *[60-09-3]* **$C_{12}H_{11}N_3$, M 197.2, CI 11000, m 126°, 128°, b >360°, pK^{25} ~2.82.** Crystallise this dye from EtOH, CCl_4, petroleum ether/*C_6H_6, or a MeOH/H_2O mixture (brown-yellow needles with a blue lustre). It is soluble in most organic solvents. [*Beilstein* **16** IV 445.]

***o*-Aminoazotoluene (Fast Garnet GBC base, 4'-amino-2,3'dimethylazobenzene, Solvent yellow 3)** *[97-56-3]* **$C_{14}H_{15}N_3$, M 225.3, m 101-103°, 101.4-102.6°, CI 11160, pK^{26} 2.29 (50% aqueous EtOH).** Recrystallise the dye twice from EtOH, once from *benzene, then dry it in an Abderhalden drying apparatus. [Cilento *J Am*

Chem Soc **74** 968 *1952*, DOI: 10.1021/ja01124a029; Sawicki *J Org Chem* **21** 605 *1956*, DOI: 10.1021/jo01112a002; *Beilstein* **16** H 334, **16** I 322, **16** II 178, **16** III 386, **16** IV 525.] **CARCINOGENIC**.

2-Aminobenzaldehyde *[529-23-7]* **C_7H_7NO, M 121.1, m 39-40°, 80-82°/2mm, pK^{20} 1.36.** Distil it in steam and recrystallise it from H_2O or EtOH/ Et_2O. The ***semicarbazone*** has **m 247°**. [Knöpfer *Monatsh Chem* **31** 87 *1910*, DOI: 10.1007/BF01520385; *Beilstein* **14** H 21, **14** II 14, **14** III 47.] ***3-Aminobenzaldehyde*** *[29159-23-7]* has **m 28-30°, pK_{Est} ~2.0.** The aldehyde crystallises as light yellow plates from ethyl acetate. The UV has λ_{max} at 227 and 327.5nm in cyclohexane. The ***acetyl*** derivative has **m 122°** (from EtOH) and the ***oxime*** has **m 195°** (yellow-brown plates from EtOH). [*Beilstein* **14** H 28, **14** I 359, **14** II 21, **14** III 53, **14** IV 46.]

4-Aminobenzamide hydrochloride *[59855-11-7]* **$C_7H_8N_2O$. HCl, M 172.6, m 284-285°, pK_{Est} ~1.7.** Recrystallise the salt from EtOH. The ***free base*** [2835-68-9] **M** 136.2, has **m 182.9°** and crystallises with $0.25H_2O$ (**m 178-179°**). [Rupe & Vogler *Helv Chim Acta* **8** 832 *1925*, DOI: 10.1002/hlca.192500801115; *Beilstein* **14** H 425, **14** III 1061.]

p-**Aminobenzeneazodimethylaniline (*N,N*-dimethyl 4,4'-azodianiline)** *[539-17-3]* **$C_{14}H_{16}N_4$, M 240.3, m 186-187°, 190°(dec), 191-191.3°, 191.5-192°.** Crystallise the azo-dye from aqueous EtOH. It has UV (95% EtOH) has λ_{max} at 410nm (log ε 4.48) + 440nm (log ε 4.46), and (25% aqueous EtOH) at 418s nm (log ε 4.36) + 458nm (log ε 4.48). [Sawicki *J Org Chem* **22** 915 *1957*, DOI: 10.1021/jo01359a016; 1084 *1957*, DOI: 10.1021/jo01360a024; Brode & Piper *J Am Chem Soc* 63 1502 *1941*, DOI: 10.1021/ja01851a005; *Beilstein* **16** H 335, **16** I 319, **16** III 375, **16** IV 516.]

o-**Aminobenzoic acid (2-AA, anthranilic acid)** *[118-92-3]* **$C_7H_7NO_2$, M 137.1, m 144.5-144.8°, 144.9-145.4°, 144.6-145.6°, 145°, pK_1^{25} 2.94, pK_2^{25} 4.72.** Crystallise anthranilic acid from water (charcoal). It has also been recrystallised from 50% aqueous acetic acid. It sublimes in a vacuum. Sugihara and Newman [*J Org Chem* **21** 1445 *1956*, DOI: 10.1021/ja01851a005] found that by adding a small amount (~0.05%) of detergent [Aerosol-OTB (sodium dioctylsulfosuccinate, American Cyanamide Co.), Triton-X-100 (alkyl aryl polyethyleneglycol ether, Rohm & Haas Co.) or Oronite D-60 (sodium akylarylsulfonate, Oronite Chemical Co.)] to the saturated aqueous (or solvent) solution, purer crystals of the acid are obtained. The crystals are filtered off, washed several times with cold H_2O on the funnel until the filtrate does not foam, indicating removal of detergent from the crystals. These are dried to constant weight *in vacuo* over $CaCl_2$ then in a drying pistol (using P_2O_5) for 24hrs at 40 mm. This procedure should produce crystals with sharper melting points. [*Beilstein* **14** IV 1004.] The amide, ***anthranilamide*** *[88-68-6]* **$C_7H_7NO_2$, M 137.1, m 111-113°,** is similar to the acid in being used for non-selective fluorescent labeling of glycans containing a free reducing end. Its fluorescence has λ_{ex} at 330nm and λ_{em} 420nm. [Bigge et al. *Anal Biochem* **230** 229 *1995*, DOI:10.1006/abio.1995.1468; *Beilstein* **14** IV 1010.] ***m-Aminobenzoic acid*** *[99-05-8]* has **m 174°, 178-180°, pK_1^{25} 3.29, pK_1^{25} 5.10.** Crystallise the acid from water. Soluble in hot EtOH and in Et_2O. Darkens in the presence of light. [Neilsen et al. *J Chem Soc* 371 *1962,* DOI: 10.1039/JR9620000361; *Beilstein* **14** IV 1092.] The ***hydrochloride*** *[15151-51-6]* **$C_7H_7NO_2$. HCl, M 173.6, m 260-280°(dec)** is prepared in EtOH/HCl, washed with Et_2O and dried *in vacuo*. [*Beilstein* **14** III 992.] ***p-Aminobenzoic acid*** **(Vitamin H_1, PABA)** *[150-13-0]* has **m 187-188°, pK_1^{25} 2.45, pK_1^{25} 4.85.** Purify *p*-aminobenzoic acid by dissolving it in 4-5% aqueous HCl at 50-60°, decolorising with charcoal and carefully precipitating it with 30% Na_2CO_3 to pH 3.5-4 in the presence of ascorbic acid. It can be recrystallised from water, EtOH or EtOH/water mixtures. Its solubility (w/v) in H_2O is 0.6% (25°) and 1.1% (100°), in EtOH it is 12.5% (~25°), in Et_2O it is 2.0% (~25°), and it is slightly soluble in $*C_6H_6$ but is almost insoluble in petroleum ether. It is an *anti-rickettsial*. [*Beilstein* **14** IV 1126.] The ***dimethylammonium salt*** *[6018-84-4]* **$C_{17}H_{18}N_2O_2$, M 282.3,** is freely soluble in H_2O and the crystals from Me_2CO have **m 170-173°.** ***Potassium* p-*aminobenzoate*** *[138-84-1]* **$C_7H_7KNO_2$, M 175.2, decomp at high temperatures,** is prepared by dissolving 0.1 mole in MeOH, adding the calculated volume of KOMe, partially evaporating the solvent and recrystallising the salt from MeOH. Dry it in an oven at 105° and store it *in vacuo* over $CaCl_2$. (Meyers et al. *J Am Chem Soc* **89** 3565 *1967*, DOI: 10.1021/ja00990a038.] Its solubility in cold H_2O is ~20% w/v, and more so in hot H_2O. It crystallises also from EtOH. It is *antifibrotic* and is a lesser gastric irritant that the acid or the ***sodium salt*** *[206557-08-6]* **$C_7H_7NNaO_2$. xH_2O, M 159.1 (anhydr)**. The

hydrazide *[5351-17-7]* **$C_7H_9N_3O$, M 151.2,** has **m 225-227°.**

o-**Aminobenzonitrile (*o*-cyanoaniline)** *[1885-29-6]* **$C_7H_6N_2$, M 118.1, m 45-48°, b 267-268°/atm, pK^{20} 1.80, pK^{25} 0.77, 0.95.** It has been prepared from *o*-chloronitrobenzene, *via* *o*-cyanonitrobenzene (with Cu bronze + CN^-) followed by reduction with $SnCl_2$/HCl. It is soluble in most organic solvents, and is extracted into Et_2O, dried ($CaCl_2$), evaporated, and the residual solid can be distilled or dried in *vacuo* over H_2SO_4 to give crystals with **m** 49.5°. Recrystallisation from CS_2 gives beautiful monoclinic prisms with **m 50-51°** which can also be crystallised from H_2O. It is a useful synthon for preparing quinazolines and other heterocyclic compounds. The ***N-acetyl derivative*** has **m 107.5-108.5°** (from AcOH) and the ***N-tosyl derivative*** has **m 170-171°** (from *iso*-PrOH). The ***picrate*** provides red crystals from H_2O with **m 109-110°**, or $*C_6H_6$ with **m 108-109°**. [Synth: Bogert & Hand *J Am Chem Soc* **24** 1031 *1902*, DOI: 10.1021/ja02025a001; Cooper & Partridge *J Chem Soc* 3429 *1954*, DOI: 10.1039/JR9540003429; *Beilstein* **14** H 322, **14** I 532, **14** II 210, **14** IV 1013.] ***p*-Aminobenzonitrile (*p*-cyanoaniline)** *[873-74-5]* has **m 86-86.5°, 85-87°, pK^{25} 1.74.** It crystallises from water, 5% aqueous EtOH or EtOH and is dried over P_2O_5, or dried *in vacuo* for 6 hours at 40°. [Moore et al. *J Am Chem Soc* **108** 2257 *1986*, DOI: 10.1021/ja00269a022; Edidin et al. *J Am Chem Soc* **109** 3945 *1987*, DOI: 10.1021/ja00247a019; *Beilstein* **14** IV 1158.]

2-Aminobenzophenone (2-benzoylaniline) *[2835-77-0]* **$C_{13}H_{11}NO$, M 197.2, m 103-107°, 105-106°, 110°, d 1.32, pK^{25} 0.33.** Dissolve the pale yellow ketone in aqueous acetic acid, filter and precipitate it with ammonia. This process is repeated several times, then the amine is recrystallised from aqueous EtOH (pale yellow crystals). It is soluble in iso-PrOH, $CHCl_3$ and Et_2O, slightly soluble in EtOH, insoluble in H_2O but soluble in acidic solution. A $CHCl_3$ solution is used to extract Pd with which it complexes (has λ_{max} at 475nm in $CHCl_3$/benzyl alcohol). The ***hydrochloride*** *[40318-20-5]* crystallises as needles **m 192-193°(dec)**. The ***E*-oxime** *[15185-37-2]* crystallises from $*C_6H_6$ with **m** 127° whereas the ***Z*-oxime** *[4844-60-4]* has **m** 156°. It also gives a ***2,4-dinitrophenylhydrazone*** which crystallises in two forms from EtOH with **m 235-236°** and **m 261-262°**. [Scheifele & DeTar *Org Synth* Coll Vol **4** 34 *1963*, DOI:10.15227/orgsyn.032.0008; *Beilstein* **14** IV 243.] ***3-Aminobenzophenone* (3-benzoylaniline)** *[2835-78-1]* has **m 81-84°, 87°, pK^{25} 0.33.** Purify as for the above 2-, or 4-isomer below, and recrystallise from H_2O (needles). The ***hydrochloride*** provides needles from dilute HCl with **m 187°** and the ***oxime*** has **m 156°**. [*Beilstein* **14** H 81.*]* ***4-Aminobenzophenone* (4-benzoylaniline)** *[1137-41-3]* has **m 123-124°, b 246°/13mm, pK^{10} 2.36, pK^{25} 2.17, pK^{40} 2.02.** This is prepared from 1 aniline/ 2 PhCOCl /$ZnCl_2$/200-210° to give a high yield of the 4-benzoylaminobenzophenone which is hydrolysed by EtOH/H_2O/NaOH to the *free* base as feathery crystals (90-95% yield). These are purified by recrystallisation from CCl_4 or aqueous EtOH. *Alternatively*, dissolve the aniline in aqueous AcOH, filter and precipitate it with ammonia. This process is repeated several times, then the amine is recrystallised from aqueous EtOH (leaflets). The ***oxime*** crystallises in two forms from aqueous EtOH (presumably *E* and *Z*) which have **m 126°** and **m 168°**; and the ***2,4-dinitrophenylhydrazone*** has **m 189-191°** (from EtOH). [Clarke & Esselen Jr *J Am Chem Soc* **33** 1135 *1911*, DOI: 10.1021/ja02220a016; *Beilstein* **14** IV 248.]

2-Aminobiphenyl (*o*-**aminobiphenyl)** *[90-41-5]* **$C_{12}H_{11}N$, M 169.2, m 47-48°, 49°, 49.3°, 49-50°, b 114°/2mm, 135°/5.5mm, 160°/11mm, 170°/15mm, 182°/30mm, 299.0°/atm, pK^{18} 3.85, pK^{20} 3.39, pK^{20} 3.03, 3.34 (50% aqueous EtOH).** It is prepared by reduction of 2-nitrobiphenyl [see 86-00-0] with $SnCl_2$/HCl [Scarborough & Waters *J Chem Soc* 89 *1927*, DOI: 10.1039/JR9270000089], or catalytically in batches of 150g by H_2 at 75 atmospheres pressure in the presence of Raney Ni, which begins at ~80° and is not allowed to rise above 100°, in 90% yield [Cookson & Mann *J Chem Soc* 2888 *1949*, DOI: 10.1039/JR9490002888]. The white solid amine crystallises from aqueous EtOH (charcoal). The ***picrate*** has **m 164-165°** (from EtOH or H_2O), the ***N-acetyl derivative*** has **m 121°** (corrected, from aqueous EtOH, or petroleum ether b 60-80°), the ***N-phenylsulfonate*** derivative has **m 292°** (from MeOH), and the ***N-tosylate*** has **m 194.1-195.6°** (from MeOH). [Dewar et al. *Org Synth* Coll Vol **5** *727 1973*, **46** *65 1966*, DOI:10.15227/orgsyn.046.0065; application: Morgan & Walls *J Chem Soc* 2225 *1932*, DOI: 10.1039/JR9320002225; *Beilstein* **12** H 1317, **12** I 546, **12** II 747, **12** III 3124, **12** IV 3223.] ***p*-Aminobiphenyl** *[92-67-1]* has **m 53°, b 191°/16mm, pK^{18} 4.38.** Crystallise it from water or EtOH. [*Beilstein* **12** IV 3241.] **CARCINOGENIC.**

5-Amino-2-bromobenzoic acid (3-Amino-6-bromobenzoic acid) *[2840-02-0]* **$C_7H_6BrNO_2$, M 216.0, m 171-179°(bath temp 180°), 180°, 200-201°, $pK_{Est(1)}$ ~1.7, $pK_{Est(2)}$ ~4.4.** Crystallise the acid from H_2O or $*C_6H_6$ (**m**

128°). The ***acetyl*** derivative crystallises from H_2O (as *monohydrate*) or absolute EtOH with **m 196-197°** (*anhydrous*). 4-Amino-4'-chlorobiphenyl *[135-68-2]* **$C_{12}H_{10}ClN$, M 203.6, m 132-133°, 134°, pK_{Est} ~4.0.** Crystallise the amine from petroleum ether, EtOH or aqueous EtOH. The ***acetyl*** derivative has **m 245°** from EtOH. [Dewar & James *J Chem Soc* 4265 *1958*, DOI: 10.1039/JR9580004265; Gelmo *Chem Ber* **39** 4175 *1906,* DOI: 10.1002/cber.190603904117; *Beilstein* **12** H 1319, **12** II 757, **12** IV 3269.]

2-Amino-4,6-dichlorophenol *[527-62-8]* **$C_6H_5Cl_2NO$, M 178.0, m 95-96°, $pK_{Est(1)}$ ~3.1, $pK_{Est(2)}$ ~6.8.** Also available commercially as the hydrochloride in the form of a dark brown powder. It can be purified by dissolving 50g of crude hydrochloride in boiling H_2O (500 ml), treating it twice with animal charcoal under reflux, filtering off the charcoal followed by adding $NaHCO_3$ solution to neutrality (litmus paper). The dark solid is collected and dried first with $CaCl_2$, then P_2O_5. The dried base (6g) sublimes under high vacuum (0.06 mm during 4 hours, at bath temperature 70-80°) to give pure snow white aminodichlorophenol (5.75g). Crystallise the phenol from CS_2 or *benzene. The ***hydrochloride***, crystallises on adding concentrated HCl to a solution in H_2O. It has **m 280-285°** after recrystallisation from EtOH. [Meyer *Helv Chim Acta* **41** 1890 *1958*, DOI: 10.1002/hlca.19580410643; *Beilstein* **13** II 185, **13** III 856, **13** IV 889.]

4-Amino-*N,N*-diethylaniline hydrochloride *[16713-15-8]* **$C_{10}H_{16}N_2$. HCl, M 200.7, m 233.5°, pK^{22} 6.61.** Recrystallise the salt from EtOH. The ***free base*** *[93-05-0]* **$C_{10}H_{16}N_2$, M 164.2** distils at **105-108°/3mm, 115-116°/5mm, 139-140°/10mm, 260-262°/~760mm**, d_4^{25} **1.01**, n_D^{20} **1.571**, solidifies on cooling, and the solid has **m 19-21°.** [Bent et al. *J Am Chem Soc* **73** 3100 *1951*, DOI: 10.1021/ja01151a037; *Beilstein* **13** H 75, **13** I 22, **13** II 40, **13** III 113, **13** IV 109.]

4-Amino-3,5-diiodobenzoic acid *[2122-61-4]* **$C_7H_5I_2NO_2$, M 388.9, m ~350°, $pK_{Est(1)}$ 0.4, $pK_{Est(2)}$ ~1.6.** Purify the iodo-acid by dissolving it in dilute NaOH and precipitating with dilute HCl. *Alternatively*, dissolve it in aqueous NH_3 and acidify it with AcOH. Dry it in air. The solubility of the *Na salt* in H_2O is 2.56% at 25°. [Klemme & Hunter *J* Org *Chem* **05** 508 *1940*, DOI: 10.1021/jo01211a004; *Beilstein* **14** H 439, **14** III 1161, **14** IV 1284.]

2-Aminodiphenylamine (***N*-phenyl-*o*-phenylenediamine**) *[534-85-0]* **$C_{12}H_{12}N_2$, M 184.2, m 77-80°, 79-80°, $pK_{Est(1)}$ ~3.8 (NH_2), $pK_{Est(2)}$ <~0.** Crystallise the amine from H_2O or EtOH. The ***hydrochloride*****,** prepared by shaking an ethereal solution of the amine with 10% hydrochloric acid, has **m 115.5-117°(dec).** [Lane & Williams *J Chem Soc* 1468 *1955*, DOI: 10.1039/JR9550001468; *Beilstein* **13** IV 43.]

4-Aminodiphenylamine *[101-54-2]* **$C_{12}H_{12}N_2$, M 184.2, m 68-72°, b 155°/0.026mm, pK^{25} 5.20, $pK_{Est(2)}$ <~0, pK^{20} 5.24 (50% EtOH).** It crystallises from EtOH with **m 66°**, and from ligroin with **m 75°**. It can be distilled at high vacuum. The ***hydrochloride*** crystallises from MeOH (**m 240-241°**). [Allen et al. *J Chem Soc*

234 *1954,* DOI: 10.1039/JR9540000234; *Beilstein* **13** H 76, **13** I 23, **13** II 40, **13** III 113, **13** IV 113.]

2-Amino-1,2-diphenylethanol (1,2-diphenylethanolamine, *four stereoisomers*) *[530-36-9]* **$C_{14}H_{15}NO$, M 213.3, m 165°, $pK_{Est(1)}$ ~7.5.** Recrystallise the ethanol from EtOH. The *1R,2S-(-)- [23190-16-1]* and the *1S,2R(+)-[23364-17-2]* ***enantiomers*** also crystallise from EtOH and have **m 142-145°, $[\alpha]_D^{25}$ (-) and (+) 7 (c 0.6, EtOH)**. The ***enantiomers*** *1R,2R-(+)-***2-amino-1,2-diphenylethanol** *[88082-66-0]* and *1S,2S-(-)-***2-amino-1,2-diphenylethanol** *[23190-66-0]* have **m 116-119°** and **$[\alpha]_D^{25}$ (+) 124 and (-) 124 (c 0.87, EtOH)**. [Masters et al. *J Org Chem* **56** 5666 1991, DOI: 10.1021/jo00019a038; Masters & Hegedus *J Org Chem* **58** 4547 *1993*, DOI: 10.1021/jo00069a012; *Beilstein* **13** IV 2150.]

2-Aminodiphenylmethane (2-benzylaniline) *[28059-64-5]* **$C_{13}H_{13}N$, M 183.2, m 52°, 51-54°, b 172°/12mm and 190°/22mm, $pK_{Est(1)}$ ~4.2.** Crystallise 2-benzylaniline from ether and distil it in a vacuum. **3-aminodiphenylmethane (3-benzylaniline)** *[61424-26-8]* has **m 48-52°,** and **4-aminodiphenylmethane (4-benzylaniline)** *[1135-12-2]* has **m 38-38°** and **pKa 4.78.** [*Beilstein* **12** IV 3279.]

1-Aminofluorene (1-fluorenamine) *[6344-63-0]* **$C_{13}H_{11}N$, M 181.2, m 124.0-124.6°, 125-126°, 125-126°, pK^{25} 3.87, pK^{40} 3.67, and pK^{25} 3.57 (70% EtOH).** Prepared by acid hydrolysis of 1-fluorenylurethane (starting from fluorine-1-carboxylic acid), extracted into Et_2O, and first crystallised from dilute EtOH, then purified by recrystallising from *C_6H_6/petroleum ether. It forms a ***2,4,7-trinitrofluorenone complex***, **$C_{13}H_{11}N.C_{13}H_5N_3O_7$,** which crystallises from *C_6H_6 as beautiful black needles (**m 211-211.8°**, corrected). [Grantham et al. *J Org Chem* **26** 1008 *1961*, DOI: 10.1021/jo01063a006; Bergmann & Orchin *J Am Chem Soc* **71** 1111 *1949*, DOI: 10.1021/ja01171a502; *Beilstein* **12** H 1331, **12** IV 337.] ***2-Aminofluorene* (2-fluorenamine)** *[153-78-6]* has **m 127.8-128.8°, 132-133°, pK^{25} 4.64, pK^{40} 4.42.** Wash the amine well with H_2O, recrystallise it from Et_2O or 50% aqueous EtOH (25g with 400ml), and dry it in a vacuum. Store it in the dark. [Bavin *Org Synth* Coll Vol **5** 30 *1973*, DOI: 10.15227/orgsyn.040.0005, Grantham et al. *J Org Chem* **26** 1008 *1961*, DOI: 10.1021/jo01063a006; *Beilstein* **12** H 1331, **12** IV 337.]

9-Aminofluorene (9-fluorenamine) *[525-03-1]* **$C_{13}H_{11}N$, M 181.2, m 64-65°, pK^{25} 7.56 (70% EtOH).** Purify it by converting it to the hydrochloride with HCl, then basify it with NH_3 and recrystallise it from petroleum ether (**m** 62-63°) or from hexane. It was originally prepared by reduction of 9-fluorenone oxime with Zn and AcOH, isolated as the hydrochloride then basified as stated here. ***Note***: the high basicity of the 9-amino group (compare with above fluorenamines) is probably due to its being attached to a *benzylic-type* carbon atom. The ***hydrochloride*** *[5978-75-6]* **M** 217.7, has **m ~255°**(dec, from EtOH). [Ingold & Wilson *J Chem Soc* 1493 *1933*, DOI: 10.1039/JR9330001493; Mathieu *Bull Soc Chim Fr* 1526 *1971*, Grantham et al. *J Org Chem* **26** 1008 *1961*, DOI: 10.1021/jo01063a006; *Beilstein* **12** H 1331, **12** I 553, **12** II 780, **12** III 3297, **12** IV 3390.]

1-Amino-4-hydroxyanthraquinone *[116-85-8]* **$C_{14}H_9NO_3$, M 239.2, m 207-208°, $pK_{Est(1)}$ ~2.6 (NH_2), $pK_{Est(2)}$ ~9.0 (OH).** Purify it by TLC on SiO_2 gel plates (0.75mm thick) using toluene/acetone (9:1) as eluent. The main band is scraped off and extracted with MeOH. The solvent is evaporated, and the dye is dried in a drying pistol [Land et al. *JCS Faraday Trans 1* **72** 2091 *1976*, DOI: 10.1039/F19767202091]. It has also been recrystallised from aqueous EtOH. [*Beilstein* **14** H 268, **14** I 503, **14** II 168, **14** III 652, **14** IV 891.]

3-Amino-4-hydroxytoluene (2-amino-*p*-cresol) *[95-84-1]* **C_7H_9NO, M 123.2, m 135°, 137-138°, $pK_{Est(1)}$ ~4.7(NH_2), $pK_{Est(2)}$ ~9.6 (OH).** Recrystallise the cresol from H_2O, Et_2O or toluene. It sublimes *in vacuo* as plates or needles. The ***hydrochloride*** has **m 222-224°** (dec, from aqueous EtOH). [*Beilstein* **13** H 601, **13** I 227, **13** II 338, **13** III 1576, **13** IV 1712.] ***4-Amino-3(5)-hydroxytoluene* (2-amino-*m*-cresol)** *[2835-98-5]* has **m 159°, 159-162°, $pK_{Est(1)}$ ~5.4 (NH_2), $pK_{Est(2)}$ ~10.2 (OH).** Crystallise it from H_2O, 50% EtOH, or toluene. [*Beilstein* **13** H 590, **13** III 1552.] ***2-Amino-5-hydroxytoluene* (4-amino-*m*-cresol)** *[2835-99-6]* **C_7H_9NO, M 123.2, m 162°(dec), 177-179°(dec), $pK_{Est(1)}$ ~5.4 (NH_2), $pK_{Est(2)}$ ~10.4 (OH).** Crystallise it from 50% EtOH. [*Beilstein* **13** H 593, **13** IV 1698.]

5-Aminoindane *[24425-40-9]* **$C_9H_{11}N$, M 133.2, m 37-38°, b 131°/15mm, 146-147°/25mm, 247-249°/745mm, pK^{16} 5.31.** Distil the indane, and then recrystallise it from petroleum ether. [*Beilstein* **12** I 511, **12** III 2798.]

1*RS*,2*SR*-(±)-*cis*-1-Amino-2-hydroxyindane (*cis*-1-amino-2-indanol) *[7480-35-5]* **$C_9H_{11}NO$, M 149.2, m 132-133°, 134-135°, pK_{Est} ~8.5.** It is obtained by hydrolysis of (±)-*cis*-indano[1,2-*d*]-2-oxazolidone [in turn formed by solvolysis of ethyl *N*-(*trans*-2-iodo-1-indan)carbamate, m 159.5-160° in 87% yield by refluxing in dry diglyme for 14 hours]. The *cis*-2-oxazolidone (360mg) is dissolved in 0.85N methanolic KOH (20ml), diluted with H_2O (5ml) and refluxed under N_2 for 18 hours, evaporated to dryness *in vacuo*, the residue is extracted with Et_2O, filtered, dried (Mg_2SO_4), concentrated to a small volume and cooled to -12°, and the ***amino-2-indanol*** is collected as white plates (2 crops, m 134-135° and 133-134°) in 79% yield. [Hassner et al. *J Org Chem* **32** 540 *1967*, DOI: 10.1021/jo01278a006.] Similarly, hydrolysis of *2-phenyl-3a,8a-dihydro-8H-indeno[1,2-d]oxazole* with diluted H_2SO_4 (16 hours reflux), cool, basify with 10N NaOH, extract with $CHCl_3$, dry (Mg_2SO_4), and evaporation gives an 88% yield of the ***(±)-amino-alcohol*** (**m 132-133°**). It can also be prepared from (±)-hydrindan-1,2-epoxide as described in the following entry. Its ^{1}HNMR (400MHz, $CDCl_3$, TMS) has δ at 2.0-2.5 (br s, 3H), 2.95 (dd, *J* = 3 and 15Hz, 1H), 3.1 (dd, *J* = 7 and 15Hz, 1H), 4.28 (d, *J* = 7Hz, 1H), 4.4 (m, 1H), 7.2-7.35 (m, 4H). [Thompson et al. *J Med Chem* **35** 1685 *1992*, DOI: 10.1021/jm00088a003.] Large scale preparations of the (±)-*cis*-1-amino-2-indanol from indene *via* the (±)*trans*- acylamido-indanol by hydrolysis with strong acids (HCl, H_2SO_4 or $MeSO_3H$) which invert the OH stereochemistry have been patented [Gao et al. USP appl 5,599,985 *1997*; *Chem Abstr* **123** 55421b *1995*, Gao et al. USP 5,616,808 *1997*, *Chem Abstr* **126** 250997h *1997*]. [*Beilstein* **13** II 398a, 399d, **13** III 1841, **13** IV 2033.]

1*S*,2*R*-(-)-*cis*-1-Amino-2-hydroxyindane [(-)-*cis*-1-amino-2-indanol)] *[126456-43-7]* **$C_9H_{11}NO$, M 149.2, m 117-117.5°, 118-121°, $[\alpha]_D^{20}$ -61° (c 0.5, $CHCl_3$), $[\alpha]_D^{25}$ -62 (c 1.0, MeOH).** This enantiomer has been prepared in several ways in high state of optical purity. Oxidation of indene *[95-13-6]* using Jacobsen's salen catalyst *R*,*R*-MnCl/NaOCl/CH_2Cl_2 gave *1R,2S-indane-1,2-epoxide* in 84%ee, which on treatment with NH_3/MeOH then PhCOCl/NaOH followed by 80% H_2SO_4 provided *2-phenyl-3aS,8aR-dihydro-8H-indeno[1,2-d]oxazole* [see (±) above] by a C-1 chirality transfer process which gave the desired 1*S*,2*R*-(-)-aminoindanol on hydrolysis. *Alternatively*, oxidation of indene using Jacobsen's salen catalyst *S*,*S*-MnCl/PhCl/NaOCl and P_3NO {*4-(3-phenylpropyl)pyridine-N-oxide* see *[34122-28-6]*} gave the enantiomeric 1*S*,2*R*-indane-1,2-epoxide which was reacted with Oleum/MeCN then hydrolysed with H_2O (by C-2 chirality transfer *via* a Ritter reaction) to give the same desired 1*S*,2*R*-(-)-aminoindanol 78-80% yield with high optical purity. [Senanayake *Aldrichimica Acta* **31** 3 *1998*, Senanayake et al. *Tetrahedron Lett* **36** 3993 *1995*, DOI: 10.1016/0040-4039(95)00696-A; Senanayake et al. *Tetrahedron Lett* **37** 3271 *1996* DOI: 10.1016/0040-4039(96)00565-5.] In a different approach *N*-(L—phenylalanyl)-(±)-amino-2-indanol was prepared [84% yield, from (±)-aminoindanol and BOC-L-phenylalanine *via* the 1-hydroxybenzotriazole/dimethyl 3-{3-(dimethylamino)-propyl}carbodiimide procedure], and the diastereoisomeric mixture was separated by low pressure chromatography on silica gel, eluting with 8% MeOH in $CHCl_3$ to give the faster moving L-Phe—1*S*,2*R*-1-aminoindan-2-ol diastereoisomer (40% yield). A mixture of this diastereomer (30g, 0.1mol), EtOH (1L) and 20% aqueous NaOH (265ml) was refluxed for 16 hours, concentrated to remove EtOH, diluted with H_2O (100ml) and brine (100ml), extracted with $CHCl_3$ (3 x 600ml), the combined extracts were dried (Mg_2SO_4), filtered and evaporated to give **1*S*,2*R*-1-aminoindan-2-ol** (14g, 93%) as a white solid **m 114-115°**. Recrystallisation from Et_2O/hexanes gave analytically pure white rods **m 117-117.5°**, with little loss of material, and with $[\alpha]_D^{25}$ -62 (c 1.0, MeOH), with ^{1}HNMR (400MHz, $CDCl_3$, TMS) which had δ at 2.0-2.5 (br s, 3H), 2.95 (dd, *J* = 3 and 15Hz, 1H), 3.1 (dd, *J* = 7 and 15Hz, 1H), 4.28 (d, *J* = 7Hz, 1H), 4.4 (m, 1H), 7.2-7.35 (m, 4H), same as the racemate. [Thompson et al. *J Med Chem* **35** 1685 *1992,* DOI: 10.1021/jm00088a003.] Both enantiomers of this *cis*-aminoalcohol have also been obtained *via* enzymatic transformations [Didier et al. *Tetrahedron* **47** 4941 *1991*, DOI: 10.1016/S0040-4020(01)80959-5]. The oxazolines, oxazolidin-2-ones and the 2-*N*-tosylamides derived from the two enantiomers have been explored extensively as *chiral auxiliaries* [Senanayake *Aldrichimica Acta* **31** 3 *1998*]. For the preparation of CBS-oxazaboroline catalysis (**C**orey-**B**akshi-**S**hibata) see Chapter 6, Catalysis-Part 1. **NOTE:** Both enantiomers are commercially available from Sepracore in gram to hundred kilogram quantities [Hong et al. *Tetrahedron Lett* **35** 6631 *1994*, DOI: 10.1016/S0040-4039(00)73453-8, see also Stinson *Chemical and Engineering News* May 16 p.6 *1994*.] [*Beilstein* **13** II 398a, 399d, **13** III 1841, **13** IV 2033.]

1*R*,2*S*-(+)-*cis*-1-Amino-2-hydroxyindane [(+)-*cis*-1-amino-2-indanol)] *[136030-00-7]* **$C_9H_{11}NO$, M 149.2, m 118-121°, $[\alpha]_D^{20}$ +63 (c 0.2, $CHCl_3$).** This compound was prepared using the same syntheses as for its enantiomer (preceding entry) and purified in the same way. It can be also obtained from the slower moving chromatographic band of the L-phenylalaninyl diastereoisomer (see preceding entry).

2-Amino-5-iodotoluene *[13194-68-8]* **C_7H_8IN, M 233.0, m 87°, pK_{Est} ~3.6.** Crystallise it from 50% EtOH. [*Beilstein* **12** IV 1807.]

1-Amino-4-methylaminoanthraquinone *[1220-94-6]* **$C_{15}H_{12}N_2O_2$, M 252.3, $pK_{Est(1)}$ ~1, $pK_{Est(2)}$ <~4.** Purify the quinone by TLC on silica gel plates using toluene/acetone (3:1) as eluent. The main band is scraped off and extracted with MeOH. The solvent is evaporated, and the residue is dried in a drying pistol [Land et al. *JCS Faraday Trans 1* **72** 2091 *1976*, DOI: 10.1039/F19767202091]. [*Beilstein* **14** H 198, **14** I 462, **14** III 440, **14** IV 458.]

4-Aminomethylbenzenesulfonamide hydrochloride (Mafenide HCl) *[138-37-4]* **$C_7H_{10}N_2O_2S$. HCl, M 222.3, m 256°, 265-267° (also reported), pK_1^{20} 8.18 (NH_2), pK_2^{20} 10.23 ($SONH_2$).** Crystallise the salt from dilute HCl or 95% EtOH and dry it in a vacuum at 100°. [Miller et al. *J Am Chem Soc* **62** 2099 *1940*, DOI: 10.1021/ja01865a053; Bergeim & Barker *J Am Chem Soc* **66** 1459 *1944*, DOI: 10.1021/ja01237a012.] The ***free base*** *[138-39-6]* **$C_7H_{10}N_2O_2S$, M 186.2**, has **m 151-152°** (from EtOH), the ***acetate salt*** **(Mafatate)** *[13009-99-9]* **$C_7H_{10}N_2O_2S.C_2H_4O_2$, M 246.2**, also has **m 151-152°** (from AcOH), and the ***propionate salt*** **(Sulfomyl)** *[12001-72-8]* **$C_7H_{10}N_2O_2S.C_3H_6O_2$, M 260.3**, has **m 158°**. The ***sulfate salt*** has **m 254-255°** (from aqueous EtOH). [*Beilstein* **14** III 2223, **14** IV 2799.] All these compounds are effective antibacterials.

3-Amino-2-naphthoic acid *[5959-52-4]* **$C_{11}H_9NO_2$, M 187.2, m 212-215°(dec), 214°(dec), $pK_{Est(1)}$ ~1.5 $pK_{Est(2)}$ ~4.0.** Crystallise the naphthoic acid from aqueous EtOH. Ehanolic and ethereal solutions are yellow in colour with green fluorescence. The amino acid is used for the determination of Cu, Ni and Co. The ***sodium salt*** is difficultly soluble in H_2O, but forms leaflets from it, and is also sparingly soluble in EtOH. The ***ethyl ester*** **$C_{13}H_{13}NO_2$** crystallises from EtOH in yellow needles from aqueous EtOH and has **m 115-115.5°**. [Allen & Bell *Org Synth* Coll Vol **3** 78 *1955*, DOI: 10.15227/orgsyn.022.0019; *Beilstein* **14** III 1341.]

4-Amino-5-naphthol-2,7-disulfonic acid *[90-20-0]* **$C_{10}H_9NO_7S_2$, M 319.3, pK_1^{20} 3.54, pK_2^{20} 8.55; pK_1^{25} 3.63, pK_2^{25} 8.83.** A slightly alkaline solution of Na_2CO_3 (*ca* 22g) in water (litmus) is added to a solution of 100g of the dry acid in 750ml of hot distilled water, followed by 5g of activated charcoal and 5g of Celite. The suspension is stirred for 10 minutes and filtered by suction. The acid is then precipitated by adding *ca* 40ml of conc HCl (solution is blue to Congo Red), then filter it by suction through a shark skin filter circular sheet (or hardened filter paper) and wash it with 100ml of distilled water. The purification process is repeated. The acid is dried overnight in an oven at 60° and stored in a dark bottle. The ***diethylamine salt*** has **m 306-307°**(dec, from aqueous EtOH). [Post & Moore *Anal Chem* **31** 1872 *1959*, DOI: 10.1021/ac60155a060]. [*Beilstein* **14** H 840, **14** I 758, **14** II 502, **14** III 2292, **14** IV 2824.]

1-Amino-2-naphthol hydrochloride *[1198-27-2]* **$C_{10}H_9NO$. HCl, M 195.7, m 250°(dec), $pK_{Est(1)}$ ~3.7 (NH_2), $pK_{Est(2)}$ ~9.9 (OH).** Crystallise the salt from the minimum volume of hot water containing a few drops of stannous chloride in an equal weight of hydrochloric acid (to reduce atmospheric oxidation). Filter the solution and add half its volume of concentrated HCl and set aside. The salt crystallises almost quantitatively. Dry it in a vacuum in the dark (**m** 260°). The salt is more stable than the ***free base*** which has **m 150°** (darkening at 130°) and its ***O-methyl ether*** has **m 49°** and **b 159-159°/9mm**. [Desai et al. *J Chem Soc* 324 *1938,* DOI: 10.1039/JR9380000321; *Beilstein* **13** H 666, **13** I 268, **13** II 408, **13** III 1875, **13** IV 2080.]

1-Amino-2-naphthol-4-sulfonic acid *[116-63-2]* **$C_{10}H_9NO_4S$, M 239.3, m 290°(dec), 295°(dec), $pK_{Est(1)}$ <0 , $pK_{Est(2)}$ ~2.8 (NH_2), $pK_{Est(3)}$ ~8.8.** Purify it by warming 15g of the acid, 150g of $NaHSO_3$ and 5g of Na_2SO_3 (anhydrous) with 1L of water to *ca* 90°, shaking until most of the solid had dissolved, then filtering hot. The precipitate obtained by adding 10ml of concentrated HCl to the cooled filtrate is collected, washed with 95% EtOH until the washings are colourless, and is dried under vacuum over $CaCl_2$. It is stored in a dark-coloured bottle, in the cold [Chanley et al. *J Am Chem Soc* **74** 4347 *1952*, DOI: 10.1021/ja01137a030]. The ***Na salt***, $C_{10}H_8NNaO_4S$, forms needles from hot H_2O; a solution which has blue fluorescence. [Fieser **2** 42; Hiers & Hager, DOI: 10.15227/orgsyn.011.0012; *Beilstein* **14** IV 2825.]

2-Amino-4-nitrobenzoic acid (4-nitroanthranilic acid) *[619-17-0]* **$C_7H_6N_2O_4$, M 182.1, m 257°(dec), 269°(dec), pK_1^{25} 0.65, pK_2^{25} 3.70.** Recrystallise it from water, EtOH (**m 271°**) or aqueous EtOH (**m 269°**).

The ***acetyl*** derivative has **m 217°** (from EtOH), **m 222°** (from aqueous EtOH). [Chapman & Stephen *J Chem Soc* 1791 *1925*, DOI: 10.1039/CT9252701791; *Beilstein* **14** II 234, **14** III 975, **14** IV 1087.]

5-Amino-2-nitrobenzoic acid *[13280-60-9]* **$C_7H_6N_2O_4$, M 182.1, m 235°(dec), 236-238°, $pK_{Est(1)}$ ~1.1, $pK_{Est(2)}$ ~1.2.** Crystallise the acid from water. [*Beilstein* **14** III 1021.]

1-Amino-4-nitronaphthalene *[776-34-1]* **$C_{10}H_8N_2O_2$, M 188.2, m 190-193°, 195°, 196-197°, pK^{20} 0.54.** It crystallises from EtOH, ethyl acetate or aqueous NH_3 as light yellow crystals. The ***acetyl*** derivative also forms yellow crystals, **m 192.5-193.5°**, from Me_2CO. [*Beilstein* **12** I 530, **12** II 704, **12** III 2971, **12** IV 3114.]

2-Amino-4-nitrophenol (**2-hydroxy-5-nitroaniline**) *[99-57-0]* **$C_6H_6N_2O_3$, M 154.1, m 80-90° (hydrate), 142-143° (anhydrous), 146°, $pK_{Est(1)}$ ~3.9 (NH_2), $pK_{Est(2)}$ ~9.2.** Crystallise the phenol from water and dry it in a vacuum. It is slightly soluble in MeOH or AcOH, but is more soluble in hot *C_6H_6, EtOH and dilute AcOH. With Ac_2O at room temperature it forms the ***N-monoacetyl derivative*** with **m 279-280°** (crystallising in clusters of needles from a large volume of boiling EtOH). On long boiling with excess of Ac_2O it forms, with difficulty, the ***O,N-diacetyl derivative*** with **m 187-188°** (crystallising in needles or prisms from boiling EtOH in which it is relatively soluble) [Hewitt & King *J Chem Soc* **129** 817 *1926*, DOI: 10.1039/JR9262900817]. [Hartman & Silloway *Org Synth* Coll Vol **3** 82 *1955*, DOI: 10.15227/orgsyn.025.0005; *Beilstein* **13** IV 896.] ***2-Amino-5-nitrophenol*** (**2-hydroxy-4-nitroaniline**) *[121-88-0]* has **m 198-202°(dec), 207-208°, $pK_{Est(1)}$ ~3.8, $pK_{Est(2)}$ ~9.3.** It is best obtained by treating 6-nitrobenzoxazolone with NH_3 in an autoclave, but can be achieved more simply by treatment with hydrazine [Bower & Stephens *J Chem Soc* 325 *1951*, DOI: 10.1039/JR9510000325]. Recrystallisation of the phenol from water gives orange or dark brown needles m 207-208°. Its UV has λ_{max} at 390nm (ε 13,000) (EtOH) [Pedersen *J Org Chem* **23** 255 *1958*, DOI: 10.1021/jo01096a028]. With cold Ac_2O it forms the ***N-monoacetyl derivative*** with **m 171-172°** (crystallising from large volume of EtOH). On boiling with Ac_2O it forms the ***O,N-diacetyl derivative*** with **m 193-194°** (crystallising as felt fine needles from boiling EtOH), and the acetylation mother liquors provide a ***triacetyl derivative*** with **m 138-139°** (crystallising as fern-like needles from boiling absolute EtOH) [Hewitt & King *J Chem Soc* **129** 817 *1926*, DOI: 10.1039/JR9262900817]. [*Beilstein* **13** H 390, **13** I 121, **13** II 194, **13** III 887.**13** IV 903.]

RS*-(±)-3-Amino-3-(4-nitrophenyl)propionic acid** *[35005-61-9]* **$C_9H_{10}N_2O_4$, M 210.2, m 215°(dec), 220-226° (dec), 226°(dec), browning at 215°), $pK_{Est(1)}$ ~3.0, $pK_{Est(2)}$ ~9.5.** The acid crystallises from 50% aqueous EtOH. The ***hydrochloride has **m 218-220°(dec**). The ***N-benzoyl derivative*** has **m 204-205°** (from MeOH) and the ***N-benzoyl-hydrazide*** has **m 226-227°** (from MeOH or EtOH). [Posner *Justus Liebigs Ann Chem* **389** 44 *1912*, DOI: 10.1002/jlac.19123890102; *Beilstein* **14** I 603, **14** IV 1548.]

2-Aminophenol *[95-55-6]* **C_6H_7NO, M 109.1, m 170-175°, 175-176°, pK_1^{25} 4.65, pK_2^{25} 9.75.** Purify it by dissolving it in hot water, decolorising with activated charcoal, filtering and cooling to induce crystallisation. Maintain an atmosphere of N_2 over the hot phenol solution to prevent its darkening by oxidation [Charles & Freiser *J Am Chem Soc* **74** 1385 *1952*, DOI: 10.1021/ja01126a007]. It can also be crystallised from EtOH using the same precautions. Its solubility (w/v) in H_2O is 2.0%, in EtOH it is 4.3%, and is very soluble in Et_2O but much less so in *C_6H_6. It sublimes *in vacuo*. Store in the dark, preferably under N_2. [*Beilstein* **13** IV 805.] Crystals of the *hydrochloride* become grey in colour on standing in air. ***3-Aminophenol*** *[591-27-5]* has **m 122-123°, b 164°/11mm, pK_1^{25} 4.25, pK_2^{25} 9.90.** Crystallise it from hot water or toluene. Its solubility (w/v) in H_2O is 2.5% at ~10°, it is very soluble in hot H_2O, alcohols and Et_2O, but much less so in *C_6H_6. Store it in the dark, preferably under N_2. [*Beilstein* **13** IV 952.] ***4-Aminophenol*** *[123-30-8]* has **m 186°, 189.6-190.2°, 190° (under N_2), b 130.2°/0.3mm, 150°/3mm, 167°/8mm, 284°/atm (dec), pK_1^{25} 5.38, pK_2^{25} 10.4.** It is light and oxygen sensitive and turns pink on standing. Crystallise it from EtOH, then water, excluding oxygen. It sublimes at 110°/0.3mm. It has been purified by chromatography on alumina with a 1:4 (v/v) mixture of absolute EtOH/*benzene as eluent. Its solubility (w/v) in H_2O is 0.4% (15°), 0.65% (25°), 1.5% (50°), 4.7% (80°) and 9% (~100°). It is almost insoluble in $CHCl_3$ and *C_6H_6, is soluble in absolute EtOH (4.5% at 0°) and ethyl methyl ketone (9.3% at 58.5°). [*Beilstein* **13** IV 1014.] ***4-Aminophenol hydrochloride*** *[51-78-5]* **C_6H_7NO. HCl, M 145.6, m 306°(dec).** Purify the salt by treating an aqueous solution with saturated $Na_2S_2O_3$, filtering under N_2, then recrystallising it from 50% EtOH twice and once from absolute EtOH [Livingston & Ke

J Am Chem Soc **72** 909 *1950*, DOI: 10.1021/ja01158a068]. [*Beilstein* **13** III 993.]

4-Aminophenylacetic acid *[1197-55-3]* **$C_8H_9NO_2$, M 151.2, m 196-197°**(corrected)**, 199-200°(dec), 201°(dec), pK_1^{20} 3.60, pK_2^{20} 5.26.** It has been prepared by the Willgerott reaction from 4-aminoacetophenone, sulfur and morpholine; and acidifying with AcOH. [Schwenk & Papa *J Org Chem* 11 798 1946, DOI: 10.1021/jo01176a023; King & McMillan *J Am Chem Soc* **68** 2335 *1946*, DOI: 10.1021/ja01215a058]. Also recrystallise the acid from hot water (60-70ml/g, leaflets). The ***hydrochloride***, is quite soluble in H_2O, soluble in EtOH, but has been recrystallised from H_2O and then from EtOH, and melts in the range **215** to **240°** depending on the heating rate. The ***ethyl ester*** forms platelets from H_2O **(m 49.5°, 51°)** or EtOH, and the ***N-benzoyl derivative***, **m 205-206°**, forms needles from EtOH. [Albert & Goldacre *Nature* **149** 245 *1942*, DOI: 10.1038/149245a0; *Beilstein* **14** H 456, **14** I 589, **14** II 280, **14** III 1182.]

1RS,2RS-2*-Amino-1-phenylbutan-1-ol [α-(α-aminopropyl)benzyl alcohol]** *[(±)-threo 5897-76-7]* **$C_{10}H_{15}NO$, M 165.1, m 79-80°, pK_{Est} ~9.7.** Crystallise the ***free base of the *threo* isomer from *benzene/petroleum ether which has **m 79-80°**. The ***threo-hydrochloride***, **m 204-205°**, crystallises from EtOH [Abrams & Kipping *J Chem Soc* 1480 *1936*, DOI: 10.1039/JR9360001480; Rebstock et al. *J Am Chem Soc* **73** 3666 *1951*, DOI: 10.1021/ja01152a030]. The ***1RS,2RS-erythro*** isomer has **m 80.5-81°** and its ***hydrochloride*** has **m 242°** [Hartung et al. *J Am Chem Soc* **52** 3317 *1930*, DOI: 10.1021/ja01371a046.] [*Beilstein* **13** II 390, **13** III 1791, **13** IV 1952.]

N*-Aminophthalimide** *[1875-48-5]* **$C_8H_6N_2O_2$, M 162.2, m 200-202°, 200-205°, pK_{Est} ~0.** The amino-imide is prepared by adding phthalimide (12g) to hydrazine hydrate (4.4g) in 95% EtOH (80ml), shaking for 2 minutes at ~20°, the spongy mass is rapidly heated under reflux for 3 minutes (NH_3 evolved), H_2O (50ml), is added and the clear solution is poured into H_2O (200ml) whereby the amino-imide crystallised during 1 hour. It is recrystallised from 96% EtOH (solubility is ~2% at boiling temperature) to form a yellow solution from which the amino-imide crystallises on cooling. It sublimes *in vacuo* at *ca* 150°. It solidifies after melting, and remelts at 338-341° (see **m** of phthalhydrazide in 'Heterocyclic Compounds' in this Chapter). On boiling for a few minutes with a little Ac_2O it is converted to the ***N-acetyl derivative, **m 228-230°** after recrystallisation from H_2O. ***N-Benzylideneaminophthalimide***, is obtained by boiling a 96% EtOH solution (25ml) containing benzaldehyde (1g) *N*-aminophthalimide (1g) under reflux for 1 hour, allowing to crystallise overnight and recrystallising the colourless needles, **m 166-167°**, from EtOH. ***N-p-Anisylideneamino-phthalimide***, is similarly obtained, and forms stout sulfur-yellow crystals **m 198-191°** from EtOH. [Drew & Hatt *J Chem Soc* 16 *1937*, DOI: 10.1039/JR9370000016; *Beilstein* **22/11** V 122.]

4-Aminopropiophenone (PAPP) *[70-69-9]* **$C_9H_{11}NO$, M 149.2, m 140°, b 180°/10mm, pK_{Est} ~2.2.** Crystallise it from water (yellow needles) or aqueous EtOH. The ***hydrochloride*** *[6170-25-8]* **$C_9H_{11}NO$. HCl, M 185.7,** has **m 188-189°** (yellow needles from aqueous EtOH/HCl drops), and the ***semicarbazone*** has **m 139-140°** (from EtOH/H_2O). [Derick & Bornmann *J Am Chem. Soc* **35** 1269 *1913*, DOI: 10.1021/ja02198a014; *Beilstein* **14** H 59, **14** I 375, **14** III 146, **14** IV 139.] It is an antidote for cyanide poisoning.

4-(2-Aminopropyl)phenol (Hydroxyamphetamine) *[103-86-6]* **$C_9H_{13}NO$, M 151.2, m 125-126°, $pK_{Est(1)}$ ~9.4 (OH), $pK_{Est(2)}$ ~9.7(NH_2), pK^{25} 9.31.** Crystallise the phenol from *benzene. The ***R-(-)-enantiomer*** crystallises from EtOH or *C_6H_6 with **m 110.5-111.5°** and **$[\alpha]_D^{17}$ -52.0 (c 1, EtOH).** The ***(±)-hydrochloride*** has **m 171-172°** (EtOH/Et_2O), and the ***2,4-dinitrophenylhydrazone*** has **m 190-192°** (EtOH). [*Beilstein* **13** I 251, **13** III 1709, **13** IV 1871.]

1-Aminopyrene *[1606-67-3]* **$C_{16}H_{11}N$, M 217.3, m 115-117°, 117-118°, pK_1^{25} 2.91 (50% aqueous EtOH), pK_2^{25} 2.77 (50% aqueous EtOH).** Crystallise it from hexane. [*Beilstein* **12** IV 3460.]

4-Aminosalicylic acid (PAS, *p*-aminosalicylic acid) *[65-49-6]* **$C_7H_7NO_3$, M 153.1, m 150-151°(dec), 139-141°(evolving CO_2), 150-151°(dec), [capillary melting points)], 220°(dec), and 240 ±1° [average of 5 samples on a Dennis & Shelton m.p. apparatus], pK_1^{25} 1.78 (CO_2H), pK_2^{25} 3.63 (NH_2), pK^{25} 13.74 (OH).** Crystallise the acid from EtOH. *Alternatively*, purify it *via* the barium salt. ***NOTE:*** The melting point is not a good criterion of purity, and the most nearly correct value is **240°** [see Seaman et al. *J Am Chem Soc* **71** 2940

1949, DOI: 10.1021/ja01176a521]. Its solubility (w/v) in EtOH at ~25º is 4.8%, but is less in H_2O which is 0.2%, even less in Et_2O and almost insoluble in $*C_6H_6$. The ***ethyl ester*** forms needles from EtOH with **m 115º**. The ***benzoyl derivative*** (prepared from PAS and benzoyl chloride in pyridine) has **m 185-187º**. The ***hydrochloride***, **m 224º(dec)**, is crystallised from EtOH/HCl. Its alkali salts are more soluble in H_2O and as such are more useful, and decompose at high temperatures. The ***potassium salt*** **(Paskalium)** *[133-09-5]* **$C_7H_6KNO_3$, M 191.2**, is freely soluble in H_2O and less subject to stomach irritation than the free acid or the Na salt. The ***sodium salt dihydrate*** **(Aminacyl)** *[6018-19-5]* **$C_7H_6NNaO_3$. $2H_2O$, M 211.2**, has a solubility in H_2O at ~25º of 50% and is sparingly or almost insoluble in most organic solvents. The ***calcium salt*** **(Nippas calcium)** *[133-15-3]* **$C_{14}H_{12}CaN_2O_6$, M 344.3,** has a solubility in H_2O at ~25º of 14.3%, but slowly hydrolyses and darkens in colour. [Erlenmeyer et al. *Helv Chim Acta* **31** 988 *1948*, DOI: 10.1002/hlca.19480310404; Sheehan *J Am Chem Soc* **70** 1665 *1948*, DOI: 10.1021/ja01184a516, Hassan et al. *Anal Profiles Drug Subs* **10** 1 *1981*, DOI: 10.1016/S0099-5428(08)60636-X; *Beilstein* **14** IV 1967.] It is an antibacterial and is used in tuberculosis.

5-Aminosalicylic acid (5-amino-2-hydroxybenzoic acid, Mesalamine, 5-AS) *[89-57-6]* **$C_7H_7NO_3$, M 153.1, m 276-280º, 283º(dec), pK_1^{25} 2.74 (CO_2H), pK_2^{25} 5.84 (NH_2).** It crystallises as needles from H_2O containing a little $NaHSO_3$ to avoid aerial oxidation to the quinone-imine. The ***Me ester*** gives needles from $*C_6H_6$, **m 96º**, and the ***hydrazide*** has **m 180-182º** (from H_2O). [Fallab et al. *Helv Chim Acta* **34** 26 *1951*, DOI: 10.1002/hlca.19510340104; Shavel *J Am Pharm Assoc* **42** 402 *1953*, PMID: 13069333; *Beilstein* **14** IV 2058.] It is anti-inflammatory, and is a substrate for peroxidase used in ELISA tests.

9-Aminotriptycene *[793-41-9]* **$C_{20}H_{15}N$, M 269.3, m 221-221..5º, 223.5-224.5º, pK^{25} ~10.68.** Prepared by catalytic reduction of 9-nitrotrypticene *[797-67-1]* with Pd/C [Theilacker et al. *Chem Ber* **93** 1658 *1960*, DOI: 10.1002/cber.19600930728; Theilacker & Beyer *Chem Ber* **94** 2968 *1961*, DOI: 10.1002/cber.19610941121], the aminotriptycene formed can then be recrystallised from ligroin as white prisms. The ^{1}H NMR (400MHz, $CDCl_3$, and TMS) has δ at 7.47 (1-H, 8-H, 13-H), 7.05 (2-H, 7-H, 14-H), 7.00 (3-H, 6-H, 15-H), 7.37 (4-H, 5-H, 16-H), 5.40 (10-H, bridgehead) and 2.56 (NH_3) with $J_{1,2}$ = 7.5Hz, $J_{1,3}$ = 0.5Hz, $J_{1,4}$ = 0.0Hz, $J_{2,3}$ = 7.4Hz, $J_{2,4}$ = 1.2Hz and $J_{3,4}$ = 7.4Hz; the ^{13}C NMR (100MHz, $CDCl_3$, and TMS) has δ at 119.2 (1-C, 8-C, 13-C), 124.8 (2-C, 7-C, 14-C), 125.1 (3-C, 6-C, 15-C), 123.1 (4-C, 5-C, 16-C), 144.8 (4a-C, 10a-C, 11-C), 146.5 (9a-C, 8a-C, 12-C), 64.3 (9-C) and 53.1 (10-C); and the ^{13}C NMR for the solid state has been recorded but is only slightly different from the solution spectrum. [Imashiro et al. *J Am Chem Soc* **109** 729 *1987*, DOI: 10.1021/ja00237a016].

p-tert*-Amylphenol (*p*-2,2-dimethylpropylphenol)** *[80-46-6]* **$C_{11}H_{16}O$, M 164.3, m 88-89º, 93.5-94.2º, 94-96º, b 112-º/3mm,138º/15mm, 262º/760mm, d_4^{20} 0.962, pK_{Est} ~10.2.** Purify *via* its benzoate, as for phenol. After evaporating the solvent from its solution in ether, the material is recrystallised (from the melt) to a constant melting point. It is insoluble in H_2O but soluble in most organic solvents. The ***benzoyl derivative has **m 60º** (from EtOH). [Berliner et al. *J Am Chem Soc* **76** 507 *1954*, DOI: 10.1021/ja01631a052; Huston et al. *J Am Chem Soc* **67** 899 *1945*, DOI: 10.1021/ja01222a005; *Beilstein* **6** H 548, **6** I 269, **6** II 506, **6** III 1965, **6** IV 3383.]

Aniline *[62-53-3]* **C_6H_7N, M M 93.1, m -6.0º, b 68.3/10mm, 184.4º/760mm, d_4^{20} 1.0220, n_D^{20} 1.585, n_D^{20} 1.5832, pK^{25} 4.60.** Aniline is *hygroscopic*. It can be dried with KOH or CaH_2, and distilled under reduced pressure. Treatment with stannous chloride removes sulfur-containing impurities, reducing the tendency to become coloured by aerial oxidation. It can be crystallised from Et_2O at low temperatures. More extensive purifications involve preparation of derivatives, such as the double salt of aniline hydrochloride and cuprous chloride or zinc chloride, or *N*-acetylaniline (**m 114º**) which can be recrystallised from water. Redistilled aniline is dropped slowly into a strong aqueous solution of recrystallised oxalic acid. Aniline oxalate (**m 174-175º**) is filtered off, washed several times with water and recrystallised three times from 95% EtOH. Treatment with saturated Na_2CO_3 solution regenerated aniline which was distilled from the solution, dried and redistilled under reduced pressure [Knowles *Ind Eng Chem* **12** 881 *1920*, DOI: 10.1021/ie50129a017]. *Alternatively*, after refluxing with 10% acetone for 10hrs, aniline is acidified with HCl (to Congo Red) and extracted with Et_2O until colourless. Its hydrochloride is crystallised repeatedly before aniline is liberated with cold alkali, dried over solid KOH, and distilled. This sulfur-free product remains colourless in air [Hantzsch & Freese *Chem Ber*

27 2529 *1894,* DOI: 10.1002/cber.189402702255; Hantzsch & Freese *Chem Ber* **27** 2966 *1894*, DOI: 10.1002/cber.189402703601*894*]. Non-basic materials, including nitro compounds, are removed from aniline in 40% H_2SO_4 by passing steam through the solution for 1 hour. Pellets of KOH are then added to liberate the aniline which is steam distilled, dried with KOH, distilled twice from zinc dust at 20mm, dried with freshly prepared BaO, and finally distilled from BaO in an all-glass apparatus [Few & Smith *J Chem Soc* 753 *1949*, DOI: 10.1039/JR9490000753]. Aniline is absorbed through skin and is **TOXIC**. [*Beilstein* **12** IV 223.] ***Aniline hydrobromide*** *[542-11-0]* **C_6H_7N. HBr, M 174.0,** has **m 286°.** Crystallise the hydrobromide from water or EtOH and dry it at 5mm over P_2O_5. Also recrystallise it four times from MeOH containing a few drops of concentrated HBr by addition of petroleum ether (b 60-70°), then dry it to constant weight over paraffin chips *in vacuo* [Gutbezahl & Grunwald *J Am Chem Soc* **75** 559 *1953*, DOI: 10.1021/ja01099a014]. It precipitates from EtOH solution on addition of Et_2O, and the filtered solid is recrystallised from EtOH and dried *in vacuo*. Store it in the dark. [Buchanan et al. *J Am Chem Soc* **108** 1537 *1986*, DOI: 10.1021/ja00267a025; *Beilstein* **12** III 232.] ***Aniline hydrochloride*** *[142-04-1]* **C_6H_7N. HCl, M 129.6,** has **m 196-198°, 200.5-201°.** Purification is as for aniline HBr. [*Beilstein* **12** IV 232.] ***Aniline hydroiodide*** *[45497-73-2]* **C_6H_7N. HI, M 220.0, it decomposes on heating.** Purification is as for aniline HBr; store it in the dark. [*Beilstein* **12** III 232.]

m-**Anisaldehyde (3-methoxybenzaldehyde)** *[591-31-1]* **M 136.2, b 143°/50mm, d_4^{20} 1.117, n_D^{20} 1.553.** Wash it with saturated aqueous $NaHCO_3$, then H_2O, dry it with anhydrous $MgSO_4$ and distil it under reduced pressure under N_2. Store it under N_2 in sealed glass ampoules. [*Beilstein* **8** IV 241.] *p*-***Anisaldehyde*** **(4-methoxybenzaldehyde)** *[123-11-5]* has **m -1°, b 249°/atm, 89-90°/2mm, d_4^{20} 1.119, n_D^{20} 1.576.** Wash the aldehyde with saturated aqueous $NaHCO_3$, then H_2O, steam distil, extract the distillate with Et_2O, dry ($MgSO_4$) the extract, filter and distil this under a vacuum and N_2. Store it in glass ampoules under N_2 in the dark. [*Beilstein* **8** IV 252.] ***4-Methoxybenzaldehyde dimethylacetal*** *[2186-92-7]* **$C_{10}H_{14}O_3$, M182.2,** with **b 85-87°/0.1mm, n_D^{20} 1.505,** has been used as a protecting reagent for diols, as in carbohydrate chemistry, which can be easily and selectively removed under mild conditions [Kloosterman et al. *Recl Trav Chim Pays-Bas* **103** 243 *1984*, DOI: 10.1002/recl.19841030706; Peters et al. *Tetrahedron* **43** 3803 *1987*, DOI: 10.1016/S0040-4020(01)86866-6; Johansson & Samuelsson *JCS Perkins I* 2371 *1984*, DOI: 10.1039/P19840002371]. [*Beilstein* **8** H 74.]

o-**Anisidine (2-methoxyaniline)** *[90-04-0]* **C_7H_9NO, M 123.2, m ~5°, b 109°/17mm, 119°/21mm, 225°/atm, d_4^{20} 1.096, n_D^{20} 1.575, pK^{25} 4.52.** It is separated from the *m*- and *p*- isomers by steam distillation. It is also separated from its usual synthetic precursor *o*-nitroanisole by dissolving it in dilute HCl (pH <2.0) extracting the nitro impurity with Et_2O, adjusting the pH to ~8.0 with NaOH, extracting the amine into Et_2O or steam distilling. Extract the distillate with Et_2O, dry the extract (Na_2SO_4), filter, evaporate and fractionate the residual oil. Protect the almost colourless oil from light which turns it yellow in color. [Biggs & Robinson *J Chem Soc* 388 *1961*, DOI: 10.1039/JR9610000388; Nodzu et al. *Yakugaku Zasshi (J Pharm Soc Japan)* **71** 713, 715 *1951*, *Beilstein* **13** IV 806.] *m*-***Anisidine*** **(3-methoxyaniline)** *[536-90-3]* has **m -1° to +1°, b ~5°, b 79°/1mm, 128°/17mm, 251°/atm, d_4^{20} 1.101, n_D^{20} 1.583, pK^{25} 4.20.** *o*-Isomer impurity can be removed by steam distillation. Another possible impurity is the precursor 3-nitroanisole which can be removed as for the preceding *o*-isomer and fractionating using an efficient column. It is a yellow liquid. [Gilman & Kyle *J Am Chem Soc* **74** 3027 *1952*, DOI: 10.1021/ja01132a023; Bryson *J Am Chem Soc* **82** 4858 *1960*, DOI: 10.1021/ja01503a028; Kadaba & Massie *J Org Chem* **22** 333 *1957*, DOI: 10.1021/jo01354a610; *Beilstein* **13** IV 953.] *p*-***Anisidine*** **(4-methoxyaniline)** *[104-94-9]* has **m 57°, pK^{25} 5.31.** Crystallise *p*-anisidine from H_2O or aqueous EtOH. Dry it in a vacuum oven at 35° for 6 hours and store it in a dry box. It does not distil with steam (see above). [Moore et al. *J Am Chem Soc* **108** 2257 *1986*, DOI: 10.1021/ja00269a022.] Purify it also by vacuum sublimation [Guarr et al. *J Am Chem Soc* **107** 5104 *1985*, DOI: 10.1021/ja00304a015]. [*Beilstein* **13** IV 1015.]

Anisole *[100-66-3]* **C_7H_8O, M 108.1, m -37.5°, b 43°/11mm, 153.8°/760mm, d^{15} 0.9988, n_D^{20} 1.5143, pK^0 -6.61 (aqueous H_2SO_4).** Shake anisole with half its volume of 2M NaOH, and the emulsion is allowed to separate. Repeat three times, then wash twice with water, dry over $CaCl_2$, filter, dry over sodium wire and finally distil it from fresh sodium under N_2 using a Dean-Stark trap (samples in the trap being rejected until free from turbidity) [Caldin et al. *JCS Faraday Trans 1* **72** 1856 *1976*, DOI: 10.1039/F19767201856]. ***Alternatively***, dry it with $CaSO_4$ or $CaCl_2$, or by refluxing with sodium or BaO with crystalline $FeSO_4$ or by passage through an alumina column. Traces of phenols are removed by prior shaking with 2M NaOH, followed

by washing with water. It has been be purified by zone refining. [*Beilstein* **6** IV 548.]

2-*p*-Anisyl-1,3-indanone (anisindione, Unidone) *[117-37-3]* **$C_{16}H_{12}O_3$, M 252.3, m 156-157°, pK^{20} 4.09.** Crystallise anisindione from acetic acid or EtOH. [Horeau & Jacques *Bull Soc Chim Fr* 53 *1948*, Koelsch *J Am Chem. Soc* **58** 1331 *1936,* DOI: 10.1021/ja01299a005; *Beilstein* **8** III 2931.] It is an anticoagulant.

Anthracene *[120-12-7]* **$C_{14}H_{10}$, M 178.2, m 215-216°, 218°, b 342°/760mm, pK^{25} -7.4 (aqueous H_2SO_4).** Likely impurities are anthraquinone, anthrone, carbazole, fluorene, 9,10-dihydroanthracene, tetracene and bianthryl. Carbazole is removed by continuous-adsorption chromatography [see Sangster & Irvine *J Chem Phys* **24** 670 *1956* DOI: org/10.1063/1.1742596] using a neutral alumina column and eluting with *n*-hexane. [Sherwood in *Purification of Inorganic and Organic Materials*, Zief (ed), Marcel Dekker, New York, *1969*.] The solvent is evaporated, and anthracene is sublimed under vacuum, then purified by zone refining, under N_2 in darkness or non-actinic light. It has also been purified by co-distillation with ethylene glycol (boils at 197.5°), from which it can be recovered by addition of water, followed by crystallisation from 95% EtOH, *benzene, toluene, a mixture of *benzene/xylene (4:1), or Et_2O. It has also been chromatographed on alumina with petroleum ether in a dark room (to avoid photo-oxidation of adsorbed anthracene to anthraquinone). Other purification methods include sublimation in a N_2 atmosphere (in some cases after refluxing with sodium), and recrystallisation from toluene [Gorman et al. *J Am Chem Soc* **107** 4404 *1985*, DOI: 10.1021/ja00301a006]. Anthracene has been crystallised from EtOH, chromatographed through alumina in hot *benzene *(fume hood)* and then sublimed in a vacuum in a pyrex tube that has been cleaned and baked at 100°. (For further details see Craig & Rajikan *JCS Faraday Trans 2*, **74** 292 *1978*, DOI: 10.1039/F29787400292; and Williams & Zboinski *JCS Faraday Trans 1* **74** 618 *1978*, DOI: 10.1039/F29787400618.) It has been chromatographed on alumina, recrystallised from *n*-hexane and sublimed under reduced pressure. [Saltiel *J Am Chem Soc* **108** 2674 *1986*, DOI: 10.1021/ja00270a028; Masnovi et al. *J Am Chem Soc* **108** 1126 *1986*, DOI: 10.1021/ja00266a003.] *Alternatively*, recrystallise it from cyclohexane, chromatograph it on alumina with *n*-hexane as eluent, and recrystallise two more times [Saltiel et al. *J Am Chem Soc* **109** 1209 *1987*, DOI: 10.1021/ja00238a034]. Anthracene is fluorescent and forms a ***picrate complex***, **m 139°**, on mixing the components in $CHCl_3$ or *C_6H_6, but decomposes on attempted crystallisation. [*Beilstein* **5** IV 2281.]

Anthracene-9-carboxylic acid (anthroic acid) *[723-62-6]* **$C_{15}H_{10}O_2$, M 222.2, m 213-217°, 214°(dec), pK^{20} 3.65.** Crystallise the acid from EtOH. It is fluorescent in EtOH with λ_{max} at 254nm (0.1% EtOH). The corresponding alcohol ***9-anthracenemethanol*** *[1468-95-7]* **$C_{15}H_{12}O$, M 208.3,** has **m 162-164°** (from MeOH); and the respective methacrylate ester ***9-anthracenylmethyl methacrylate*** *[31645-35-9]* **$C_{19}H_{16}O_2$, M 276.3,** has **m 80-85°** [from *C_6H_6/petroleum ether (b 40-60°) and λ_{max} at 249nm (EtOH).] [*Beilstein* **9** IV 2671.]

9-Anthraldehyde (anthracene-9-carboxaldehyde) *[642-31-9]* **$C_{15}H_{10}O$, M 206.2, m 103-105°, 104-105°.** Crystallise the aldehyde from acetic acid or EtOH. It forms a *charge-transfer complex* with TCNE (tetracyanoethylene) in $CHCl_3$. [Masnovi et al. *J Am Chem Soc* **108** 1126 *1986*, DOI: 10.1021/ja00266a003; *Beilstein* **7** IV 1738.] The **syn-*oxime*** *[34810-13-4]* **$C_{15}H_{11}NO$, M 221.3,** has **m 162-164°** (from MeOH) [*Beilstein* **7** III 2528].

Anthranol (enol tautomer of anthone, see below) *[529-86-2]* **$C_{14}H_{10}O$, M 196.2, m 120°(rapid heating), 160-170°(dec. but sainters >100°), pK^{25} -5.5 (aqueous H_2SO_4).** Crystallise anthrol from glacial acetic acid or aqueous EtOH. It is the less stable of two tautomers and is obtained by heating anthrone in aqueous NaOH (but not in cold NaOH) whereby it dissolves to form the sodium salt of anthrol. On cautious acidification anthrol precipitates as a yellowish-brown solid. It changes into anthrone on keeping, as it does on melting (120° in a preheated bath). The melting point depends on the initial bath temperature, and recrystallisation may cause it to tautomerise to ***anthrone*** (see below). The ***acetate*** (**m 134°**) crystallises from petroleum ether (**m 134°**) or EtOH (**m 135.5-137°**). [Meyer *Justus Liebigs Ann Chem* **379** 37 *1911*, DOI: 10.1002/jlac.19113790104; Barnett et al. *J Chem Soc* 885 *1928*, DOI: 10.1039/JR9280000885, for tautomerism see Almdal et al. *Acta Chem Scand* Series B **40** 230 *1986*, DOI:10.3891/acta.chem.scand.09-1425.] An absolute EtOH solution consists of 89% anthrone and 11% anthranol in equilibrium.

Anthranthrone *[641-13-4]* **$C_{22}H_{10}O_2$, M 306.3, m 300°, 415°, pK^{25} -7.9 (aqueous H_2SO_4).** It is prepared by

intramolecular *bis*-cyclisation (dehydration) of 1,1'-dinaphthyl-8,8'-dicarboxylic acid and is purified by recrystallisation from chlorobenzene, nitrobenzene or $CHCl_3$ (**m 340°**). [*Beilstein* **7** I 451, **7** II 783, **7** III 4406, **7** IV 2694.]

Anthraquinone *[84-65-1]* **$C_{14}H_8O_2$, M 208.2, m 284-286°, 286°, m 377°/atm, 379-381°/atm, pK^{25} -8.27 (aqueous H_2SO_4).** Crystallise anthraquinone from $CHCl_3$ (38ml/g), *benzene, or boiling acetic acid, wash it with a little EtOH and dry it under vacuum over P_2O_5. Its solubility (w/w) in EtOH is 0.44% (at 25°) and 2.3% (at ~78°); in Et_2O it is 0.11% (at 25°); in $CHCl_3$ it is 0.63% (at ~25°) and 1.6% (at ~61°); and in $*C_6H_6$ it is 0.26% (at ~25°) and 1.8% (at ~80°). [*Beilstein* **7** IV 2556.]

Anthrarufin (1,5-dihydroxy-9,10-anthraquinone) *[117-12-4]* **$C_{14}H_8O_4$, M 240.1, m 279°(dec), 280°(dec), pK_1^{25} 9.90, pK_2^{25} 11.05.** Purify anthrarufin by column chromatography on silica gel with $CHCl_3/Et_2O$ as eluent, followed by recrystallisation from acetone. *Alternatively*, recrystallise it from glacial acetic acid [Flom & Barbara *J Phys Chem* **89** 4489 *1985*, DOI: 10.1021/j100267a017]. [*Beilstein* **7** III 2359, **8** IV 3268.]

1,8,9-Anthratriol (1,9,8-trihydroxyanthracene) *[480-22-8]* **$C_{14}H_{10}O_3$, M 226.2, m 176-181°, pK_{Est} ~9.5.** Crystallise it from petroleum ether and dry it *in vacuo*. [*Beilstein* **6** IV 7602.]

Anthrimide (1,1'-imino-bis-anthraquinone, 1,1'-dianthrimide) *[82-22-4]* **$C_{28}H_{15}NO_4$, M 429.4, m >250°(dec).** Crystallise anthrimide from chlorobenzene (red needles) or nitrobenzene (red rhombs). The needles are copper-like and metallic-looking. It is poorly soluble in organic solvents. [Eckert & Steiner *Monatsh Chem* **35** 1129 *1914*, DOI:10.1007/BF01518035.]

Anthrone *[90-44-8]* **$C_{14}H_{10}O$, M 194.2, m 155°, pK^{25} -5.5 (aqueous H_2SO_4).** This stable keto tautomer of 9-anthranol (above) provides yellow crystals from a 3:1 mixture of $*C_6H_6$/petroleum ether (b 60-80°) (10-12ml/g), or successively from $*C_6H_6$ then EtOH. Dry it *in vacuo*. [Meyer *Org Synth* Coll Vol **1** 60 *1941*, DOI: 10.15227/orgsyn.008.0008; *Beilstein* **6** IV 4930.] An absolute EtOH solution consists of 89% anthrone and 11% anthranol in equilibrium.

(±)-Atrolactic acid ($0.5H_2O$) (2-hydroxy-2-phenylpropionic acid) *[515-30-0]* **$C_9H_{10}O_3$. $0.5H_2O$, M 166.2, m 94.5-95°(anhydrous), 88-91° ($0.5H_2O$), pK^{18} 3.53.** Crystallise the acid from water (4g/20ml boiling H_2O with charcoal, filter and cool overnight at 0-5°) and dry it at 55°/0.5mm [Eliel & Freeman *Org Synth* Coll Vol **4** 58 *1963*, DOI: 10.15227/orgsyn.033.0007]. The ***(±)-ethyl ester*** *[76496-51-0]* has **b 250°/~760mm, 129-130°/13mm**. [*Beilstein* **10** H 259, **10** I 113, **10** II 157, **10** III 560, **10** IV 467.] ***(±)-Atrolactamide*** *[2019-68-3, S-5908-94-1]* has **m 101-102°** (leaflets from CH_2Cl_2), and is freely soluble in H_2O [prep. form the ethyl ester and ammonia see McKenzie & Smith *J Chem Soc* **121** 1348 *1922*, DOI: 10.1039/CT9222101348; and by hydrolysis of the nitrile with fuming HCl see Staudinger & Ruzicka *Justus Liebigs Ann Chem* **380** 291 *1911*, DOI: 10.1002/jlac.19113800303], and is an *anticonvulsant*.

R*-(-) and *S*-(+) Atrolactic acid** *[R 3966-30-1 and S 13113-71-8]* **$C_9H_{10}O_3$, M 166.2, m 115-116°, 116-117°, *R* $[\alpha]_D^{14.6}$ -37.7 (c 3.3 EtOH) and $[\alpha]_D^{14.6}$ –51.1 (c 2.2, H_2O), *S* $[\alpha]_D^{14.6}$ +37.7 (c 3.5 EtOH).** Recrystallise them from $*C_6H_6$ or $*C_6H_6$/petroleum ether and dry them in a vacuum. [McKenzie & Clough *J Chem Soc* 1016 *1910*, DOI: 10.1039/CT9109701016; Meyers & Slade *Synth Commun* **6** 601 *1976*, DOI: 10.1080/00397917608063555; *Beilstein* **10** II 157, **10** III 560, **10** IV 657.] ***S(+)-Atrolactamide *[5908-94-1]*, obtained from the ethyl ester and ammonia has **m 62.5-63.5°** (glassy rhombic plates from $*C_6H_6$), **$[\alpha]_D^{14}$ +12.6 (c 1.87, EtOH), $[\alpha]_D^{15}$ +12.8 (c 2.23, Me_2CO)** and is freely soluble in H_2O [McKenzie & Smith *J Chem Soc* **121** 1348 *1922*, DOI: 10.1039/CT9222101348]. It is an anticonvulsant.

Auramine O (4,4'-bis-dimethylaminobenzophenone imine hydrochloride) *[2465-27-2]* **$C_{17}H_{22}ClN_3$, M 321.9, m >250°(dec), pK^{25} 10.71 (free base), 9.78 (carbinolamine).** It crystallises from EtOH as the hydrochloride and is very slightly soluble in $CHCl_3$, its UV has λ_{max} at 434nm (ε 370). The ***free base*** (carbinolamine) has **m 136°** (from $*C_6H_6$). [Goldacre & Phillips *J Chem Soc* 1724 *1949*, DOI: 10.1039/JR9490001724; Conrad et al. *Biochemistry* **9** 1540 *1970*, DOI: 10.1021/bi00809a010; *Beilstein* **14** IV 256.]

Aurin tricarboxylic acid *[4431-00-9]* **$C_{22}H_{14}O_9$, M 422.4, m 300°.** The acid is dissolved in aqueous NaOH, $NaHSO_3$ solution is added until the colour is discharged and then the tricarboxylic acid is precipitated with HCl. [Heisig & Lauer *Org Synth* Coll Vol **I** 54 *1941*, DOI: 10.15227/orgsyn.009.0008; *Beilstein* **10** IV 4161]. Do not extract the acid with hot water because it softens, forming a viscous mass. Make a solution in aqueous NH_3. ***Aurin tricarboxylic acid ammonium salt*** **(Aluminon, ATA)** *[569-58-4]* **$C_{22}H_{14}O_9$. $3NH_3$, M 473.4, m 220-225°(dec)** is the NH_4 salt which polymerises readily in aqueous solution, in which it is freely soluble, forming a stable free radical. It has a variety of physiological activities. It forms brilliantly coloured salts (lakes) with Al, Cr, Fe and Be ions, and is used for the estimation of Al in tissues, H_2O and foodstuffs due to the colour that it forms. Store dry preferably in the dark.

4-Azidoaniline hydrochloride *[91159-79-4]* **$C_6H_6N_4$. HCl, M 170.6, m 165°(dec).** Purify it by dissolving it in EtOAc with dry HCl gas followed by addition of cold dry Et_2O. Dry it *in vacuo* over P_2O_5. The ***free base*** has **m 66°(dec)** (MeOH) and the ***picrate*** has **m 64-65°(dec)** (MeOH). The IR has ν_{max} (Nujol) at 2110cm^{-1} (N_3). [Escher et al. *Helv Chim Acta* **62** 1217 *1979*, DOI: 10.1002/hlca.19790620432; Maffei & Rivolta *Gazetta Chim Ital* **84** 750 *1954*, *Beilstein* **12** H 772, **12** IV 1741.]

Azobenzene *[103-33-3]* **$C_{12}H_{10}N_2$, M 182.2, m 65-68°, 68°, b 293°/atm, pK^{25} 2.48.** Ordinary azobenzene is nearly all in the *trans*-form. It is partly converted into the *cis*-form on exposure to light [for isolation see Hartley *J Chem Soc* 633 *1938*, DOI: 10.1039/JR9380000633, and for spectra of *cis*- and *trans*-azobenzenes, see Winkel & Siebert *Chem Ber* **74B** 670 *1941*, DOI: 10.1002/cber.19410740503]. *trans*-Azobenzene is obtained by chromatography on alumina using 1:4 *C_6H_6/heptane or petroleum ether, and it crystallises from EtOH (after refluxing for several hours) or hexane. All operations should be carried out in diffuse red light or in the dark. It is almost insoluble in H_2O but soluble in organic solvents and AcOH. [cf: Vogel *Practical Organic Chemistry* 3rd Edn Longmans, London, p 631 *1959*, *Beilstein* **16** IV 8.]

Azolitmin B (colouring matter from Litmus) *[1395-18-2]* **M ~3300, m >250°(dec).** It is a mixture of water soluble dyes extracted from lichens. It crystallises from water as dark violet scales, or as a red powder by precipitating 0.5g from H_2O (80ml) by addition of EtOH (20ml). It is an indicator which is red at pH 4.5 and blue at pH 8.3. The chromophore of litmus components is *7-hydroxyphenoxaz-1-one*. [cf. Kolthoff & Rosenblum *Acid-Base Indicators*, Macmillan, NY, pp160-162, 365-366 *1937*.]

p,p'-**Azoxyanisole (4,4'-dimethoxyazoxybenzene)** *[1562-94-3]* **M 258.3, transition temperatures: 118.1-118.8°, 135.6-136.0°, pK^{25} -5.23 (20% aqueous EtOH + 80% aqueous H_2SO_4).** Crystallise the dye from absolute or 95% EtOH, or acetone, and dry it by heating under vacuum or sublime it in a vacuum onto a cold finger. [*Beilstein* **16** II 326.]

Azoxybenzene (Fenazox) *[495-48-7]* **$C_{12}H_{10}N_2O$, M 198.2, m 36°** ***[trans,*** *20972-43-4]***, m 87°** ***[cis,*** *21650-65-7]***, pK^{25} -6.16 (20% aqueous EtOH + 80% aqueous H_2SO_4).** Crystallise azoxybenzene from EtOH or MeOH, and dry it for 4 hours at 25°/10^{-3}mm. Sublime it before use. [Bigelow & Palmer *Org Synth* Coll Vol **II** 57 *1943*, DOI: 10.15227/orgsyn.011.0016; *Beilstein* **16** II 326.] *Cis*- and *trans*- azoxybenzene were respectively prepared by oxidation of the respective *cis*- and *trans*- azobenzenes with perbenzoic acid in *C_6H_6. The rates of reactions (second order rates at 25°) showed that *cis*-azobenzene was oxidised to *cis*-azoxybenzene much more rapidly than the *trans*- isomer. After the oxidation of the *trans*- isomer in the dark, the reaction mixture was washed with dilute Na_2CO_3 solution to remove acids, then H_2O, dried, the solvent was evaporated and the residue was purified by chromatography on Al_2O_3 with light petroleum which gave *trans*-azoxybenzene, **m 36°**. When this oxidation was carried out in the presence of sunlight, *cis*-azoxybenzene, **m 86°** was obtained. Similar oxidation of *cis*-azobenzene, in the dark, but without chromatographic purification gave a yellow solid which was freed from *trans*-azoxybenzene by trituration with petroleum ether (b 40-60°) *ca* 4 times to give the much less soluble *cis*-azoxybenzene, **m 87°**. When heated at 100° for 0.5hr, this *cis*-compound was converted into *trans*-azoxybenzene, **m 36°**. ***Note***: that when *cis*-azoxybenzene was reduced with $LiAlH_4$ in dry Et_2O only *trans*-azobenzene, **m 68°** was obtained, and was unchanged after resolidification. [Badger et al. *J Chem Soc* 2143 1953, DOI: 10.1039/JR9530002143.] *Trans*-azoxybenzene is insoluble in H_2O but is steam volatile; and its solubility (w/w at ~15°) in absolute EtOH is 17.5%, but much higher, 43.5%, in petroleum ether (b 40-60°).

p,p-**Azoxyphenetole (4,4'diethoxyazoxybenzene)** *[4792-83-0]* **$C_{16}H_{18}N_2O_3$, M 286.3, m 137-138°, 138.5°,** (melts to a turbid liquid crystal at *ca* **165°** which clarifies at **167.5°).** Crystallise the dye from toluene or EtOH. For the melting character see Homfray [*J Chem Soc* **97** 1669 *1910*, DOI: 10.1039/CT9109701669]. It has λ_{max} at 360nm [Purvis *J Chem Soc* **107** 660 *1915*, DOI: 10.1039/CT9150700660]. [*Beilstein* **16** H 638, **16** I 384, **16** II 326.]

Azulene *[275-51-4]* **$C_{10}H_8$, M 128.2, m 98.5-99°, 98-100°, b 115-135°/10mm, 242°/atm, pK^{25} -1.65 (aqueous H_2SO_4).** Crystallises from EtOH in intensely blue prisms or leaflets with the odour of naphthalene. It forms a ***trinitrobenzene complex*** **$C_{16}H_{11}N_3O_6$, m 166.5-167.7°,** when mixed with one equivalent of 1,3,5-trinitrobenzene which recrystallised from EtOH as fine brown needles. Azulene can be recovered from this complex by running it on a thick Al_2O_3 TLC plate and eluting with cyclohexane-*C_6H_6 (1:1) which separates the components. Also, sublimation of the complex at 150° in a CO atmosphere produces azulene as blue metallic-looking plates, **m 98.5-99°**. ***Azulene trinitrotoluene complex*** **$C_{17}H_{13}N_3O_6$, m 99.5-100°**, is prepared similarly with trinitrotoluene and recrystallised from EtOH. [Plattner & Pfau *Helv Chim Acta* **20** 224 *1937*, DOI: 10.1002/hlca.19370200133.] Azulene has UV with λ_{max} (logε) at 272nm (5.1), 296nm (3.9), 326nm (3.9), 340nm (4.0) and 358nm (3.5) in hexane. [Susz et al. *Helv Chim Acta* **20** 469 *1937*, DOI: 10.1002/hlca.19370200173, and IR: Plattner & Wyss *Helv Chim Acta* **24** 483 *1941*, DOI: 10.1002/hlca.19410240166; *Beilstein* **5** IV 1636.]

Benzalacetone (*trans*-**4-phenyl-3-buten-2-one)** *[122-57-6]* **$C_{10}H_{10}O$, M 146.2, m 41.5°, 42°, b 81.7°/0.1mm, 127°/10mm, 161°/40mm. 260-262°/atm, $d_4^{45.2}$ 1.0079, $n_D^{45.9}$ 1.5836.** Crystallise it from petroleum ether (b 40-60°), or distil it, preferably under reduced pressure. It is steam volatile, and is soluble in most organic solvents but not in petroleum ether. [Drake & Allen *Org Synth* Coll Vol **I** 77 *1941*, DOI: 10.15227/orgsyn.003.0017; *Beilstein* **7** IV 1003.]

Benzalacetophenone (Chalcone) *[94-41-7]* **$C_{15}H_{20}O$, M 208.3, m 56-58°, 57-58°, b 208°/25mm, 345-348°/atm (some dec), d_4^{62} 1.0712, n_D^{62} 1.5836. pK^{25} -5.73 (aqueous H_2SO_4).** Crystallise it from EtOH by warming to 50° (about 5ml/g), iso-octane, or toluene/petroleum ether, or recrystallise it from MeOH, and then twice from hexane. SKIN IRRITANT. [Kohler & Chadwell *Org Synth* Coll Vol **I** 78 *1941*, DOI: 10.15227/orgsyn.002.0001; *Beilstein* **7** IV 1658.]

Benzaldehyde *[100-52-7]* **C_7H_6O, M 106.1, m -56.5°, -26°, b 62°/10mm, 179.0°/760mm, d_4^{20} 1.044, n_D^{20} 1.5455, pK^{25} -7.1 (aqueous H_2SO_4).** To diminish its rate of oxidation, benzaldehyde usually contains additives such as hydroquinone or catechol. It can be purified *via* its bisulfite addition compound but usually distillation (under nitrogen at reduced pressure) is sufficient. Prior to distillation it is washed with NaOH or 10% Na_2CO_3 (until no more CO_2 is evolved), then with saturated Na_2SO_3 and H_2O, followed by drying with $CaSO_4$, $MgSO_4$ or $CaCl_2$. Its solubility in H_2O is 0.3% but it is steam volatile. Benzaldehyde has the odour of almonds as it is a component of *amygdalin* which is present in bitter almonds and apricot pits. [Prepn from benzal chloride: Vogel *Practical Organic Chemistry* 3rd Edn Longmans, London, p 693 *1959*, *Beilstein* **7** IV 505.] ***Amygdalin*** (*R*(D)-mandelonitrile 6-*O*-β-D-glucosido-β-D-glucoside) *[29883-15-6]* **$C_{20}H_{27}NO_{11}$, M 457.4**, is the cyanohydrin glycoside of benzaldehyde which is hydrolysed by acid or enzymatically to benzaldehyde, HCN and two molecules of glucose [Conn *Int Rev Biochem (Biochemistry of Nutrition 1A)* **27** 21 *1979*]. ***anti-Benzaldoxime*** *[932-90-1]* **C_7H_7NO, M 121.1,** has **m 33-34°.** Crystallise the oxime from diethyl ether by adding petroleum ether (b 60-80°). The *syn*-isomer *[622-32-2]* has **b 121-124°/12mm, m 34-36°**. [*Beilstein* **7** H 218, **7** IV 527.] It has also been crystallised from dilute aqueous NH_3, H_2O, Me_2CO, then *C_6H_6 using a Soxhlet extractor. Its solubility (w/v at ~20°) in EtOH is 16.7% and in pyridine it is 30.3%. Dry it in an oven at 110° for 8 hours and store in a desiccator over 99% H_2SO_4. It can be purified by zone melting or by sublimation. [Bates & Hobbs *J Am Chem Soc* **73** 2151 *1951*, DOI: 10.1021/ja01149a070; *Beilstein* **9** IV 725.]

Benzamidine *[618-39-3]* **$C_7H_8N_2$, M 120.2, m 65-70°, 64-66°, pK^{20} 11.6.** It is liberated from its hydrochloride chloride (see below) by treatment with 5M NaOH, extracted into Et_2O, dried (Na_2SO_4), filtered, evaporated and the residue was sublimed *in vacuo*. [*Beilstein* 9 H 280, 9 I 123, 9 II 199, **9** 1264, 9 IV 898.]

Benzamidine hydrochloride hydrate *[hydrate 206752-36-5; anhydrous 1670-14-0]* **$C_7H_8N_2$. HCl. H_2O, M 156.6 (anhydrous), m 86-88° (hydrate), m 169-173° (anhydrous), pK^{20} 11.6 (see free base above).** Recrystallise it from dilute HCl (crystals contain xH_2O) or EtOH/few drops HCl; dry it in a vacuum. It is a proteolytic inhibitor [Jeffcoate & White *J Clin Endocrinol Metab* **38** 155 *1974*, DOI: org /10.1210/jcem-38-1-155; *Beilstein* **9** IV 898.]

Benzanilide *[93-98-1]* **$C_{13}H_{11}NO$, M 197.2, m 163°, 164°, b 117-119°/10mm, pK^{55} 1.26.** Crystallise benzanilide from petroleum ether (b 70-90°) using a Soxhlet extractor, and dry it *in vacuo* overnight at 120°. Also crystallise it from EtOH. Its solubility (w/v) in EtOH is 1.6% (at ~20°) and 14.3% (at ~78°), and it is sparingly in Et_2O but almost insoluble in H_2O. [Webb *Org Synth* Coll Vol **I** 82 *1941*, DOI: 10.15227/orgsyn.007.0006; *Beilstein* **12** IV 417.]

Benz[a]anthracene (1,2-benzanthracene, tetraphene) *[56-55-3]* **$C_{18}H_{12}$, M 228.3, m 157-159°, 159-160°, 167°, b 437.6°/atm.** Crystallise 1,2-benzanthracene from AcOH, MeOH, EtOH or *C_6H_6 (charcoal), then chromatograph it on alumina from sodium-dried *benzene (twice), using vacuum distillation to remove *benzene. Final purification is by vacuum sublimation. [Fieser & Hershberg *J Am Chem Soc* **59** 2502 *1937*, DOI: 10.1021/ja01291a008; *Beilstein* **5** IV 2549.]

Benz[a]anthracene-7,12-dione *[2498-66-0]* **$C_{18}H_{10}O_2$, M 258.3, m 169.5-170.5°, 169-171°**. Crystallise the dione from MeOH (charcoal), toluene, toluene/hexane, Me_2CO, or AcOH. *Alternatively*, purify it by sublimation *in vacuo*, or by zone refining. [*Beilstein* **7** H 826, **7** I 440, **7** II 760, **7** III 4278, **7** IV 2644.]

Benzanthrone *[82-05-3]* **$C_{17}H_{10}O$, M 230.3, m 168-170°, 170°, 170-173°, pK^{25} -3.2 (aqueous H_2SO_4).** Crystallise benzanthrone from EtOH or xylene. The solubility (w/w at ~20°) in *PhCl is 2.05%, in *C_6H_6 is 1.61% and in AcOH it is 0.52%. On a larger scale benzanthrone (~58g) is dissolved in tetrachloroethane (175ml, b 147°/atm), charcoal (12g) is added and boiled under reflux for 15min, filtered, the carbon is washed with hot solvent (50ml), the combined hot filtrates are diluted with boiling EtOH (750ml) and set aside to crystallise. Pure benzanthrone, m 170-171°, separates as yellow needles (~50g, after drying *in vacuo*). [Macleod & Allen *Org Synth* Coll Vol **2** 62 *1941*, DOI: 10.15227/orgsyn.014.0004; *Beilstein* **7** IV 1819.]

***Benzene** *[71-43-2]* **C_6H_6, M 78.1, f 5.5°, b 80.1°/atm, d_4^{20} 0.874, n_D^{20} 1.50110, n_D^{25} 1.49790.** For most purposes, *benzene can be purified sufficiently by shaking with conc H_2SO_4 until free from thiophene, then with H_2O, dilute NaOH and water, followed by drying (with P_2O_5, sodium, $LiAlH_4$, CaH_2, 4X Linde molecular sieve, or $CaSO_4$, or by passage through a column of silica gel, and for a preliminary drying, $CaCl_2$ is suitable), and distillation. A further purification step to remove thiophene, acetic acid and propionic acid, is crystallisation by partial freezing. The usual contaminants in dry thiophene-free *benzene are non-benzenoid hydrocarbons such as cyclohexane, methylcyclohexane, and heptanes, together with naphthenic hydrocarbons and traces of toluene. Carbonyl-containing impurities can be removed by percolation through a *Celite column impregnated with 2,4-dinitrophenylhydrazine, phosphoric acid and H_2O*. (Prepared by dissolving 0.5g DNPH in 6ml of 85% H_3PO_4 by grinding together, then adding and mixing 4ml of distilled H_2O and 10g Celite.) [Schwartz & Parker *Anal Chem* **33** 1396 *1961*, DOI: 10.1021/ac60178a036.] *Benzene has been freed from thiophene by refluxing with 10% (w/v) of Raney nickel for 15 minutes, after which the nickel is removed by filtration or centrifugation. Dry *benzene is obtained by doubly distilling high purity *benzene from a solution containing the blue ketyl formed by the reaction of sodium-potassium alloy with a small amount of benzophenone. Thiophene has been removed from *benzene (absence of a bluish-green coloration when 3ml of *benzene is shaken with a solution of 10mg of isatin in 10ml of concentrated H_2SO_4) by refluxing the *benzene (1.25L) for several hours with 40g HgO (freshly precipitated) dissolved in 40ml glacial acetic acid and 300ml of water. The precipitate is filtered off, the aqueous phase is removed and the *benzene is washed twice with H_2O, dried and distilled. *Alternatively*, *benzene dried with $CaCl_2$ has been shaken vigorously for 0.5 hour with anhydrous $AlCl_3$ (12g/L) at 25-35°, then decanted, washed with 10% NaOH, and water, dried and distilled. The process is repeated, giving thiophene-free *benzene. [Holmes & Beeman *Ind Eng Chem* **26** 172 *1934*, DOI: 10.1021/ie50290a011.] After shaking successively for about an hour with conc H_2SO_4, distilled water (twice), 6M NaOH, and distilled water (twice), *benzene is distilled through a 3-ft glass column to remove most of the water. Absolute EtOH is added and the *benzene-alcohol azeotrope is distilled. (This low-boiling distillation leaves any non-azeotrope-

forming impurities behind.) The middle fraction is shaken with distilled water to remove EtOH, and again redistilled. Final slow and very careful fractional distillation from sodium, then $LiAlH_4$ under N_2, removed traces of water and peroxides. [Peebles et al. *J Am Chem Soc* **82** 4780 *1960*, DOI: 10.1021/ja01503a006.] **Benzene liquid and vapour are very* **TOXIC, CARCINOGENIC** *and* **HIGHLY FLAMMABLE**, *and all operations should be carried out in an efficient fume cupboard and in the absence of naked flames in the vicinity*. [*Beilstein* **5** H 175, **5** I 95, **5** II 119, **5** III 469.]
Rapid purification: To dry *benzene, alumina, CaH_2 or 4A molecular sieves (3% w/v) may be used (dry for 6 hours). Then *benzene is distilled, discarding the first 5% of distillate, and stored over molecular sieves (3A, 4A) or Na wire.

[$^2H_6$]*Benzene (benzene-d_6*)** *[1076-43-3]* **C_6D_6, M 84.2, b 80°/773.6mm, 70°/562mm, 60°/399mm,40°/186.3mm, 20°/77.1mm, 10°/49.9mm, 0°/27.5mm, d_4^{20} 0.9488, d_4^{40} 0.9257, n_D^{20} 1.4991, n_D^{40} 1.4865.** Hexadeuteriobenzene of 99.5% purity is refluxed over and distilled from CaH_2 onto Linde type 5A sieves under N_2. [*Beilstein* **5** III 518, **5** IV 630.]

Benzeneazodiphenylamine (4-phenylazodiphenylamine) *[28110-26-1; 101-75-7]* **$C_{18}H_{15}N_3$, M 273.3, m 82°, 86°, 89-91°, pK^{22} 0.48.** Purify the dye by chromatography on neutral alumina using dry *C_6H_6 with 1% of dry MeOH. The major component, which gave a stationary band, is cut out and eluted with EtOH or MeOH. [Högfeldt & Bigeleisen *J Am Chem Soc* **82** 15 *1960*, DOI: 10.1021/ja01486a005.] It crystallises from petroleum ether, EtOH or aqueous EtOH, and has λ_{max} at 420nm (ε 28,000) (aqueous EtOH), and 540nm (aqueous EtOH/H_2SO_4) [Badger et al. *J Chem Soc* 1888 *1954*, DOI: 10.1039/JR9540001888; *Beilstein* **16** H 314, **16** III 343, **16** IV 457.]

1-Benzeneazo-2-naphthol (Sudan I) *[842-07-9]* **$C_{16}H_{12}N_2O$, M 248.3, m 106°, 120,5°, 132° (polymorphism) 134°, 135°, pK_{Est} ~9.5 (OH).** Crystallise the dye from EtOH. It forms Cu and Ni salts. [*Beilstein* **16** H 162, **16** I 254, **16** II 70, **16** III 129, **16** IV 228.]

Dehydrate at high vacuum over P_2O_5. [*Beilstein* **9** H 976, **9** IV 3745.] ***Benzene-1,2,4-tricarboxylic* (Trimellitic) acid (H_2O)** *[528-44-9]* has **m 229-231°(dec), 229-234°(dec), 218-220°** (also reported)**, pK_1^{25} 2.64, pK_2^{25} 4.15, pK_3^{25} 5.67.** Crystallise the acid from aqueous EtOH or glacial AcOH and dry over P_2O_5. It is soluble (w/w) at 25° in Me_2NCHO (31%), EtOH (25.3%), Me_2CO (7.9%), H_2O (2.1%), EtOAc (1.7%), petroleum ether (0.03%), CCl_4 (0.04%) and xylene (0.006%), but insoluble in CS_2, $CHCl_3$ or *C_6H_6. [*Beilstein* **9** H 976, **9** IV 3745.] Sublimation above its melting point yields the anhydride, ***4-carboxyphthalic anhydride (Trimellitic anhydride, benzene-1,2,4-benzenetricarboxylic anhydride)*** *[552-30-7]* **$C_9H_4O_5$, M 192.1, pK_{Est}^{25} 2.2,** which can be distilled under a vacuum with **b 240-245°/14mm**, and/or recrystallised from EtOAc/petroleum ether, Me_2CO/petroleum ether or Ac_2O and dried over P_2O_5/vacuum to give colourless crystals with **m 163-166°** (**161-163.5°** also reported). It is soluble (w/w) at 25° in Me_2CO (49.6%), EtOAc (21.6%), Me_2NCHO (15.5%), xylene (0.4%) and petroleum ether (0.06%). ***Trimellitic anhydride chloride (benzene-1,2,4-tricarboxylic anhydride chloride)*** *[1204-28-0]* **$C_9H_3ClO_4$, M 210.6,** has **m 66-68°** (from light petroleum b 60-80°). [*Beilstein* **18/8** V 562.] ***Benzene-1,3,5-tricarboxylic (Trimesic) acid*** *[554-95-0]* has **m >300°, 360°(dec), pK_1^{25} 2.64, pK_2^{25} 3.71, pK_3^{25} 5.01.** Crystallise the acid from water or AcOH and dry it *in vacuo*. The ***trimethyl ester*** has **m 144°** (from MeOH or MeOH/H_2O). [*Beilstein* **9** H 978, **9** IV 3747.] The ***tri-acid chloride (benzene-1,3,5-tricarbonyl chloride)*** *[4422-95-1]* **$C_9H_3Cl_3O_3$, M 265.5,** is purified by distillation, **b 180°/16mm**, and by crystallisation from low boiling petroleum ether, **m 34.5-36°** (32-38° also reported). [*Beilstein* **9** IV 3748.]

1,2,4-Benzenetriol (hydroxyhydroquinone) *[533-73-3]* **$C_6H_6O_3$, M 126.1, m 140.5-141°(sintering at 139°), pK_1^{20} 9.08, pK_2^{20} 11.82.** Crystallise the triol from Et_2O or Et_2O/EtOH, and dry it in a vacuum. It sublimes in a vacuum. The ***triacetate*, m 96.5-97°**, forms needles from absolute EtOH, the ***tri-4-nitrobenzoate*** has **m** 120°, and the ***trimethyl ether*** has **b 247°/atm**. The ***picrate*** forms orange-red needles **m 96°**. [Vliet *Org Synth* Coll Vol **1** 317 *1941*, DOI: 10.15227/orgsyn.004.0035; *Beilstein* **6** H 1087, **6** I 541, **6** II 1071, **6** III 6276.]

Benzethonium chloride (Hyamine 1622, [diisobutylphenoxyethoxyethyl]dimethylbenzyl-ammonium chloride, (*N,N*-dimethyl-*N*-[2-[2-[4-(1,1,3,3-tetramethylbutyl)phenoxy]-ethoxy]-ethyl]-benzenemethan-ammonium chloride) *[121-54-0]* **$C_{27}H_{42}ClNO_2$, M 448.1, m 164-166° (sinters at 120°, monohydrate).** Crystallise it from boiling acetone after filtering or from $CHCl_3$/petroleum ether. The crystals are filtered off, washed with diethyl ether and dried for 24 hours in a vacuum desiccator. It is a cationic antiseptic surfactant which forms crystals also from a 1:9 MeOH/Et_2O mixture. It foams in water, and is a disinfectant. [*Beilstein* **12** IV 2187.]

Benzhydrol (diphenylmethanol) *[91-01-0]* **$C_{13}H_{12}O_3$, M 184.2, m 69°, b 297°/748mm, 180°/20mm.** Crystallise benzhydrol from hot H_2O or petroleum ether (b 60-70°), petroleum ether containing a little *benzene, from CCl_4, or EtOH (1ml/g). (Its solubility in H_2O at 25° is 0.1% w/v.) An additional purification step includes passage of a *benzene solution through an activated alumina column. It sublimes in a vacuum. Also recrystallise it three times from MeOH/H_2O [Naguib *J Am Chem Soc* **108** 128 *1986*, DOI: 10.1021/ja00261a021]. [Wiselogle & Sonneborn *Org Synth* Coll Vol **1** 90 *1941*, DOI: 10.15227/orgsyn.008.0024; *Beilstein* **6** IV 4648.] § A commercial polystyrene supported version is available.

Benzidine (4,4'-diaminobiphenyl) *[92-87-5]* **$C_{12}H_{12}N_2$, M 184.2, m 128-129°, pK_1^{20} 3.85, pK_2^{20} 4.95.** Its solution in *benzene is decolorised by percolating through two 2-cm columns of activated alumina, then concentrated until benzidine crystallises on cooling. Recrystallise alternately from EtOH and *benzene to constant absorption spectrum [Carlin et al. *J Am Chem Soc* **73** 1002 *1951*, DOI: 10.1021/ja01147a035]. It has also been crystallised from hot water (charcoal) and from diethyl ether. Its solubility (w/v) in H_2O is 0.04% at 25° and 0.9% at 100°; in EtOH it is 20% at 78° and in Et_2O it is 2% at 25°. Dry it under vacuum in an Abderhalden pistol. Store it in the dark in a stoppered container. **CARCINOGENIC.** [*Beilstein* **13** IV 364.] ***Benzidine dihydrochloride*** *[531-85-1]* **$C_{12}H_{12}N_2$. 2HCl, M 257.2, m >250°(dec).** Crystallise the salt by dis-

solving in hot H_2O, and adding concentrated HCl to the slightly cooled solution. Dry it *in vacuo* over KOH. **CARCINOGENIC**. [*Beilstein* **13** IV 365.]

Benzil (dibenzoyl, diphenylethanedione) *[134-81-6]* **$C_{14}H_{10}O_2$, M 210.2, m 94-95°, 96-96.5°, b 188°/12mm, 346-348°/atm.** Crystallise benzil from *benzene after washing with alkali. (Crystallisation from EtOH did not free benzil from material reacting with alkali.) [Hine & Haworth *J Am Chem Soc* **80** 2274 *1958*, DOI: 10.1021/ja01542a060.] It has also been crystallised from CCl_4, diethyl ether or EtOH [Inoue et al. *JCS Faraday Trans 2* **82** 523 *1986*, DOI: 10.1039/F29868200523]. Its IR has ν_{max} ($CHCl_3$) at 1686, 1608 and 1460cm^{-1}. It condenses with vicinal diamines to form aza-heterocycles. [Clarke & Dreger *Org Synth* Coll Vol **I** 87 *1941*, DOI: 10.15227/orgsyn.006.0006; *Beilstein* **7** IV 2502.] Benzil forms three ***benzildioximes*** **$C_{14}H_{12}N_2O_2$, M 240.3,** which can be separated by fractional crystallisation *viz*: an α-(*anti*)-dioxime *[E,E 23873-81-6]* **m 237°**, a β-(*syn*)-dioxime *[Z,Z 572-45-2]* **m 206°**, and a γ-(*amphi*)-dioxime *[E,Z 572-43-0]* **m 166°**, and can be distinguished by the three different reactions which they undergo. The α-isomer produces an anhydride (diphenyloxazine), the β-isomer provides oxanilide, and the γ-isomer forms *N*'-benzoyl phenylurea. α-(*anti*)-Dioxime complexes with Ni^{2+} and Fe^{2+} [Singh et al. *Talanta* **26** 425 *1979*, DOI: 10.1016/0039-9140(79)80107-1]. The ***bis-semicarbazone*** **$C_{16}H_{16}N_6O_2$, m 243-244°**, crystallises in leaflets from EtOH. [*Beilstein* **7** III 3812, **7** IV 2504.] ***Benzil monohydrazone*** *[5433-88-7]* **$C_{14}H_{12}N_2O$, M 224.3,** has **m 151°(dec).** Crystallise it from EtOH. The ***monoacetyl hydrazone*** has **m 91°** (from EtOH). The ***bis-phenylhydrazone*** has **m 225°**. [Metze & Meyer *Chem Ber* **90** 481 *1957*, DOI: 10.1002/cber.19570900405; *Beilstein* **7** I 394.] ***Benzil monoxime*** *[14090-77-8]*, *[E 574-15-2]*, *[Z 574-16-3]* **$C_{14}H_{11}NO_2$, M 105.1,** has **m 140°.** The ***trans-isomer*** (α) crystallises from *C_6H_6 (must not use animal charcoal), or 30% EtOH and has **m 140°** (137-138°). The ***cis-isomer*** (β) also crystallises from *C_6H_6 but crystals have 0.5*C_6H_6 (**m 62-63°**), and the solvent free compound has **m 112°** (113-114°). ***Note*** that when pure α–isomer is boiled for 15 minutes with 1/10th of its weight of animal charcoal in the minimum volume of *C_6H_6 at its boiling point, filtered from charcoal and cooled, an excellent yield of the β–isomer + 0.5 *C_6H_6 is obtained. Pure β–isomer in aqueous alcoholic $Cu(OAc)_2$ should not produce a colour change, but if contaminated with the α–isomer a greenish colour is produced. [*Beilstein* **7** III 3812, **7** IV 2504.] The α–isomer complexes with Co^{2+}, Pd^{2+}, Ir^{3+}, Rh^{3+}, and Pt^{4+} [Singh et al. *Talanta* **26** 425 *1979*, DOI: 10.1016/0039-9140(79)80107-1].

Benzilic acid (diphenylglycollic acid) *[76-93-7]* **$C_{14}H_{12}O_3$, M 228.3, m 149-151°, 150°, pK^{18} 3.06.** Crystallise benzilic acid from *benzene (*ca* 6ml/g), or hot H_2O. The ***methyl ester*** **$C_{15}H_{14}O_3$**, distils at 187°/13mm and the distillate solidifies with **m 74-75°**. Benzo[*a*]biphenylene *[252-47-1]* **C_6H_{10}, M 202.2, m 72-73°** (compare with β-isomer below)**.** It forms yellow needles from MeOH and sublimes *in vacuo* (**m** 72.0-72.8°). The ***2,4,7-trinitrofluorenone complex*** crystallises as black needles **m 201.5-202.5°**. [Cava & Stucker *J Am Chem Soc* **77** 6022 *1955*, DOI: 10.1021/ja01627a066; Barton et al. *J Chem Soc(C)* 1276 *1967*, DOI: 10.1039/J39670001276; *Beilstein* **5** IV 2462.] ***Benzo[b]biphenylene*** *[259-56-3]* **C_6H_{10}, M 202.2,** has **242.6-243.6°.** It forms yellow crystals from *C_6H_6/cyclohexane **m 234-245°** (sublimation). Slow evaporation of a tertrahydrofuran solution gave colourless triclinic crystals suitable for X-ray diffraction studies [Ferrara et al *Acta Cryst* **C45** 57 *1989*, DOI: 10.1107/S0108270188008765]. The ***2,4,7-trinitrofluorenone complex*** crystallises as red needles from *C_6H_6/MeOH **m 214-216°**. It has been sublimed *in vacuo*. [Jensen & Coleman *Tetrahedron Lett* **No 20** 7 *1959*, DOI: 10.1016/S0040-4039(01)99477-8; Barton et al. *JCS Perkin Trans 1* 967 *1986*, DOI: 10.1039/P19860000967; *Beilstein* **5** IV 2462.]

Benzoic acid *[65-85-0]* **$C_7H_6O_2$, M 122.1, m 122.4°, 122.6-123.1°, b 132.1°/10mm, 146.7°/20mm, 162.6°/40mm, 205.8°/200mm, 249.2°/atm, pK^{15} 4.218, pK^{20} 4.208, pK^{30} 4.205, pK^{40} 4.219, pK^{50} 4.24.** For use as a volumetric standard, analytical reagent grade benzoic acid should be carefully fused to *ca* 130° (to dry it) in a platinum crucible, and then powdered in an agate mortar. Benzoic acid has been crystallised from boiling water (charcoal), aqueous acetic acid, glacial acetic acid, *C_6H_6, aqueous EtOH, petroleum ether (b 60-80°), and from EtOH solution by adding water. The solubility (w/v) in H_2O is 0.21% at 10°, 0.34% at 25°, and 6.8% at 95°. Also its solubility (w/v) in EtOH is 43.5% at ~25° and 67% at 78°; and at ambient temperatures in Et_2O and Me_2CO it is 33%, in $CHCl_3$ it is 22%, in *C_6H_6 it is 10%, in turpentine oil it is 4.3%, and in CCl_4 and CS_2 it is

3.3%. It is readily purified by fractional crystallisation from its melt and by sublimation in a vacuum at 80°. The ***S-benzylisothiuronium salt*** has **m 167°** (from EtOH/H_2O). [*Beilstein* **9** IV 273.] ***Benzoic anhydride*** *[93-97-0]* **$C_{14}H_{10}O_3$, M 226.2,** has **m 42°, b 142.8°/1mm**, **180°/5mm**, **218°/20mm**, **252.7°/60mm**, **299.1°/200mm**, **360°/atm**. Free it from benzoic acid by washing with $NaHCO_3$, then water, and drying. Crystallise it from *benzene (0.5ml/g) by adding just enough petroleum ether (b 40-60°) to cause cloudiness, then cool in ice. It can be distilled without decomposition, but preferably distilled in a vacuum. [Clarke & Rahrs *Org Synth* Coll Vol **1** 91 *1941*, DOI: 10.15227/orgsyn.003.0021; *Beilstein* **19** IV 550.]

(±)-Benzoin (2-hydroxy-2-phenylacetophenone) *[119-53-9, 579-44-2]* **$C_{14}H_{12}O_2$, M 212.3, m 137°, b 194°/12mm**, **344°/768mm**. Crystallise benzoin from CCl_4, hot EtOH (8ml/g, prisms), or 50% acetic acid. Also crystallise it from high purity *benzene, then twice from high purity MeOH, to remove fluorescent impurities [Elliott & Radley *Anal Chem* **33** 1623 *1961*, DOI: 10.1021/ac60179a002]. It is almost insoluble in H_2O (0.03 w/w%), much more so in pyridine (20 w/w%); and it can be sublimed. [Adams & Marvel *Org Synth* Coll Vol **1** 94 *1941,* DOI: 10.15227/orgsyn.001.0033; *Beilstein* **8** IV 1279.] ***(±)-α-Benzoin oxime* (*E*-oxime, Cuprone)** *[441-38-3; E 1143-89-1; 5828-63-2, 574-13-0]* **$C_{14}H_{11}NO_2$, M 227.3,** has **m 151°, 151-152°, 152°.** The oxime crystallises in prisms from *C_6H_6, and is soluble in EtOH, Et_2O, $CHCl_3$ and Me_2CO but not in H_2O. It is used for the spectroscopic determination of Cu^{2+}, Pd^{2+}, Pt^{4+}, Rh^{3+} and V^{5+}. A 0.25% solution in $CHCl_3$ is used for the extraction of Mo and W (in concentrated HCl) and for precipitating V (at pH 2-4), as well as Cu, Pd, Bi, and Au [Singh et al. *Talanta* **26** 425 *1979*, DOI: 10.1016/0039-9140(79)80107-1]. The **β–isomer (*Z*-oxime)** *[7110-50-1]* can be recrystallised from Et_2O to form prisms of the etherate, which lose Et_2O on standing in air, and the ether-free solid has **m** 99°. It also crystallises from EtOH in prisms with **m 99°**. It has antiseptic properties. [*Beilstein* **8** IV 1282.]

R*-(-)-Benzoin** *[5928-66-5]* **$C_{14}H_{12}O_2$, M 212.2, m 131-132.5°, 132°, 135-137°, $[\alpha]_D^{19}$ -115 (c 1.5, Me_2CO), $[\alpha]_D^{12}$ -118 (c 1.2, Me_2CO)** and the ***acetate forms needles with **$[\alpha]_D^{12}$ -217.7 ($CHCl_3$).** The *enantiomeric* ***S*-(+)-benzoin** *[5928-67-6]* **$C_{14}H_{12}O_2$, M 212.2, m 132°, 135-137°, $[\alpha]_D^{20}$ +118 (c 1.5, Me_2CO), $[\alpha]_D^{12}$ +120.5 (c 1.2, Me_2CO)**, and the ***E*-oxime** has **m 164°** (from EtOH) and **$[\alpha]_D^{24}$ +3 ($CHCl_3$)**. These are obtained by crystallisation of the (+)-quinidine diastereoisomeric *benzoin hydrogenphthalate* salts, followed by addition of ice-cold dilute HCl (to remove quinidine), and hydrolysis of the acid phthalates with 1N H_2SO_4/EtOH (40ml/200ml) gives the pure optically active benzoin enantiomers as needles from EtOH with the stated melting points and rotations. [Optical Resolution: Kenyon & Patel *J Chem Soc* 435 *1965*, DOI: 10.1039/JR9650000435.] [*Beilstein* **8** H 167.]

Benzonitrile *[100-47-0]* **C_7H_9N, M 103.1, m -12.9°, b 28.2°/1mm, 69.2°/10mm, 94°/40mm, 191.1°/atm, d_4^{20} 1.010, n_D^{20} 1.528.** It has been purified by steam distillation, the distillate is extracted into Et_2O, washed with dilute $NaHCO_3$, dried overnight with $CaCl_2$, and the Et_2O distilled off. The residue is then dried with $CaSO_4$, $MgSO_4$ or K_2CO_3, and distilled from P_2O_5 in an all-glass apparatus, under reduced pressure (**b 69°/10mm**), collecting the middle fraction. Distillation from CaH_2 causes some decomposition of benzonitrile. Isonitriles can be removed by preliminary treatment with concentrated HCl until the odour of isonitrile (carbylamine) has gone, followed by preliminary drying with K_2CO_3. (This treatment also removes amines.) Steam distil (to remove small quantities of carbylamine). The distillate is extracted into ether, washed with dilute Na_2CO_3, dried overnight with $CaCl_2$, and the ether is removed by evaporation. The residue is distilled at 40mm (**b 96°**) [Kice et al. *J Am Chem Soc* **82** 834 *1960*, DOI: 10.1021/ja01489a020].
Conductivity grade benzonitrile (specific conductance 2 x 10^{-8} mho) is obtained by treatment with anhydrous $AlCl_3$, followed by rapid distillation at 40-50° under vacuum. After washing with alkali and drying with $CaCl_2$, the distillate is redistilled in a vacuum several times at 35° before fractionally crystallising several times by partial freezing. It is dried over finely divided activated alumina from which it is withdrawn when required [Van Dyke & Harrison *J Am Chem Soc* **73** 402 *1951*, DOI: 10.1021/ja01145a132]. [*Beilstein* **9** IV 892.]

Benzo[ghi]perylene (1,12-benzoperylene) *[191-24-2]* **$C_{22}H_{12}$, M 276.3, m 273°, 277-278.5°, 278-280°, b >500°/atm.** It forms light green crystals on recrystallisation from *C_6H_6 or xylene and sublimes at 320-340°/0.05mm [UV: Hopff & Schweizer *Helv Chim Acta* **42** 2315 *1959*, DOI: 10.1002/hlca.19590420704; Clar *Chem Ber* **65** 846 *1932*, DOI: 10.1002/cber.19320650534; Fluoresc. Spectrum: Bowen & Brocklehurst *J Chem Soc* 3875 *1954*, DOI: 10.1039/JR9540003875]. It also recrystallises from propan-1-ol [Altman & Ginsburg *J*

Chem Soc 466 *1959*, DOI: 10.1039/JR9590000458]. The ***1,3,5-trinitrobenzene complex*** has **m 310-313°** (deep red crystals from *C_6H_6), the ***picrate*** has **m 267-270°** (dark red crystals from *C_6H_6), and the ***styphnate*** *(2,4,6-trinitroresorcinol complex)* has **m 234°** (wine red crystals from *C_6H_6). [*Beilstein* **5** IV 2766.]

3,4-Benzophenanthrene (benzo[c]phenanthrene) $C_{18}H_{12}$, *[195-19-7]* **M 228.3, m 65.6-66.2°, 68°.** Crystallise benzo[c]phenanthrene from EtOH, petroleum ether (colourless needles or leaflets), or EtOH/Me_2CO (fine needles). The ***picrate*** crystallises in red needles with **m 125.8-126.2°** (126-127°) from *C_6H_6/light petroleum. Traces of picric acid can be removed from recovered hydrocarbon by passing a *C_6H_6 solution through an Al_2O_3 column. [Newman & Joshel *J Am Chem Soc* **60** 485 *1938*, DOI: 10.1021/ja01269a069; *Beilstein* **5** III 2378, **5** IV 2552.]

Benzophenone (diphenylketone) *[119-61-9]* **$C_{13}H_{10}O$, M 182.2, m 48.5-49°, b 108.2°/1mm, 157.6°/10mm, 197.5°/40mm, 176.8°/400mm, 305.4°/10mm, d_4^{50} 1.0869, n_D^{45} 1.5975, pK^{25} -6.0(-8.4) (aqueous H_2SO_4).** Crystallise it from MeOH, EtOH, cyclohexane, *benzene or petroleum ether, then dry in a current of warm air and store it over BaO or P_2O_5. It is also purified by zone melting and by sublimation [Itoh *J Phys Chem* **89** 3949 *1985*, DOI: 10.1021/j100265a002; Naguib et al. *J Am Chem Soc* **108** 128 *1986*, DOI: 10.1021/ja00261a021; Gorman & Rodgers *J Am Chem Soc* **108** 5074 *1986*, DOI: 10.1021/ja00277a005; Okamoto & Teranishi *J Am Chem Soc* **108** 6378 *1986*, DOI: 10.1021/ja00280a040; Naguib et al. *J Phys Chem* **91** 3033 *1987*, DOI: 10.1021/j100295a078]. Its solubility at ambient temperature is 13% in EtOH, 17% in Et_2O and very high in $CHCl_3$. [Marvel & Sperry *Org Synth* Coll Vol **I** 95 *1941*, DOI: 10.15227/orgsyn.008.0026; *Beilstein* **7** H 411, **7** III 2048, **7** IV 1357.] ***Benzophenone oxime*** *[574-66-3]* **$C_{13}H_{11}NO$, M 197.2,** has **m 140-144°, 142°, 143-144°, pK^{25} 11.18.** Crystallise the oxime from MeOH (4ml/g). [*Beilstein* **7** II 355, **7** III 2063 1370.]

Benzophenone-3,3',4,4'-tetracarboxylic dianhydride (BTDA) *[2421-28-5]* **$C_{17}H_6O_7$, M 322.2, m 218-122°, 218.5-219.5°, 225.5°.** The main impurity is the free acid formed by hydrolysis (check for OH bands in the IR). This can be converted to the dianhydride by treating with Ac_2O (molar ratio of 4 to 1 of acid), heating at 110-120° for 1.5 to 2 hours, cooling to 0—5° and collecting the dianhydride. This is then dissolved in hot dioxane or Me_2CO, filtered and cooled to 10—15°. The moisture sensitive solid is collected and dried at 120—130° *in vacuo*. It sublimes at high vacuum. [Faberov et al. *J Org Chem USSR* **4** 153 (English translation) *1968*.]

Benzopinacol (1,1,2,2-tetraphenyl-1,2-ethanediol) *[464-72-2]* **$C_{26}H_{22}O_2$, M 366.5, m 170-180° (depends on heating rate), 171-173°, 188-190°.** Crystallise benzopinacol from EtOH, petroleum ether (b 90-100°), or *C_6H_6 (prisms with 1 mol of *C_6H_6). Its solubility (v/v) in 95% EtOH is 2.5% (at 78°), in *C_6H_6 it is 3.8% (at 80°), and in AcOH it is 8.7% (at 118°); but in Et_2O, $CHCl_3$ and CS_2 it is freely soluble. Since it decomposes at its melting point it is best to place the melting point tube in a bath at 150°, then to heat slowly whereby it melts at **193-195°**. [Bachmann *Org Synth* Coll Vol **2** 71 *1943*, DOI: 10.15227/orgsyn.014.0008; *Beilstein* **6** IV 7053.]

Benzo[a]pyrene (3,4-benzpyrene, benzo[dcf]chrysene) *[50-32-8]* **$C_{20}H_{12}$, M 252.3, m 177.5-178°, 179.0-179.5°, b 310-312°/10mm, 495°/atm.** A solution of 250mg of benzo[a]pyrene in 100ml of *benzene is diluted with an equal volume of hexane, then passed through a column of alumina, $Ca(OH)_2$ and Celite (3:1:1). The adsorbed material is developed with a 2:3 *benzene/hexane mixture. (It showed as an intensely fluorescent zone.) The main zone is eluted with 3:1 acetone/EtOH, and is transferred into 1:1 *benzene-hexane by adding H_2O. The solution is washed, dried with Na_2SO_4, evaporated and crystallised from *benzene by the addition of MeOH [Lijinsky & Zechmeister *J Am Chem Soc* **75** 5495 *1953*, DOI: 10.1021/ja01118a009]. *Alternatively*, it can be chromatographed on activated alumina, eluted with a cyclohexane/*benzene mixture containing up to 8% *benzene, and the solvent is evaporated under reduced pressure [Cahnmann *Anal Chem* **27** 1235 *1955*, DOI: 10.1021/ac60104a009], and crystallised from EtOH [Nithipatikom & McGown *Anal Chem* **58** 3145 *1986*, DOI: 10.1021/ac00127a050]. [*Beilstein* **5** III 2517, **5** IV 2687.] It intercalates with DNA. **CARCINOGENIC.** ***Benzo[e]pyrene*** **(1,2-benzpyrene)** *[192-97-2]* has **m 178-179°, 178-180°.** Purify it by passage through an Al_2O_3 column (Woelm, basic, activity I), elute with *C_6H_6 and recrystallise from 2 volumes of EtOH/*C_6H_6 (4:1). It forms colourless or light yellow prisms or needles. [Campbell *J Chem Soc* 3659 *1954*, DOI: 10.1039/JR9540003659; Buchta & Kröger *Justus Liebigs Ann Chem* **705** 190 *1967*, DOI: 10.1002/jlac.19677050122.] The ***1,3,5-trinitrobenzene complex*** has **m 253-254°** (orange needles from EtOH),

the ***picrate*** prepared by mixing 20mg in 1ml of *C_6H_6 with 20mg of picric acid in 2ml *C_6H_6, collecting the deep red crystals, and recrystallising from *C_6H_6 has **m 228-229°** [NMR: Cobb & Memory *J Chem Phys* **47** 2020 *1967*, DOI:org/10.1063/1.1712232]. [*Beilstein* **5** III 2520, **5** IV 2689.] **CARCINOGEN.**

p-**Benzoquinone** *[106-51-4]* **$C_6H_4O_2$, M 108.1, m 113°, 113-115°, 115.7°, b 293°/atm.** Purify *p*-benzoquinone in one or more of the following ways: steam distillation followed by filtration and drying (e.g. in a desiccator over $CaCl_2$), recrystallisation from petroleum ether (b 80-100°), *benzene (with, then without, charcoal), water or 95% EtOH, sublimation under vacuum (e.g. from room temperature to liquid N_2) and recrystallisation from tetrachloroethylene. It slowly decomposes and should be stored, refrigerated, in an evacuated or sealed glass vessel in the dark. It should be resublimed before use. It is a radical inhibitor, solvates with H_2O in the liquid and vapour forms, and has been used as a dehydrogenating agent in the Wettstein-Oppenauer oxidation [Review: Mandell *J Am Chem Soc* **78** 3199 *1956*, DOI: 10.1021/ja01594a061; Wolfenden et al. *J Am Chem Soc* **109** 463 *1987*, DOI: 10.1021/ja00236a026; *Beilstein* **7** IV 2065.]

1-Benzosuberone (6,7,8,9-tetrahydrobenzocyclohepten-5-one) *[826-73-3]* **$C_{11}H_{12}O$, M 160.2, b 80-85°/0.5mm, 90-93°/1mm, 138-139°/12mm, 154°/15mm, 175-175°/40mm, d_4^{20} 1.086, n_D^{20} 1.5638.** Purify it by dissolving in toluene, washing with aqueous 5% NaOH, then brine, drying ($MgSO_4$), and distilling. The ***2,4-dinitrophenylhydrazone*** has **m 210.5°, 207-208°** (from $CHCl_3$/MeOH). The ***Z-O-picryloxime*** has **m 156-157°** (from Me_2CO/MeOH), the ***E-O-picryloxime*** has **m 107°**. The ***oxime*** has **m 106.5-107.5°**. [UV: Gilmore & Horton *J Am Chem Soc* **73** 1411 *1951*, DOI: 10.1021/ja01148a004; Hedden & Brown *J Am Chem Soc* **75** 3744 *1953*, DOI: 10.1021/ja01111a040; Huisgen et al. *Chem Ber* **90** 1844 *1957*, DOI: 10.1002/cber.19570900923; *Beilstein* **7** IV 1029.]

Benzoylacetone (1-phenyl-1,3-butanedione) *[93-91-4]* **$C_{10}H_{10}O_2$, M 162.2, m 58.5-59.0°, 61°, b 128-130°/10mm.** Crystallise benzoylacetone from Et_2O or MeOH and dry it under vacuum at 40°. It is readily distilled in a vacuum and the colourless distillate solidifies. [*Beilstein* **7** IV 2151.]

2-Benzoylbenzoic acid *[85-52-9]* **$C_{14}H_{10}O_3$, M 226.2, m 126-129°, 129.2, 130°, pK^{25} 3.54.** Recrystallise the acid from *C_6H_6 or cyclohexane, but it is best recrystallised by dissolving in a small volume of hot toluene and then adding just enough petroleum ether to cause turbidity, and cool. Dry it in a low vacuum at 80°. It can be sublimed at 230-240°/0.3mm [Bray et al. *J Chem Soc* 265 *1957*, DOI: 10.1039/JR9570000265]. The ***S-benzylisothiuronium salt*** has **m 177-178°** (from EtOH). [Lewenz & Serijan *J Am Chem Soc* **75** 4087 *1953*, DOI: 10.1021/ja01112a514; *Beilstein* **10** H 747, **10** IV 2977.] ***3-Benzoylbenzoic acid*** *[579-18-0]* has **m 164-166°, 165°, pK_{Est}~3.5.** Crystallise the acid from EtOH and sublime it at 160°/1mm. [*Beilstein* **10** H 752, **10** III 3304, **10** IV 2982.] ***4-Benzoylbenzoic acid*** *[611-95-0]* **$C_{14}H_{10}O_3$, M 226.2,** has **m 196.5-198°, 197-200°, pK_{Est} ~3.7.** Dissolve the acid in hot H_2O by adding enough aqueous KOH solution till distinctly alkaline, filter and then acidify with drops of concentrated HCl. Filter off, wash the solid with cold H_2O, dry it at 100°, and recrystallise it from EtOH. [Wertheim *J Am Chem Soc* **55** 2540 *1933*, DOI: 10.1021/ja01333a051; *Beilstein* **10** H 753, **10** IV 3305.]

Benzoyl chloride *[98-88-4]* **C_7H_5ClO, M 140.6, m -1.0°, b 56°/4mm, 100°/35mm, 196.8°/745mm, d_4^{20} 1.2120, n_D^{10} 1.5537.** A solution of benzoyl chloride (300ml) in *C_6H_6 (200ml) is washed with two 100ml portions of cold 5% $NaHCO_3$ solution, separated, dried with $CaCl_2$ and distilled [Oakwood & Weisgerber *Org Synth* Coll Vol **3** 112 *1955*, DOI: 10.15227/orgsyn.024.0014]. Repeated fractional distillation at 4mm Hg through a glass helices-packed column (avoiding porous porcelain or silicon-carbide boiling chips, and hydrocarbon or silicon greases on the ground joints) gave benzoyl chloride that did not darken on addition of $AlCl_3$. Further purification is achieved by adding 3 mole% each of $AlCl_3$ and toluene, standing overnight, and distilling off the benzoyl chloride at 1-2mm [Brown & Jensen *J Am Chem Soc* **80** 2291 *1958*, DOI: 10.1021/ja01542a065]. Refluxing for 2 hours with an equal weight of thionyl chloride before distillation has also been used. [*Beilstein* **9** IV 721.] *Strong* **IRRITANT**. *Use in a fume cupboard.*

Benzoyl disulfide (dibenzoyl disulfide) *[644-32-6]* **$C_{14}H_{10}O_2S_2$, M 274.3, m 131.2-132.3°.** About 300ml of solvent is blown off from a filtered solution of dibenzoyl disulfide (25g) in acetone (350ml). The remaining acetone is decanted from the solid which is recrystallised first from 300ml of 1:1 (v/v) EtOH/EtOAc, then from

300ml of EtOH, and finally from 240ml of 1:1 (v/v) EtOH/ethyl acetate. The yield is about 40% [Pryor & Pickering *J Am Chem Soc* **84** 2705 *1962*, DOI: 10.1021/ja00873a012]. [*Beilstein* **9** H 424, **9** II 289, **9** III 1977.] *Handle in a fume cupboard because of* **TOXICITY** *and obnoxious odour.*

Benzoylformic acid (phenylglyoxylic acid) *[611-73-4]* **$C_8H_6O_3$, M 150.14, m 62-65°, 64.5-65.5°, 67°, b 84°/0.1mm, 163-167°/15mm, pK^{25} 1.39 (1.79).** If the sample is oily, then it may contain H_2O. In this case dry it in a vacuum desiccator over P_2O_5 or KOH until crisp. For further purification dissolve 5.5g in hot CCl_4 (750ml), add charcoal (2g, this is necessary otherwise the acid may separate as an oil), filter, cool in ice-water until crystallisation is complete. Filter the acid off, and the solvent on the crystals is removed by keeping the acid (4.5g) in a vacuum desiccator for 2 days. Slightly yellow crystals are obtained. It can be recrystallised also from *C_6H_6/petroleum ether, and can be distilled in a vacuum. The acid is estimated by titration with standard NaOH. The ***phenylhydrazone*** is recrystallised from EtOH, **m 163-164°**, and the ***semicarbazone acid*** has **m 259°(dec)** (from EtOH). The ***methyl ester*** distils at **137°/14mm, 110-111°/2mm, n_D^{20} 1.5850**. [Baer & Kates *J Am Chem Soc* **67** 1482 *1945*, DOI: 10.1021/ja01225a022; Schaefer & Corey *J Org Chem* **24** 1825 *1959*, DOI: 10.1021/jo01093a629; *Beilstein* **10** H 654, **10** IV 2737.]

Benzoyl isothiocyanate *[532-55-8]* **$C_8H_{15}NOS$, M 163.2, m 25.5-26°, b 72.5-73°/6mm, 88-91°/20mm, 94-96°/21mm, 202.5-204°/724mm, 250-255°/atm, d_4^{20} 1.213, n_D^{20} 1.6354.** Distil the isothiocyanate over a small amount of P_2O_5, whereby the distillate crystallises in prisms. It is readily hydrolysed by H_2O to give benzamide and benzoylurea, but with NH_3 it gives ***benzoylurea* m 210°** which can be recrystallised from EtOH. [Hill & Degnan *J Am Chem Soc* **62** 1595 *1940,* DOI: 10.1021/ja01863a073; Terss & McEwen *J Am Chem Soc* **76** 580 *1954*, DOI: 10.1021/ja01631a075; Frank & Smith *Org Synth* Coll Vol **3** 735 *1955*, DOI:10.15227/orgsyn.028.0089, *Beilstein* **9** IV 777.]

Benzoyl peroxide *[94-36-0]* **$C_{14}H_{10}O_4$, M 242.2, m 95°(dec), 103-106°(dec).** Dissolve dibenzoyl peroxide in $CHCl_3$ at room temperature and precipitate it by adding an equal volume of MeOH or petroleum ether. Similarly, it is precipitated from acetone by adding two volumes of distilled water. It has also been crystallised from 50% MeOH and from diethyl ether. Dry it under vacuum at room temperature for 24 hours. Store it in a desiccator in the dark at 0°. When purifying in the absence of water it can be **EXPLOSIVE**, and operations should be done on a very small scale with adequate protection. Large amounts should be kept moist with water and stored in a refrigerator. It is a free radical initiator. [Kim et al. *J Org Chem* **52** 3691 *1987* DOI: 10.1021/jo00392a038; *Beilstein* **9** IV 777.] It is also available commercially blended with dibutyl phthalate, tricresyl phosphate, dicyclohexyl phthalate or moistened with H_2O. Its activity can be assessed by analysis [Braun *Org Synth* Coll Vol **I** 431 *1941*, DOI: 10.15227/orgsyn.008.0030].

***p*-Benzoylphenol (4-hydroxybenzophenone)** *[1137-42-4]* **$C_{13}H_{10}O_2$, M 198.2, m 132-135°, 133.4-134.8°, pK^{25} 7.95.** Dissolve *p*-benzoylphenol in hot EtOH (charcoal), filter and cool. *Alternatively*, crystallise it once from EtOH/H_2O and twice from *benzene [Grunwald *J Am Chem Soc* **73** 4934 *1951*, DOI: 10.1021/ja01154a138; Dryland & Sheppard *JCS Perkin Trans 1* 125 *1986*, DOI: 10.1039/P19860000125]. [*Beilstein* **8** IV 1263.]

***N*-Benzoyl-*N*-phenylhydroxylamine** *[304-88-1]* **$C_{13}H_{11}NO_2$, M 213.2, m 118-120°, 121-122°.** Recrystallise it from hot water, *benzene Et_2O/hexane or acetic acid. It complexes with metals. [*Beilstein* **15** III 8, **15** IV 7.]

***N*-Benzoyl-*o*-tolylhydroxylamine** *[1143-74-4]* **$C_{14}H_{13}NO_2$, M 227.3, m 104°.** Recrystallise the hydroxylamine from aqueous EtOH. [*Beilstein* **15** III 8, **15** IV 7.]

Benzyl acetate *[140-11-4]* **$C_9H_{10}O_2$, M 150.2, m -51°, b 92-93°/10mm, 134°/102mm, 214.9°/760mm, d_4^{20} 1.0562, n_D^{25} 1.4994.** Purify the acetate by fractional distillation, preferably in a good vacuum. Values of n^{25} of 1.5232-1.5242 are too high and should be nearer to 1.4994. [Merker & Scott *J Org Chem* **26** 5180 *1961*, DOI: 10.1021/jo01070a095; *Beilstein* **6** IV 2262.]

Benzyl acetoacetate *[5396-89-4]* **$C_{11}H_{12}O_3$, M 192.2, b 130°/2mm, 156-157°/10mm, 162-167°/15mm, 275-277°/atm, d_4^{20} 1.114, n_D^{20} 1.514.** Fractionate the ester and collect fractions with the expected physical prop-

erties. Otherwise add *ca* 10% by weight of benzyl alcohol and heat in an oil bath (160-170°, open vessel) for 30 minutes during which time excess of benzyl alcohol will have distilled off, then fractionate. [Baker et al. *J Org Chem* **17** 77 *1952*, DOI: 10.1021/jo01135a009; *Beilstein* **6** IV 2480.]

4'-Benzylacetophenone *[782-92-3]* **$C_{15}H_{14}O$, M 210.3, m 37°, 38°, 39°, b 197-198°/9mm, 209-210°/15mm.** Distil it in a vacuum, then recrystallise it from EtOH (*ca* 1ml/g). The ***oxime*** has **m 99.5°** (from 60% aqueous EtOH). [*Beilstein* **7** H 449, **7** III 2176.]

Benzyl alcohol *[100-51-6]* **C_7H_8O, M 108.1, m -15.3°, b 58°/1mm, 93°/10mm, 129°/60mm, 205.5°/atm, d_4^{20} 0.981, n_D^{20} 1.54033, pK^{25} 15.4.** It is usually purified by careful fractional distillation under reduced pressure in the absence of air. Benzaldehyde, if present, can be detected by UV absorption at 283nm. It has also been purified by shaking with aqueous KOH and extracting with peroxide-free diethyl ether. After washing with water, the extract is treated with saturated NaHS solution, filtered, washed, dried with CaO and distilled under reduced pressure [Mathews *J Am Chem Soc* **48** 562 *1926*, DOI: 10.1021/ja01414a002]. Peroxy compounds can be removed by shaking with a solution of Fe^{2+} followed by washing the alcohol layer with distilled water and fractionally distilling it. Its solubility at ambient temperature in H_2O is 4%w/v, and in 50% aqueous EtOH it is 67%w/v. [*Beilstein* **6** IV 2222.] § A polystyrene bound (at the *p*-position) resin which is cross-linked with divinylbenzene is available commercially.

Benzylamine *[100-46-9]* **C_7H_9N, M 107.2, m 10°, b 98°/12mm, 178°/742mm, 185°/768mm, d_4^{20} 0.981, n_D^{20} 1.5392, pK^{25} 9.33.** Dry it with NaOH or KOH, then distil it under N_2, through a column packed with glass helices, taking the middle fraction. Also distil it from zinc dust under reduced pressure. The ***picrate*** has **m 196°** (from EtOH), and the ***p-toluenesulfonamide*** has **m 116°** (from MeOH). [*Beilstein* **12** IV 2155.] ***Benzylamine hydrochloride*** *[3287-99-8]* **C_7H_9N. HCl, M 143.6,** has **m 248° (rapid heating), 253°**. Crystallise the salt from water. [*Beilstein* **12** IV 2155.]

N*-Benzylaniline (*N*-phenylbenzylamine)** *[103-32-2]* **$C_{13}H_{13}N$, M 183.4, m 36°, 37-38°, b 306-307°/atm, d_4^{20} 1.061, pK^{25} 4.04.** Crystallise the amine from petroleum ether (b 60-80°) (*ca* 0.5ml/g). The ***picrate has **m 113°** (from Et_2O). [*Beilstein* **12** H 1023, **12** I 449, **12** II 548, **12** III 2215, **12** IV 2172.]

Benzyl bromide *[100-39-0]* **C_7H_7Br, M 171.0, m -4°, -3.9°, b 85°/12mm, 127°/80mm, 192°/760mm, 198-199°/atm, d_4^{20} 1.438, n_D^{25} 1.575.** Wash benzyl chloride with concentrated H_2SO_4 (CARE), water, 10% Na_2CO_3 or $NaHCO_3$ solution, and again with water. Dry it with $CaCl_2$, Na_2CO_3 or $MgSO_4$ and fractionally distil it in the dark, under reduced pressure. It has also been thoroughly degassed at 10^{-6} mm and redistilled in the dark. This gives material with λ_{max} at (MeCN): 226nm (ε 8200) [Kosower & Mohammed *J Am Chem Soc* **93** 2709 *1971*, DOI: 10.1021/ja00740a021]. [*Beilstein* **5** IV 829.] *Handle in a fume cupboard, extremely* **LACHRYMATORY.**

Benzyl bromoacetate *[5437-45-6]* **$C_9H_9BrO_2$, M 229.1, b 96-98°/0.1mm, 146°/12mm, 166-170°/22mm, d_4^{20} 1.444, n_D^{25} 1.5412.** Dilute the ester with Et_2O, wash it with 10% aqueous $NaHCO_3$, H_2O, dry ($MgSO_4$) and fractionate it using a Fenske (glass helices packing) column. [Bergmann & Szinai *J Chem Soc* 1521 *1956*, DOI: 10.1039/JR9560001521; *Beilstein* **6** IV 2265.] **LACHRYMATORY.**

N*-Benzyl-*tert*-butylamine (*N*-*tert*-butylbenzylamine)** *[3378-72-1]* **$C_{11}H_{17}N$, M 163.3, b 91°/12mm, 109-110°/25mm, 218-220°/atm, d_4^{20} 0.899, n_D^{25} 1.4942, pK^{25} 10.19.** Dissolve the amine in Et_2O, dry it over KOH pellets, filter and fractionate it in a N_2 atmosphere to avoid reaction with CO_2 from the air. The ***hydrochloride has **m 245-246°(dec)** (from MeOH/Me_2CO) and the ***perchlorate*** has **m 200-201°**. [Freifelder et al. *J Am Chem Soc* **80** 4320 *1958*, DOI: 10.1021/ja01549a051; *Beilstein* **12** IV 2166.]

Benzyl carbamate *[621-84-1]* **$C_8H_9NO_2$, M 151.2, m 86°, 86-88°, 90-91°.** If it smells of NH_3, then dry it in a vacuum desiccator and recrystallise it from 2 volumes of toluene and dry it in a vacuum desiccator again. It forms glistening plates from toluene, and can be recrystallised from H_2O [Martell & Herbst *J Org Chem* **06** 878 *1941*, DOI: 10.1021/jo01206a013; Carter et al. *Org Synth* Coll Vol **3** 167 *1955* DOI: 10.15227/orgsyn.023.0013]. [*Beilstein* **6** IV 2278.]

Benzyl chloride *[100-44-7]* **C_7H_7Cl, M 126.6, m -48° to 43°, b 63°/8mm, 179°/atm, d_4^{20} 1.100, n_D^{20} 1.538.** Dry it with $MgSO_4$ or $CaSO_4$, or reflux it with fresh Ca turnings, then fractionally distil it under reduced pressure, collecting the middle fraction and storing it over CaH_2 or P_2O_5. It has also been purified by passage through a column of alumina. *Alternatively*, it is dried over $MgSO_4$ and distilled in a vacuum. The middle fraction is degassed by several freeze-thaw cycles and then fractionated in an 'isolated fractionating column' (which has been evacuated and sealed off at ~10^{-6} mm) over a steam bath. The middle fraction is retained. The final samples are distilled in a vacuum from this sample and again retaining the middle fraction. The purity is >99.9% (no other peaks are visible by GLC, and the NMR spectrum is consistent with the structure. [Kosower & Mohammed *J Am Chem Soc* **93** 2709 *1971*, DOI: 10.1021/ja00740a021], *Beilstein* **5** IV 809.] **IRRITANT** and s*trongly* **LACHRYMATORY.**

***N*-Benzyl-3-chloropropionamide (Beclamide)** *[501-68-8, 24752-66-7]* **$C_{10}H_{12}ClNO$, M 197.7, m 94°, 96°.** Crystallise the amide from MeOH. [*Beilstein* **12** III 2257, **12** IV 2234.] It possesses anticonvulsant activity [Ahmadi et al. *J Pharm Pharmacol* **47** 876 *1995*, DOI: 10.1111/j.2042-7158.1995.tb05757.x], and used as an adjunct in the treatment of schizophrenia [Raptis et al. *Acta Psych Scand* **8** 162 *1990*; DOI: 10.1111/j.1600-0447.1990.tb06472.x].

Benzyl cinnamate *[103-41-3]* **$C_{16}H_{14}O_2$, M 238.3, m 34-35°, 39°, b 154-157°/0.5mm, 195-200°/5mm, 228-230°/22mm, d^{15} 1.109.** Recrystallise the ester to a constant melting point from 95% EtOH. It has the odour of balsam. *Alternatively*, dissolve it in Et_2O, wash it with 10% aqueous Na_2CO_3, H_2O, dry (Na_2SO_4), evaporate and fractionate it under reduced pressure using a short Vigreux column. It decomposes when boiled at atmospheric pressure. [Eliel & Anderson *J Am Chem Soc* **74** 547 *1952*, DOI: 10.1021/ja01122a081; Bender & Zerner *J Am Chem Soc* **84** 2550 *1962*, DOI: 10.1021/ja00872a019; *Beilstein* **9** IV 2012.]

Benzyl cyanide *[140-29-4]* **C_8H_7N, M 117.1, m -24°, b 60°/1mm, 100°/8mm, 233.5°/760mm, d_4^{20} 1.015, n_D^{20} 1.523.** Any benzyl isocyanide impurity can be removed by shaking vigorously with an equal volume of 50% H_2SO_4 at 60°, washing with saturated aqueous $NaHCO_3$, then half-saturated NaCl solution, drying and fractionally distilling under reduced pressure. Distillation from CaH_2 causes some decomposition of this compound: it is better to use P_2O_5. Other purification procedures include passage through a column of highly activated alumina, and distillation from Raney nickel. *Precautions should be taken because of possible formation of free* **TOXIC** *cyanide, use an efficient fume cupboard*. [Adams & Thai *Org Synth* Coll Vol **1** 107 *1943*, DOI: 10.15227/orgsyn.002.0009; *Beilstein* **9** IV 1663.]

N*-Benzyl dimethylamine (BDMA, DMBA)** *[103-83-3]* **$C_9H_{13}N$, M 135.2, b 66-67°/15m. 83-84°/30mm, 98-99°/24mm, 181°/760mm, d_4^{20} 0.898, n_D^{20} 1.516, pK^{25} 8.91.** Dry the amine over KOH pellets and fractionate it over Zn dust in a CO_2–free atmosphere. It has a pKa^{25} of 8.25 in 45% aqueous EtOH. Store it under N_2 or in a vacuum. The ***picrate has **m 94-95°**, and the ***picrolonate*** has **m 151°** (from EtOH). [Skita & Keil *Chem Ber* **63** 34 *1930*, DOI: 10.1002/cber.19300630104; Coleman *J Am Chem Soc* **55** 3001 *1933,* DOI: 10.1021/ja01334a067; Devereux et al. *J Chem Soc* 2845 *1957*, DOI: 10.1039/JR9570002845.] The ***tetraphenyl borate salt*** has **m 182-185°**. [Crane *Anal Chem* **28** 1794 *1956*, DOI: 10.1021/ac60119a052; *Beilstein* **12** IV 2161.]

Benzyldimethyloctadecylammonium chloride *[122-19-0]* **$C_{27}H_{50}ClN$, M 424.2, m 150-158° (sinters at 120°.** Crystallise the salt from acetone, EtOAc or EtOAc/ Et_2O. [Sumiki et al. *J Agric Chem Soc Jpn* **26** 325 *1952*, *Chem Abstr* **47** 3505 *1953*, *Beilstein* **12** III 2212, **12** IV 2168.]

Benzyl ether (dibenzyl ether) *[103-50-4]* **$C_{14}H_{14}O$, M 198.3, m 1.3-3.5°, b 158-160°/0.1mm, 173-174°/21mm, 298°/atm with some dec, d_4^{20} 1.043, n_D^{20} 1.54057.** Reflux the ether over sodium, then distil it under reduced pressure. It been purified by fractional freezing. [*Beilstein* **6** IV 2240.]

N*-Benzyl-*N*-ethylaniline** *[92-59-1]* **$C_{15}H_{17}N$, M 221.3, b 170-180°/14mm, 212-222°/54mm, 285-286°/710mm, 312-313°/atm (dec), d_4^{20} 1.029, n_D^{20} 1.595, pK_{Est} ~4.6.** Dry the amine over KOH pellets and fractionate it. The ***picrate crystallises from $*C_6H_6$ as lemon yellow crystals **m 126-128°** (softening at 120°). [Forrest et al. *J Chem Soc* 303 *1951*, DOI: 10.1039/JR9510000303; IR: Hill & Meakins *J Chem Soc* 760 *1958*, DOI: 10.1039/JR9580000760; *Beilstein* **12** H 1026, **12** IV 2176.]

Benzyl ethyl ether *[539-30-0]* **$C_9H_{12}O$, M 136.2, b 65°/10mm, 186°, d_4^{20} 0.949, n_D^{20} 14955.** Dry the ether with $CaCl_2$ or NaOH, then fractionally distil it. It is insoluble in H_2O, but steam distils with it. [Letsinger & Pollart *J Am Chem Soc* **78** 6079 *1956*, DOI: 10.1021/ja01604a036; *Beilstein* **6** III 1454, **6** IV 2229.]

Benzyl ethyl ketone (1-phenylbutan-2-one) *[1007-32-5]* **$C_{10}H_{12}O$, M 148.2, b 49-49.5°/0.01mm, 66-69°/1mm, 83-85°/5mm, 101-102°/10mm, 229-233°/atm, d_4^{20} 0.989, n_D^{25} 1.5015.** Purify the ketone by fractionation using an efficient column. It can be converted into the ***oxime*** which is distilled, **b 117-118°/2mm**, **145-146°/15mm**, d_{25}^{25} 1.036, n_D^{25} 1.5363; decompose the oxime, and the ketone is redistilled. It can also be purified *via* the ***semicarbazone*** which has **m 154-155°**. [Myers et al. *J Am Chem Soc* **77** 5655 *1955*, DOI: 10.1021/ja01626a056; Hass et al. *J Org Chem* **15** 8 *1950*, DOI: 10.1021/jo01147a002; *Beilstein* **7** IV 712.]

N*-Benzylhydroxylamine hydrochloride** *[29601-98-7]* **$C_7H_{10}ClNO$, M 159.6, m 108-110°(sublimes), pK_{Est} ~4.7.** Crystallise it by dissolving it in EtOH containing a few drops of EtOH/HCl and adding dry Et_2O. The ***free base *[622-30-0]* **C_7H_9NO, M 123.1, m ~105°, b 253.9°/760mm,** can be obtained from the hydrochloride by treatment with ethanolic NH_3, filter the NH_4Cl off, and evaporate the solvent. *Alternatively*, dissolve the salt in EtOH or MeOH, shake with a strong anion exchange resin, filter off the resin and evaporate. Strong irritant of the skin, eyes and respiratory system. *All necessary precautions should be taken*. [*Beilstein* **15** H 18, **15** IV 21.]

***O*-Benzylhydroxylamine hydrochloride** *[2687-43-6]* **$C_7H_{10}ClNO$, M 159.6, m 230-235°, 234-238°(sublimes), pK_{Est} ~5.9.** Recrystallise the hydrochloride from H_2O or EtOH. [Hearn & Ward *Aust J Chem* **22** 161 *1969*, DOI: 10.1071/CH9690161]. It has antitubercular activity [Truitt et al. *J Am Chem Soc* **74** 3956 *1952*, DOI: 10.1021/ja01135a523]. *Beilstein* **6** III 1552, **6** IV 2562.]

N*-Benzylideneaniline** *[538-51-2]* **$C_{13}H_{11}N$, M 181.2, m 48° (54°), 56°, b 310°/760mm.** It is steam volatile and crystallises from *benzene or 85% EtOH. The ***picrate has **m 159°**. [Bigelow & Eatough *Org Synth* Coll Vol **1** 80 *141*, DOI: 10.15227/orgsyn.008.0022; *Beilstein* **12** H 195, **12** I 169, **12** II 113, **12** III 319, **12** IV 311.]

Benzylidene malononitrile *[2700-22-3]* **$C_{10}H_6N$, M 155.2, m 83-84°, 87°.** Recrystallise the nitrile from EtOH [Bernasconi et al. *J Am Chem Soc* **107** 3612 *1985*, DOI: 10.1021/ja00298a035]. It has λ_{max} at 307nm (EtOH). [*Beilstein* **9** H 895, **9** II 640, **9** III 4380, **9** IV 3462.]

Benzyl isocyanate *[3173-56-6]* **C_8H_7NO, M 133.2, b 82-84°/10mm, 87°/14mm, 95°/17mm, 101-104°/33mm, d_4^{20} 1.08, n_D^{20} 1.524.** Purify the isocyanate by fractionation through a two-plate column. It is a viscous liquid and is **TOXIC**. [Haworth et al. *J Chem Soc* 182 *1947*, DOI: 10.1039/JR9470000182; Ferstandig & Scherrer *J Am Chem Soc* **81** 4838 *1959*, DOI: 10.1021/ja01527a022; IR: Derkosch et al. *Monatsh Chem* **88** 35 *1957*, DOI: 10.1007/BF01075427; *Beilstein* **12** IV 2276.]

Benzyl isothiocyanate (Benzyl mustard oil) *[622-78-6]* **C_8H_7NS, M 149.2, b 123-124°/1mm, 138-140°/20mm, 255-260°/atm, d_4^{20} 1.1234, n_D^{20} 1.6039.** Dissolve benzyl isothiocyanate in Et_2O, filter, if there is any solid, and distil it through an efficient column at 11mm with a bath temperature at *ca* 150°. Characterise it by reacting (0.5ml) in EtOH (1ml) with 50% $NH_2NH_2.H_2O$ (2 ml) to give ***4-benzylthiosemicarbazide*** as colourless needles which are recrystallised from EtOH, **m 130°**. **TOXIC** [Hoggarth & Young *J Chem Soc* 1582 *1950*, DOI: 10.1039/JR9500001582; Schmidt et al. *Justus Liebigs Ann Chem* **612** 11 *1958*, DOI: 10.1002/jlac.19586120103; IR and UV: Svátek et al. *Acta Chem Scand* **13** 442 *1959*, DOI: 10.3891/acta.chem.scand.13-0442; *Beilstein* **12** IV 2276.]

Benzylmalonic acid (β-phenylisosuccinic acid) *[616-75-1]* **$C_{10}H_{10}O_4$, M 194.2, m 119-120°, 121°, pK_1^{25} 2.91, pK_2^{25} 5.87.** Crystallise the acid from *C_6H_6 or *C_6H_6/petroleum ether. [Drummond & Waters *J Chem Soc* 2456 *1954*, DOI: 10.1039/JR9540002456]. The ***bis-S-benzylisothiuronium salt*** has **m 161-162°** (from EtOH) [Friedger & Pedersen *Acta Chem Scand* **9** 1425 *1955*, DOI:10.3891/acta.chem.scand.09-1425]. [*Beilstein* **9** III 4283, **9** IV 3357.] ***Diethyl benzylmalonate*** *[607-81-8]* $C_{14}H_{18}O_4$, M 250.3, b 140-140.5°/1.5mm, 150-152°/4mm, 162-163°/10mm, d^{25} 1.064, n_D^{20} 1.486, was prepared from the acid with EtOH/*C_6H_6/H_2SO_4/24hrs then workup [Gardner & Rydon *J Chem Soc* 42 *1938*, DOI: 10.1039/JR9380000042].

(-)-*N*-Benzyl-*N*-methylephedrinium bromide [benzyl(2-hydroxy-1-methyl-2-phenethyl) dimethyl-ammonium bromide] *[58648-09-2]* **$C_{18}H_{24}BrNO$, M 350.3, m 209-211°, 212-214°, $[\alpha]_D^{25}$ -3.8° (c 1.45, MeOH), $[\alpha]_D^{20}$ -5.3° (c 1.45, MeOH).** Recrystallise the bromide from MeOH/Et_2O. [Horner & Brich *Justus Liebigs Ann Chem* 710 *1978*, DOI: 10.1002/jlac.197819780504.] The ***chloride*** is recrystallised from EtOAc/*n*-hexane, **m 198-199°** $[\alpha]_D^{25}$ -8.67° (c 1.45, MeOH). [Julia et al. *JCS Perkin Trans 1* 574 *1981*, DOI: 10.1039/P19810000574; *Beilstein* **13** IV 1890.]

Benzyl 4-nitrophenyl carbonate *[13795-24-9]* **$C_{14}H_{11}NO_5$, M 273.2, m 78-80°.** Dissolve the carbonate in Et_2O, wash with H_2O (3x) and saturated aqueous NaCl, dry ($MgSO_4$), evaporate this in a vacuum and recrystallise the residue from a small volume of MeOH, **m 78-79°**. *Alternatively*, dissolve it in Et_2O, wash it with N HCl (2x), 0.5N $NaHCO_3$ (4x) then H_2O, dry (Na_2SO_4), evaporate the Et_2O and recrystallise the residue from *C_6H_6/petroleum ether, **m 79-80°**. The ***2-nitro-isomer*** has **m 27-28°, b 151°/11mm**. [Khosla et al. *Indian J Chem* **5** 279 *1967*, Wolman et al. *J Chem Soc (C)* 689 *1967*, DOI: 10.1039/J39670000689; *Beilstein* **6** IV 2277.]

Benzyloxyacetyl chloride *[19810-31-2]* **$C_9H_9ClO_2$, M 184.6, b 81°/0.2mm, 84-87°/0.4mm, 105-107°/5mm, d_4^{20} 1.19, n_D^{20} 1.523.** Check the IR to see if there are OH bands. If so, then it may be contaminated with free acid formed by hydrolysis. Add oxalyl chloride (amount depends on contamination and needs to be judged, *ca* 3mols), heat at 50° in the absence of moisture for 1 hour and fractionate twice, **b 81°/0.2mm** (with bath temperature at 81°). Excessive heating results in decomposition to give benzyl chloride. The ***anilide*** is formed by adding aniline in $CHCl_3$ solution and has **m 49°**. It has been used for the synthesis of various β-lactams [Jayaraman et al. *J Org Chem* **59** 932 *1994*, DOI: 10.1021/jo00083a042; van Brabandt et al. *J Org Chem* **71** 7083 *2006*, DOI: 10.1021/jo0608319]. [Fischer & Gohlke *Helv Chim Acta* **16** 1130 *1933*, DOI: 10.1002/hlca.193301601140; *Beilstein* **6** IV 2470.]

2-Benzyloxybenzoic acid (salicylic acid benzyl ether) *[14389-86-7]* **$C_{14}H_{12}O_3$, M 228.2, m 73-77°, pK_{Est} ~4.1.** It has been prepared from salicylic acid (in 95% EtOH) and benzyl chloride in the presence 5 N aqueous NaOH and refluxed for 4 hours, followed by concentration and acidification. The substance may contain salicyclic acid as impurity, so the dried product should be heated at 120° under reduced pressure (2mm) to remove any salicylic acid and then recrystallised from 70% EtOH (colourless plates, **m 70°**). [Cavallito & Buck *J Am Chem Soc* **65** 2140 *1943*, DOI: 10.1021/ja01251a034; *Beilstein* **10** III 247, **10** IV 316.] ***3-Benzyloxybenzoic acid*** *[69026-14-8]* has **m 133-137°, 135.5-136°, pK_{Est} ~4.1.** Recrystallise this acid from acetic acid (colourless plates, **m 137-138°, 134°** also reported). [Kipping & Wren *J Chem Soc* 3246 *1957*, DOI: 10.1039/JR9570003246; Jones *J Chem Soc* 430 *1943*, DOI: 10.1039/JR9430000430, *Beilstein* **10** II 41, **10** III 100.] ***4-Benzyloxybenzoic acid*** *[1486-51-7]* has **m 188°, 189-192°, 193.5-194.5°, pK_{Est} ~4.1.** Purify it by recrystallising from aqueous EtOH (charcoal, colourless plates), and by vacuum sublimation at 120°. It crystallises also from 95% EtOH. The ***benzyl ester*** crystallises as colourless needles, **m 115°**, from 95% EtOH [Kipping & Wren *J Chem Soc* 3246 *1957*, DOI: 10.1039/JR9570003246; Cavallito & Buck *J Am Chem Soc* **65** 2140 *1943*, DOI: 10.1021/ja01251a034; *Beilstein* **10** II 93, **10** III 290, **10** IV 351.]

Benzyloxybutan-2-one *[6278-91-7]* **$C_{11}H_{14}O_2$, M 178.2, b 90-92°/0.1mm, 88-91°/0.5mm, 121-126°/5mm, d_4^{20} 1.0275, n_D^{20} 1.5040.** Dissolve the ketone in $CHCl_3$, wash with H_2O, aqueous saturated $NaHCO_3$, H_2O, dry ($MgSO_4$), evaporate the $CHCl_3$, and fractionate it. [Hoffman et al. *J Am Chem Soc* **79** 2316 *1957*, DOI: 10.1021/ja01566a080; *Beilstein* **6** IV 2255.]

Benzyloxycarbonyl chloride (Cbz-Cl, BOC-Cl, benzyl chloroformate) *[501-53-1]* **$C_8H_7ClO_2$, M 170.6, b 85-87°/7mm, 103°/20mm, 173°/724mm, d_4^{20} 1.195, n_D^{20} 1.5190.** The commercial material is usually better than 95% pure and may contain some toluene, benzyl alcohol, benzyl chloride and HCl. After long storage, e.g. two years at 4°, Greenstein and Winitz [*The Chemistry of the Amino Acids* **Vol 2** p. 890, J Wiley and Sons NY, *1961*] recommended that the liquid should be flushed with a stream of dry air, filtered and stored over sodium sulfate to remove CO_2 and HCl which are formed by decomposition. It may further be distilled from an oil bath at a temperature below 85° because Thiele and Dent [*Justus Liebigs Ann Chem* **302** 245 *1898*, DOI: 10.1002/jlac.18983020302] stated that benzyloxycarbonyl chloride decarboxylates to benzyl chloride slowly at 100° and vigorously at 155°. Redistillation at higher vacuum below 85° yields material which shows

no other peaks than those of benzyloxycarbonyl chloride by NMR spectroscopy. [Carter et al. *Org Synth* Coll Vol **3** 167 *1955*, DOI: 10.15227/orgsyn.023.0013; *Beilstein* **6** IV 2278.] **LACHRYMATORY** and **TOXIC**.

p-**(Benzyloxy)phenol (monobenzone)** *[103-16-2]* **$C_{13}H_{12}O_2$, M 200.2, m 122.5°, pK_{Est} ~10.1.** Crystallise it from EtOH or H_2O, and dry (P_2O_5) under vacuum. It causes loss of pigment. [Walba et al. *J Am Chem Soc* **108** 5210 *1986*, DOI: 10.1021/ja00277a027; *Beilstein* **6** IV 5778.]

S*-(-)-3-Benzyloxypropan-1,2-diol (1-benzyl-*sn*-glycerol)** *[17325-85-8]* **$C_{10}H_{14}O_3$, M 182.2, m 24-26°, b 117-118°/10^{-4}mm, 115-116°/0.02mm, 121-123°/0.2mm, 125°/0.5mm, 261°/atm, d_4^{20} 1.1437, n_D^{22} 1.5295, $[\alpha]_D^{25}$ -5.9 (neat).** Purify the *S*-(-)-diol (obtained by starting from D-mannitol) by fractional distillation. ***R*-(+)-3-Benzyloxypropan-1,2-diol (3-benzyl-*sn*-glycerol)** *[56552-80-8]* was shown to have **m 25-29°** and **$[\alpha]_D^{20}$ +5.5 (c 20, $CHCl_3$).** The ***racemate has *[4799-67-1]*. [Baer et al. *J Biol Chem* **230** 447 *1958*, Gigg & Gigg *J Chem Soc C* 1865 *1967*, DOI: 10.1039/J39670001865; *Beilstein* **6** IV 2247.]

2-Benzylphenol (α-phenyl-*o*-cresol) *[28994-41-4]* **$C_{13}H_{12}O$, M 184.2, m 20.2-20.9°, 52°, 54°, b 121-123°/1mm, 175°/18mm, 312°/760mm, n_D^{20} 1.5994-1.5995, pK_{Est} ~10.0.** Distil 2-benzylphenol in a vacuum and the distillate crystallises on cooling to a solid with **m ~21°** (22-23° in a sealed capillary tube). This forms a ***phenylcarbamate*** **m 117.5-118°** (needles from ligroin), and with MeI/Me_2CO/K_2CO_3 (in a tube at 100°) provides the corresponding ***2-benzylphenyl methyl ether*** **b 159-160°/12mm**. It has a stable form **B** with **m ~52°** and an unstable form **A** with **m ~21°**. The second form is obtained by recrystallisation from EtOH, or by warming the lower melting form (an exothermic change). On cooling molten crystals of **B** provides crystals of the **A** form. The IR shows strong phenolic -OH absorption at ν_{max} at 3390cm^{-1} (2.95μ). [Kremers et al. *Justus Liebigs Ann Chem* **442** 210 *1925*, DOI: 10.1002/jlac.19254420114; Kornblum & Lurie *J Am Chem Soc* **81** 2705 *1959*, DOI: 10.1021/ja01520a030; *Beilstein* **6** H 675, **6** IV 4628.] ***4-Benzylphenol* (α-phenyl-*p*-cresol)** *[101-53-1, 7563-63-5]* **$C_{13}H_{12}O$, M 184.2,** has **m 79-81°, 84°, 84.5-85.5°, b 154-157°/4mm, 198-200°/10mm, 322°/atm, pK_{Est} ~10.2.** Crystallise 4-benzylphenol from water. [Ziegenbein et al. *Chem Ber* **88** 1906 *1955*, DOI: 10.1002/cber.19550881213; McKinney & Reynolds *Talanta* **1** 46 *1958*, DOI:10.1016/0039-9140(58)80007-7; *Beilstein* **6** H 675, **6** I 324, **6** II 629, **6** III 3357, **6** IV 4640.]

4-*N*-Benzylsulfanilamide (Septazen) *[1709-54-2]* **$C_{13}H_{14}N_2O_2S$, M 262.3, m 175°, 178°.** Crystallise Septazen from dioxane/H_2O, EtOH/H_2O or Me_2CO (**m** 174.5-175.8°). Its solubility in H_2O at 37° is 0.03-0.43mg/100ml. [*Beilstein* **14** III 2026.]

Benzylthiocyanate (benzyl rhodanide) *[3012-37-1]* **C_8H_7NS, M 149.2, m 39-41°, 43°, 42-44°, b 230-235°/atm, 256°(dec).** Crystallise the thiocyanate from EtOH or aqueous EtOH. [*Beilstein* **6** H 460, **6** I 228, **6** II 434, **6** III 1600, **6** IV 2680.]

Benzyl toluene-*p*-sulfonate *[1024-41-5]* **$C_{14}H_{14}O_3S$, M 262.3, m 58°, 58.5-58.8°.** Crystallise the ester from petroleum ether (b 40-60°), $CHCl_3$/hexane or Et_2O/*C_6H_6. Dry it *in vacuo* but **not** in a desiccator over $CaCl_2$ as it causes hydrolysis of the ester. [Emmons & Ferris *J Am Chem Soc* **75** 2257 *1953*, DOI: 10.1021/ja01105a509; *Beilstein* **11** II 48, **11** III 207, **11** IV 273.]

Benzyltributylammonium bromide *[25316-59-0]* **$C_{19}H_{33}BrN$, M 356.4, m 169-171°, 174-175°.** Recrystallise the bromide from EtOAc/EtOH and EtOH/Et_2O. [Kantor & Hauser *J Am Chem Soc* **73** 4122 *1951*, DOI: 10.1021/ja01153a022; Petersen et al. *J Am Chem Soc* **81** 3264 *1959*, DOI: 10.1021/ja01522a027; *Beilstein* **12** IV 2166.]

Benzyl 2,2,2-trichloroacetimidate *[81927-55-1]* **$C_9H_8Cl_3NO$, M 252.5, m 3-4°, b 106-114°/0.5mm, d_4^{20} 1.349, n_D^{20} 1.545.** Purify the imidate by distillation to remove up to 1% of $PhCH_2OH$ as stabiliser. A solution in hexane can be stored for up to 2 months without decomposition. It is *hygroscopic* and has to be stored dry. Small amounts can be purified by preparative TLC on 2mm Merck plates pre-coated with silica gel 60 F-245, eluted with hexane and the spots detected by UV light (or spraying a side run with 5% H_2SO_4 in EtOH and heating). This procedure separates the *benzimidate* from any trichloroacetamide or *N*-benzyl-trichloroacetamide impurities; the latter could be formed on heating such as distillation *via* a rearrangement. Its IR has ν_{max} at 3380

(NH) and 1670(C=N)cm^{-1} among other peaks. [For Synthesis and NMR see Wessel et al. *JCS Perkin Trans 1* 2247 *1985*, DOI: 10.1039/P19850002247, and Clizbe & Overman *Org Synth* **58** 4 *1978*, DOI:.10.15227/orgsyn.058.0004; Cramer et al. *Chem Ber* **91** 1049 *1958*, DOI: 10.1002/cber.19580910530; *Beilstein* **6** IV 2265.]

Benzyltrimethylammonium chloride *[56-93-9]* **$C_{10}H_{16}ClN$, M 185.7, m 238-239°(dec).** A 60% aqueous solution of the salt is evaporated to dryness under a vacuum on a steam bath, and then left in a vacuum desiccator containing a suitable drying agent. The solid residue is dissolved in a small volume of boiling absolute EtOH and precipitated by adding an equal volume of diethyl ether with cooling. After washing, the precipitate is dried under a vacuum [Karusch *J Am Chem Soc* **73** 1246 *1951*, DOI: 10.1021/ja01147a110]. [*Beilstein* **12** IV 2162.] It is available commercially as a 60% solution in H_2O with d^{20} 1.072g/ml and n_D^{20} 1.470. ***Benzyltrimethylammonium fluoride monohydrate and x-hydrate*** **(BTAF)** *[H_2O 329-97-5; xH_2O 127582-36-9]* **$C_{10}H_{16}FN.H_2O$, M 169.2 (anhydr),** has **m 181-189°.** It is a good source of *naked fluoride ions* for catalysis in methylation reaction of Me_3SiO-cycloalkanes. BTAF is most reactive when it is as free from H_2O as possible. It has been prepared by adding ~4.7% aqueous HF (*ca* 8.6ml) to 40% methanolic Triton B (10ml, benzyltrimethylammonium hydroxide, see below) until the pH of the solution reaches 8—7. The solvent is removed in a vacuum of ~1mm and the residue is dried at 50°/0.5mm for 20 hours (oil pump with liquid N_2 trap). The highly hygroscopic BTAF (~3.5g) is pulverised and stored over P_2O_5. It decomposes above 100°, but drying at 90°/0.1mm/48hr or 30°/0.1mm to constant weight (2 days) produces a reasonably useful catalyst which has been used together with 4A molecular sieves in dry THF, dioxane or MeCN [Kuwajima et al. *J Am Chem Soc* **104** 1025 *1982*, DOI: 10.1021/ja00368a018]. Aldol condensations with trimethylsilylcyclopropanes, using BTAF or dry tetra-*n*-butylammonium fluoride (TBAF) were similarly achieved [Paquette et al. *J Am Chem Soc* **106** 6442 *1984*, DOI: 10.1021/ja00333a068].

Benzyltrimethylammonium hydroxide (Triton B) *[100-85-6]* **$C_{10}H_{16}N.OH$, M 167.3, d 0.91.** A 38% solution (as supplied) is decolorised (charcoal), then evaporated under reduced pressure to a syrup, with final drying at 75°/1mm pressure. The *anhydrous* base is obtained by prolonged drying over P_2O_5 in a vacuum desiccator. [*Beilstein* **12** IV 2162.] It is commercially available as a 40wt% solution in H_2O with d^{25} 1.059g/ml, n_D^{20} 1.43; and as a 40w% solution in MeOH with d^{25} 0.92g/ml.

Bibenzyl (1,2-diphenylethane, dibenzyl) *[103-29-7]* **$C_{14}H_{14}$, M 182.3, m 50-53°, 52.0-52.5°, 52.5-53.5°, b 284°/atm, d_4^{20} 0.9782.** Crystallise bibenzyl from hexane, MeOH, or 95% EtOH. It has also been sublimed under vacuum, and further purified by percolation through columns of silica gel and activated alumina. It is prepared by reduction of benzoin or benzyl [Clemmensen *Chem Ber* **47** 688 *1914*, DOI: 10.1002/cber.191404701107], but is best obtained by catalytic reduction of stilbene. Thus a mixture of stilbene (5g, see [103-30-0]) in dioxane (200ml) and Raney Ni (22g) is refluxed with stirring for 24 hours. The catalyst is filtered off, the filtrate is evaporated *in vacuo*, and the residue is recrystallised from MeOH to give an 80% yield of bibenzyl m 52.0-52.5°. Its FT-IR (melt) has ν_{max} at 3062.6, 1601.7, 1494.9, 1030.2, 906.0, 752.1, 696.9, 580.2 and 519.3 cm^{-1}; its ^{1}H NMR (300MHz, $CDCl_3$, TMS) has δ at 7.27 (t, 4H, arom-H), 7.18 (t, 6H, arom-H) and 2.90 (s, 4H, benzylic-H); and its ^{13}C NMR (15MHz, $CDCl_3$, $CDCl_3$ as internal standard with δ at ~77.0) has δ at 141.7, 128.36, 128.24, 125.83 and 37.89. [Kleiderer & Kornfeld *J Org Chem* **13** 455 *1948*, DOI: 10.1021/jo01161a022.] [*Beilstein* **5** IV 1868.]

(±)-1,1'-Bi-(2-naphthol) [1,1'-di-(2-naphthol), BINOL] *[602-09-5, 41024-90-2]* **$C_{20}H_{14}O_2$, M 286.3, m 215-217°, 218°, $pK_{Est(1)}$ ~7.1, $pK_{Est(2)}$ ~11.2.** Crystallise the binaphthol from toluene or *benzene (10ml/g). When crystallised from chlorobenzene it has **m 238°**. Its solubility in dioxane is 5%. [*Beilstein* **6** IV 7020.] ***1,1'-Bi-(2-naphthol)*** **[1,1'-di-(2-naphthol)]** *[R-(+)- 18531-94-7], [S-(-)- 18531-99-2]* have **m 207.5-208.5°, 209-211°, $[\alpha]_D^{20}$ (+) and (-) 37.4.0 (c 0.5, THF), $[\alpha]_{546}^{25}$ (+) and (-) 51 (c 0.1, THF), pK as above.** Dissolve it in cold 2.5N NaOH, extract with CH_2Cl_2, and acidify with 5% HCl. Collect the white precipitate and recrystallise it from aqueous EtOH and dry it in a vacuum [Akimoto & Yamada *Tetrahedron* **27** 5999 *1971*, DOI: 10.1016/S0040-4020(01)91765-X]. It is optically stable in dioxane-water (100°/24 hours). *Racemisation*: 72% in 1.2N HCl at 100°/24 hours, and 68% in 0.67M KOH in BuOH at 118°/23 hours [Kyba et al. *J Am Chem Soc* **95** 2692 *1973*, DOI: 10.1021/ja00789a051]. It was also crystallised from *C_6H_6 (solubility is 1%) using Norite, or EtOH/H_2O after chromatography through silica gel, eluting with Me_2CO/*C_6H_6. [Kyba et al. *J Org*

Chem **42** 4173 *1977*, DOI: 10.1021/jo00862a001; see also Brussee & Jansen *Tetrahedron Lett* **24** 3261 *1983*, DOI: 10.1016/S0040-4039(00)88151-4; Akimoto & Yamada *Tetrahedron* **27** 5999 *1971*, DOI: 10.1016/S0040-4020(01)91765-X; *Beilstein* **6** IV 7020.]

1,1'-Binaphthyl *[(±)- 32507-32-7* and *604-53-5*, *R(-)- 24161-30-6*, *S(+)- 734-77-0]* **$C_{20}H_{14}$, M 254.3, m 145°, 159°, b ~240°/13mm, (±, 2 forms), 153-154°, 154°, (+) and (-), $[\alpha]_D^{20}$ (-) and (+) ~220 (*C_6H_6).** Purify 1,1'-binaphthyl through a silica gel column with Me_2CO/*C_6H_6 [or Al_2O_3 with 10% *C_6H_6/petroleum ether (b 30-60°)] and recrystallise it from EtOH, pentane, or slow evaporation of *C_6H_6, Me_2CO or Et_2O solutions. Half life ~10 hours at 25° in various solvents. [Wilson & Pincock *J Am Chem Soc* ***97*** 1474 *1975*, DOI: 10.1021/ja00839a033; Akimoto & Yamada *Tetrahedron* **27** 5999 *1971*, DOI: 10.1016/S0040-4020(01)91765-X; *Beilstein* **5** I 358, **5** II 642, **5** III 2465, **5** IV 2634.] ***2,2'-Binaphthyl*** **(β, β'-binaphthyl)** *[61-78-2]* has **m 188°.** Crystallise the 2,2'-binaphthyl from *C_6H_6, or Et_2O/*C_6H_6 (**m 187-189°**). The ***2,4,7-trinitrofluorenone complex*** forms orange-red needles from EtOH/*C_6H_6 (**m 170.6-171°**). [*Beilstein* **5** H 727, **5** I 359, **5** II 643, **5** III 2467, **5** IV 2636.]

Biphenyl (diphenyl) *[92-52-4]* **$C_{12}H_{10}$, M 154.2, m 68-75°, 70-71°, b 112°/7mm, 255°/760mm, d_4^{20} 0.992.** Crystallise biphenyl from EtOH, MeOH, aqueous MeOH, petroleum ether (b 40-60°) or glacial acetic acid. Free it from polar impurities by passage through an alumina column in *benzene, followed by evaporation. The residue has been purified by distillation in a vacuum and by zone refining. Treatment with maleic anhydride removes anthracene-like impurities. It has been recrystallised from EtOH followed by repeated vacuum sublimation and passage through a zone refiner. [Taliani & Bree *J Phys Chem* **88** 2351 *1984*, DOI: 10.1021/j150655a033; *Beilstein* **5** H 576, 5 I 271, **5** II 479, **5** III 1726, **5** IV 1807.]

4-Biphenylcarbonyl chloride *[14002-51-8] -4]* **$C_{13}H_9ClO$, M 216.7, m 110-112°, 114-115°.** Dissolve the carbonyl chloride in a large volume of petroleum ether (10 x, b 50-70°), filter it through a short column of neutral alumina, evaporate to dryness *in vacuo* and recrystallise it from petroleum ether (b 60-80°). [*Beilstein* **9** IV 2480.] **LACHRYMATORY.**

Biphenyl-2-carboxylic (2-phenylbenzoic) acid *[947-84-2]* **$C_{13}H_{10}O_2$, M 198.2, m 111-113°, 114°, b 199°/10mm, 343-344°/atm, pK^{25} 3.46.** Crystallise the acid from *C_6H_6/petroleum ether or aqueous EtOH. [*Beilstein* **9** IV 2472.] ***Biphenyl-4-carboxylic*** **(4-phenylbenzoic) acid** *[92-92-2]* has **m 220-225°, 228°, pK^{25} 5.66 (in 50% 2-butoxyethanol)** and is similarly purified. [*Beilstein* **9** IV 2479.]

2,4'-Biphenyldiamine *[492-17-1]* **$C_{12}H_{12}N_2$, M 184.2, m 45°, b 363°/760mm, $pK_{Est(1)}$ ~4.8, $pK_{Est(2)}$ ~3.9.** Crystallise the diamine from aqueous EtOH or petroleum ether (**m** 54-54.5°). [*Beilstein* **9** III 416, **9** IV 360.]

Biphenyl-4,4'-dicarboxylic acid *[787-70-2]* **$C_{14}H_{10}O_4$, M 242.2, m >300°, $pK_{Est(1)}$ ~3.5, $pK_{Est(2)}$ ~4.3.** The dicarboxylic acid is a white amorphous or microcrystalline substance which does not melt or sublime. It is best purified by precipitation of an aqueous alkaline solution with mineral acid, washing well with H_2O and drying *in vacuo* at 100°. It is characterised by conversion to ***diphenyl-4,4'-dicarbonyl chloride*** (with PCl_5) [Work *J Chem Soc* 1315 *1940*, DOI: 10.1039/JR9400001315], or by phase transfer catalysis with $SOCl_2$ + $BuEt_3N^+Cl^-$ in 1,2-dichloroethane [Burdett *Synthesis* 441 *1991*, DOI: 10.1055/s-1991-26487,] which crystallises from *C_6H_6 with **m 184°**. The di-acid chloride gives the ***dimethyl ester*** with MeOH which has **m 215-217°** (plates from MeOH, **m's** of **214°** and **224°** were also reported)**.** The ***diethyl ester*** is similarly prepared with EtOH and has **m 122°** (from EtOH). *The* ***4,4'-dicarbonitrile****[1591-30-6]* **$C_{14}H_8N_2$, M 204.2**, prepared from the dicarbonyl chloride and aqueous ammonia followed by dehydration, or from benzidine *via*, a *bis* Sandmeyer reaction, has **m 238-240°**. [*Beilstein* **9** II 665, **9** III 4519, **9** IV 3563.] The dicarboxylic acid was successfully used to make dendrimers with polyhydrophobic and hydrophilic arms *via* intermediate polyhydroxyphenyl esters [Zubarev et al. *Org Lett* **8** 1367 *2006*, DOI: 10.1021/ol060080x].

Biphenylene *[259-79-0]* **$C_{12}H_8$, M 152.2, m 111°, 113-114°.** Biphenylene forms yellow crystals from cyclohexane, MeOH (**m 110-111°**) or EtOH (**m 111-112°**). It sublimes *in vacuo*. The ***2,4,7-trinitrofluorenone complex*** has **m 154°** and the ***picrate*** gives red needles **m 122°** from EtOH. [*Beilstein* **5** I 298, **5** II 530, **5** III 1935, **5** IV 2137.]

(±)–α-(4-Biphenylyl)butyric acid *[959-10-4]* **$C_{16}H_{16}O_2$, M 240.3, m 124-125°, pK_{Est} ~4.5.** Crystallise the acid from MeOH, petroleum ether or AcOH (**m** 123-125°). [*Beilstein* **9** III 3370, **9** IV 2558.] ***γ-(4-Biphenylyl)butyric acid*** *[6057-60-9]* has **m 118°, 120-121°, pK_{Est} ~4.8.** Crystallise the acid from MeOH (**m 118°**) or *C_6H_6 (**m 118-119°**). [*Beilstein* **9** I 290, **9** III 3370, **9** IV 2558.]

Bis-(*p*-bromophenyl) ether *[53563-56-7]* **$C_{12}H_8Br_2O$, M 328.0, m 60.1-61.7°.** Crystallise the ether twice from EtOH, petroleum ether, once from *benzene and dry it *in vacuo* [Purcell & Smyth *J Am Chem Soc* **83** 1063 *1961*, DOI: 10.1021/ja01466a013]. [*Beilstein* **6** III 745, **9** IV 1048.]

2*R*,3*R*-(+)-1,4-Bis-(4-chlorobenzyloxy)-2,3-butanediol *[85362-86-3]* **and 2*S*,3*S*-(-)-1,4-Bis-(4-chlorobenzyloxy)-2,3-butanediol** *[85362-85-2]* **$C_{18}H_{20}Cl_2O_4$, M 371.3, m 72-74°, 76-77°, $[\alpha]_D^{20}$ (+) and (-) 6.4 (c 3.1 $CHCl_3$).** Recrystallise the diols from toluene-hexane. IR (KBr) has ν_{max} at 3250, 1598, 1493, 1085 cm^{-1}; ^1H NMR ($CDCl_3$) has 2.6-2.9 (2H, m, O*H* x 2), 3.4-3.7 (4H, m, CH-CH_2O x2), 3.7-4.0 (2H, m, C*H* x2), 4.47 (4H, s, CH_2Ar x 2), 7.05-7.35 (8H.m. aromatic protons). They are useful reagents for optical resolution of racemates. [Terashima et al. *Tetrahedron Lett* **23** 4107 *1982*, DOI: 10.1016/S0040-4039(00)88360-4; Tamoto et al. *Tetrahedron* **40** 4617 *1984*, DOI: 10.1016/S0040-4020(01)91522-4.]

***N*,*N*-Bis-(2-chloroethyl) 2-naphthylamine (chlornaphthazine)** *[494-03-1]* **$C_{14}H_{15}Cl_2N_4$, M 268.3, m 54-56°, b 210°/5mm, pK_{Est} ~5.3.** Crystallise it from petroleum ether. At 15° it is soluble in EtOH (3.2%), Et_2O (50%), Me_2CO (84%) and *C_6H_6 (80%). It is a nitrogen mustard. [*Beilstein* **12** III 2996, **12** IV 3126.] **CARCINOGENIC.**

1,4-Bis-(chloromethyl)durene (1,4-bischloromethyl-2,3,5,6-tetramethylbenzene) *[3022-16-0]* **$C_{12}H_{16}Cl_2$, M 231.2, m 197-198°.** Crystallise it three times from *C_6H_6 (**m 193-194°**) or petroleum ether (**m 195-196°**), then dry it *in vacuo* in a drying pistol. [Fuson et al. *J Am Chem Soc* **75** 5952 *1953*, DOI: 10.1021/ja01119a050; *Beilstein* **5** IV 1140.]

2,2-Bis-(*p*-chlorophenyl)-1,1-dichloroethane (*p,p*'-DDD) *[72-54-8]* **$C_{14}H_{10}Cl_4$, M 320.1, m 109-110°, 109-111°, 111-112°.** Crystallise DDD from EtOH and dry it *in vacuo*. The purity is checked by TLC. [*Beilstein* **5** III 1830.] **TOXIC INSECTICIDE.**

2,2-Bis-(*p*-chlorophenyl)-1,1-dichloroethylene (*p,p*'-DDE) *[72-55-9]* **$C_{14}H_8Cl_4$, M 318.0, m 89-91°.** Crystallise DDE from MeOH or EtOH and dry it *in vacuo*. The purity is checked by TLC. It is a metabolite of DDT. [Gätzi & Stammbach *Helv Chim Acta* **29** 563 *1946,* DOI: 10.1002/hlca.19460290308; *Beilstein* **5** H 639, **5** III1891.] **POSSIBLE CARCINOGEN.**

2,2-Bis-(4-chlorophenyl)-1,1,1-trichloroethane (*p,p*'-DDT, 1,1,1-trichloro-2,2-bis(*p*-chlorophenyl)ethane) *[50-29-3]* **$C_{14}H_9Cl_5$, M 354.5, m 108°, 108.5-109°, 107-110°.** Crystallise DDT from *n*-propyl alcohol (5ml/g), then dry it in air or an air oven at 50-60°. *Alternatively*, crystallise it from 95% EtOH, and the purity is checked by TLC. [*Beilstein* **5** III 1833.] **TOXIC INSECTICIDE.**

4,4'-Bis-(diethylamino)benzophenone *[90-93-7]* **$C_{21}H_{28}N_2O$, M 324.5, m 89-92°, 93-95°, 95-96°, b ~300°/10mm, $pK_{Est(1)}$ ~1.8, $pK_{Est(2)}$ ~3.3.** Crystallise the phenone from EtOH (25ml/g) and dry it under vacuum. Its ***picrate*** forms yellow needles from EtOH with **m 178.5°**. [*Beilstein* **14** II 59.]

Bis-(4-dimethylaminobenzylidene)benzidine *[6001-51-0]* **$C_{30}H_{30}N_4$, M 446.6, m 318°, pK_{Est} ~0.** Crystallise the benzidine from nitrobenzene. [*Beilstein* **14** H 35.]

3,4-Bis-(4-hydroxyphenyl)hexane (Hexesterol, Homoestrol, Syntrogène) *[5635-50-7 (no configuration), 84-16-2 (meso-3RS,4-SR)]* **$C_{18}H_{22}O_2$, M 270.4, m 185-186°, 187°.** Free it from diethylstilboestrol by zone refining. Crystallise *meso*-Hexesterol from *benzene or aqueous EtOH (**m 185-188°**). The ***meso-dibenzoyl*** derivative has **m 236-237°.** The ***3RS,4RS(±)-racemate*** *[5776-72-7]* crystallises from petroleum ether, *C_6H_6/petroleum ether, Et_2O/petroleum ether, or MeOH/H_2O and has **m 128-129°**. The ***(±)-diacetyl*** derivative has **m 137-139°**, and the ***(±)-dipropionyl derivative*** **(Retalon)** , **m 127-128°**, crystallises from light petroleum.

The ***(±)-dibenzoyl*** derivative has **m 123-124°**. ***Hexesterol 4,4'-diphosphoric acid ester*** *(Cytostatin) [4188-82-0]* **$C_{18}H_{24}O_8P_2$, M 430.3,** is acidic and is soluble in aqueous alkaline solutions. The ***3R,4R(+)-isomer*** [26614-21-1] and ***3S,4S(-)-isomer*** *[26614-22-2]* crystallise from Et_2O/petroleum ether with **m 80-80.5°** and have $[\alpha]_D^{17}$ (+) and (-) 17.7 (c 5, EtOH). Their ***dibenzoyl*** derivatives have **m 116.5°**. [*Beilstein* **6** III 5503, **6** IV 6761.] They have estrogenic activity where the optically active forms are more potent, and they have antineoplastic activity. [Aboul-Enein et al. *Anal Profiles Drug Subst* **11** 347 *1982,* DOI: 10.1016/S0099-5428(08)60269-5; Kharasch & Kleiman *J Am Chem Soc* **65** 491 *1941*, DOI: 10.1021/ja01244a001.]

4,4-Bis(4-hydroxyphenyl)valeric acid [diphenolic acid, DPA] *[126-00-1]* **$C_{17}H_{14}O_4$, M 286.3, m 168-171°, 171-172°, $pK_{Est(1)}$~ 4.8 (CO_2H), $pK_{Est(2)}$~ 7.55 (OH), $pK_{Est(3)}$~9.0 (OH)**. When recrystallised from *C_6H_6, the crystals have 0.5 mol of *C_6H_6 (**m** 120-122°, lower melting modification), and when recrystallised from toluene, the crystals have 0.5 mol of toluene. Purify the acid also by recrystallisation from hot H_2O which provides the higher melting modification. It is soluble in Me_2CO, AcOH, EtOH, propan-2-ol, methyl ethyl ketone. It can also be recrystallised from AcOH, heptane/Et_2O or Me_2CO/*C_6H_6. It has λ_{max} at 225 and 279nm in EtOH. The ***methyl ester*** has **m 87-89°** (aqueous MeOH to give the *trihydrate*). [Bader & Kontowicz *J Am Chem Soc* **76** 4465 *1954*, DOI: 10.1021/ja01646a053; *Beilstein* **10** IV 1890.]

1,4-Bismethylaminoanthraquinone (Disperse Blue 14) *[2475-44-7]* **$C_{16}H_{14}N_2O_2$, M 266.3, m 220-222°, C.I. 61500, λ_{max} 640 (594)nm.** Purify the anthraquinone by thin-layer chromatography on silica gel plates, using toluene/acetone (3:1) as eluent. The main band is scraped off and extracted with MeOH. The solvent is evaporated and the dye is dried in a drying pistol [Land et al. *JCS Faraday Trans 1* **72** 2091 *1976*, DOI: 10.1039/F19767202091]. It crystallises from *n*-butanol with **m 221-222°** and has λ_{max} at 539 and 644nm (EtOH). [*Beilstein* **14** H 198, **14** III 440, **14** IV 459.]

Bis-(1-naphthylmethyl)amine *[5798-49-2]* **$C_{22}H_{19}N_2$, M 329.4, m 62°, 63-64°, pK_{Est} ~8.4.** Crystallise the amine from petroleum ether (pale yellow crystals), Et_2O (**m** 73-74°) or *C_6H_6 (**m** 62°). The ***hydrochloride*** crystallises from H_2O as colourless needles **m** 239°, and the ***picrate*** has **m** 206°(202°). [For the reduction of 1-cyanonaphthalene with Ni/H_2 see Rupe & Becherer *Helv Chim Acta* **6** 880 *1923*, DOI: 10.1002/hlca.19230060196; for the determination of nitrates see Konek *Chem Abstr* **28** 5779 *1934*, *Beilstein* **12** II 741, **12** IV 3195.]

Bis-(4-nitrophenyl) carbonate *[5070-13-3]* **$C_{13}H_8N_2O_7$, M 304.2, m 142-143°**. Dissolve the carbonate in $CHCl_3$, wash it with 2N NaOH (3 x) and once with concentrated HCl, dry (Na_2SO_4), evaporate and crystallise the residue from toluene (authors say prisms from 15 volumes of *benzene). [For preparation of activated 4-nitrophenyl esters of protected *H*-amino acids see Glatthard & Matter *Helv Chim Acta* **46** 795 *1963*, and Tolle *J Am Chem Soc* **104** 6883 *1982*, DOI: 10.1021/ja00388a114; and for the preparation of ureas see Izdebski & Pawlak *Synthesis* 423 *1989*, DOI: 10.1055/s-1989-27272; *Beilstein* **6** III 820.]

Bis-(4-nitrophenyl) ether *[101-63-3]* **$C_{12}H_8N_2O_5$, M 260.2, m 142-143°, 144.4-144.7°, 147-148°.** Crystallise the ether twice from *C_6H_6 or petroleum ether and dry it *in vacuo*. [*Beilstein* **6** II 822, **6** IV 1290.]

Bis-(4-nitrophenyl) methane *[1817-74-9]* **$C_{13}H_{10}N_2O_4$, M 258.3, m 183°, 184°, 187°.** Crystallise the methane twice from *C_6H_6, petroleum ether or AcOH (**m 188.6-189.6°**), and dry it *in vacuo*. [*Beilstein* **5** III 1797, **5** IV 1853.]

Bis-(trifluoroacetoxy)iodobenzene (BTI) *[2712-78-9]* **$C_{10}H_5F_6IO_4$, M 430.0, m 112-114° (dec), 120-121°, 124-126°.** Crystallise the iodo compound from warm trifluoroacetic acid and dry it over NaOH pellets. Recrystallise it also from Me_2CO/petroleum ether. Its melting point depends on the heating rate. [Spyroudis & Varvoglis *Synthesis* 445 *1975*, DOI: 10.1055/s-1975-23796; application: Almond et al. *Org Synth* **66** 132 *1988*, DOI: 10.15227/orgsyn.066.0132.] The cyclisation of styrylamines to *N*-alkyl and *N*-aryl indoles in $CHCl_3$ is mediated by BTI under mild conditions (30 minutes at room temperature) [Du et al. *Org Lett* **8** 5919 *2006*, DOI: 10.1021/ol062288o].

***N*-BOC-1,2-phenylenediamine [(2-aminophenyl]carbamic acid, *tert*-butyl ester)]** *[146651-75-4]*

$C_{11}H_{16}NO_2$, M 208.3, m 109-114°. Purify the ester by recrystallisation from $CHCl_3$/hexane (1:1, v/v) and dry it *in vacuo*. [Seto et al. *J Am Chem Soc* **115** 1321 *1993*, DOI: 10.1021/ja00057a015; Sessler et al. *J Am Chem Soc* **127** 11442 *2005*, DOI: 10.1021/ja0522938.]

Brilliant Green (4-dimethylaminotriphenyl carbinol, Emerald Green, Malachite Green G) *[633-03-4]* **$C_{27}H_{14}N_2O_4S$, M 482.7, m 209-211°(dec), pK^{25} 4.75.** Purify the dye by precipitating the *perchlorate* from aqueous solution (0.3%) after filtering, heating to 75° and adjusting to pH 1-2 with dilute H_2SO_4 to form the HSO_4^- salt. It has λ_{max} at 623nm, and changes colour from yellow to green at pH 0.0 to pH 2.6 respectively. Recrystallise it from EtOH/water (1:4) [Kerr & Gregory *Analyst (London)* **94** 1036 *1969*, DOI: 10.1039/AN9699401036]. [*Beilstein* **13** IV 2281.] It is used as an external and internal antiseptic.

4-Bromoacetanilide *[103-88-8]* **C_8H_8FBrNO, M 214.1, m 165-169°, 167°.** Crystallise the anilide from aqueous MeOH or EtOH. Purify it by zone refining. [*Beilstein* **12** IV 1504.] It has analgesic and antipyretic properties.

4-Bromoacetophenone *[99-90-1]* **C_8H_7BrO, M 199.1, m 49-51°, 54°, b 117°/7mm, 130°/15mm, 255°/atm.** Crystallise it from EtOH, MeOH or from petroleum ether (b 80-100°). The ***oxime*** **m 128.5°** crystallises from aqueous EtOH. [Tanner *J Org Chem* **52** 2142 *1987*, DOI: 10.1021/jo00387a005; *Beilstein* **7** IV 647.]

ω–Bromoacetophenone (phenacyl bromide) *[70-11-1]* **C_8H_7BrO, M 199.1, m 48-51°, 50°, 57-58°, 135°/18mm** Crystallise the bromide from EtOH, MeOH or petroleum ether (b 80-100°). [Tanner *J Org Chem* **52** 2142 *1987*, DOI: 10.1021/jo00387a005; *Beilstein* **7** IV 649.] **LACHRYMATORY.** Useful for characterising acids as ***phenacyl esters*** by reaction with sodium salts of acids in EtOH or aqueous EtOH.

4-Bromoaniline *[106-40-1]* **C_6H_6BrN, M 172.0, m 66°, pK^{25} 3.86.** Recrystallise the base (with much loss) from aqueous EtOH or EtOH/Et_2O. The ***benzoyl*** derivative has **m 204°** (from EtOH). [*Beilstein* **12** IV 1497.]

2-Bromoanisole (1-bromo-2-methoxybenzene) *[578-57-4]* **C_7H_7BrO, M 187.0, m 2.5°, b 124°/40mm, 223°/atm, d_4^{20} 1.513, n_D^{25} 1.5717.** Crystallise the anisole by repeated partial freezing, then distil it under reduced pressure. [*Beilstein* **6** IV 1037.] ***4-Bromoanisole*** **(1-bromo-4-methoxybenzene)** *[104-92-7]* has **M 13.4°, b 99-100°/18mm, 124°/40mm, d_4^{20} 1.495, n_D^{25} 1.5617.** Crystallise the anisole by repeated partial freezing, then distil it under reduced pressure. [*Beilstein* **6** III 741, **6** IV 1044.]

9-Bromoanthracene *[1564-64-3]* **$C_{14}H_9Br$, M 257.1, m 98-100°.** Crystallise 9-bromoanthracene from MeOH or EtOH followed by sublimation *in vacuo*. [Masnovi et al. *J Am Chem Soc* **108** 1126 *1986*, DOI: 10.1021/ja00266a003; *Beilstein* **5** IV 2295.]

4-Bromobenzal diacetate *[55605-27-1]* **$C_{11}H_{11}BrO_4$, M 287.1, m 95°.** Crystallise the diacetate from hot EtOH (3ml/g). [Liebermann & Connor *Org Synth* Coll Vol **2** 441 *1948*, DOI: 10.15227/orgsyn.018.0061; *Beilstein* **7** II 182, **7** IV 579.]

Bromobenzene *[108-86-1]* **C_6H_5Br, M 157.0, m -31°, b 28°/5mm, 40°/10mm, 68.6°/40mm, 110°/200mm, 155.9°/atm, d_4^{20} 1.495, n_D^{20} 1.5588, n_D^{15} 1.56252.** Wash bromobenzene with concentrated H_2SO_4 (CARE) then 10% NaOH or $NaHCO_3$ solutions, and H_2O. Dry it with $CaCl_2$ or Na_2SO_4, or pass it through activated alumina, before refluxing with, and distilling from, CaH_2, using a glass helix-packed column. [*Beilstein* **5** IV 670.]

4-Bromobenzene diazonium tetrafluoroborate *[673-40-5]* **$C_6H_4BBrF_4N_2$, M 270.8, m 133°(dec), 135-140° (dec), 135°(dec).** Wash the salt with Et_2O until the wash is colourless and allow it to dry by blowing N_2 over it. Store it at 0-4° in the dark. [Schiemann & Pillarsky *Chem Ber* **64** 1340 *1931*, DOI: 10.1002/cber.19310640622; *Beilstein* **16** III 517.]

2-Bromobenzonitrile *[2042-37-7]* **C_7H_4BrN, M 182.0, m 52-54°, 55.8°, 56°, 53-57°, b 251-253°/754mm.** The nitrile is prepared from 2-bromobenzoic acid by treatment with $SOCl_2$ (23 hours boiling) and distilling to give ***2-bromobenzoyl chloride***, **b 120-126°/15mm, n_D^{20} 1.5925,** which on treatment with 12 equivalents of NH_3

gives a 98% yield of ***2-bromobenzamide*** **m 159.5-161.5°** *[4001-73-4]*. By boiling this amide with excess of $SOCl_2$ for 17 hours followed by evaporation and steam distillation gives an 84% yield of the nitrile that forms needles when crystallised from H_2O. [Lutz et al. *J Org Chem* **12** 617 *1947*, DOI: 10.1021/jo01169a001.] It has also been prepared by the method of Miller [*Org Synth* Coll Vol **3** 646, 648 *1955*, DOI: 10.15227/orgsyn.029.0075] in which the amide is treated with a large excess of $POCl_3$ in the presence of sodium metabisulfite ($Na_2S_2O_5$) to give the nitrile (**m 55-55.5°**) [Herbst & Wilson *J Org Chem* **22** 1142 *1957*, DOI: 10.1021/jo01361a002]. [*Beilstein* **9** H 348, **9** II 232, **9** III 1387, **9** IV 1013.]

2-Bromobenzoic acid (*o*-bromobenzoic acid) *[88-65-3]* **$C_7H_5BrO_2$, M 201.0, m 148.9°, 150°, pK^{20} 2.88.** Crystallise the acid from *C_6H_6 or MeOH. The ***anilide*** has **m 141°** (from EtOH/H_2O). [*Beilstein* **9** IV 1011.] ***3-Bromobenzoic acid*** **(*m*-bromobenzoic acid)** *[585-76-2]* has **m 155°, pK^{25} 3.81.** Crystallise the acid from acetone/water, MeOH or acetic acid. The ***anilide*** has **m 137°** (from EtOH/H_2O). [*Beilstein* **9** IV 1013.] ***3-Bromobenzoic acid hydrazide*** *[39115-96-3]* **$C_7H_7BrN_2O$, M 215.1,** prepared by heating the acid chloride or ester with excess of hydrazine hydrate and recrystallising from EtOH or aqueous EtOH has **m 157-159°** [*Beilstein* **9** H 351]. ***4-Bromobenzoic acid*** **(*p*-bromobenzoic acid)** *[586-76-5]* has **m 251-252°, 254-256°, 257-258°, pK^{25} 3.96.** Crystallise the acid from MeOH, or MeOH/water mixture, 90% EtOH and Et_2O. The ***methyl ester*** has **m 81°** from Et_2O or dilute MeOH. The ***anilide*** has **m 197°** (from EtOH). [Hale & Thorp *J Am Chem Soc* **35** 262 *1913*, DOI: 10.1021/ja02192a008; Vandenbelt et al. *Anal Chem* **26** 726 *1954*, DOI: 10.1021/ac60088a031; *Beilstein* **9** IV 1017.] The acid is also obtained by oxidation of 4-bromoalkyl (Pr, *iso*-Pr, Bu, *iso*-Bu and *sec*-Bu)benzenes (5ml) in refluxing solutions of concentrated HNO_3 (100ml) and H_2O [Lamneck *J Am Chem Soc* **76** 1106 *1954*, DOI: 10.1021/ja01633a051]. ***4-Bromobenzoic acid hydrazide*** *[5933-32-4]* **$C_7H_7BrN_2O$, M 215.1,** prepared by heating the ester, or acid chloride (see below) with excess of hydrazine hydrate and recrystallising from EtOH or aqueous EtOH has **m 165-167°** [*Beilstein* **9** H 354].

4-Bromobenzophenone *[90-90-4]* **$C_{13}H_9BrO$, M 261.1, m 79-84°**, **81°**, **81-82°**, **b 350°/atm.** Crystallise the phenone from EtOH. The ***2,4-dinitrophenylhydrazone*** forms orange-red leaflets from dioxane/EtOH with **m 207-209°**. [Allen & Van Allan *J Am Chem Soc* **66** 7 *1944*, DOI: 10.1021/ja01229a003; *Beilstein* **7** H 422, **7** III 2079, **7** IV 1378.]

4-Bromobenzoyl acetonitrile *[4592-94-3]* **C_9H_6BrNO, M 224.1, m 160-164°, 162.4-163.4°.** The nitrile is purified by dissolving in slightly alkaline H_2O (charcoal), filtering and acidifying with HCl to give colourless needles (**m 162-163°**). It recrystallises from EtOH. With Me_2SO_4/KOH at 130° it gives ***4-bromo–β-methoxy-cinnamylnitrile*** **m 58.5-59.5°** (from high boiling petroleum ether) [Fuson & Wolf *J Am Chem Soc* **61** 1940 *1939*, DOI: 10.1021/ja01877a002; Grothaus & Dains *J Am Chem Soc* **58** 1334 *1936*, DOI: 10.1021/ja01299a006]. [*Beilstein* **10** III 2998.]

4-Bromobenzoyl chloride *[586-75-4]* **C_7H_4BrClO, M 219.5, m 36-39°, 39.8°, 41°, b 62°/0.1mm, 104.5°/6mm, 126.4-127.2°/14mm, 174°/102mm.** Check IR of a film to see if OH bands are present. If absent then recrystallise from petroleum ether and dry it *in vacuo*. If OH bands are weak, then distil it *in vacuo* and recrystallise if necessary. If OH bands are very strong, then treat with an equal volume of redistilled $SOCl_2$ reflux for 2 hours, then evaporate excess of $SOCl_2$ and distil the residual oil or low melting solid. Store it in the dark away from moisture. **LACHRYMATORY**. [Martin & Partington *J Chem Soc* 1175 *1936*, DOI: 10.1039/JR9360001175; *Beilstein* **9** IV 1023.]

4-Bromobenzyl bromide *[589-15-1]* **$C_7H_6Br_2$, M 249.9, m 60-61°, 61-62.5°, 62-64°, b 115-124°/12mm, 125-135°/12mm.** It has been prepared by peroxide catalysed bromination, and recrystallised from EtOH, or/and distillation in a vacuum using a Fenske-type column (e.g. 31 cm in length packed with 1/16 in glass helicies with a take-off of the cold finger type) [Goerner & Nametz *J Am Chem Soc* **73** 2940 *1951*, DOI: 10.1021/ja01150a509]. [*Beilstein* **5** H 308, **5** IV 836.] **LACHRYMATORY**, use an efficient fume cupboard. ***p-Bromobenzyl chloride*** *[589-17-3]* **C_7H_6BrCl, M 205.5,** has **m 38-39°, 40-41°, b 100-115°/12mm, 136-137°/27mm.** It has been prepared by peroxide catalysed chlorination, and recrystallised from EtOH, and/or distil it in a vacuum using a Fenske-type column (e.g. 31 cm in length packed with 1/16 inch glass helicies with a take-off of the cold finger type) [Goerner & Nametz *J Am Chem Soc* **73** 2940 *1951*, DOI: 10.1021/ja01150a509]. [*Beilstein* **5** IV 832.] **LACHRYMATORY**, use an efficient fume cupboard.

2-Bromobiphenyl *[2052-07-5]* **$C_{12}H_9Br$, M 233.1, m 1.5-2.0°, b 140°/11mm, 148-150°/10mm, 297-298°/atm, d_4^{25} 1.352, n_D^{20} 1.6248.** 2-Bromobiphenyl is prepared from 2-aminobiphenyl (12g) in hot constant-boiling aqueous HBr (21g, 3-equivalents) by diazotisation at 5° with a solution of $NaNO_2$ (6g) in H_2O (10ml), then excess of HNO_2 is removed at the end of the reaction by addition of urea with stirring for 20 minutes. This solution is added dropwise into a solution of CuBr (from 15g of $CuSO_4$) in constant-boiling aqueous HBr (20ml) with stirring, set aside for 20 minutes, after which the brown complex is decomposed by heating on a steam bath for 2 hours. The dark oil is extracted into Et_2O, the extract is filtered through glass wool, washed with H_2O, dilute NaOH, H_2O again, dried ($CaCl_2$), filtered, evaporated and the residual oil is distilled to give a pale yellow oil (7g, b 146-152°/12mm). Further purification can be achieved by dissolving it in $*C_6H_6$, passing through an alumina column and eluting with $*C_6H_6$, evaporating to dryness and distilling the residual oil (b 148-150°/10mm) to yield pure colourless 2-bromobiphenyl. This has been recrystallised from pentane at -40° to give a liquid with a freezing point of 1.5-2.0°. [de la Mare & Hassan *J Chem Soc* 3004 *1957*, DOI: 10.1039/JR9570003004; Augood et al. *J Chem Soc* 3412 *1953*, DOI: 10.1039/JR9530003412; NMR: Brownstein *J Am Chem Soc* **80** 2300 *1958*, DOI: 10.1021/ja01150a509; *Beilstein* **5** H 580, **5** II 485, **5** III 1742, **5** IV 1818.] It is used for the preparation of John-Phos and related catalytic ligands (see Chapter 5, Catalysis—Part 2). ***3-Bromobiphenyl*** *[2113-57-7]* has **b 103-104°/0.2mm, 110°/1mm, 158-167°/11mm, 169-173°/17mm, d_4^{25} 1.3976, n_D^{20} 1.6380.** 3-Bromobiphenyl can be prepared by bromination of 2-acetamidobiphenyl (m 118-119° from aqueous AcOH) with one molecular equivalent of Br_2 in AcOH; the monobromo derivative (m 127-127.5° from EtOH) is hydrolysed with 95% EtOH/conc HCl (1.4:1, 4 hours reflux) poured into excess of H_2O, basified and filtered off to give 2-amino-5-bromobiphenyl (m 53-56°). The base is subsequently diazotised and the diazonium salt is deaminated by warming with Cu bronze or with hypophosphorous acid [cf. Kornblum in *Organic Reactions* J. Wiley & Sons NY, **II** 294 *1944*] to yield crude 3-bromobiphenyl which is isolated by steam distillation, extraction of the distillate with $*C_6H_6$, washing the extract successively with, dilute NaOH, H_2O, concentrated H_2SO_4, H_2O, drying (K_2CO_3), evaporating and distilling. This can be purified further by passing a solution of it in $*C_6H_6$ through an Al_2O_3 column, eluting with $*C_6H_6$, and the combined eluates are distilled. The distillate is dissolved in petroleum ether (b 40-60°), washed several times with concentrated H_2SO_4, H_2O again, aqueous $NaHCO_3$, H_2O again, dried ($CaCl_2$), filtered, the solvent is evaporated off and the residue is fractionally distilled to give pure *3-bromobiphenyl*. [de la Mare & Hassan *J Chem Soc* 3004 1957, DOI: 10.1039/JR9570003004; Lichtin & Leftin *J Am Chem Soc* **74** 4207 *1952*, DOI: 10.1021/ja01136a510; Huber et al. *J Am Chem Soc* **68** 1109 *1946*, DOI: 10.1021/ja01210a060]. It has also been prepared in low yield (13%) from diazotized *m*-bromoaniline and $*C_6H_6$ according to Gomberg and purified as above [Marvel et al. *J Am Chem Soc* **61** 77 *1939*, DOI: 10.1021/ja01870a022, also see 4-bromobiphenyl below]. [*Beilstein* **5** II 485, **5** III 1742, **5** IV 1818.] ***4-Bromobiphenyl*** *[92-66-0]* has **m 82-86°, 88.8-89.2°, 89.5°, 90°, b 170-175°/8mm, 310°/atm.** This biphenyl is prepared by the method of Gomberg & Bachmann [*Org Synth* Coll Vol **1** 113 *1944*, DOI: 10.15227/orgsyn.008.0042] from diazotised 4-bromoaniline and benzene, then extract into Et_2O, wash with base, acid, brine, dry (Na_2SO_4), filter, evaporate and recrystallise to constant melting point from absolute EtOH (89.7°, after drying *in vacuo*). [Elks et al. *J Chem Soc* 1284 *1940*, DOI: 10.1039/JR9400001284; Augood et al. *J Chem Soc* 3412 *1953*, DOI: 10.1039/JR9530003412; *Beilstein* **5** H 580, **5 I 275, 5** II 485, **5** III 1742, **5** IV 1819.]

1-Bromo-2-chlorobenzene *[694-80-4]* **C_6H_4BrCl, M 191.5, m -12°, b 79-82°/14mm, 200-202°/atm, 204°/atm, d_4^{25} 1.638, n_D^{20} 1.582.** *o*-Chlorobromobenzene has been prepared in at least three different ways. It is obtained in 54% yield by carrying out a Sandmeyer reaction from *o*-chloroaniline *via* diazotisation (using $NaNO_2$/HBr) and decomposing it with CuBr in 48% aqueous HBr. Steam distil off the product, basify the distillate with 20% aqueous NaOH (extract it into Et_2O if quantities are small), dry the organic layer (Na_2SO_4), filter and distil [Fry & Grote *J Am Chem Soc* **48** 710, *1926*, DOI: 10.1021/ja01414a025]. The second procedure involves adding Br (32g) in CCl_4 (50ml) during 20 minutes to refluxing silver 2-chlorobenzoate in CCl_4 (250ml), boil for a further 30 minutes to complete the decarboxylation, filter off the AgBr, wash the filtrate with aqueous Na_2SO_3 (until red colour of Br is discharged), aqueous 0.5M Na_2CO_3 (2 x 25ml), evaporate the solvent and distil bromochlorobenzene (38-48% yield) [Dauben & Tilles *J Am Chem Soc* **72** 3185 *1950*, DOI: 10.1021/ja01163a105; Barnes & Prochaska *J Am Chem Soc* **72** 3188 *1950*, DOI: 10.1021/ja01163a106]. The third procedure involves phase transfer catalytic radical bromination. *o*-Chlorobenzene free radical is generated from the respective *o*-benzenediazonium$^+$ BF_4^- with KOAc/THF and a

catalytic amount of 18-crown-6 using $CBrCl_3$ as brominating agent to produce *o*-bromochlorobenzene in 70% yield, a great improvement on the Sandmeyer method [Korzeniowski & Gokel *Tetrahedron Lett* 3519 *1977*, DOI: 10.1016/S0040-4039(01)83281-0]. [*Beilstein* **5** H 209, **5** I 115, **5** II 161, **5** III 562, **5** IV 680.]

4-Bromo-4'-chlorobenzophenone *[27428-57-5]* **$C_{13}H_8BrClO$, M 295.6, m 150°.** Crystallise the phenone from EtOH or $*C_6H_6$ and further purify it by zone refining (100 passes) [Groves & Turner *J Chem Soc* 509 *1929*, DOI: 10.1039/JR9290000509; Lin & Hanson *J Phys Chem* **91** 2279 *1987*, DOI: 10.1021/j100293a014]. [*Beilstein* **7** II 360, **7** III 2081.]

2'-Bromo-2,6-dimethoxybiphenyl *[755017-61-9]* **$C_{14}H_{13}BrO_2$, M 293.2, m 141-142°, 143-146°.** This intermediate, which is used for the preparation of the ligand S-Phos, is synthesised by adding *n*-BuLi (9.60ml, 1.6M solution in hexanes, 15.4mmol, 1.2 equivalents) *via* a syringe over 5 minutes to a cold (0°) solution of 1,3-dimethoxybenzene (2.00ml, 15.3mmol, 1.2 equivalents, *[151-10-0]*) in dry THF (30ml), allowing the temperature to rise to ~25°, then it is stirred for 5 hours. The mixture is re-cooled (0°) and 2-bromochlorobenzene (1.50ml, 12.8mmol, 1.0 equivalents, [694-80-4]) is added dropwise *via* a syringe over 15 minutes while stirring vigorously; and the burgundy coloured solution is stirred for a further 15 minutes at 0°. MeOH (0.25ml) is added *via* syringe to decompose excess BuLi, the whole is evaporated to dryness *in vacuo*, the residue is then stirred with Et_2O (50ml) and H_2O (50ml), the layers are separated, the aqueous phase is extracted with Et_2O (2 x 25ml), the combined Et_2O solutions are dried ($MgSO_4$), filtered and evaporated *in vacuo*. The yellow residue is recrystallised from MeOH to provide the analytically pure biphenyl (3.03g, 81%) as pale yellow crystals. The IR (film) has ν_{max} at 2964, 1584, 1472, 1432, 1248, 1108, 1025, 783 cm^{-1}; the ^1H NMR [100MHz, $CDCl_3$] has δ at 7.69 (dd, *J* = 6.9, 1.1Hz, 1H), 7.34-7.40 (m, 2H), 7.20-7.28 (m, 2H), 6.68 (d, *J* = 8.5Hz, 2H), 3.76 (s, 6H) from TMS; the ^{13}C NMR [75MHz, ^1H decoupled, $CDCl_3$] has δ at 157.8, 136.25, 132.52, 132.47, 129.6, 128.8, 127.1, 125.4, 119.0, 104.2, 56.2 from TMS. [Barder et al. *J Am Chem Soc* **127** 4685 *2005*, DOI: 10.1021/ja042491j.]

4-Bromo-*N*,*N*-dimethylaniline *[586-77-6]* **$C_8H_{10}BrN$, M 200.1, m 55°, b 264°/atm, pK 19.2 (acidic), pK^{25} 4.23.** Reflux it for 3 hours with two equivalents of Ac_2O, then fractionally distil it. [*Beilstein* **12** IV 1499.]

1-Bromo-2,4-dinitrobenzene *[584-48-5]* **$C_6H_3BrN_2O_4$, M 247.0, m 72.5-73°, 75°.** Crystallise it from ethyl ether, isopropyl ether, 80% EtOH or absolute EtOH. [*Beilstein* **5** III 640, **5** IV 749.]

***N*-(2-Bromoethyl)phthalimide** *[574-98-1]* **$C_{10}H_8BrNO_2$, M 254.1, m 81-83°, 82.5-83.5°.** The following is to be carried out in an efficient **FUME HOOD**. Dissolve the compound (180g) in CS_2 (500 ml) by refluxing for 15 minutes (to cause the separation of the most likely impurity, 1,2-diphthalimidoethane), filter and evaporate under reduced pressure. The product forms light tan crystals (**m 78-80°**). Recrystallise it from EtOH (charcoal) [the compound (50g) is dissolved in hot 75% EtOH (200ml), boiled for *ca* 10 minutes, carbon is added (5g, Norite), filter and cool to 0°], to give white crystals (40g) which can be recrystallised (**m 80-81°**); and further recrystallisation gives **m 82-83°**. [Salzberg & Supniewski *Org Synth* Coll Vol **I** 119 *1932*, DOI: 10.15227/orgsyn.007.0008; Landini & Rolla *Synthesis* 389 *1976*, DOI: 10.1055/s-1976-24051; *Beilstein* **21/10** V 275.]

3-Bromo-5-hydroxybenzoic acid *[140472-69-1]* **$C_7H_5BrO_3$, M 217.0, m 233.5°, 237-241°, $pK_{Est(1)}$ ~2.3, $pK_{Est(2)}$ ~13.0.** The acid crystallises from H_2O (**m 238-239°**), and with Me_2SO_4 it yields the ***5-methoxy*** derivative with **m 190-191°** (from EtOH). The ***5-methoxy-methyl ester***, prepared by reaction of the acid chloride with MeOH, has **b 156-157°/4mm**. [Baddar et al. *J Chem Soc* 469 *1955*, DOI: 10.1039/JR9550000465; *Beilstein* **10** IV 333.]

2-Bromomethylanthraquinone (MAQ-Br) *[7598-10-9]* **$C_{15}H_9BrO_2$, M 301.1, m 200-202°, 203°(dec).** Recrystallise the quinone from AcOH, wash the crystals with a little Et_2O, dry it in air and then in a vacuum at 100°. It is prepared by bromination of 2-methylanthraquinone with $Br_2/PhNO_2$ at 145-150°, or *N*-bromosuccinimide in CCl_4 containing a trace of $(PhCOO)_2$. [*Beilstein* **7** IV 2576.]

2-(Bromomethyl)benzonitrile *[22115-41-9]* **C_8H_6BrN, M 196.0, m 72-74°, 72-73°, 79°, b 152-155°/15mm.** Purify the nitrile by steam distillation. Extract the distillate with Et_2O, dry the extract (Na_2SO_4), evaporate and

distil the residue. The solidified distillate can be recrystallised from petroleum ether or cyclohexane. ^{1}H NMR ($CDCl_3$) with δ at 7.8-7.2 (m 4H), 4.62 (s, 2H); the IR has ν_{max} at 2238 cm^{-1}. [Drory *Chem Ber* **24** 2563 *1891*, DOI: 10.1002/cber.18910240254; Borsche et al. *Chem Ber* **67** 675 *1934*, DOI: 10.1002/cber.19340670428; Buckley et al. *Aust J Chem* **22** 577 *1969*, DOI: 10.1071/CH9690577; *Beilstein* **9** III 2312.] **LACHRYMATORY**, use an efficient fume cupboard.

4-Bromo-α-methylbenzyl alcohol *[(±) 5391-88-8, 25675-29-0, R-(+) 76155-78-7, S-(-) 100760-04-1]* **C_8H_9BrO, M 201.1.** The (±)-racemate is purified by distillation in a vacuum (**b 90°/1mm, 119-121°/7mm**, **d** 1.46) and it solidifies on cooling (**m 36-37°**) [Overberger et al. *Org Synth* Coll Vol **3** 200 *1955*, DOI: 10.15227/orgsyn.028.0028]. The ***(±)-tosyl*** derivative *[114200-15-6]* has **m 56-57°**. The *R-(+)-enantiomer* is also purified by distillation in a vacuum (**b 110°/3mm**, d_4^{25} 1.322, n_D^{20} 1.569) and has $[\alpha]_D^{20}$ +39 (c 1, $CHCl_3$), +32.9 (c 1.39, MeOH). The *S-(-)-enantiomer* is similarly purified, and has respective negative optical rotations. [Stein et al. *Can J Chem* **63** 3442 *1985*, DOI: 10.1139/v85-565; Cervinka et al. *Col Czech Chem Commun* **51** 401 *1986*, DOI: 10.1135/cccc19860401; *Beilstein* **6** II 447.]

2-(Bromomethyl)-naphthalene *[939-26-4]* **$C_{11}H_9Br$, M 221.1, m 52-54°, 56°, 56-57°, b 133-136°/0.8mm, 214°/100mm.** Dissolve the bromo compound in toluene, wash it with saturated aqueous $NaHCO_3$, dry (Mg SO_4), evaporate, fractionally distil the residue and recrystallise the solidified distillate from EtOH. [Chapman & Williams *J Chem Soc* 5035, *1952*, DOI: 10.1039/JR9520005035; Bergmann & Szmuszkovicz *Bull Soc Chim Fr* **20** 566 *1953*, *Beilstein* **5** IV 1698.] **LACHRYMATORY.**

1-Bromonaphthalene *[90-11-9]* **$C_{10}H_7Br$, M 207.1, m -2 to -1°** and **m 6.2°** (to modifications), **b 84.2°/1mm, 118°/6mm, 133.6°/10mm, 172.2°/40mm, 281.1°/760mm, d_4^{20} 1.4834, $n_D^{16.5}$ 1.66011.** Purify 1-bromonaphthalene by passage through activated alumina, and three vacuum distillations. It darkens in air on standing when distilled at atmospheric pressure but not so when distilled in a vacuum below 15mm. It is used in *refractometry*, e.g. determination of H_2O in EtOH by the cloud method, determination of refractive index of crystals when immersed in it, for determination of fat content; and in microscopy as a general immersion oil when mixed with polymerised castor oil. The ***1,3,5-trinitrobenzene complex***, **m 137°**, crystallises in yellow needles from EtOH. [Clarke & Brethen *Org Synth* Coll Vol **I** 121 *1941,* DOI: 10.15227/ orgsyn.001.0035; *Beilstein* **5** H 547, **5** IV 1665.] ***2-Bromonaphthalene*** *[580-13-2]* has **m 52-55°, 54-56°, 59°, 123-127°/5mm, 281.1°/760mm, d^{25} 1.605g/ml, n_D^{20} 1.663.** Purify 2-bromonaphthalene by fractional elution from a chromatographic column of activated alumina. Crystallise it from EtOH. [*Beilstein* **5** IV 1667.]

1-Bromo-2-naphthol *[573-97-7]* **$C_{10}H_7BrO$, M 223.1, m 76-78°, 83°, 84°, pK_{Est} ~8.0.** Distil the naphthol at 10mm then recrystallise it from *C_6H_6/petroleum ether (b 30-60°) **m 80-81°**. The ***benzoyl*** derivative has **m 98.5-99.5°** (from MeOH). [Hazlet *J Am Chem Soc* **62** 2156 *1940*, DOI: 10.1021/ja01865a065; *Beilstein* **6** H 650, **6** II 604, **6** III 2994.] ***6-Bromo-2-naphthol*** *[15231-91-1]* has **m 122-124°, 122-126°, pK_{Est} ~9.1.** Crystallise the naphthol from EtOH or *C_6H_6/petroleum ether (**m** 128°). The ***benzoyl*** derivative has **m 122°**, (from EtOH). [Ruggli & Michels *Helv Chim Acta* **14** 779 *1931*, DOI: 10.1002/hlca.19310140411; *Beilstein* **6** H 651, **6** II 605, **6** III 2996.]

ω-Bromo-4-nitroacetophenone *[99-81-0]* **$C_8H_6BrO_3$, M 244.1, m 94-99°, 98°.** Crystallise it from *C_6H_6/petroleum ether. [*Beilstein* **7** IV 661.] **IRRITANT.**

2-Bromonitrobenzene (2-bromo-1-nitrobenzene) *[577-19-5]* **$C_6H_4BrNO_2$, M 202.1, m 40 to 42°, 43°, b 261°/atm.** Crystallise it twice from petroleum ether, using charcoal before the first crystallisation. [*Beilstein* **5** III 618, **5** IV 728.] ***3-Bromonitrobenzene*** **(3-bromo-1-nitrobenzene)** *[585-79-5]* has **m 51° to 54°, 53.5-55.5°, 55-56°, b 256°/atm.** Crystallise it twice from petroleum ether, using charcoal before the first crystallisation. [*Beilstein* **5** III 618, **5** IV 729.]

4-Bromonitrobenzene (4-bromo-1-nitrobenzene) *[586-78-7]* **$C_6H_4BrNO_2$, M 202.1, m 124 to 126°, 127°, b 255-256°/atm.** Crystallise it twice from petroleum ether, using charcoal before the first crystallisation. [*Beilstein* **5** III 619, **5** IV 729.]

4-Bromophenacyl bromide *[99-73-0]* **$C_8H_6Br_2O$, M 277.9, m 108 to 110°, 109-110°, 110-111°.** Crystallise the bromide from EtOH (*ca* 8ml/g). Useful for making phenacyl esters for characterising carboxylic acids by reacting with the Na salt of the acid. [Langley *Org Synth* Coll Vol **1** 127 *1941*, DOI: 10.15227/orgsyn.009.0020; *Beilstein* **7** IV 652.]

2-Bromophenol *[95-56-7]* **C_6H_5BrO, M 173.0, m 3 to 7°, 6°, b 195°/atm, d_4^{20} 1.492, n_D^{20} 1.589, pK^{20} 8.508, pK^{30} 8.400, pK^{35} 8.352, pK^{40} 8.308, pK^{50} 8.231.** Purify the phenol by at least two passes through a chromatographic column and distil it. [*Beilstein* **6** IV 1037.] ***3-Bromophenol*** *[591-20-8]* has **m 28 to 32°, 31°, b 88-89°/3mm, 236°/atm, pK^{20} 9.099, pK^{30} 8.967, pK^{35} 8.907, pK^{40} 8.853, pK^{50} 8.753, pK^{60} 8.666.** Purify the phenol by at least two passes through a chromatographic column and distil it. [Carpenter et al, *J Org Chem* **16** 586 *1951*, DOI: 10.1021/jo01144a011; *Beilstein* **6** IV 1037.] ***4-Bromophenol*** *[106-41-2]* has **m 64°, 235-236°/atm, pK^{25} 9.36, $pK^{31.9}$ 9.244, $pK^{39.7}$ 9.152, $pK^{45.3}$ 9.073, $pK^{50.8}$ 9.019, $pK^{56.0}$ 8.971, $pK^{58.6}$ 8.947.** Crystallise the phenol from $CHCl_3$, CCl_4, petroleum ether (b 40-60°), Et_2O or water (14.3wt% at ~25°), and dry it at 70° under vacuum for 2 hours. It is used as a disinfectant. [*Beilstein* **6** IV 1043.]

4-Bromophenoxy)acetic acid *[1878-91-7]* **$C_8H_7BrO_3$, M 231.1, m 157°, 158°, pK^{25} 3.13.** Crystallise the acid from EtOH or H_2O (**m 161.4-161.8°**). [Hayes & Branch *J Am Chem Soc* **65** 1555 *1943*, DOI: 10.1021/ja01248a031; *Beilstein* **6** III 747, **6** IV 1052.]

3-(4-Bromophenoxy)propionic acid *[93670-18-9]* **$C_9H_9BrO_3$, M 245.1, m 146°, pK_{Est} ~4.2.** Crystallise the acid from EtOH, MeOH or *C_6H_6/hexane (**m 144-145°**). [*Beilstein* **6** III 748, **6** IV 1052.]

4-Bromophenylacetic acid *[1878-68-8]* **$C_8H_7BrO_2$, M 215.0, m 112-113°, 113-115°, 114°, pK^{25} 4.19.** The acid crystallises from H_2O as needles. The ***acid chloride*** has **b 238°/760mm, m 50°**, the **4-*nitrobenzyl ester*** forms elongated prisms from EtOH with **m 128-129°**, and the ***anilide*** has **m 174-175°**. [Dippy & Williams *J Chem Soc* 161 *1934*, DOI: 10.1039/JR9340000161; Campbell & McKail *J Chem Soc* 1251 *1948*, DOI: 10.1039/JR9480001251; Schwenk & Papa *J Org Chem* **11** 798 *1946*, DOI: 10.1021/jo01176a023; *Beilstein* **9** III 2275.]

4-Bromophenylhydrazine *[589-21-9]* **$C_8H_7BrO_2$, M 187.1, m 108-109°, pK^{20} -5.6 (aqueous H_2SO_4), pK^{25} 5.05.** Crystallise the hydrazine from H_2O. The ***hydrochloride*** crystallises from EtOH/H_2O with **m 213-214°**, and the ***tosylate*** has **m 212°** (from EtOH). [*Beilstein* **15** H 434, **15** I 117, **15** II 160, **15** III 289, **15** IV 282.]

4-Bromophenyl isocyanate *[2493-02-9]* **C_7H_4BrNO, M 189.0, m 41-42°, 42-44°, b 158°/14mm.** Crystallise the isocyanate from petroleum ether (b 30-40°). It has a pungent odour. [*Beilstein* **12** H 647, **12** I 321.]

4-Bromophenyl isothiocyanate *[1985-12-2]* **C_7H_4BrNO, M 214.1, m 56-58°.** Recrystallise the isothiocyanate from boiling *n*-hexane. Any insoluble material is most probably the corresponding urea. It is also purified by steam distillation, cool the receiver, add NaCl and extract in Et_2O, wash the extract with N H_2SO_4, dry ($MgSO_4$), evaporate and recrystallise the residual solid. [Cymerman-Craig et al. *Org Synth* Coll Vol **4** 700 *1963*, DOI: 10.15227/orgsyn.036.0056; cf. Dains et al. *Org Synth* Coll Vol **1** 447 *1941*, DOI: 10.15227/orgsyn.006.0072; *Beilstein* **6** IV 1051, **12** II 354, **12** III 1463p, **12** IV 1519.]

***N*-(3-Bromopropyl)phthalimide** *[5460-29-7]* **$C_{11}H_{10}BrNO_2$, M 268.1, m 72-74°, 74°.** Place it in a Soxhlet and extract it with Et_2O, whereby the bis-phthalimido impurity is not extracted. Evaporate the Et_2O and recrystallise the residue from EtOH, aqueous EtOH or petroleum ether. [Gabriel & Weiner *Chem Ber* **21** 2669 1888, DOI: 10.1002/cber.18880210288; Gaudry *Can J Chem* **31** 1060 *1953*, DOI: 10.1139/v53-139; *Beilstein* **21/10** V 1277.]

5-Bromosalicyl hydroxamic acid *[5798-94-7]* **C_7H_6BrNO, M 210.1, m 232°(dec), $pK_{Est(1)}$~ 1.5, $pK_{Est(2)}$~ 7.0, $pK_{Est(3)}$~ 8.7.** Crystallise the hydroxamic acid from H_2O (**m 249°**) or from EtOH (**m 232° dec**). It sublimes *in vacuo* and sublimate has **m 235°**. It complexes with metals and is tuberculostatic. [*Beilstein* **10** IV 221.]

4-Bromostyrene *[2039-82-9]* **C_8H_7Br, M 183.1, b 49.5-50°/2.5mm, 87-88°/12mm, 89°/16mm, 102-104°/**

20mm, d_4^{20} 1.3984, n_D^{20} 1.5925. It polymerises above 75° in the presence of benzoyl peroxide. To purify, if it has not gone to a solid resin, dissolve it in Et_2O, dry ($MgSO_4$) and add *ca* 0.1g of 4-*tert*butylcatechol (polymerisation inhibitor) per 100g of bromostyrene. Filter, evaporate this under reduced pressure (use as high a vacuum as possible) and distil the residue. Store it in dark bottles in the presence of the inhibitor (at above concentration). [Overberger & Saunders *Org Synth* Coll Vol **3** 204 *1955*, DOI: 10.15227/orgsyn.028.0031; *Beilstein* **5** IV 1349.]

2-Bromotoluene *[95-46-5]* **C_7H_7Br, M 171.0, m -27°, b 58-60°/10mm, 74°/19mm, 181.7°/760mm, d_4^{20} 1.422, n_D^{20} 1.556.** Fractionally distil it through an efficient column. It can be separated from its isomers by gas chromatography on a column of 'Sil-o-cel' firebrick (30-40mesh, 80 parts) coated with 5% (20 parts) of ICI E301 con rubber with N_2 carrier gas at 170°/atm and 100ml/minute and using a conductivity cell detector. [Cowley et al. *J Chem Soc* 1799 *1959*, DOI: 10.1039/JR9590001799; *Beilstein* **5** H 304, **5** I 153, **5** II 234 **5** III 704, **5** IV 825.] ***4-Bromotoluene*** *[106-38-7]* has **m 28°, b 184°/atm, d_4^{20} 1.390.** Crystallise it from EtOH [Traylor & Stewart *J Am Chem Soc* **108** 6977 *1986*, DOI: 10.1021/ja00282a023]. [*Beilstein* **5** IV 827.]

α-Bromo-4-toluic acid [4-(bromomethyl)benzoic acid] *[6232-88-8]* **$C_8H_7BrO_2$, M 215.0, m 224 to 229°, 229-230°, pK_{Est} ~3.2.** Crystallise the acid from Me_2CO. [*Beilstein* **9** IV 1745.]

α-Bromo-*p*-xylene (4-methylbenzyl bromide) *[104-81-4]* **C_8H_9Br, M 185.1, m 35°, 38°, b 120°/15mm, 218-220°/740mm.** Crystallise the bromide from EtOH or pentane. [*Beilstein* **5** H 385, **5** IV 969.] **STRONG LACHRYMATOR.**

2-*tert*-Butoxycarbonyloxyimino-2-phenylacetonitrile (BOC-ON) *[58632-95-4]* **$C_{13}H_{14}N_2O_3$, M 246.3, m 87-89°.** Triturate the solid with 90% aqueous MeOH, filter, wash with 90% aqueous MeOH and dry it in a vacuum. Recrystallise it from MeOH (needles or plates), but use warm MeOH and cool to crystallise; *do not boil as it decomposes slowly*. Its IR has ν_{max} at 1785 (C=O) cm^{-1} and NMR ($CDCl_3$) usually shows two *tert*-butyl singlets for *syn* and *anti* isomers. Store it in a brown bottle (fridge). It evolves CO_2 at room temperature (stoppered bottle can explode!), but can be stored over silica gel which may extend its useful life to more than a year. [Itoh et al. *Org Synth* **59** 95 *1980*, DOI: 10.15227/orgsyn.059.0095.]

4-Butoxyphenylacetic acid *[4547-57-3]* **$C_{12}H_{16}O_3$, M 208.3, m 86-87°, 88.5°, pK_{Est} ~4.4**. Recrystallise it from petroleum ether (b 40-60°). [McElvain & Carney *J Am Chem Soc* **68** 2592 *1946*, DOI: 10.1021/ja01216a051; *Beilstein* **10** IV 545.]

***n*-Butyl 4-aminobenzoate (Butamben)** *[94-25-7]* **$C_{11}H_{15}NO_2$, M 193.2, m 57-59°, b 174°/8mm, pK_{Est} ~2.5.** Crystallise Butamben from EtOH, or/and distil it in a high vacuum. It is poorly soluble in H_2O (0.014w/v%). It is used as a local anaesthetic. [*Beilstein* **14** IV 1130.]

***tert*-Butylammonium bromide** *[60469-70-7]* **$C_4H_{12}BrN$, M 154.1, m >250°(dec).** Recrystallise the salt several times from absolute EtOH or by dissolving in absolute EtOH and adding Et_2O slowly to crystallise the salt. Dry it thoroughly at 105°. [IR: Chenon & Sandorfy *Can J Chem* **36** 1181 *1958*, DOI: 10.1139/v58-173; *Beilstein* **4** IV 659.]

2-*tert*-Butylanthracene *[13719-97-6]* **$C_{18}H_{18}$, M 234.3, m 148-149°.** Recrystallise the anthracene from EtOH and finally purify it by TLC. [*Beilstein* **5** IV 2364.]

n*-Butylbenzene** *[104-51-8]* **$C_{10}H_{14}$, M 134.2, m -88°, b 22.7°/1.0mm, 48.8°/5mm, 76.3°/20mm, 102.6°/60mm, 136.9°/200mm, 183.3°/atm, d_4^{20} 0.860, n_D^{20} 1.4897, n_D^{25} 1.487.** Distil butylbenzene from sodium. Wash it with small portions of conc H_2SO_4 until the acid is no longer coloured, H_2O then aqueous Na_2CO_3(**care**). Dry it ($MgSO_4$), and distil it twice from Na, collecting the middle fraction [Vogel *J Chem Soc* 607 *1948*, DOI: 10.1039/JR9480000607]. [*Beilstein* **5** IV 1033.] ***tert-Butylbenzene *[98-06-6]* has **m -51.8°, b 13.0°/1.0mm, 39.0°/5mm, 65.5°/20mm, 90.6°/60mm, 123.7°/200mm, 169.1°/atm, d_4^{20} 0.8669, n_D^{20} 1.493, n_D^{25} 1.490.** Wash it with cold concentrated H_2SO_4 until a fresh portion of acid is no longer coloured, then with 10% aqueous NaOH (care-effervescence), followed by distilled water until neutral. Dry it ($CaSO_4$), and distil it in a

glass helices-packed column, taking the middle fraction. [*Beilstein* **5** IV 1045.]

4-*tert*-Butyl benzoyl chloride *[1710-98-1]* **$C_{11}H_{13}ClO$, M 196.7, b 135°/10mm, 149.9-150.5°/14mm, 266-268°(dec), d_4^{20} 1.082, n_D^{20} 1.536.** Distil it in a vacuum. If IR shows OH group, then treat it with thionyl chloride or oxalyl chloride at *ca* 50° for 30 minutes, evaporate and fractionate it in a vacuum using a short column. Strongly **LACHRYMATORY**; use a good fume hood. [Fuson & Tull *J Am Chem Soc* **71** 2544 *1949*, DOI: 10.1021/ja01175a086; Tsuno et al. *Bull Chem Soc Jpn* **32** 960 *1959*, DOI: org/10.1246/bcsj.32.960; Swain et al. *J Am Chem Soc* **72** 5426 *1950*, DOI: 10.1021/ja01168a017; *Beilstein* **9** III 2526.]

4-*tert*-Butylcatechol *[98-29-3]* **$C_{10}H_{14}O_2$, M 166.22, m 47-48°, 55-56°, 58°, b 285°/atm, $pK_{Est(1)}$ ~9.5, $pK_{Est(2)}$ ~13.0.** Distil it in a vacuum, then recrystallise it from pentane or petroleum ether (or $*C_6H_6$). [*Beilstein* **6** IV 6014.]

6-*tert*-Butyl-1-chloro-2-naphthol *[525-27-9]* **$C_{14}H_{15}ClO$, M 234.7, m 76°, b 185°/15mm, pK_{Est} ~8.0.** Recrystallise the naphthol from petroleum ether. Its *methyl ether* has **m 115°** (from EtOH/petroleum ether). [Buu-Hoi et al. *J Org Chem* **15** 1060 *1950*, DOI: 10.1021/jo01151a024; *Beilstein* **6** IV 4367.]

2-*tert*-Butyl-4,5-dimethylphenol *[1445-23-4]* **$C_{12}H_{18}O$, M 178.3, b 144-150°/20mm, pK_{Est} ~11.8.** It is obtained by placing 3,4-dimethylphenol (170g, 1.39mol, m ~65°, see [95-65-8]), concentrated H_2SO_4 (1.5ml) and a magnetic stirrer bar in a medium pressure vessel, then purging the closed vessel with isobutylene while heating and stiring vigorously at 70° (which keeps the phenol in a molten state) under an isobutylene pressure of 20 psi. The reaction is complete when the liquid stops expanding. The mixture is cooled, Et_2O is added and the mixture is washed with saturated aqueous $NaHCO_3$ (3 x 150ml), the combined organic layers are dried ($MgSO_4$), filtered, the solvent is evaporated and the residual oil is distilled to give *2-tert-butyl-4,5-dimethylphenol*, and its ^1H NMR (400MHz, $CDCl_3$, TMS) has δ at 7.02 (s, 1H, aromatic C*H*), 6.49 (s, 1H, aromatic C*H*), 2.19 (s, 3H, CH_3), 2.17 (s, 3H, CH_3), 1.40 (s, 9H, $C(CH_3)_3$). ***Note*** *tert-butyl 3,4-dimethylphenyl ether is formed instead when lower temperatures and very small amounts of acid are used* [Stevens *J Org Chem* **20** 1232 *1955*, DOI: 10.1021/jo01126a010; Alexander et al. *J Am Chem Soc* **120** 4041 *1998*, DOI: 10.1021/ja974353i; Albert *J Am Chem Soc* **76** 4983 *1954*, DOI: 10.1021/ja01648a068; for *acetyl derivative* see Fischer & Teo *Can J Chem* **56** 258 *1978*, DOI: 10.1139/v78-041.]

2-*tert*-Butyl hydroquinone *[1948-33-0]* **$C_{10}H_{18}O$, M 166.2, m 125-127°, 127-128°, 129°, $pK_{Est(1)}$ ~10.5. $pK_{Est(2)}$ ~11.6.** Recrystallise the hydroquinone from H_2O or MeOH and dry it in a vacuum at 70°. Store it in a dark container. [Stroh et al. *Angew Chem* **69** 699 *1957*, DOI: 10.1002/ange.19570692202; *Beilstein* **6** IV 6013.]

2-*tert*-Butyl-4-methoxyphenol (2-*tert*-butyl-4-hydroxyanisole, BHA) *[121-00-6]* **$C_{11}H_{16}O$, M 180.3, m 64.1°, pK_{Est} ~10.8.** Fractionally distil the phenol *in vacuo*, then pass it as a solution in $CHCl_3$ through alumina, and evaporate the eluate. Recrystallise the residue from petroleum ether. [*Beilstein* **6** IV 6013.]

4-*tert*-Butylnitrobenzene *[3282-56-2]* **$C_{10}H_{13}NO_2$, M 179.2, m 28.4°, b 135°/10mm, 140-142°/15mm, n_D^{20} 1.5230.** Recrystallise it three times by partially freezing a mixture of the mono-nitro isomers, then recrystallise it twice from MeOH and dry it *in vacuo* [Brown *J Am Chem Soc* **81** 3232 *1959*, DOI: 10.1021/ja01522a018]. [*Beilstein* **5** H 418, **5** I 203, **5** II 321, **5** III 943, **5** IV 1052.]

***tert*-Butyl perphthalic acid (monoperoxyphthalic acid 1-*tert*-butyl ester)** *[15042-77-0]* **$C_{12}H_{14}O_5$, M 238.2, m 104-104.5° (dec), pK_{Est} ~6.2.** Crystallise the per acid-ester from Et_2O or Et_2O/petroleum ether and dry it over H_2SO_4. The ester was prepared from *tert*-butylhydroperoxide and phthalic anhydride [Davies et al. *J Chem Soc* 1541 *1953*, DOI: 10.1039/JR9530001541]. *Possibly* **EXPLOSIVE**. [*Beilstein* **9** IV 3260.]

4-*tert*-Butylphenol *[98-54-4]* **$C_{10}H_{14}O$, M 150.2, m 96 to 101°, 98°, 99°, b 236-238°/atm, pK^{25} 10.39.** Crystallise the phenol to constant melting point from petroleum ether (b 60-80°). It sublimes *in vacuo*. Also purify it *via* the benzoate, as for phenol. The ***salicylate ester*** *[87-18-30]* has **m 63-64°** (from aqueous EtOH, or EtOH). [*Beilstein* **6** IV 3296.]

4-*tert*-Butylphenoxyacetic acid *[1798-04-5]* **$C_{12}H_{16}O_3$, M 208.3, m 86.5°, 88-89°, 94°, 96.5°, pK_{Est} ~2.9.** Crystallise the acid from petroleum ether or petroleum ether/*C_6H_6 mixture. [*Beilstein* **6** H 524, **6** III 1869.]

***tert*-Butyl phenyl carbonate** *[6627-89-0]* **$C_{11}H_{14}O_3$, M 194.2, b 74-78°/0.5mm, 83°/0.6mm, d_4^{20} 1.05, n_D^{20} 1.480.** If IR is free from OH, then purify it by redistillation; otherwise dissolve it in Et_2O, wash it with 5% HCl, then H_2O, dry it ($MgSO_4$), evaporate and distil it through a Claisen head under vacuum. Care should be taken as distillation of large quantities can lead to decomposition with liberation of CO_2 and isobutylene; **take the necessary precautions.** Used for mono-Boc protection of some α,ω-diamines [Pittelkow et al. *Org Synth* **84** 209 *2007*, DOI: 10.15227/orgsyn.084.0209]. [Carpino *J Am Chem Soc* **79** 98 *1957*, DOI: 10.1021/ja01558a026; *Beilstein* **6** IV 629.]

***n*-Butyl phenyl ether** *[1126-79-0]* **$C_{10}H_{14}O$, M 150.2, b 95°/17mm, 210.20°/760mm, d_4^{20} 0.935, n_D^{20} 1.4969.** Dissolve it in diethyl ether, wash first with 10% aqueous NaOH to remove traces of phenol, then repeatedly with distilled water, followed by evaporation of solvent and distillation under reduced pressure [Arnett & Wu *J Am Chem Soc* **82** 5660 *1960*, DOI: 10.1021/ja01506a027]. [*Beilstein* **6** H 143, **6** I 82, **6** II 145, **6** III 550, **6** IV 558.]

***N-tert*-Butyl α-phenyl nitrone (PBN)** *[3376-24-7]* **$C_{11}H_{15}NO$, M 177.2, m 73-74°.** Crystallise PBN from hexane. It is a free radical trap. Its solubility in H_2O is 2.9% and slightly less so in aqueous saline (2.3%), but more soluble in organic solvents. Its UV has λ_{max} in EtOH at 224 (ε 7,240) and 293.5 (ε 17,700) nm; and in MeCN at 298 (ε 17,2716) nm. [cf. Janzen *Methods Enzymology* **105** 188 *1984*, DOI: 10.1016/S0076-6879(84)05025-4; *Beilstein* **7** IV 519.]

4-*tert*-Butyltoluene *[98-51-1]* **$C_{11}H_{16}$, M 148.2, m -53.2°, b 91°/28mm, 189-192°/atm, d_4^{20} 0.854, n_D^{20} 1.4920.** A sample containing 5% of the *meta*-isomer is purified by selective mercuration. Fractional distillation of the solid arylmercuric acetate, after removal from the residual hydrocarbon, gives pure *p-tert*-butyltoluene [Stock & Brown *J Am Chem Soc* **81** 5615 *1959*, DOI: 10.1021/ja01530a024]. [*Beilstein* **5** H 439, **5** III 1003, **5** IV 1079.]

***tert*-Butyl 2,4,5-trichlorophenyl carbonate** *[16965-08-5]* **$C_{11}H_{11}Cl_3O_3$, M 297.6, m 64-66°, 67-68.5°.** Crystallise the carbonate from a mixture of MeOH (90ml) and water (6ml) using charcoal [Broadbent et al. *J Chem Soc (C)* 2632 *1967*, DOI: 10.1039/J39670002632; Fieser **2** 55].

Caffeic acid (3,4-dihydroxycinnamic acid) *[331-39-5]* **$C_9H_8O_4$, M 180.2, m 195°, 211 to 213°(dec) 223-225° (softens at *ca* 195°), pK_1^{25} 4.62, pK_2^{25} 9.07.** Recrystallise this antioxidant from strong aqueous solutions as yellow crystals, but forms a *monohydrate* from dilute solutions. Yellow alkaline solutions become orange probably because of oxidation to quinones. It is much more soluble in hot than in cold H_2O, and its solubility in EtOH is 5w/v%. The ***methyl ester* $C_{10}H_{10}O_4$, m 152-153°**, forms colourless needles from H_2O. It was found in green coffee and is an inhibitor of leukotrienes. [Herrmann *Pharmazie* **11** 433 *1956*, PMID: 13370323; *Beilstein* **10** IV 1776.]

Capsaicin (*E-N*-[(4-hydroxy-3-methoxyphenyl)-methyl]-8-methyl-6-nonenamide) *[404-86-4]* **$C_{18}H_{27}NO_3$, M 305.4, m 64-66°, 65°, 66.1°, b 210-220°/0.01mm, ε 7000 (281nm, EtOH).** Recrystallise capsaicin from petroleum ether (b 40-60°), or petroleum ether/Et_2O (9:1). Also purify it by chromatography on neutral Al_2O_3 (grade V) and elute successively with *C_6H_6, *C_6H_6/EtOAc (17:3) then *C_6H_6/EtOAc (7:3), and distil it at 120°/10^{-5}mm, then repeatedly recrystallise the needles from isopropanol (charcoal). [Crombie et al. *J Chem Soc* 1007 *1955*, DOI: 10.1039/JR9550001007; Bennett & Kirby *J Chem Soc(C)* 442 *1968*, DOI: 10.1039/J39680000442.] It is the active principle in cayenne pepper; and a burning taste is experienced at concentrations as low as 1 in 100,000. It **causes pain,** used in Police work as a deterrant but is **neurotoxic. STRONG IRRITANT.** [Bevan & Szolcsanyi *Trends in Pharmacol Sci* **11** 331 *1990*, DOI:10.1016/0165-6147(90)90237-3; *Beilstein* **13** IV 2588].

4-(Carbamoylmethoxy)acetanilide *[14260-41-4]* **$C_{10}H_{12}N_2O_3$, M 208.2, m 208°.** Crystallise the anilide from water.

***N*-Carboethoxyphthalimide (*N*-ethoxycarbonylphthalimide)** *[22509-74-6]* **$C_{10}H_9NO_4$, M 219.2, m 87-89°, 90-92°.** Crystallise the imide from toluene/petroleum ether (or *benzene/petroleum ether). It is partly soluble in Et_2O, *benzene and $CHCl_3$. [Heller & Jacobsohn *Chem Ber* **54** 1107 *1921*, DOI: 10.1002/cber.19210540529; *Beilstein* **21/10** V 428.]

3-Carboxybenzaldehyde (3-formylbenzoic acid, isophthalaldehydic acid) *[619-21-6]* **$C_8H_6O_3$, M 150.1, m 173°, 173-175°, pK^{25} 3.84.** The acid was prepared in several ways including the following two. *m*-Bromomethylbenzoic acid (3g) is allowed to react with hexamine (3.9g) in $CHCl_3$ (30ml) by refluxing for 3 hours, cooled, the hexamine quaternary salt (4.7g) is collected, dried *in vacuo*, and decomposed by boiling in 50% aqueous acetic acid for 2 hours. The solution is cooled, diluted with an equal volume of H_2O and chilled to give a crop of the desired acid as needles, which are washed with aqueous $NaHCO_3$ and dried. A further crop can be obtained by extracting the acidic filtrate with Et_2O to give total yield of 48%. [Dyer et al. *J Chem Soc* 4778, 4781 *1952*, DOI: 10.1039/JR9520004778]. *Alternatively*, ***m*-carboxycinnamic acid** (m 268-270°, 8.6g) in 1N Na_2CO_3 (50ml) and H_2O (400ml) is treated slowly at 4-5° with 5% of aqueous $KMnO_4$ (80ml) with vigorous stirring. MnO_2 is removed by filtration, the filtrate is concentrated to 150ml, acidified with 5N HCl and the mixture of acids that separated, together with the solution, are extracted thoroughly with Et_2O, which on evaporation give 3-formylbenzoic acid (3.6g) which is purified by recrystallisation from H_2O. [Berner *Acta Chem Scand* **10** 1208 *1956*, DOI: 10.1016/0165-6147(90)90237-3]. The ***acid chloride*** *[75650-38-3]* has **b 130°/20mm**, the ***methyl ester*** *[52178-50-4]* has **m 53°**, the ***ethyl ester*** *[33745-47-0]* has **d^{18} 1.093** and **b 278°/atm**, the ***amide*** has **m 190°(dec)**, the ***oxime*** has **m 188°**, the ***semicarbazone*** has **m 275°(dec)** (from aqueous EtOH), the ***bis(2-hydroxyethyl)amine salt*** has **m 167°** (yellow crystals from aqueous EtOH), and the ***phenylhydrazone*** has **m 164°**. [Irreverre et al. *J Biol Chem* **236** 1093 *1961*, Davies et al. *J Chem Soc* 2202 *1922*, DOI: 10.1039/CT9222102202; Simonis *Chem Ber* **45** 1584 *1912*, DOI: 10.1002/cber.19120450224; *Beilstein* **10** H 671, **10** I 317, **10** II 465, **10** III 2990, **10** IV 2750.]

4-Carboxybenzaldehyde (4-formylbenzoic acid, terephthalaldehydic acid) *[619-66-9]* **$C_8H_6O_3$, M 150.1, m 247°, 248°(dec), ~250°, 248-250°, 256°, pK^{25} 3.77.** Of the many syntheses of this acid, the more convenient one is by refluxing a solution of the commercially available 4-bromomethylbenzoic acid (21.0g, 6232-88-8) with 10% $Cu(NO_2)_2$ (300ml) for 6 hours, cooling, filtering off the solid and recrystallising from glacial AcOH (100ml) to give fine plates, which on further recrystallisation from H_2O, provide pure *4-formylbenzoic acid* as fine needles (2.2g 56%). The ***phenylhydrazone*** has **m 221-222°** [Stewart & Walker *Can J Chem* **35** 1561 *1957*, DOI: 10.1139/v57-204], the ***2,4-dinitrophenylhydrazone*** has **m 319.5-320.5°**, after crystallisation from pyridine then $PhNO_2$ [Bowen & Wilkinson *J Chem Soc* 747 p 750 *1950*, DOI: 10.1039/JR9500000747], the ***oxime*** has **m 216-217°** [Wheeler et al. *J Org Chem* **22** 547 *1957*, DOI: 10.1021/jo01356a022]. The acid is also obtained by hydrolysis of the ***methyl ester***, **m 61-61°** (from petroleum ether), **b 135°/12mm**, by aqueous H_2SO_4; the ester having been prepared from methyl 4-cyanobenzoate by reaction with $ZnCl_2$/HCl [Slotta & Kethur *Chem Ber* **71** 335 *1938*, DOI: 10.1002/cber.19380710224]. The UV in hexane of the *formyl acid* has λ_{max} (ε) at 249 (17,500), 257 (15,500) [*B*-band], and 279 (1,650), 288 (1,950), 298 (1,600) [*C-band*] nm [Dearden & Forbes *Can J Chem* **36** 1362 *1958*, DOI: 10.1139/v58-201]. [for pK see Humffray et al. *JCS Chem Comm* 610 *1965*, DOI: 10.1039/C19650000610; *Beilstein* **10** H 671, **10** I 317, **10** II 465, **10** III 2989, **10** IV 2752.]

4-Carboxyphenylacetonitrile *[6627-91-4]* **$C_9H_7NO_2$, M 161.2, m 114-115°.** Crystallise the nitrile (with considerable loss) from *benzene, glacial acetic acid or H_2O. The ***methyl ester*** has **m 47-48°** (from $*C_6H_6$). [Price & Rogers *Org Synth* Coll Vol **3** 174 *1955*, DOI: 10.15227/orgsyn.022.0030; *Beilstein* **9** H 859, **9** II 618, **9** III 4267.]

Catechol (1,2-dihydroxybenzene, pyrocatechol) *[120-80-9]* **$C_6H_6O_2$, M 110.1, m 100-103°, 105°, b 104°/5mm, b 134°/20mm, b 161°/60mm, 197.7°/100m, 245.5°/atm, d^{25} 1.344, pK_1^{25} 9.45, pK_2^{25} 12.8.** Crystallise catechol from *benzene or toluene (prisms) and sublime it *in vacuo*. It darkens in air, but more rapidly in aqueous solution. It is steam volatile with solubility in H_2O of ~ 43.5w/v%. It is an antiseptic. [Rojo et al. *Anal Chem* **58** 2988 *1986*, DOI: 10.1021/ac00127a020; *Beilstein* **6** IV 5557.]

Cation exchange resin. The resin should be conditioned before use by successive washing with water, EtOH and water, and taken through two H^+-Na^+-H^+ cycles by successive use of M NaOH, water and M HCl then

washed with water until neutral.

Chamazulene (1,4-dimethyl-7-ethylazulene, *see also Guaiazulene below*) *[529-05-5]* **$C_{14}H_{16}$, M 184.3, b 145°/11mm, 161°/12mm, d_4^{20} 0.9883.** The blue oil occurs in flower oil of chamomile, *Artemisia*. *Matricaria* and tansy. It can be purified by chromatography on Al_2O_3 (Basic I) and eluting the blue band with petroleum ether. The hydrocarbon is then redistilled at high vacuum. Its UV has λ_{max} at 370nm (log ε 3.7, heptane). The ***trinitrobenzene complex***, crystallises as violet-black needles from absolute EtOH with **m 131.5-132.5°**. The ***picrate*** has **m 115-116°** (from EtOH), and the ***styphnate*** has **m 92-93°** (from EtOH). [Ruzicka & Rudolph *Helv Chim Acta* **9** 118 *1926*, DOI: 10.1002/hlca.19260090114; Meisels & Weizmann *J Am Chem Soc* **75** 3865 *1953*, DOI: 10.1021/ja01111a531; Mukherjee, Dunn and Houk *J Am Chem Soc* **101** 251 *1979*, DOI: 10.1021/ja00495a058; *Beilstein* **5** III 1677, **5** IV 1751.]

***p*-Chloranil (2,3,5,6-tetrachloro-1,4-benzoquinone)** *[118-75-2]* **$C_6Cl_6O_2$, M 245.9, m 289°(dec), 290°, 294.2-294.6°(sealed tube).** Crystallise *p*-chloranil from acetic acid, acetone, *benzene, EtOH or toluene, dry it in a vacuum over P_2O_5, or from acetic acid and drying over NaOH in a vacuum desiccator. It can be sublimed under vacuum at 290°. A sample may contain significant amounts of the *o*-chloranil isomer as impurity. Purify it by triple sublimation under vacuum and recrystallise before use. It is soluble in $CHCl_3$, CCl_4 and CS_2. **It is a skin and mucous membrane irritant, and is TOXIC**. It has been used as a fungicide. [UV: Pummerer et al. *Chem Ber* **85** 535 *1952*, DOI: 10.1002/cber.19520850608; Brook *J Chem Soc* 5035 p 5040 *1952*, DOI: 10.1039/JR9520005035; *Beilstein* **7** IV 2083.]

Chloranilic acid (2,5-dichloro-3,6-dihydroxy-1,4-benzoquinone) *[87-88-7]* **$C_6H_2Cl_2O_4$, M 209.0, m 283-284°, ~300°, pK_1^{25} 1.22, pK_2^{25} 3.01.** A solution of 8g of quinone in 1L of boiling water is filtered while hot, then extracted twice at about 50° with 200ml portions of *benzene. The aqueous phase is cooled in ice-water. The red crystals are filtered off, washed with three 10ml portions of water, and dried at 115°. It can be sublimed *in* vacuo. [Weissbart & Rysselberghe *J Phys Chem* **61** 765 *1957*, DOI: 10.1021/j150552a015.] The ***diacetate*** has **m 182-185°** [Conant & Fieser *J Am Chem Soc* **46** 1858 *1924*, DOI: 10.1021/ja01673a014; Thamer & Voigt *J Phys Chem* **56** 225 *1952*, DOI: 10.1021/j150494a018]. [*Beilstein* **8** IV 2707.] It is a moderately strong acid and forms salts. The ***barium salt*** *[32458-20-1]* **$C_6BaCl_2O_4.3H_2O$, M 398.3,** is used for sulfate determination.

4-Chloroacetanilide *[539-03-7]* **C_8H_8ClNO, M 169.6, m 176 to 178°, 179°.** Crystallise the anilide from EtOH or aqueous EtOH. [*Beilstein* **12** IV 1178.]

ω-Chloroacetophenone (phenacyl chloride) *[532-27-4]* **C_8H_7ClO, M 154.6, m 54 to 56°, 58-59°, b 244-245°/atm, d^{15} 1.324.** Crystallise it from MeOH, aqueous EtOH, CCl_4, or petroleum ether. It is a skin, eyes and respiratory irritant — take all necessary precautions when preparing or using it. [Tanner et al. *J Org Chem* **52** 2142 *1987*, DOI: 10.1021/jo00387a005; *Beilstein* **7** IV 641.]

o*-Chloroaniline** *[95-51-2]* **C_8H_7ClN, M 127.6, m -1.9°, b 84.5°/10mm, 108.4°/30mm, 208.8°/760mm, d_4^{20} 1.213, n_D^{20} 1.588, pK^{25} 2.66.** Free it from small amounts of the *p*-isomer by dissolving in one equivalent of H_2SO_4 and steam distilling. The *p*-isomer remains behind as the sulfate. [Sidgwick & Rubie *J Chem Soc* 1013 *1921*, DOI: 10.1039/CT9211901013.] An alternative method is to dissolve it in warm 10% HCl (11ml/g of amine) and on cooling, ***o*-chloroaniline hydrochloride** separates out. The latter can be recrystallised until the acetyl derivative has a constant melting point (**m** 90°). (In this way, yields are better than *via* the recrystallisation of the *picrate* from EtOH or of the acetyl derivative from petroleum ether.) [King & Orton *J Chem Soc* 1377 *1911*, DOI: 10.1039/CT9119901377]. [*Beilstein* **12** III 1281, **12** IV 1115.] ***p*-Chloroaniline** *[106-47-8]* has **m 70-71°, b 106.8-107.3-.5°/12mm, 116°/17mm, d_4^{20} 1.175, pK^{25} 3.98.** Crystallise the aniline from MeOH, petroleum ether (b 30-60°), or 50% aqueous EtOH, then *benzene/petroleum ether (b 60-70°), and then dry it in a vacuum desiccator. It can be distilled under vacuum (**b** 75-77°/3mm). It sublimes in a very high vacuum. The ***acetate crystallises from aqueous MeOH (**m 178°, 180°**) or EtOH or AcOH (**m 173-174°**) and has **b 331.3°/760mm**. [*Beilstein* **12** III 1325, **12** IV 1116.]

***p*-Chloroanisole** *[623-12-1]* **C_7H_7ClO, M 142.6, b 79°/11.5mm, 196.6°/760mm, d_4^{20} 1.164, $n_D^{25.5}$ 1.5326.** Wash the anisole with 10% (by volume) of aqueous H_2SO_4 (three times), 10% aqueous KOH (three times), and

then with water until neutral. Dry it ($MgSO_4$), and fractionally distil it from CaH_2 through a glass helices-packed column under reduced pressure. [*Beilstein* **16** IV 822.]

1-Chloroanthracene *[4985-70-0]* **$C_{14}H_9Cl$, M 212.9,** has **m 79°, 80.5-81.5°**, **81°**, **81-82°**, **83.5°**. It has been prepared by Zn/NH_3 reduction of 1-chloroanthraquinone and purified by recrystallisation from AcOH (leaflets). It is soluble in EOH and Et_2O. Store it in the dark as it polymerises in the presence of light. Its UV ($CHCl_3$) has bands at λ_{max} nm(ε) 255.5 (153,000), 328(1,900), 342(3,300), 360(5,750) and 380(4,900). The ***picrate*** has **m 101-102°**. 2-Chlorobenzonitrile *[873-32-5]* **C_7H_4ClN, M 137.6, m 43°, 45-46°, b 232°/atm.** Crystallise the nitrile to a constant melting point from *benzene/petroleum ether (b 40-60°), and/or distil it. [*Beilstein* **9** IV 965.]

4-Chlorobenzophenone *[134-85-0]* **$C_{13}H_9ClO$, M 216.7, m 74°, 75-76°, b 195-196°/17mm.** Recrystallise it from EtOH, and/or distil it under vacuum. [Wagner et al. *J Am Chem Soc* **108** 7727 *1986*, DOI: 10.1021/ja00284a041; *Beilstein* **7** H 419, **7** I 227, **7** II 359, **7** III 2072, **7** IV 1375.]

4-Chlorobenzotrifluoride (*o*-chlorotrifluoromethylbenene) *[88-16-4]* **$C_7H_4ClF_3$, M 180.6, m –6.37°, b 19.6°/3mm, 152.3°/760mm, d_4^{25} 1.364, n_D^{25} 1.4533.** Dry the trifluoride over $CaSO_4$, and distil it at high reflux ratio through a silvered vacuum-jacketed glass column packed with one-eighth inch glass helices [Potter & Saylor *J Am Chem Soc* **73** 90 *1951*, DOI: 10.1021/ja01145a032]. [*Beilstein* **5** H 302, **5** III 692, **5** IV 814.] ***3-Chlorobenzotrifluoride*** *[98-15-7]* has **m –56.49°, b 50°/31mm, 137.6°/760mm, d_4^{20} 1.3345, n_D^{20} 1.4432.** Purify it as for *o*-chlorobenzotrifluoride above. [*Beilstein* **5** III 692, **5** IV 814.] ***4-Chlorobenzotrifluoride*** *[98-56-6]* has **m –33.18°, b 19.3°/5mm, 138.6°/760mm, d_4^{30} 1.3278, n_D^{30} 1.4430.** Purify it as for *o*-chlorobenzotrifluoride above. It is useful as a dielectric fluid. [*Beilstein* **5** IV 815.]

4-Chlorobenzyl chloride *[104-83-6]* **$C_7H_6Cl_2$, M 161.0, m 28-29°, b 96°/15mm, 216-222°/atm.** Dry it over $CaSO_4$, then fractionally distil it under reduced pressure. Crystallise it from heptane or dry diethyl ether at low temperature. [*Beilstein* **5** IV 816.] **LACHRYMATORY.**

***trans*-4-Chlorocinnamic acid** *[1615-02-7]* **$C_9H_7ClO_2$, M 182.6, m 243°, 248-250°, 249-251°, pK^{25} 4.41**. Recrystallise the acid from EtOH or aqueous EtOH (charcoal). Its UV has λ_{max} at 275nm (EtOH). [Walling & Wolfstirn *J Am Chem Soc* **69** 852 *1947*, DOI: 10.1021/ja01196a033; *Beilstein* **9** H 596, **9** II 395, **9** III 2727, **9** IV 2033.]

4-Chloro-3,5-dimethylphenol *[88-04-0]* **C_8H_9ClO, M 156.6, m 114°, 115.5°, 116°, b 246°/atm, pK^{25} 9.70.** Crystallise the phenol from *benzene or toluene. It is steam volatile, has low solubility in cold H_2O (0.03w/v%) but is much more soluble in EtOH (50%). It is antibacterial and a strong antiseptic and germicide. [*Beilstein* **6** IV 3152.]

1-Chloro-2,4-dinitrobenzene *[97-00-7]* **$C_6H_3ClN_2O_4$, M 202.6, m 48-50°, 51°, 52-54°, 54°, b 315°/atm, d_4^{20} 1.697.** Usually it is recrystallised from EtOH or MeOH. It has also been crystallised from Et_2O, $*C_6H_6$, $*C_6H_6$/petroleum ether or isopropyl alcohol. A preliminary purification step is to pass its solution in *benzene through an alumina column. It has also been purified by zone refining. It exists in three forms: one stable and two unstable. The stable form crystallises as yellow needles from Et_2O, **m 51°**, **b 315°/760mm** with some decomposition, and is soluble in EtOH. A labile form also crystallises from Et_2O, **m 43°**, and is more soluble in organic solvents. The second labile form has **m 27°**. [Hoffman & Dame, *J Am Chem Soc* **41** 1013 *1919*, DOI: 10.1021/ja02227a012; Welsh *J Am Chem Soc* **63** 3276 *1941*, DOI: 10.1021/ja01857a014; Littlejohn & Smith *J Chem Soc* 2476 *1957*, DOI: 10.1039/JR9570002476; *Beilstein* **5** IV 744.]

4-Chloro-3,5-dinitrobenzoic acid *[118-97-8]* **$C_7H_3ClN_2O_6$, M 246.6, m 159-161°, 163°, pK_{Est} ~2.5.** Crystallise the acid from EtOH/H_2O, EtOH or $*C_6H_6$. The 1:1 ***naphthalene complex*** (by fusing various ratios of ingredients and recrystallising from EtOH) has **m 122°**. [*Beilstein* **9** H 416, **9** III 1953, **9** IV 1360.]

Chlorogenic [1-(3,4-dihydroxycinnamoyloxy)-D-quinic] acid *[327-97-9]* **$C_{16}H_{18}O_9$, M 354.3, m 208°, $[\alpha]_D^{25}$ -36 (c 1, H_2O), pK_1^{25} 3.59, pK_5^{25} 8.59.** Recrystallise the acid from water (solubility is 4% at room temp-

erature), and dry it at 110°. It gives a yellow solution in aqueous base and complexes with Fe. [*Beilstein* **10** H 537, **10** I 271, **10** II 378, **10** III 2408, **10** IV 2259.]

Chlorohydroquinone (2-chloro-1,4-dihydroxybenzene) *[615-67-8]* **$C_6H_5ClO_2$, M 144.6, m 100°, 104°, 106°, b 263°/atm, pK_1^{25} 8.81, pK_2^{25} 10.78.** Crystallise the hydroquinone from $CHCl_3$ or toluene. [*Beilstein* **6** IV 5767.]

1-Chloro-4-iodobenzene *[637-87-6]* **C_6H_4ClI, M 238.5, m 53-54°, 56.2°, b 104.2°/16mm, 226-227°/atm, d_4^{57} 1.886.** Distil it in a vacuum then recrystallise it from EtOH. [Sugden *J Chem Soc* 1167 *1924*, DOI: 10.1039/CT9242501167; *Beilstein* **5** H 221, **5** III 579, **5** IV 695.]

5-Chloro-2-methoxyaniline (2-amino-4-chloroanisole, 5-chloro-*o*-anisidine) *[95-03-4]* **C_7H_8ClNO, M 157.6, m 81-83°, 82-84°, 84°, pK^{25} 3.56.** Purify the aniline by steam distillation and recrystallisation from H_2O or 40% aqueous EtOH. The ***N-acetate*** forms needles from hot H_2O with **m 104°**, the ***N-benzoyl*** derivative forms needles from aqueous EtOH with **m 77-78°**, and the ***picrate*** has **m 194°(dec)**. [Raiford & Colbert *J Am Chem Soc* **48** 2652 *1926*, DOI: 10.1021/ja01421a022; *Beilstein* **13** IV 879.]

3-Chloro-4-methoxyphenethylamine *[7569-87-1]* **$C_9H_{12}ClNO$, M 185.7, b 140°/0.6mm, d_4^{25} ~1.081, n_D^{20} ~1.553, pK^{25} ~9.8.** This strong base is prepared by reduction of ***3-chloro-4-methoxyphenylacetonitrile*** (176mmol, b 140-145°/0.1-0.1mm, m 55-56°, [7569-58-6]) in THF (100ml) with $LiAlH_4$ (8.0g, 210mmol) suspended in THF (250ml) under reflux for 5 hours. The greenish coloured solution is carefully decomposed with ice cold H_2O, the solids are filtered off, washed with Et_2O, the combined organic liquids are dried (Na_2SO_4), filtered, evaporated and the crude brown residual amine is distilled in as high a vacuum as possible to give a clear oil (11.4g, 35%). It absorbs CO_2 from air and is best stored in an inert atmosphere. Its ^1H NMR [60MHz, $CDCl_3$] has δ at 7.20 (d, 1H, Ar*H*2), 7.04 (q, 1H, Ar*H*6), 6.83 (d, 1H, Ar*H*5), 3.88 (s, 3H, OCH_3), 3.12-2.20 (m, 4H, $PhCH_2CH_2N$), 1.28 (s, 2H, NH_2) ppm from TMS [Charifson et al. *J Med Chem* **31** 1941 *1988*, DOI: 10.1021/jm00118a012]. *Alternatively*, the amine is prepared from the respective phenethyl bromide and dry NH_3 in EtOH followed by dilution with Et_2O, washing with aqueous NaOH, and evaporation. The residue is dissolved in 5% aqueous HCl and evaporated to dryness to give ***3-chloro-4-methoxyphenethylamine hydrochloride*** *[7569-60-0]* **M 186.1, m 192-195°,** as an apparently amorphous white powder when crystallisation from EtOH/Et_2O is attempted [Fosdick et al. *J Am Chem Soc* **68** 840 *1946*, DOI: 10.1021/ja01209a038]. The ***N-benzoyl*** derivative *[115514-67-5]* **m 137-140°** is a colourless solid which is insoluble in Et_2O. [*Beilstein* **13** III 1650.]

9-Chloromethyl anthracene *[24463-19-2]* **$C_{15}H_{11}Cl$, M 226.7, m 138°, 140°, 141-142°(dec), 141-142.5°**. If it is free from OH in the IR then recrystallisation from hexane/*C_6H_6 or *C_6H_6 (as needles). If OH is present, then some solvolysis has occurred. In this case treat 8.5g of it with $SOCl_2$ (4.8g) in dioxane (60ml) and reflux for 5 hours, then evaporate to dryness and wash the residue with cold *C_6H_6 and recrystallise it. It has been used as a protecting agent for phenols, thiophenols, mercaptans and carboxylic acids. It has a low fluorescence emission maximum at 412nm and is soluble in $CHCl_3$ and hexane. With KI/Me_2CO it forms the *iodomethyl* derivative. [Fierens et al. *Helv Chim Acta* **38** 2009 *1955*, DOI: 10.1002/hlca.19550380740; Hunter et al. *J Org Chem* **21** 1512 *1956*, DOI: 10.1021/jo01118a633; *Beilstein* **5** III 3152, **5** IV 2313.]

4-Chloro-2-methylphenol *[1570-64-5]* **C_7H_7ClO, M 142.6, m 49°, b 112-114°/18mm, 225°/760mm, pK^{25} 9.71.** Purify the phenol by crystallisation from petroleum ether (**m** 51°) and by zone melting. [*Beilstein* **6** H 359, **6** I 174, **6** II 332, **6** III 1264, **6** IV 1987.] **4-Chloro-3-methylphenol** *[59-50-7]* has **m 63-65°, 66°, 67°, b 238°/760mm, pK^{25} 9.55.** Crystallise the phenol from petroleum ether (m 66°) or *C_6H_6. It is dimorphic, with the second form having **m 55.5°.** Its solublility in H_2O is 0.38w/v% at 20°, but is much more at 100°, and in most organic solvents. A clear dilute aqueous solution turns yellow on standing in air, probably due to oxidation. Store in dark containers. It is a strong antiseptic, and disinfectant. [Kornholm et al. *Environ Sci Technol* **35** 3247 *2001*, DOI: 10.1021/es000275e; *Beilstein* **6** H 381, **6** I 187, **6** II 355, **6** III 1315, **6** IV 2064.]

4-Chloro-2-methylphenoxyacetic acid (MCPA, Agroxone) *[94-74-6]* **$C_9H_9ClO_3$, M 200.6, m 113-117°, 120°, 122-123°, pK^{20} 3.62(3.05)**. It is insoluble in H_2O (solubility is 0.55g/L at 20°) and recrystallises from

*C_6H_6 or chlorobenzene as plates [Jönsson et al. *Acta Chem Scand* **6** 993 *1952*, DOI: 10.3891/acta.chem.scand.06-0993]. The ***S-benzylisothiouronium salt*** has **m 164-165°**, and the Cu^{2+} salt has **m 247-249°(dec)** [Armarego et al. *Nature* **183** 1176 *1959*, DOI:10.1038/1831176a0; UV: Grabe *Acta Chem Scand* **4** 806 *1950*, DOI: 10.3891/acta.chem.scand.04-0806, IR: Sjöberg *Acta Chem Scand* **4** 798 *1950*, DOI: 10.3891/acta.chem.scand.04-0798]. [*Beilstein* **6** IV 1991.] It forms a considerably more water soluble ***Sodium salt*** **(Chiptox)** *[3653-48-3]* **$C_9H_8ClNaO_3$, M222.6** It is a plant growth substance and a herbicide.

2-Chloromethyl-2-phenylpropane (neophyl chloride, 1-chloro-2-methyl-2-phenylpropane, β-chloro-*tert*-butylbezene) *[515-40-2]* **$C_{10}H_{13}Cl$, M 168.7, b 53°/1.0mm, 95.1-95.2°/10mm, 97°/13.0mm, 104°/18.0mm, 120°/30mm, 111°/90.0mm, 222°/741mm (dec), d_4^{25} 1.5228, n_D^{20} 1.5250.** It is prepared by adding β-methalyl chloride (603g, 6.66 moles, CH_2=C(Me)-CH_2Cl, 3-chloro-2-methyl-1-propene, prepared by the chlorination of butylene, b 71.5-72.5°/760mm, d_4^{20} 0.9165, n_D^{20} 1.4274 *[563-47-3]*, *Beilstein* **1** IV 803) into a vigorously stirred mixture of *benzene (1404g, 18.5 moles, washed twice with concentrated H_2SO_4 and used as such) and concentrated H_2SO_4 (104g, 1 mole) at 20° which required 12 hours, and stirring is continued for a further 11 hours at room temperature. The organic layer is collected, excess of *C_6H_6 is distilled off and the residue is fractionated through an 8-plate column to give pure (99.1 ±0.3% by acetolysis) *neophyl chloride* (765.5g, 68%). It is less reactive than neopentyl chloride towards Na metal and less reactive still towards EtNa, and both are inert towards most basic reagents. [Whitmore et al. *J Am Chem Soc* **65** 1469 *1943*, DOI: 10.1021/ja01248a010; Smith & Sellas *Org Synth* Coll Vol **4** 702 *1963*, DOI: 10.15227/orgsyn.032.0090; *Beilstein* **5** IV 1048.] It readily forms the Grignard reagent ***neophyl magnesium chloride*** *[35293-35-7]* **M 193.0**, with Mg in Et_2O; and a 0.5M solution of this reagent in Et_2O is available commercially. It reacts with solid CO_2 to give an 82% yield of ***β-phenylisovaleric acid*** *[1010-48-6]* (**m 58-59.5°,** from petroleum ether b 60-90°); and oxidation provides a 72% yield of ***2-methyl-2-phenylpropan-1-ol*** *[2173-69-5]* (**b 131°/30mm, n_D^{20} 1.5261**) whose ***phenylurethane*** has **m 59.5-60.5°**, ***α-naphthylurethane*** has **m 91.5-92.5°**, and its ***p-toluenesulfonate*** has **m 74-75°**. [Whitmore et al. *J Am Chem Soc* **65** 1469 *1943*, DOI: 10.1021/ja01248a010; Fainberg & Winstein *J Am Chem Soc* **78** 2763 *1956*, DOI: 10.1021/ja01125a001; Winstein et al. *J Am Chem Soc* **74** 1113 *1952*, DOI: 10.1021/ja01125a001.]

***N*-(Chloromethyl)phthalimide** *[17564-64-6]* **$C_9H_6ClNO_2$, M 195.6, m 131-135°, 134-135°, 136.5°.** Purify the imide by recrystallisation from EtOAc or CCl_4 or *via* the 1:1 complex with pyridine [Sakellarios *J Am Chem Soc* **70** 2822 *1948*, DOI: 10.1021/ja01188a516; Böhme et al. *Chem Ber* **92** 1258 *1959*, DOI: 10.1002/cber.19590920604]. [*Beilstein* **21/10** V 372.]

1-Chloronaphthalene *[90-13-1]* **$C_{10}H_7Cl$, M 162.6, f -2.3°, b 81°/1.0mm, 111-113°/5mm, 136-136.5°/20mm, 259.3°/760mm, d_4^{20} 1.194, n_D^{20} 1.6326.** Wash the chloronaphthalene with dilute $NaHCO_3$, then dry it with Na_2SO_4 and fractionally distil it *in vacuo*. It is steam volatile. *Alternatively*, before distillation, it is passed through a column of activated alumina, or dried with $CaCl_2$, then distilled from sodium. It can be further purified by fractional crystallisation by partial freezing or by crystallisation of its ***picrate*** to constant melting point (**m 132-133°**) from EtOH, and recovering it from the picrate. The ***styphnate complex*** **$C_{10}H_7Cl.C_6H_3N_3O_8$,** (**m 112°**) crystallises in yellow needles. [*Beilstein* **5** III 1570, **5** IV 1658.] It is a useful liquid in refractometry (cf. 1-bromonaphthalene above). ***2-Chloronaphthalene*** *[91-58-7]* has **m 59.5-60°, 61°, b 121-122°/12mm. 264-266°/760mm.** Distil 2-chloronaphthalene in a vacuum, then crystallise it from 25% EtOH/water, then dry it *in vacuo* (see the 1-isomer above). It is steam volatile. [*Beilstein* **5** III 1573, **5** IV 1660.]

1-Chloro-2-naphthol *[633-99-8]* **$C_{10}H_7ClO$, M 178.6, m 70°, 71°, pK_{Est} ~8.3.** Crystallise the naphthol from petroleum ether. The ***acetate*** has **m 42-43°**. [*Beilstein* **6** I 315, **6** II 603, **6** III 2990, **6** IV 4289.] ***2-Chloro-1-naphthol*** *[606-40-6]* has **m 64-65°, 65°, pK^{20} 9.9 (aqueous EtOH).** Crystallise the naphthol from petroleum ether. [*Beilstein* **6** I 308, **6** II 581, **6** III 2933, **6** IV 4230.] ***4-Chloro-1-naphthol*** *[604-44-4]* has **m 116-117°, 120-121°, pK^{25} 8.86, 10.7 (aqueous EtOH).** Crystallise the naphthol from EtOH or $CHCl_3$. It is a useful chromogenic peroxidase substrate for enzyme-linked detection methods. [Elias *Am J Clin Pathol* **73** 797 *1980* DOI: 10.1093/ajcp/73.6.797; *Beilstein* **6** H 611, **6** II 582, **6** III 2933, **6** IV 4233.]

4-Chloro-2-nitroaniline *[89-63-4]* **242°/atm, M 172.6, m 114-115°, 116-116.5°, 117°, 119°, pK^{25} -0.99.** Crystallise the aniline from hot H_2O (**m** 115.8-116°), EtOH, EtOH/H_2O or *C_6H_6, and dry it for 10 hours at 60°

in vacuo. It has **m 115.5-116°** after sublimation. [*Beilstein* **12** I 355, **12** II 396, **12** III 1649, **12** IV 1669.]

2-Chloro-4-nitrobenzamide (Aklomix) *[3011-89-0]* **$C_7H_5ClN_2O_3$, M 200.6, m 170-171°, 172°.** Crystallise the amide from EtOH (grey scales). It is used against proptozoal and bacterial (tuberculostatic) infections. [Jensen & Ploug *Acta Chem Scand* **3** 13 *1949*, DOI: 10.3891/acta.chem.scand.03-0013; Grohmann *Chem Ber* **24** 3808 (3813) *1891*, DOI: 10.1002/cber.189102402258; *Beilstein* **9** H 404, **9** III 1768.]

2-Chloro-1-nitrobenzene (*o*-chloronitrobenzene) *[88-73-3]* **$C_6H_4ClNO_2$, M 157.6, m 31°, 32.8-33.2°, b 245-246°/atm, 246°/atm d^{25} 1.348.** Crystallise the yellow solid from EtOH, MeOH or pentane (charcoal). It can be distilled at atmospheric pressure. [*Beilstein* **5** IV 721.] ***3-Chloro-1-nitrobenzene (m*-chloronitrobenzene)** *[121-73-3]* has **m 43°, 45.3-45.8°, 46°, 47°, b 117°/12mm, 236°/atm, d^{25} 1.534.** Crystallise the nitrobenzene from MeOH or 95% EtOH (charcoal), then pentane. [Hartman & Brethen *Org Synth* Coll Vol **1** 126 *1964*, *Beilstein* **5** IV 722.] ***4-Chloro-1-nitrobenzene* (*p*-chloronitrobenzene)** *[100-00-5]* has **m 80-83°, 83.5-84°, b 113°/8mm, 242°/atm, $d_4^{100.5}$ 1.2914.** Crystallise the nitrobenzene from 95% EtOH (charcoal) and sublime it *in vacuo*. [Emmons *J Am Chem Soc* **76** 3470 *1954*, DOI: 10.1021/ja01642a030; Newman & Fones *J Am Chem Soc* **69** 1221 *1947*, DOI: 10.1021/ja01197a514; *Beilstein* **5** IV 723.]

3-Chloroperbenzoic acid (MCPBA) *[937-14-4]* **$C_7H_5ClO_3$, M 172.6, m 92-94°(dec), pK^{25} 7.57.** Recrystallise MCPBA from CH_2Cl_2 [Traylor & Miksztal *J Am Chem Soc* **109** 2770 *1987*, DOI: 10.1021/ja00243a033]. Peracid of 99+% purity can be obtained by washing commercial 85% material with phosphate buffer pH 7.5 and drying the residue under reduced pressure. *Alternatively*, the peracid can be freed from *m*-chlorobenzoic acid by dissolving 50g/L of *benzene and washing with an aqueous solution buffered at pH 7.4 (NaH_2PO_4/NaOH) (5 x 100ml). The organic layer is dried over $MgSO_4$ and carefully evaporated under vacuum. *Necessary care should be taken in case of* **EXPLOSION**. The solid is recrystallised twice from CH_2Cl_2/Et_2O and stored at 0° in a plastic container as glass catalyses the decomposition of the peracid. The acid is assayed iodometrically [Schwartz & Blumbergs *J Org Chem* **29** 1976 *1964*, DOI: 10.1021/jo01030a078]. [Bortolini et al. *J Org Chem* **52** 5093 *1987*, DOI: 10.1021/jo00232a006; McDonald et al. *Org Synth* Coll Vol **6** 276 *1988*, DOI: 10.15227/orgsyn.050.0015; *Beilstein* **9** IV 972.] A most useful oxidant in organic chemistry. Commercial peracid is ~80-85% pure and the contaminants are 3-chlorobenzoic acid (a stronger acid, pK^{25} 3.83) and H_2O. It is exceedingly stable, with less than 1% loss of activity in a year at ~25°. The solubility of pure peracid at 25° (w/w%) is in H_2O (0,154), hexane (1.4), CCl_4(2.1), $*C_6H_6$ (8.0), $CHCl_3$ (9.8), CH_2Cl_2(11.2), EtOAc (51.0), *t*-BuOH (69.0), Et_2O (89.4) and EtOH (113.0). [Fieser **1** 135, **2** 68.]

2-Chlorophenol *[95-57-8]* **C_6H_5ClO, M 128.6, m 8.8°, b 61-62°/10mm, 176°/760mm, d^{25} 1.241, n_D^{20} 1.558. pK^{25} 8.34.** Pass 2-chlorophenol at least twice through a gas chromatography column. It has also been purified by fractional distillation. [*Beilstein* **6** IV 782.] ***3-Chlorophenol*** *[108-43-0]* has **m 32°, 33°, 34°, b 44.2°/1mm, 214°/760mm, d^{25} 1.218, n_D^{20} 1.563. pK^{25} 9.13.** It could not be obtained solid by crystallisation from petroleum ether. It is best purified by distillation under reduced pressure. [*Beilstein* **6** IV 810.] ***4-Chlorophenol*** *[106-48-9]* has **m 40°, 43°, 45°, 100-101°/10mm, 220°/atm, d^{25} 1.306, pK^{25} 9.38.** Distil the phenol, then crystallise it from petroleum ether (b 40-60°) or hexane, and dry it under vacuum over P_2O_5 at room temperature. [Bernasconi & Paschalis *J Am Chem Soc* **108** 2969 *1986*, DOI: 10.1021/ja00271a027; *Beilstein* **6** IV 820.]

4-Chlorophenoxyacetic acid (4-PCA) *[122-88-3]* **$C_8H_7ClO_3$, M 186.6, m 157°, 159°, pK^{20} 3.00, 4.15 (50% aqueous EtOH).** Crystallise the acid from EtOH or aqueous AcOH. It is a plant growth substance and a herbicide. [*Beilstein* **6** IV 845.] ***4-Chlorophenoxyacetyl chloride*** *[4122-68-3]* **$C_8H_6Cl_2O_2$, M 205.0,** has **m 18.8°** and **b 142°/17mm, d^{25} 1.314, n_D^{20} 1.5468,** and typical of acid chlorides, is an irritant and is corrosive.

(±)-α-4-Chlorophenoxypropionic acid *[3307-39-9]* **$C_9H_9ClO_3$, M 200.6, m 116°, pK_{Est} ~3.2.** Crystallise the acid from EtOH or HCOOH (**m** 114.5-115.5°). It is a plant growth substance. The ***R(+)-*** and ***S(-)-enantomers*** have **m** 103-104° (from petroleum ether) and $[\alpha]_D^{25}$ (+) and (-) 41 (c 1, EtOH). [*Beilstein* **6** III 695, **6** IV 850.] ***β-4-Chlorophenoxypropionic acid*** *[3284-79-5]* has **m 136°, 138°, 140°, pK_{Est} ~4.2.** Crystallise the acid from EtOH. It is a plant growth substance. [*Beilstein* **6** III 696, **6** IV 851.]

3-Chlorophenylacetic acid *[1878-65-5]* **$C_8H_7ClO_2$, M 170.6, m 74°, 76°, 79°, pK^{25} 4.11.** Crystallise the acid from EtOH/water, or as needles from *C_6H_6 or H_2O (charcoal). The ***acid chloride*** (prepared by boiling with $SOCl_2$) has **b 127-129°/15mm**. [Dippy & Williams *J Chem Soc* 161 *1934*, DOI: 10.1039/JR9340000161; Misra & Shukla *J Indian Chem Soc* **28** 480 *1951*, *Beilstein* **9** III 2263, **9** IV 1674.] ***4-Chlorophenylacetic acid*** *[1878-66-6]* has **m 102°, 105°, 106°, pK^{25} 4.12.** Purify it as for 3-chlorophenylacetic acid. The ***acid chloride*** *[25025-34-0]* **$C_8H_6Cl_2O$, M 189.0,** (prepared by boiling with $SOCl_2$) has **b 85°/1mm** and **d ^{25} 1.292**, **n $^{20}_{D}$ 1.5510**. [*Beilstein* **9** III 2263, **9** IV 1675.]

4-Chloro-1-phenylbutan-1-one (γ-chlorobutyrophenone) *[939-52-6]* **$C_{10}H_{11}ClO$, M 182.7, m 19° to 20°, b 120-121°/3mm, 134-137°/5mm, d $^{20}_{4}$ 1.149, n $^{20}_{D}$ 1.55413.** Fractionate the ketone several times using a short column. It recrystallises from petroleum ether at -20° in glistening white rosettes and is filtered at 0°, and dried in a vacuum desiccator over H_2SO_4. The ***semicarbazone*** has **m 136-137°**. [Conant et al. *J Am Chem Soc* **46** 1882 *1924*, DOI: 10.1021/ja01673a015; Cloke *J Am Chem Soc* **51** 1174 *1929*, DOI: 10.1021/ja01379a028; Hart & Curtis *J Am Chem Soc* **79** 931 *1957*, DOI: 10.1021/ja01561a042; *Beilstein* **7** IV 711.]

1-(2-Chlorophenyl)-1-(4-chlorophenyl)-2,2-dichloroethane (Mitotane, *o,p'*-DDD) *[53-19-0]* **$C_{14}H_{10}Cl_4$, M 320.1, m 75.8-76.8°, 76-78°.** Purify Mitotane by recrystallisation from pentane, MeOH or EtOH. It is soluble in isooctane and CCl_4. [Haller et al. *J Am Chem Soc* **67** 1591 *1945*, DOI: 10.1021/ja01225a058; *Beilstein* **5** IV 1883.]

3-(4-Chlorophenyl)-1,1-dimethylurea (Monuron, CMU) *[150-68-5]* **$C_9H_{11}ClN_2O$, M 198.7, m 171°, 170.5-171.5° (176-177°** also reported). Crystallise monuron from MeOH. The pH of a saturated solution in H_2O is *ca* 6.3, and it forms a more soluble ***trichloroacetate salt*** **(Urox), $C_9H_{11}ClN_2O.C_2HCl_3O_2$, m 78-81°**, which is an effective herbicide against monocotyledonous plants. [*Beilstein* **12** IV 1191.]

4-Chloro-1,2-phenylenediamine *[95-83-0]* **$C_6H_7ClN_2$, M 142.6, m 69-70°, 73°, pK $^{25}_{1}$ -0.27 (aqueous H_2SO_4), pK $^{25}_{2}$ 3.35 (3.67).** Recrystallise the diamine from petroleum ether. [*Beilstein* **13** IV 68.]

4-Chlorophenyl isocyanate *[104-12-1]* **C_7H_4ClNO, M 153.6, m 26°, 28-31°, 31-32°, 32°, 32.5°, b 80.6-80.9°/9.5mm, 115-117°/45mm, d^{25} 1.20, n $^{20}_{D}$ 1.5618**. Purify the isocyanate by recrystallisation from petroleum ether (b 30-40°) or better by fractional distillation. **TOXIC irritant.** [*Beilstein* **12** III 1376, **12** IV 1213.]

4-Chlorophenyl isothiocyanate *[2131-55-7]* **C_7H_4ClNS, M 169.6, m 42°, 44°, 43-45°, 45°, 46°, 47°, b 110-115°/4mm, 135-136°/24mm.** Check the IR first to see if free from OH frequencies. Triturate it with petroleum ether (b 30-60°) and decant the solvent. Repeat this 5 times. The combined extracts are evaporated under reduced pressure to give almost pure compound as a readily crystallisable oil with a pleasant anise odour. It can be recrystallised from the minimum volume of EtOH at 50° (do not boil too long as it could react). It can be purified by vacuum distillation. [van der Kerk et al. *Org Synth* Coll Vol **5** 223 *1973*, DOI: 10.15227/orgsyn.045.0019; *Beilstein* **12** IV 1214.] **It is an IRRITANT and causes dermatitis; use gloves.**

4-Chlorophenyl 2-nitrobenzyl ether *[109669-56-9]* **$C_{13}H_{10}ClNO_3$, M 263.7, m 44.5°, b 154-156°/3mm, 208°/11mm.** Distil it under reduced pressure, and it crystallises from EtOH (**m 44-45°**) or MeOH (**m 46°**) as yellow needles. [*Beilstein* **6** II 210, **6** III 801, **6** IV 1253.] ***4-Chlorophenyl 4-nitrobenzyl ether*** *[5442-44-4]* has **m 77°, b 215°/12mm.** Distil it in a vacuum and crystallise it from EtOH, MeOH (**m** 75.5-76°) or petroleum ether (**m 76°, 77°**). Its UV has λ_{max} at 222 and 302nm (EtOH). [*Beilstein* **6** II 222, **6** III 821, **6** IV 1288.]

4-Chlororesorcinol *[95-88-5]* **$C_6H_5ClO_2$, M 144.6, m 105°, 106°, 108°, b 147°/18mm, pK $_{Est(1)}$ ~9.2, pK $_{Est(2)}$ ~10.1.** Crystallise it from boiling CCl_4 (10g/L, charcoal) and dry it in air. [*Beilstein* **6** II 818.] **IRRITANT.**

5-Chlorosalicaldehyde *[635-93-8]* **$C_7H_5ClO_2$, M 156.6, m 98.5-99°, 99.5°, 101°, 102°, pK^{25} 7.4.** Steam distil it, then crystallise it from aqueous EtOH or *C_6H_6 (**m** 100°). It forms complexes with Cu^{2+} and Fe^{2+} . [*Beilstein* **8** H 53, **8** II 45, **8** III 181, **8** IV 224.]

4-Chlorothiophenol *[106-54-7]* **C_6H_5ClS, M 144.6, m 49°, 51-52°, 53.5-54°, b 205-207°/atm, pK^{25} 6.14.**

Recrystallise the thiophenol from aqueous EtOH. The ***SMe ether*** has **m 129°** and the ***SEt ether*** has **m 64°**. [D'Souza et al. *J Org Chem* **52** 1720 *1987*, DOI: 10.1021/jo00385a014; *Beilstein* **6** H 326, **6** I 149, **6** III 1034.]

2-Chlorotoluene *[95-49-8]* **C_7H_7Cl, M 126.6, m -36°, b 159°/atm, d_4^{20} 1.083, n_D^{20} 1.5255.** Dry 2-chlorotoluene for several days with $CaCl_2$, then distil it from Na using a glass helices-packed column. It is steam volatile. [cf: Marvel & McElvain *Org Synth* Coll Vol **1** 170 *1941*, DOI: 10.15227/orgsyn.003.0033; *Beilstein* **5** IV 805.] ***3-Chlorotoluene*** *[108-41-8]* has **m -48°, b 161-163°/atm, d_4^{20} 1.072, n_D^{20} 1.522.** Purify it as for 2-chlorotoluene above. [cf: Marvel & McElvain *Org Synth* Coll Vol **1** 170 *1941*, DOI: 10.15227/orgsyn.003.0033; *Beilstein* **5** IV 806.] ***4-Chlorotoluene*** *[106-43-4]* has **m 7.2°, b 162.4°/atm, d_4^{20} 1.07, n_D^{20} 1.521.** Dry it with BaO, fractionally distil it, then fractionally crystallise it by partial freezing. [cf: Marvel & McElvain *Org Synth* Coll Vol **1** 170 *1941*, DOI: 10.15227/orgsyn.003.0033; *Beilstein* **5** IV 806.]

Chrysene (1,2-benzanthracene) *[218-01-9]* **$C_{18}H_{13}$, M 228.3, m 254°, 255-256°, b 254°/atm, d_4^{20}** 1.274. Purify chrysene by chromatography on alumina from petroleum ether in a darkened room. Its solution in $*C_6H_6$ is passed through a column of decolorising charcoal, then crystallised by concentrating the eluate. It has also been purified by crystallising from $*C_6H_6$ or $*C_6H_6$/petroleum ether, and by zone refining. [Gorman et al. *J Am Chem Soc* **107** 4404 *1985*, DOI: 10.1021/ja00301a006]. It is freed from 5*H*-benzo[*b*]carbazole by dissolving it in *N*,*N*-dimethylformamide and successively adding small portions of alkali and iodomethane until the fluorescent colour of the carbazole anion no longer appears when alkali is added. The chrysene (and alkylated 5*H*-benzo[*b*]carbazole) separate on addition of water. Final purification is by crystallisation from ethylcyclohexane and/or from 2-methoxyethanol [Bender et al. *Anal Chem* **36** 1011 *1964*, DOI: 10.1021/ac60212a018]. It can be sublimed in a vacuum. [*Beilstein* **5** IV 2554.]

Chrysoidine G (4-phenylazo-1,3-benzenediamine monohydrochloride, CI 11270, basic orange 2) *[532-82-1]* **$C_{12}H_{13}ClN_4$, M 248.7, m 235° (dec) (118-118.5° also reported? free base) λ_{max} 449nm, pK_1 3.32, pK_2 5.21.** It is a red-brown powder which is recrystallised from H_2O. It gives a yellow solution in concentrated H_2SO_4 which turns orange on dilution. Its solubility at 15° is 5.5% (H_2O), 4.75% (EtOH), 6.0% (cellosolve), 9.5% (ethylene glycol), 0.005% (xylene) and is insoluble in $*C_6H_6$. The ***hydroiodide*** has **m 184°** (from EtOH) and the ***picrate*** forms red needles with **m 196°**. [Muramatsu *Bull Chem Soc Jpn* **31** 864 *1958*, *Beilstein* **6** IV 561.] The ***free base*** *[9495-54-5]* **$C_{12}H_{12}N_4$** is CI Solvent Orange 3. The ***citrate salt*** *[5909-04-6]* is an antiseptic. The dye and its salts yield orange solutions in EtOH, and are chiefly used for colouring cotton and silk. They are also used in microscopy for staining microorganisms, and they complex with Cu^{2+} ions.

trans*-Cinnamaldehyde** *[14271-10-9]* **C_9H_8O, M 132.2, m -4°, -7.5°, -9°, b 80°/0.4mm, 85.8°/1.1mm, 125-128°/11mm, 152.2°/40mm, 163.7°/60mm, 199.3°/200mm, 246°/760mm (dec), d_4^{20} 1.0510, n_D^{20} 1.623.** Purify the aldehyde by steam distillation (solubility is 1 in 700 parts H_2O) followed by distillation *in vacuo*. The *cis*-isomer has **b 67-69°/40mm** and d_4^{20} 1.0436 and n_D^{20} 1.5937. The ***trans-semicarbazone has **m 210°(dec)** from $CHCl_3$/MeOH, (***cis-semicarbazone*** has **m 196°**), the ***trans-phenylsemicarbazone*** has **m 177°** from $CHCl_3$/MeOH (the ***cis-phenylsemicarbazone*** has **m 146°**), the ***trans-*** and ***cis- 2,4-dinitrophenylhydrazone*** have **m 250°(dec)** from MeOH [Gamboni et al. *Helv Chim Acta* **38** 255 *1955*, DOI: 10.1002/hlca.19550380130; Holum *J Org Chem* **26** 4814 *1961*, DOI: 10.1021/jo01070a009]. [*Beilstein* **9** IV 984.]

***cis*-Cinnamic acid (*Z*-3-phenyl-2-propenoic acid)** *[102-94-3]* **$C_9H_8O_2$, M 148.2, m 68° (for *allo*-form), pK^{25} 3.93.** The *cis*-acid is prepared by catalytic reduction of phenylpropiolic acid and after distillation in a high vacuum at ~95° it gives the most stable *allo*-isomer **m 68°.** Recrystallisation from petroleum ether yields **Liebermann's *iso*-cinnamic acid m 58°**. When the *allo*-acid (**m 68°**) is heated at 20° above its melting point in a sealed capillary for 0.5 hours and allowed to cool slowly, **Erlenmyer's *iso*-cinnamic acid m 42°** is formed. This form can also be obtained in larger amounts by heating the *allo*-acid at 80° for 3 hours, and on cooling it remains liquid for several weeks but gives the **m 42°** acid on innoculation with the crystals from the capillary tube. This form is unchanged in 6 weeks when kept in a dark cupboard. All three forms have the same pK values and the same rate of bromination. There is also a very labile form with **m 32°**. [Liebermann, *Chem Ber* **26** 1571 *1893*, DOI: 10.1002/cber.18930260275; Claisen & Crismer *Justus Liebigs Ann Chem* **218** 129 *1883*, DOI: 10.1002/jlac.18832180203; Robinson & James *J Chem Soc* 1453 *1933*, DOI: 10.1039/JR9330001453; Berthoud & Urech *Helv Chim Acta* **13** 437 *1930*, DOI: 10.1002/hlca.19300130403; McCoy & McCoy *J Org*

Chem **33** 2354 *1968*, DOI: 10.1021/jo01270a037; *Beilstein* **9** IV 2001.]

trans*-Cinnamic (*E*-3-phenyl-2-propenoic) acid** *[140-10-3, 621-82-9 for E-Z mixture]* **$C_9H_8O_2$, M 148.2, m 132°, 134.5-135°, pK^{25} 4.42 (4.50).** Crystallise the acid from *benzene, CCl_4, hot water, water/EtOH (3:1), or 20% aqueous EtOH. Dry it at 60° *in vacuo*. It is steam volatile. [*Beilstein* **9** IV 2002.] ***trans-Cinnamoyl chloride *[102-92-1]* **C_9H_7ClO, M 166.6,** has **m 35-37°, b 101°/2mm, 154°/25mm, 256-258°/atm, $d_4^{37.6}$ 1.6202, $n_D^{37.6}$ 1.1632.** Refractionate it in a vacuum until the distillate solidifies on cooling, and recrystallise the yellow distillate from petroleum ether. The ***trans-amide*** has **m 145-150°** (from H_2O) [*Beilstein* **9** III 2711]. [Adams & Ulich *J Am Chem Soc* **42** 605 *1920*, DOI: 10.1021/ja01448a024; Bergmann et al. *J Chem Soc* 2522 *1952*, DOI: 10.1039/JR9520002522; *Beilstein* **9** H 587, **9** I 233, **9** II 390, **9** III 2710, **9** IV 2020.] ***trans-Cinnamic anhydride*** *[538-56-7]* **$C_{18}H_{14}O_3$, M 278.4,** has **m 136°.** Crystallise the anhydride from *C_6H_6 or toluene/petroleum ether (b 60-80°) or EtOH (**m 135-136°**). It is insoluble in H_2O. [*Beilstein* **9** III 2703, **9** IV 2018.]

***N*-Cinnamoyl-*N*-phenylhydroxylamine** *[7369-44-0]* **$C_{15}H_{13}NO_2$, M 239.3, m 158-163°.** Recrystallise the hydroxylamine from EtOH.

Cinnamyl alcohol *[104-54-1]* **$C_9H_{10}O$, M 134.2, m 30°, 33°, b 143.5°/14mm, λ_{max} 251nm (ε 18,180 M^{-1} cm^{-1}).** Crystallise the alcohol from diethyl ether/pentane. [*Beilstein* **6** I 281.]

Coniferyl alcohol [4-hydroxy-3-methoxy-cinnamyl alcohol, 3-(4-hydroxy-3-methoxy-phenyl)-2-propen-1-ol] *[458-35-5]* **$C_{10}H_{12}O_3$, M 180.2, m 73°, 74°, 75°, 80°, b 163-165°/3mm, pK^{25} 9.54.** It is soluble in EtOH and insoluble in H_2O. It can, however, be recrystallised from EtOH and distilled in a vacuum. It polymerises in dilute acid. The ***benzoyl*** derivative has **m 95-96°** (from petroleum ether), and the ***tosylate*** has **m 66°**. [Derivatives: Freudenberg & Achtzehn *Chem Ber* **88** 10 *1955*, DOI: 10.1002/cber.19550880103; UV: Herzog & Hillmer *Chem Ber* **64** 1288 *1931*, DOI: 10.1002/cber.19310640614; *Beilstein* **6** II 1093.]

Coronene *[191-07-1]* **$C_{24}H_{12}$, M 300.4, m 438-440°, 442°, b 525°/atm, λ_{max} 345nm (log ε 4.07).** Crystallise coronene from *benzene or toluene, then sublime it in a vacuum. [*Beilstein* **5** III 2651.] It is an *n*-channel organic semiconductor [Newman et al *Chem Mater* **16** 4436 *2004*, DOI: 10.1021/cm049391x], and used to prepare MBE-grown layered superconductors [Schuerlein, Schmidt et al. *Japanese Journal of Applied Physics, Part 1* **34** 3837 *1995*, DOI: 10.1143/JJAP.34.3837].

o*-Cresol** *[95-48-7]* **C_7H_8O, M 108.1, m 30.9°, b 191°/760mm, n_D^{41} 1.536, n_D^{40} 1.534, pK^{25} 10.22.** It can be freed from *m*- and *p*-isomers by repeated fractional distillation, It crystallises from *benzene by addition of petroleum ether. It has been fractionallly crystallised by partial freezing of its melt. The ***3,5-dinitrobenzoate (prepared from 3,5-dinitrobenzoyl chloride in dry pyridine, and recrystallised from EtOH or aqueous Me_2CO) has **m 138°**. [*Beilstein* **6** IV 1940.] ***m-Cresol*** *[108-39-4]* has **f 12.0°, b 202.7°/atm, d_4^{20} 1.034, n_D^{20} 1.544, pK^{25} 0.09.** Separation of the *m*- and *p*-cresols requires chemical methods, such as conversion to their sulfonates [see Englund et al. *J Am Chem Soc* **45** 189 *1953*, DOI: 10.1021/ie50517a055]. An equal volume of H_2SO_4 is added to *m*-cresol, stirred with a glass rod until solution is complete. Heat for 3 hours at 103-105°. Dilute carefully with 1-1.5 volumes of water, heat to boiling point and steam distil until all unsulfonated cresol has been removed. Cool and extract the residue with ether. Evaporate the solution until the boiling point reaches 134° and steam distil off the *m*-cresol. Another purification method involves distillation, fractional crystallisation from the melt, then redistillation. Free from *p*-cresol by solution in glacial acetic acid and bromination by about half of an equivalent amount of bromine in glacial acetic acid. The acetic acid is distilled off, then fractional distillation of the residue under vacuum gives bromocresols from which 4-bromo-*m*-cresol is obtained by crystallisation from hexane. Addition of the bromocresol in glacial acetic acid slowly to a reaction mixture of HI and red phosphorus or (more smoothly) of HI and hypophosphorus acid, in glacial acetic acid, at reflux, removes the bromine. After an hour, the solution is distilled at atmospheric pressure until layers are formed. Then it is cooled and diluted with water. The cresol is extracted with ether, washed with water, $NaHCO_3$ solution and again with water, dried with a little $CaCl_2$ and distilled [Baltzly et al. *J Am Chem Soc* **77** 2522 *1955*, DOI: 10.1021/ja01614a049]. *m*-Cresol is the exclusive phenolic formed from *o*- and *p*- toluic acids when heated with $CuCO_3$, MgO, H_2O and air at ~230° [Kaeding et al. *J Am Chem Soc* **53** 805 *1961*,

DOI: 10.1021/ie50622a023]. The ***3,5-dinitrobenzoate*** (prepared from 3,5-dinitrobenzoyl chloride in dry pyridine, and recrystallised from EtOH or aqueous Me_2CO) has **m 165°**. [*Beilstein* **6** IV 2035.] Separation of the *m*- and *p*-cresols have been achieved by extractive crystallisation [Chivate & Shah *Chem Eng Sci* **5** 232 *1956*, DOI:10.1016/0009-2509(56)80035-3]. *p-**Cresol** [106-44-5]* **C_7H_8O, M 108.1, m 34.8°, b 201.9°, n^{41} 1.531, n^{46} 1.529, pK^{25} 10.27.** It can be separated from *m*-cresol by fractional crystallisation of its melt. Purify it by distillation, by precipitation from *benzene solution with petroleum ether, and *via* its benzoate, as for phenol. Dry it under vacuum over P_2O_5. It has also been crystallised from petroleum ether (b 40-60°) and by conversion to sodium *p*-cresoxyacetate which, after crystallisation from water is decomposed by heating with HCl in an autoclave [Savard *Ann Chim (Paris)* **11** 287 *1929*]. *p*-Cresol, free from its isomers, can be prepared by fusing sodium *p*-toluenesulfonate with KOH (but not with NaOH) at 300-320° followed by treatment with H_2SO_4, steam distillation, drying and distillation (**b 94-95°/15mm, m 31.4°**) in 63-72% yield [Hartman *Org Synth* Coll Vol **1** 175 *1941*, DOI: 10.15227/orgsyn.003.0037]. *p*-Cresol can be freed from contaminating *o*- and *m*- isomers by reaction with a tenth of its weight of 2,6-dichloroquinone chloroimide (which reacts with the latter two isomers to form a blue colour) [Gibbs *J Am Chem Soc* **49** 839 *1927*, DOI: 10.1021/ja01402a027]. The ***3,5-dinitrobenzoate*** (prepared from 3,5-dinitrobenzoyl chloride in dry pyridine, and recrystallised from EtOH or aqueous Me_2CO) has **m 189°**. [For UV see: Sreeramamurty *Trans Faraday Soc* **47** 1256 *1951*, DOI: 10.1039/TF9514701256; *Beilstein* **6** II 2093.]

***o*-Cresolphthalein [3,3-bis(4-hydroxy-3-methylphenyl)-1(3*H*)isobenzofura-1-one]** *[596-27-0]* **$C_{22}H_{18}O_4$, M 346.4, m 219° to 221°, 223°, 221.3-223.6°, λ_{max} 381nm** and **566nm, pKa 9.4.** It is prepared by heating *o*-cresol (2 mols), phthalic anhydride (1 mol) and anhydrous zinc chloride (0.5 mol) at 120°/3hrs [Hubacher et al. *J Am Pharm Assoc* **42** 23 *1953*, DOI: 10.1002/jps.3030420108], and finally purified by recrystallisation from EtOH. It is soluble in alcohol, but only slightly soluble in H_2O. Hence dissolve it in the smallest volume of EtOH, add H_2O to turbidity, then allow the EtOH to evaporate off and collect the white solid, dry it and recrystallise it from 95% EtOH. It is used in analytical chemistry as an indicator where in aqueous solution at pH ~8 it is colourless but turns red in alkaline solution, e.g. at pH 9.8 (cf: pKa at 9.4). Unlike some other phthaleins it is inactive as a laxative. [*Beilstein* **18** V/4 193.]

***o*-Cresolphthalein Complexone {Metalphthalein, Phthalein purple, 3,3-bis[5-(*N*,*N*-di(carboxymethyl)-aminomethyl)-4-hydroxy-3-methylphenyl)-1(3*H*)isobenzofuran-1-one)}** *[2411-89-4]* **$C_{32}H_{32}N_2O_{12}$, M 636.6, m 181° to 185°(dec), 186°(dec), λ_{max} 575nm, pK_1 2.2, pK_2 2.9, pK_3 7.0, pK_4 7.8, pK_5 11.4, pK_6 12.0.** *o*-Cresolphthalein (see previous entry, a complexone precursor without the two bis-carboxymethylaminomethyl groups) is a contaminant and is one of the starting materials. It can be removed by dissolving the reagent in H_2O and adding a 3-fold excess of sodium acetate and fractionally precipitating it by dropwise addition of HCl to the clear filtrate. Wash the white precipitate with cold H_2O and dry the *monohydrate* at 30° in a vacuum (0.01mm). The pure material gives a single spot on paper chromatography (eluting solvent EtOH/water/phenol, 6:3:1, and developing with NaOH). [Anderegg et al. *Helv Chim Acta* **37** 113 *1954*, DOI: 10.1002/hlca.19540370114.] It complexes with Mg^{2+}, Ba^{2+}, Sr^{2+}, Ca^{2+}, Cd^{2+} and Zn^{2+}, and is an excellent indicator for the complexometric titration of alkaline earth metals which show colour changes (e.g. red/pink, red/rose, red/colourless) in NH_3-buffer at pH 10—11 [cf. Bishop *Indicators* Pergamon Press *1972*, Library of Congress Cat Card No 78-171464]. It has also been used, in the presence of Ba^{2+}, for the titration of sulfate ions. [*Beilstein* **18** III/IV 8141.]

o-**Cresotic acid (3-methylsalicylic acid)** *[83-40-9]* **$C_8H_8O_3$, M 152.2, m 163-164°, 165°, 165-166°, pK_1^{25} 3.32.** Crystallise the acid from water. It is steam volatile. [*Beilstein* **10** H 220, **10** II 131, **10** III 505, **10** IV 601.] *m-**Cresotic acid*** **(4-methylsalicylic acid)** *[50-85-1]* has **m 173°, 176°, 177°, (182-183°), pK_1^{25} 3.15, pK_2^{25} 13.35.** Crystallise the acid from water. It is steam volatile. It sublimes at 130°/11mm. [*Beilstein* **10** H 233, **10** II 137, **10** III 521, **10** IV 617.] *p-**Cresotic acid*** **(5-methylsalicylic acid)** *[89-56-5]* has **m 150°, 151°, 152°, 151-154°, pK_1^{25} 3.40, pK_2^{25} 13.45.** Crystallise the acid from H_2O. It is steam volatile, and decomposes somewhat on sublimation. [*Beilstein* **10** H 227, **10** II 134, **10** III 516, **10** IV 610.]

Crystal Violet Chloride {Gentian violet, *N*-4[bis[4-(dimethylaminophenyl)methylene]-2,5-cyclohexadien-1-ylidene]-*N*-methylmethaninium chloride} *[548-62-9]* **$C_{25}H_{30}ClN_3$, M 408.0, m 205°(dec), pK 9.36.** Crystallise the greenish dye (with a metallic lustre) from water (20ml/g), the crystals being separated from the chilled solution by centrifugation, then wash them with chilled EtOH (solubility is 1g in 10 ml of hot EtOH) and

diethyl ether and dry under vacuum. It is soluble in $CHCl_3$ but insoluble in Et_2O. The carbinol is precipitated from an aqueous solution of the dye-hydrochloride, using excess NaOH, then dissolve in HCl and recrystallise it from water as the chloride [UV and kinetics: Turgeon & La Mer *J Am Chem Soc* **74** 5988 *1952*, DOI: 10.1021/ja01143a050]. The ***carbinol base*** has **m** 195° (needles from EtOH). The ***diphthalate*** (blue and turns red in H_2O) crystallises from H_2O, **m 153-154°(dec at 185-187°)**[Chamberlain & Dull *J Am Chem Soc* **50** 3088 *1928*, DOI: 10.1021/ja01398a035]. [*Beilstein* **13** H 233, **13** IV 2284.] Its solubility in glycerin is 6.7w/v%. It is used as a biological stain for Gram bacteria, with iodine for chromosome and nucleoli stain, and is an amyloid stain. It is anthelmintic and is a topical antibacterial.

Cumene (isopropyl benzene) *[98-82-8]* **C_9H_{12}, M 120.2, m -96°, b 69-70°/41mm, 152.4°/760mm, d_4^{20} 0.864, n_D^{20} 1.49146, n_D^{25} 1.48892.** Usual purification is by washing it with several small portions of concentrated H_2SO_4 (until the acid layer is no longer coloured), then with water, 10% aqueous Na_2CO_3, again with water, and drying with $MgSO_4$, $MgCO_3$ or Na_2SO_4, followed by fractional distillation. It can then be dried with, and distilled from, Na, NaH or CaH_2. Passage through columns of alumina or silica gel removes oxidation products. It has also been steam distilled from 3% NaOH, and azeotropically distilled with 2-ethoxyethanol (which is subsequently removed by washing out with water). [*Beilstein* **5** IV 985.]

Cumene hydroperoxide *[80-15-9]* **$C_9H_{11}O_2$, M 152.2, b 60°/0.2mm, 100-101°/8mm, d_4^{20} 1.028, n_D^{24} 1.5232.** Purify the hydroperoxide by adding 100ml of 70% material slowly and with agitation to 300ml of 25% NaOH in water, keeping the temperature below 30°. The resulting crystals of the sodium salt are filtered off, washed twice with 25 ml portions of *benzene, then stirred with 100ml of *benzene for 20 minutes. After filtering off the crystals and repeating the washing, they are suspended in 100ml of distilled water and the pH is adjusted to 7.5 by addition of 4M HCl. The free hydroperoxide is extracted into two 20ml portions of *n*-hexane, and the solvent is evaporated under vacuum at room temperature, the last traces being removed at 40-50°/1mm [Fordham & Williams *Can J Res* **27B** 943 *1949*, DOI: 10.1139/cjr49b-096]. Petroleum ether, **but not diethyl ether**, can be used instead of *benzene, and powdered solid CO_2 can replace the 4M HCl. [*Beilstein* **6** IV 3221.] *The material is potentially* **EXPLOSIVE.**

Cuminaldehyde (4-isopropylbenzaldehyde) *[122-03-2]* **$C_{10}H_{12}O$, M 148.2, b 82-84°/3.5mm, 120°/23mm, 131-135°/35mm, 235-236°/760mm, d_4^{20} 0.978, n_D^{20} 1.5301.** A likely impurity is the benzoic acid. Check the IR for the presence of OH from CO_2H, and the CO frequencies. If the acid is present, then dissolve the aldehyde in Et_2O, wash it with 10% $NaHCO_3$ until effervescence ceases, then with brine, dry over $CaCl_2$, evaporate and distil the residual oil, preferably under vacuum. It is almost insoluble in H_2O, but soluble in EtOH and Et_2O. The ***thiosemicarbazone*** has **m 147°** after recrystallisation from aqueous EtOH, MeOH or *C_6H_6. [Crounse *J Am Chem Soc* **71** 1263 *1949*, DOI: 10.1021/ja01172a035; Bernstein et al. *J Am Chem Soc* **73** *906* 1951, DOI: 10.1021/ja01147a007; Gensler & Berman *J Am Chem Soc* **80** 4949 *1958*, DOI: 10.1021/ja01551a048; *Beilstein* **7** H 318, **7** II 347, **7** III 1095, **7** IV 723.]

9-Cyanoanthracene (anthracene-9-carbonitrile) *[1210-12-4]* **$C_{15}H_9N$, M 203.2, m 173-174°, 173-177°.** Recrystallise the nitrile from EtOH (until a single sharp maximum at 256.5nm is obtained) or toluene, and sublime it in a vacuum in the dark under N_2 [Ebied et al. *JCS Faraday Trans 1* **76** 2170 *1980*, DOI: 10.1039/F19807602170; Kikuchi et al. *J Phys Chem* **91** 574 *1987*, DOI: 10.1021/j100287a017]. [*Beilstein* **9** I304.] The dimer below can be thermally monomerised at *ca* 120°.

9-Cyanoanthracene photodimer *[33998-38-8]* **$C_{30}H_{18}N_2$, M 406.4, dec to monomer above ~147°.** Purify the dimer (obtained by UV irradiating the above monomer at **λ** 350-370nm**)** by dissolving it in the minimum amount of $CHCl_3$ followed by addition of EtOH at 5° [Ebied et al. *JCS Faraday Trans 1* **75** 1111 *1979*, DOI: 10.1039/F19797501111; Ebied et al. *JCS Faraday Trans 1* **76** 2170 *1980*, DOI: 10.1039/F19807602170].

4-Cyanobenzoic acid *[619-65-8]* **$C_8H_5NO_2$, M 147.1, m 219°, 219-221° (dec), pK^{25} 3.55.** Crystallise the acid from water and dry it in a vacuum desiccator over Sicapent. [*Beilstein* **9** IV 3324.] ***4-Cyanobenzoyl chloride*** *[6068-72-0]* **C_8H_4ClNO, M 165.6,** has **m 68-70°, 69-70°, 73-74°, b 132°/8mm, 150-151°/25mm.** If the IR shows the presence of OH, then treat it with $SOCl_2$ boil for 1 hour, evaporate and distil it in a vacuum. The distillate solidifies and can be recrystallised from petroleum ether. It is moisture sensitive and an **IRRITANT.**

[Ashley et al. *J Chem Soc* 103 *1942*, DOI: 10.1039/JR9420000103; Fuson et al. *J Org Chem* **16** 648 *1951*, DOI: 10.1021/jo01144a018.] [*Beilstein* **9** III 4255, **14** IV 3327.]

p-**Cyanophenol** (*p*-**hydroxybenzonitrile**) *[767-00-0]* **C_7H_5NO, M 119.1, m 110°, 113°, pK^{25} 7.97.** Crystallise the phenol from petroleum ether, *benzene or water and keep it under vacuum over P_2O_5. [Bernasconi & Paschelis *J Am Chem Soc* **108** 2969 *1986*, DOI: 10.1021/ja00271a027.] [*Beilstein* **10** H 167, **10** IV 441.]

Cyclohexylbenzene (phenylcyclohexane) *[827-52-1]* **$C_{12}H_{16}$, M 160.3, m 6.8°, b 237-239°/atm, 239-240°/atm, d_4^{20} 0.950, n_D^{20} 1.5258.** Purify it by fractional distillation, and by fractional freezing. [*Beilstein* **5** IV 1424.]

Cyclopropyldiphenylcarbinol (cyclopropyldiphenylmethanol) *[5785-66-0]* **$C_{16}H_{16}O$, M 224.3, m 86-87°.** Crystallise the carbinol from *n*-heptane or *C_6H_6/pentane (**m** 82-83°). It sublimes at 60°/0.001mm. The ***2,4-dinitrobenzoate*** has **m 140°**. [*Beilstein* **6** III 3517, **6** IV 4888.]

p-**Cymene (4-isopropyltoluene)** *[99-87-6]* **$C_{10}H_{14}$, M 134.2, m -67.9°, b 177.1°/760mm, 176-178°/atm, d_4^{20} 0.8569, n_D^{20} 1.4909, n_D^{25} 1.4885.** It occurs in essential oils of plants. Wash *p*-cymene with cold, concentrated H_2SO_4 until there is no further colour change, then repeatedly with H_2O, 10% aqueous Na_2CO_3 and H_2O again. Dry it over Na_2SO_4, $CaCl_2$ or $MgSO_4$, and distil it. Further purification steps include steam distillation from 3% NaOH, percolation through silica gel or activated alumina, and a preliminary reflux for several days over powdered sulfur. Store it over CaH_2. [*Beilstein* **5** IV 1060.] *o*-**Cymene (2-isopropyltoluene)** *[527-84-4]* **$C_{10}H_{14}$, M 134.2,** has **m -71.5° (-81.5°** and **-75.2°**, unstable forms) **b 178.15°/760mm, 176-178°/atm, d_4^{20} 0.8766, n_D^{20} 1.5006,;** and *m*-**Cymene (3-isopropyltoluene)** *[535-77-3]* **$C_{10}H_{14}$, M 134.2,** has **m -64°, b 175.14°/760mm, d_4^{20} 0.8610, n_D^{20} 1.4930** and can be purified as described above for the *p*-isomer.

Deoxybenzoin (**2-phenylacetophenone**) *[451-40-1]* **$C_{14}H_{12}O$, M 196.3, m 54-55°, 60°, b 177°/12mm, 320°/760mm.** Crystallise deoxybenzoin from EtOH and/or distil it in a vacuum. [*Beilstein* **7** II 368, **7** III 2098, **7** IV 1393.]

(±)-Desyl bromide (α-bromo-desoxybenzoin, ω-bromo-ω–phenyl acetophenone) *[484-50-0]* **$C_{14}H_{11}BrO$, M 275.2, m 56°, 57.1-57.5°, 56°.** Crystallise it from 95% EtOH. It can be purified like the following (±)-desyl chloride. Store it in dark containers as it is more sensitive to light than the following chloride. [*Beilstein* **7** H 436, **7** II 370, **7** III 2122.] ***(±)-Desyl chloride*** **(α-chloro-desoxybenzoin, ω-chloro-ω–phenyl acetophenone)** *[447-31-4]* **$C_{14}H_{11}ClO$, M 230.7,** has **m 62-64°, 66-67°, 67.5°, 68°.** For the purification of small quantities recrystallise it from petroleum ether (b 40-60°), but use MeOH or EtOH for larger quantities. For the latter solvent, dissolve 12.5g of chloride in 45ml of boiling EtOH (95%), filter and the filtrate yields colourless crystals (7.5g) on cooling. A further crop (0.9g) can be obtained by cooling in an ice-salt bath. It turns brown on exposure to sunlight but it is stable in sealed dark containers. The ***R(+)-enantiomer*** has **m 75-76°** (from petroleum ether) and $[\alpha]_{546}$ +168.4 (c 0.6, Me_2CO) [Roger & Wood *J Chem Soc* 811 *1954*, DOI: 10.1039/JR9540000811]. [Henley & Turner *J Chem Soc* 1182 *1931*, DOI: 10.1039/JR9310001182; Ward *Org Synth* Coll Vol **2** 159 *1943*, DOI: 10.15227/orgsyn.012.0020; *Beilstein* **7** H 436, **7** I 234, **7** II 369, **7** III 2106, **7** IV 1396.]

Diacetoxyiodobenzene (iodobenzenediacetate) *[3240-34-4]* **$C_{10}H_{11}IO_4$, M 322.1, m 158°, 163-165°.** The purity of diacetoxyiodobenzene can be checked by treatment with H_2SO_4 then KI, and the liberated I_2 is estimated with standard thiosulfate. It has been recrystallised from 5M acetic acid and dried overnight in a vacuum desiccator over $CaCl_2$. The surface of the crystals may become slightly yellow but this does not affect its usefulness. [Sharefkin & Saltzman *Org Synth* Coll Vol **5** 660 *1973*, DOI: 10.15227/orgsyn.043.0062; *Beilstein* **5** IV 693.] It is a very useful reagent for the synthesis of a variety of heterocyclic compounds [Pradash & Singh *Aldrichimica Acta* **27** 15 *1994*, Guthikonda et al. *Tetrahedron* **62** 11331 *2006*, DOI:10.1016/j.tet.2006.07.099].

1,2-Diacetyl benzene *[704-00-7]* **$C_{10}H_{10}O_2$, M 162.2, m 39° to 41°, 41-42°, b 110°/0.1mm, 148°/20mm.**

Purify it by distilling and by recrystallising from petroleum ether. The ***bis-2,4-dinitrophenylhydrazone*** has **m 221° (dec)**. [Halford & Weissmann *J Org Chem* **17** 1646 *1952*, DOI: 10.1021/jo50012a012; Riemschneider & Kassahn *Chem Ber* **92** 1705 *1959*, DOI: 10.1002/cber.19590920735; *Beilstein* **7** III 3501, **7** IV 2155.] ***1,4-Diacetyl benzene*** *[1009-61-6]* has **m 111° to 113°, 113-5-114.2°, b 128-130°/3mm.** Crystallise it from EtOH (**m 114°**) or *benzene and dry it in a vacuum over $CaCl_2$. Also purify it by dissolving it in acetone, treating with Norit, evaporating and recrystallising from MeOH. The ***dioxime*** has **m 248-259°**. [Wagner et al. *J Am Chem Soc* **108** 7727 *1986*, DOI: 10.1021/ja00284a041]. [*Beilstein* **7** H 686, **7** II 624, **7** III 3504, **7** IV 2156.]

1,4-Diaminoanthraquinone *[128-95-0]* **$C_{14}H_{10}N_2O_2$, M 238.3, m 265°, 268°, 269°.** Purify the anthraquinone by thin-layer chromatography on silica gel using toluene/acetone (9:1) as eluent. The main band is scraped off and extracted with MeOH. The solvent is evaporated, and the quinone is dried in a drying pistol [Land et al. *JCS Faraday Trans 1* **72** 2091 *1976*, DOI: 10.1039/F19767202091]. It crystallises from EtOH (**m 269°**) in dark violet crystals. Store it in sealed ampoules in the dark. [*Beilstein* **14** H 197, **14** II 113, **14** III 437, **14** IV 458.] ***1,5-Diaminoanthraquinone*** *[129-44-2]* has **m 319°.** Recrystallise it from aniline (**m 313-314°**), EtOH or acetic acid [Flom & Barbara *J Phys Chem* **89** 4489 *1985*, DOI: 10.1021/j100267a017]. [*Beilstein* **14** H 303, **14** I 467, **14** II 116, **14** III 466, **14** IV 479.] ***2,6-Diaminoanthraquinone*** *[131-14-6]* has **m 310-320°.** Crystallise it from pyridine or nitrobenzene (red needles). Column-chromatography on Al_2O_3/toluene is used to remove a fluorescent impurity, then it is recrystallised from EtOH. [*Beilstein* **14** I 471, **14** II 120, **14** III 480, **14** IV 486.]

3,3'-Diaminobenzidine *[91-95-2]* **$C_{12}H_{14}N_4$, M 214.3, m 175°, 177°, $pK_{Est(1)}$ ~3.3, $pK_{Est(2)}$ ~4.7 (free base).** Dissolve the tetrahydrochloride (below) in H_2O (e.g. 1g in 20ml), cool the solution to 20°, then add it with stirring to a mixture of crushed ice (20g) and aqueous 10N NaOH (2ml), check that the pH is above 10, otherwise add more NaOH (keep cool). Filter off the free base and wash it thoroughly with cold H_2O. Recrystallise it from H_2O or EtOH and dry it over KOH *in vacuo*. *Alternatively*, liberate the free base with concentrated aqueous NH_3, in which case a dry product can be obtained more readily. [*Beilstein* **13** IV 530.] The free base or its hydrochloride (below) are substrates for peroxidase [Herzog & Fahimi *Anal Biochem* **55** 554 *1973*, DOI: 10.1016/0003-2697(73)90144-9], stain nucleic acids and are reagents for the spectrophotometric determination of Se [Cheng *Anal Chem* **28** 1738 *1956*, DOI: 10.1021/ac60119a027]. ***3,3'-Diaminobenzidine tetrahydrochloride (2H_2O)*** *[2H_2O: 7411-49-6; xH_2O: 868272-85-9]* **$C_{12}H_{14}N_4$. 4HCl. xH_2O, M 396.1, 360.1 (anhydr),** has **m >300°(dec), $pK_{Est(1)}$ ~3.3, $pK_{Est(2)}$ ~4.7 (free base).** Dissolve the salt in hot water, cool slightly and precipitate it with conc HCl, then dry it over solid NaOH. [*Beilstein* **13** IV 530.]

3,4-Diaminobenzoic acid *[619-05-6]* **$C_9H_8N_2O_2$, M 152.2, m 208°(dec), 210°(dec), 213°(dec), 228-229°, pK_1^{25} 2.57 (4-NH_2), pK_2^{25} 3.39 (3-NH_2), $pK_{Est(3)}$ ~5.1 (CO_2H).** Crystallise it from H_2O or toluene. [*Beilstein* **15** IV 1503.] ***3,5-Diaminobenzoic acid*** *[535-87-5]* has **m 228°(dec), 235°(dec), 238°(dec), 240°(dec), pK^{25} 5.13 (CO_2H), pK^{25} 7.12 (in 80% aqueous 2-$MeOCH_2CH_2OH$).** Crystallise the acid from water to give needles of the *monohydrate*, which loses H_2O above ~100°. The ***dihydrochloride*** *[535-87-5]* **$C_9H_8N_2O_2$.2HCl, M 225.1,** has **m 226-228°(dec)** [>300°(dec) also reported]. It is used for the detection of *nitrites*. The ***ethyl ester*, m 84°**, crystallises from aqueous EtOH or Et_2O. [*Beilstein* **14** H 453, **14** III 1179, **14** IV 1304.]

3,4-Diaminobenzophenone (4-benzoyl-*o*-phenylenediamine) *[39070-63-8]* **$C_{13}H_{12}N_2O$, M 212.3, m 116-117°, $pK_{Est(1)}$ ~ <0, $pK_{Est(2)}$ ~2.5.** Crystallise it from *C_6H_6/petroleum ether and sublime it *in vacuo* [Ayyanger et al. *Org Prep Proced Int* **23** 627 *1991*, DOI: 10.1080/00304949109457915; *Beilstein* **14** II 225]. ***4,4'-Diaminobenzophenone*** *[611-98-3]* has **m 242-244°, 243-245°, 246.5-247.5° (after sublimation at 0.0006mm), pK_1^{25} 1.37, pK_2^{25} 2.92.** Purify the phenone by recrystallisation from EtOH and by sublimation in high vacuum. The ***dihydrochloride*** has **m 260°(dec)** (from EtOH), and the ***thiosemicarbazone*** has **m 207-207.5°(dec)** (from aqueous EtOH). [Kuhn et al. *Chem Ber* **75** 711 *1942*, DOI: 10.1002/ cber.19420750614; *Beilstein* **14** IV 255.]

1,2-Diamino-4,5-dichlorobenzene *[5348-42-5]* **$C_6H_6Cl_2N_2$, M 177.0, m 158°, 162°, 162-163°, 163°, 164°, $pK_{Est(1)}$ ~1.0, $pK_{Est2)}$ ~2.9.** Reflux the amine with activated charcoal in CH_2Cl_2, followed by recrystallisation from Et_2O/petroleum ether or petroleum ether [Koola & Kochi *J Org Chem* **52** 4545 *1987*, DOI: 10.1021/jo00229a022]. *Alternatively*, recrystallise the diamine from hexane, *C_6H_6, petroleum ether or H_2O (Na_2SO_4), and sublime it at 150°/15mm. [*Beilstein* **13** IV 72.]

4,4'-Diamino-3,3'-dinitrobiphenyl (3,3'-dinitrobenzidine) *[6271-79-0]* **$C_{12}H_{10}N_4O_4$, M 274.2, m 275°, pK_{Est} ~ -0.2.** Recrystallise the biphenyl from aqueous EtOH, pyridine/EtOH or nitrobenzene to give scarlet needles. Diazotisation of this benzidine gives the tetrazo-biphenyl which on decomposition in boiling EtOH provided ***3,3'-dinitrobiphenyl*** *[958-96-3]* **$C_{12}H_8N_2O_4$, M 244.2, m 200°**, as orange-yellow needles, after crystallisation form 50% aqueous AcOH [Hodgson & Holt *J Chem Soc* 1431 *1934*, DOI: 10.1039/JR9340001431; *Beilstein* **13** H 236, **13** I 68, **13** II 108, **13** III 415, **13** IV 387.]

4,4'-Diaminodiphenylamine *[537-65-5]* **$C_{12}H_{13}N_3$, M 199.3, m 158°, pK_{Est} ~5.0.** Crystallise the amine from water (its solubility at 25° is 0.42%). [*Beilstein* **13** H 110, **13** I 36, **13** II 55, **13** III 256, **13** IV 203.]

4,4'-Diaminodiphenyl ether (4,4'-oxydianiline, DADPE) *[101-80-4]* **$C_{12}H_{12}N_2O$, M 200.2, m 185°, 186-187°, 188°, 190°, 192°, 240°/10mm, pK^{25} 5.12 (50% EtOH).** This base has been prepared by several syntheses including, condensation of *p*-nitrophenol with *p*-chloroaniline, nitration of diphenyl ether to 4,4'-dinitrodiphenyl ether and reduction with hydrazine and Raney Ni [Shamis & Dashevski *J Org Chem, USSR Engl Transl* **3** 1005 *1967*], a Friedel-Crafts reaction of diphenyl ether (AcCl, $AlCl_3$) to 4,4'-diacetyldiphenyl ether (m 99-100°), conversion to the dioxime (m 180-183°), and a bis-Beckman rearrangement (AcOH, Ac_2O, HCl gas) gives 4,4'-bis-acetamidodiphenyl ether (90%). This amide (46g) in H_2O (600ml) and concentrated HCl (60ml) is refluxed for 2 hours until it all dissolved, filtered (charcoal), the filtrate is basified with Na_2CO_3 solution, the precipitate is filtered off, washed with H_2O, and dried at 100-110° to give the ***free base*** (32g). It is purified by zone melting and/or by sublimation at high vacuum. In the UV it has λ_{max} at 248 and 300nm in EtOH. [Franovskii et al. *J Org Chem, USSR Engl Transl* **6** 2315 *1970*.] The ***benzenesulfonate salt*** crystallises from MeOH with **m 286-288°(dec)**. [*Beilstein* **13** H 441, **13** I 148, **13** III 106, **13** IV 1038.]

4,4'-Diaminodiphenylmethane (MDA) *[101-77-9]* **$C_{13}H_{14}N_2$, M 198.3, m 91.6-92°, 92-93°, b 232°/9mm, 398°/atm, pK_{Est} ~4.9.** Crystallise the amine from water, 95% EtOH or *benzene. [*Beilstein* **13** IV 390.] Care, as it can cause liver damage. It inhibits corrosion.

2,7-Diaminofluorene *[524-64-4]* **$C_{13}H_{12}N_2$, M 196.3, m 160°, 162°, 165°, pK_{Est} ~4.6.** Recrystallise it from H_2O. [*Beilstein* **13** IV 449.] It is used as an analytical reagent for bromide, chloride, nitrate, Cd^{2+}, Cu^{2+}, $Co^{2+}$and Zn^{2+}.

1,4-Diaminonaphthalene *[2243-61-0]* **$C_{10}H_{10}N_2$, M 158.2, m 114°, 116°, pK_1^{25} 5.87, pK_1^{25} 2.78.** Purify as for the 1,5-somer below. It forms dark green to black crystals which are insoluble in H_2O. On prolonged standing in air it oxidises (to the quinon-imine then to 1,4-naphthoquinone?). It is prepared commercially from 1,4-dibromonaphthalene (40g), 25% ammonia (350ml), and a catalyst [e.g. anhydrous CuCl (6g)] in an autoclave at 150°/6hrs in ~60% yield. [Zechlin et al. US Pat 6,538,158 B2 *2003*, to Bayer Aktiengesellschaft.] ***1,5-Diaminonaphthalene*** *[2243-62-1]* has **m 185°, 187°, 190°, pK^{25} 4.12, $pK_{Est(2)}$ ~2.0.** Recrystallise the amino-naphthalene from boiling H_2O, but this is wasteful due to poor solubility. Boil it in chlorobenzene (charcoal), filter hot and cool the filtrate (preferably under N_2). This gives colourless crystals. Dry it in a vacuum till free from chlorobenzene (odour), and store it in sealed ampoules under N_2 away from light. [*Beilstein* **13** IV 340.] ***1,8-Diaminonaphthalene*** *[479-27-6]* has **m 60°, 65°, 66.5°, b 205°/12mm, pK^{25} 4.44 (in 1-0% aqueous EtOH).** Crystallise 1,8-diaminonaphthalene from water or aqueous EtOH, and sublime it in a vacuum. It is an antioxidant used in lubricating oils, and for the detection of nitrite and Se. The ***dihydrochloride*** **m 280°**, forms leaflets from aqueous HCl. The ***N,N'-dimethyl*** derivative *[20734-56-9]* has **m 103-104°** and **pK^{25}** 5.61, the ***N,N,N'-trimethyl-*** derivative *[20734-57-0]* has **m 29-30°** and **pK^{25}** 6.43. [Hodgson et al. *J Chem Soc* 202 *1945*, DOI: 10.1039/JR9450000202; *Beilstein* **13** IV 344.] ***2,3-Diaminonaphthalene*** *[771-97-1]* has **m 199°, pK^{21} 3.54 (in 50% aqueous EtOH).** Crystallise the diamine from water, or dissolve it in 0.1M HCl, by heating to 50°. After cooling, the solution is extracted with decalin to remove fluorescent impurities, and centrifuged. [*Beilstein* **13** IV 346.]

2,5-Di-*tert*-amylhydroquinone *[79-74-3]* **$C_{16}H_{26}O_2$, M 250.4, m 179-180°, 185.8-186.5°.** Crystallise the hydroquinone under N_2 from boiling AcOH (7ml/g) plus boiling water (2.5ml/g). [Stolow & Bonaventura *J Am Chem Soc* **85** 3636 *1963*, DOI: 10.1021/ja00905a023]. Store it in sealed ampoules under N_2 away from light. It is an antioxidant. [*Beilstein* **6 H** 952, 6 III 4748.]

Di-n-amyl phthalate (dipentyl phthalate) *[131-18-0]* **$C_{18}H_{26}O_4$, M 306.4, b 204-206°/11mm, d_4^{25} 1.023, n_D^{20} 1.489.** Wash the ester with aqueous Na_2CO_3, then distilled water. Dry it with $CaCl_2$ and distil it in a vaccum. Store it in a vacuum desiccator over P_2O_5. [*Beilstein* **9** IV 3178.]

Diazoaminobenzene (1,3-diphenyltriazene) *[136-36-6]* **$C_{12}H_{11}N_3$, M 197.2, m 99°, 100°.** Crystallise the triazene from petroleum ether (b 60-80°) (**m** 94-96°), 60% MeOH/water or 50% aqueous EtOH (charcoal) containing a small amount of KOH. Its solubility in petroleum ether (b 60-80°) is ~6%. Also purify it by chromatography on alumina/toluene and elute with toluene/petroleum ether. Store the pale yellow needles in the dark. [Hartman & Dickey *Org Synth* Coll Vol **2** 163 *1943*, DOI: 10.15227/orgsyn.014.0024; *Beilstein* **16** H 687, **16** I 404, **16** II 351, **16** III 643, **16** IV 904.]

Dibenzalacetone [DBA, bda, *trans-trans-***1,5-diphenyl-1,4-dien-3-one, 1,5-(bisphenyl)-penta-1*E*,4*E*-diene-3-one]** *[538-58-9]* **$C_{17}H_{14}O$, M 234.3, m 107°, 111°, 112°, 113°, 120-122°**. Purify the ketone by flash chromatography (150 mesh Al_2O_3 deactivated with 6% v/w H_2O) using petroleum ether 40-60°/EtOAc (4/1, v/v), and the yellow solid is recrystallised by layering a concentrated CH_2Cl_2 solution with hexane (i.e. CH_2Cl_2/hexane, 1:4, v/v). Also recrystallise the ketone from hot ethyl acetate (2.5ml/g) or EtOH. It has been also crystallised from petroleum ether b 30-60°. The IR (CH_2Cl_2) has ν_{max} at 1657m, 1651m (C=O), 1627vs (C=C), 1591w (C= C aromatic), 1574w (C= C aromatic), 983m (C=C trans) cm^{-1}; and UV has λ_{max} (THF) at 233 (π-π*) and 321 (n- π*) nm; the ^1H NMR (400MHz, $CDCl_3$) has δ at 7.65-7.15 (m, 10 H, ArH), 4.4 (dd, *J* = 5.8, 10.0 Hz, 1 H, C3a-H), 3.45-3.30 (m, 1 H, C6-H), 3.15-3.00 (m, 1 H, C6-H), 1.90-1.55 (m, 3 H, C4-H, C5-H_2), 0.95-0.75 (m, 1 H, C4-H), 0.40 (s, 3 H, B-CH_3). The ***trans-trans- 2,4-dinitrophenylhydrazone*** has **m 181°**. [Conrad & Dolliver *Org Synth* Coll Vol **2**167 *1943*, DOI: 10.1002/9780470132487.ch37; *Beilstein* **7** IV 1747.] *Cis-cis-**1,5-diphenyl-1,4-dien-3-one (Z,Z-isomer)***, prepared by catalytic reduction of 1,5-diphenylpentadiyne-3-one using Lindlar's catalyst in 60% yield, is a yellow oil **b 130°/0.02mm,** whose ***2,4-dinitrophenylhydrazone***, prepared under mild conditions (in the absence of light), has **m 92°**; whereas under the usual conditions it gave the *trans-trans-2,4-dinitrophenylhydrazone*. Acid hydrolysis of the *cis-cis*-hydrazone m 92° gave the *trans-trans-* ketone. Catalytic reduction of 1,5-diphenylpent-1-ene-4-yn-3-one with Lindlar's catalyst gave *cis-trans-**1,5-diphenyl-1,4-dien-3one (Z,E-isomer)***, in 50% yield which crystallised from EtOH in yellow needles **m 60°**, and its ***2,4-dinitrophenylhydrazone*** prepared in the usual manner has **m 159°**. Exposing the *cis-cis*-ketone to normal light for 24 hours caused complete conversion to the *trans-trans*-ketone, whereas no isomerisation occurred during one month in the absence of light. C*is-trans*-1,5-diphenylpentadiene-3-one remained unchanged after several days exposure to normal light. On heating the *cis-cis-ketone* in MeOH with concentrated hydrochloric acid at 100° for 5 minutes produced an ~1:1 mixture of *cis-trans-* and *trans-trans-* isomers. There is no evidence of light catalysed isomerisations. The three geometrical isomers have different NMR, IR and UV spectra, e.g. in the IR (KBr?) the *Z,Z*-isomer has ν_{max} at 971 (10.3mμ) cm^{-1} for *trans*-C=C [compare with above 983cm^{-1} in CH_2Cl_2 solution], a band which is absent in the *E,E*-isomer and replaced by a band at ν_{max} at 761 (13.15mμ) cm^{-1} for *cis*-C=C frequency which is also present in the *E,Z*-isomer. Furthermore in the UV the *Z,Z*-isomer has λ_{max} at 330nm (ε 34,000), the *E,Z*-isomer has λ_{max} at 295nm (ε 20,000) and the *E,Z*-isomer has λ_{max} at 287nm (ε 11,000). [Dinwiddie et al. *J Org Chem* **27** 327 *1962*, DOI: 10.1021/jo01048a529.] These dienones readily form carbocyclic and heterocyclic compounds, and are useful ligands for making stable zero-valent neutral complexes with Pd(0), e.g. $Pd(dba)_2$ and $Pd(dba)_3$ [Rettig & Maitlis *Inorg Synth* **17** 134 *1977*, Ukai et al. *J Organomet. Chem* **65** 253 *1974*, DOI:10.1016/S0022-328X(00)91277-4,] which are important catalysts [see Chapter 5 in this book, and J. Tsuji *Organic Synthesis with Palladium Compounds* Springer Verlag, Berlin, *1980* E-I. Negishi (Ed), *Handbook of Organopalladium for Organic Synthesis, Vol 1 and 2,* J, Wiley & Sons, NY, *2002*. ISBN 471315060.]

Dibenz[*a,h*]anthracene (1,2:5,6-dibenzanthracene) *[53-70-3]* **$C_{22}H_{14}$, M 278.4, m 262°, 265°, 266-267°, b 524°/atm.** The yellow-green colour (due to other pentacyclic impurities) is removed from it by crystallising from *benzene or by selective oxidation with lead tetraacetate in acetic acid [Moricon et al. *J Am Chem Soc* **82** 3441 *1960*, DOI: 10.1021/ja01498a051]. It can be recrystallised from AcOH and sublimed. [*Beilstein* **5** IV 2722.]

***trans*-1,2-Dibenzoylethylene (*trans*-1,4-diphenyl-2-butane-1,4-dione)** *[959-28-4]* **$C_{16}H_{12}O_2$, M 236.3, m 109°, 111°, 112°.** It crystallises from MeOH or EtOH as yellow needles [Keller et al. *Helv Chim Acta* **29** 512

1946, DOI: 10.1002/hlca.19460290304]. The ***dioxime*** has **m 210-211º(dec)** from AcOH. [IR: Kuhn et al. *J Am Chem Soc* **72** 5058 *1950*, DOI: 10.1021/ja01167a066; Yates *J Am Chem Soc* **74** 5376 *1952*, DOI: 10.1021/ja01141a047; Erickson et al. *J Am Chem Soc* **73** 5301 *1951*, DOI: 10.1021/ja01155a086; [Lutz *Org Synth* Coll Vol **3** 248 *1955*, DOI: 10.15227/orgsyn.020.0029; *Beilstein* **7** IV 2578.]

Dibenzoylmethane (1,3-diphenyl-1,3-propanedione) *[120-46-7]* **$C_{15}H_{12}O_2$, M 224.3, m 77º, 79º, 80º, 219-221º/18mm.** Crystallise dibenzoylmethane from petroleum ether or MeOH. The ***oxime***, **m 165º**, crystallises from Et_2O. [Allen at al, *Org Synth* Coll Vol **1** 205 *1941*, DOI: 10.15227/orgsyn.008.0060; *Beilstein* **7** IV 2512.]

2,3,6,7-Dibenzphenanthrene (pentaphene) *[222-93-5]* **$C_{22}H_{14}$, M 276.3, m 255-256º, 257º.** Purify pentaphene through Al_2O_3 with $^*C_6H_6$ or xylene as eluent. It crystallises from xylene as yellow plates and sublimes in high vacuum. The ***dipicrate*** forms orange needles **m 184º** from $^*C_6H_6$. (Clar & John *Ber* **64** 986 *1931*, Clar & Stewart *J Chem Soc* 3215 *1951*, DOI: 10.1039/JR9450000202; Marsili & Isola *Tetrahedron Lett* 3023 *1965*, DOI: 10.1016/S0040-4039(01)89252-2; Franck & Zander *Chem Ber* **99** 396 *1966*, DOI: 10.1002/cber.19660990205.]

Dibenzyl amine *[103-49-1]* **$C_{14}H_{15}N$, M 197.3, m -26º, b 113-114º/0.1mm, 174-175º/6mm, 270º/250mm, 300º (partial dec), d_4^{20} 1.027, n_D^{20} 1.576, pK[25] 8.52.** Purify the amine by distillation in a vacuum. **It causes burns to the skin.** The ***dihydrochloride*** has **m** 265-266º (from MeOH/HCl), and the ***tetraphenyl boronate*** has **m 129-133º**. [Bradley & Maisey *J Chem Soc* 247 *1954*, DOI: 10.1039/JR9540000247; Hall *J Phys Chem* **60** 63 *1956*, DOI: 10.1021/j150535a017; Donetti & Bellora *J Org Chem* **37** 3352 *1972*, DOI: 10.1021/jo00986a036; *Beilstein* **12** IV 2179.] It is used for the detection of cobalt, iron and cyanate ion.

N,N'*-Dibenzylethylenediamine (benzathine, DBED)** *[140-28-3]* **$C_{16}H_{30}N_2$, M 240.4, m 26º, b 195º/4mm, d_4^{20} 1.02, n_D^{20} 1.563, $pK_{Est(1)}$~ 5.9, $pK_{Est(2)}$~ 8.9.** Dissolve DBED in acid, extract with toluene, basify, extract it with Et_2O, dry over solid KOH, evaporate and fractionate it *in vacuo*. The ***diacetate crystallises from H_2O by addition of EtOH and has **m 111º** (solubility in H_2O is ~25%). The ***dihydrochloride*** has **m 306-308º** (from H_2O) and the ***dipicrate*** has **m 212º(dec)** (from H_2O). [Frost et al. *J Am Chem Soc* **71** 3842 *1949*, DOI: 10.1021/ja01179a510; *Beilstein* **12** H 1067, **12** III 2304.]

Dibenzyl ketone (1,3-diphenyl-2-propanone) *[102-04-5]* **$C_{15}H_{14}O$, M 210.3, m 32º, 34º, 330º/atm.** Fractionally crystallise it from its melt, then crystallise it from petroleum ether. It has been purified by recrystallisation form anhydrous Et_2O at -70º. Store it in the dark. [*Beilstein* **7** IV 1420.]

Dibenzyl malonate *[15014-25-2]* **$C_{17}H_{16}O_4$, M 284.3, b 188-190º/0.2mm, 193-196º/1mm, d_4^{20} 1.158, n_D^{20} 1.5452.** Dissolve the ester in toluene, wash it with aqueous $NaHCO_3$, H_2O, dry over $MgSO_4$, filter, evaporate and distil it at high vacuum. [Ginsburg & Pappo *J Am Chem Soc* **75** 1094 *1953*, DOI: 10.1021/ja01101a025; Baker et al. *J Org Chem* **17** 77 *1952*, DOI: 10.1021/jo01135a009; *Beilstein* **6** IV 2270.]

2,4-Dibromoaniline *[615-57-6]* **$C_6H_5Br_2N$, M 250.9, m 79º, 80º, pK[25] 1.87.** Crystallise the aniline from aqueous EtOH. The ***picrate*** has **m 124º**. [*Beilstein* **12** H 655, **12** I 326, **12** II 356, **12** III 1471, **12** IV 1532.]

9,10-Dibromoanthracene *[523-27-3]* **$C_{14}H_8Br_2$, M 336.0, m 222-224º, 226º.** Recrystallise it from toluene, xylene or CCl_4 (yellow needles), and sublime it in a vacuum [Johnston et al. *J Am Chem Soc* **109** 1291 *1987*, DOI: 10.1021/ja00239a001]. [Heilbron & Heaton *Org Synth* Coll Vol **1** 207 *1941*, DOI: 10.15227/orgsyn.003.0041; *Beilstein* **5** H 665.]

1,4-Dibromobenzene *[106-37-6]* **$C_6H_4Br_2$, M 235.9, m 87.8º.** Steam distil the dibromobenzene, then crystallise it from EtOH or MeOH and dry it in the dark under vacuum. Purify it by zone melting. [*Beilstein* **5** IV 683.]

2,5-Dibromobenzoic acid *[610-71-9]* **$C_7H_4Br_2O_2$, M 279.9, m 156º, 157º, 159º, pK_{Est} ~1.5.** Crystallise the acid from water or EtOH. [*Beilstein* **9** H 358, **9** I 147, **9** II 237, **9** III 1428, **9** IV 1027.]

(±)-2,2'-Dibromo-1,1'-binaphthyl *[74866-28-7, (±) 76284-65-6]* **$C_{20}H_{12}Br_2$, M 412.1, m 178-183°, 180.5-181°.** Purify the binaphthyl by chromatography through a silica gel column (70-230mesh) using hexane as eluent. It gives pale yellow crystals from EtOH with **m 187.3-187.9°**. The ***R*-(+)-*enantiomer*** *[86688-08-6]* crystallises from hexane with **m 157-157.5°** and $[\alpha]_D^{25}$ +32.9 (c 1, pyridine) [Brown et al. *J Org Chem* **50** 4345 *1985*, DOI: 10.1021/jo00222a029]. [Okamoto et al. *J Am Chem Soc* **103** 6971 *1981*, DOI: 10.1021/ja00413a038; *Beilstein* **5** III 2465.]

4,4'-Dibromobiphenyl *[92-86-4]* **$C_{12}H_8Br_2$, M 312.0, m 163°, 164°, 165°, b 355-360°/760mm.** Crystallise it from MeOH. [*Beilstein* **5** IV 1820.]

α,α-Dibromodeoxybenzoin (α,α-dibromobenzyl phenyl ketone) *[15023-99-1]* **$C_{14}H_{10}Br_2O$, M 354.0, m 111.8-112.7°.** Crystallise α,α-dibromo deoxybenzoin from acetic acid, 50% aqueous EtOH (prisms, **m 109-112°**) or Et_2O (**m 112°**). [Curtius & Lang *J Prakt Chem* **44** 547 *1891*, DOI: 10.1002/prac.18910440147; *Beilstein* **7** H 436, **7** III 2114.]

2,5-Dibromonitrobenzene *[3460-18-2]* **$C_6H_3Br_2NO_2$, M 280.9, m 84°, 85-86°.** It crystallises from Me_2CO or EtOH. [*Beilstein* **5** H 250, **5** II 190, **5** III 621, **5** IV 732.]

2,6-Dibromo-4-nitrophenol *[99-28-5]* **$C_6H_3Br_2NO_3$, M 296.9, m 143-144°, pK^{25} 3.39.** Crystallise the phenol from aqueous EtOH, 50% aqueous AcOH (**m 144-145°**, dec varies with rate of heating). Dry it in an oven at 40-60° or *in vacuo* over NaOH. [Hartman & Dickey *Org Synth* Coll Vol **2** 173 *1943*, DOI: 10.15227/orgsyn.015.0006; *Beilstein* **6** H 246, **6** I 123, **6** II 234, **6** III 849, **6** IV 1366.]

2,4-Dibromophenol *[615-58-7]* **$C_6H_4Br_2O$, M 251.9, m 35°, 37°, 38°, 41-42°, b 154°/10mm, 239°/760mm, pK^{25} 7.79.** Crystallise the phenol from $CHCl_3$ at -40°, or distil it in a vacuum. [*Beilstein* **6** H 202, **6** I 106, **6** II 188, **6** III 753, **6** IV 1061.] ***2,6-Dibromophenol*** *[608-33-3]* has **m 53°, 56-57°, b 138°/10mm, 255-256°/740mm, pK^{25} 6.67.** Distil the phenol under vacuum (at 10mm), then crystallise it from cold $CHCl_3$ or from EtOH/water. [*Beilstein* **6** H 202, **6** I 106, **6** II 188, **6** III 755, **6** IV 1064.]

α,α'-Dibromo-*o*-xylene *[91-13-4]* **$C_8H_8Br_2$, M 264.0, m 91°, 94°, 95°, 95-96°, 98-99°, b 129-130°/4.5mm.** Crystallise it from $CHCl_3$ or petroleum ether, and/or distil it under vacuum. [Wenner *J Org Chem* **17** 523 *1952*, DOI: 10.1021/jo01138a003; *Beilstein* **5** H 366, **5** I 180, **5** II 285, **5** III 819, **5** IV 929.] ***α,α'-Dibromo-m-xylene*** *[626-15-3]* has **m 75°, 77°, 78-79°, b 156-160°/12mm, 135-140°/20mm** (also reported)**.** Crystallise it from acetone or *benzene, and fractionally distil it under vacuum. [Wenner *J Org Chem* **17** 523 *1952*, DOI: 10.1021/jo01138a003; *Beilstein* **5** H 374, **5** I 184, **5** II 294, **5** III 839, **5** IV 946.] ***α,α'-Dibromo-p-xylene*** *[623-24-5]* has **m 143.4°, 142-144°, 145-147°, b 155-158°/12-15mm, 245°/760mm.** Distil it under a vacuum and recrystallise it from EtOH, *benzene or chloroform. [Wenner *J Org Chem* **17** 523 *1952*, DOI: 10.1021/jo01138a003; *Beilstein* **5** H 385, **5** I 187, **5** II 301, **5** III 859, **5** IV 970.]

α-Dibutylamino-α-(4-methoxyphenyl)acetamide (Ambucetamide) *[519-88-0]* **$C_{17}H_{28}N_2O_2$, M 292.4, m 134°.** Crystallise ambucetamide from EtOH containing 10% diethyl ether. [Janssen *J Am Chem Soc* **76** 6192 *1954*, DOI: 10.1021/ja01652a098; *Beilstein* **14** IV 2101.] Antispasmotic.

2,5-Di-*tert*-butyl aniline *[21860-03-7]* **$C_{14}H_{23}N$, M 205.4, m 103°, 104°, 103-106°, pK^{25} 3.34 (50% aqueous MeOH), 3.58 (90% aqueous MeOH).** The aniline recrystallises from EtOH in fine needles after steam distillation. It has a pKa^{25} of 3.58 (50% aqueous EtOH). The ***tosylate*** has **m 164°** (from AcOH). [Bell & Wilson *J Chem Soc* 2340 *1956*, DOI: 10.1039/JR9560002340; Carpenter et al. *J Org Chem* **16** 586 *1951*, DOI: 10.1021/jo01144a011; Bartlett et al. *J Am Chem Soc* **76** 2349 *1954*, DOI: 10.1021/ja01638a019; *Beilstein* **12** IV 2891.]

***p*-Di-*tert*-butylbenzene** *[1012-72-2]* **$C_{14}H_{22}$, M 190.3, m 77°, 78°, 80°, 236°/760mm.** Crystallise it from Et_2O or EtOH and dry it under vacuum over P_2O_5 at 55°. [Tanner et al. *J Org Chem* **52** 2142 *1987*, DOI: 10.1021/jo00387a005; *Beilstein* **5** II 344.]

2,6-Di-*tert*-butyl-1,4-benzoquinone *[719-22-2]* **$C_{14}H_{20}O_2$, M 220.3, m 65°, 66°, 67°.** It can be recrystallised from MeOH and sublimes in a vacuum. [*Beilstein* **7** IV 2116.] ***3,5-Di-tert-butyl-1,2-benzoquinone*** *[3383-21-9]* has **m 112-114°, 113-114°.** It can be recrystallised from MeOH or petroleum ether, and forms fine red plates or rhombs. [Flaig et al. *Justus Liebigs Ann Chem* **597** 196 *1955*, DOI: 10.1002/jlac.19555970304; IR: Ley & Müller *Chem Ber* **89** 1402 *1956*, DOI: 10.1002/cber.19560890607; *Beilstein* **7** IV 2113.]

3,5-Di-*tert*-butyl catechol *[1020-31-1]* **$C_{14}H_{22}O_2$, M 222.3, m 96°, 97°, 99°, 99-100°, $pK_{Est(1)}$ ~11.0, $pK_{Est(2)}$ ~13.1**. Recrystallise the catechol from petroleum ether. [Ley & Müller *Chem Ber* **89** 1402 *1956*, DOI: 10.1002/cber.19560890607; UV Flaig et al. *Z Naturforschung* **10b** 668 *1955*.] Also purify it by crystallising three times from pentane [Funabiki et al. *J Am Chem Soc* **108** 2921 *1986*, DOI: 10.1021/ja00271a022].

2,6-Di-*tert*-butyl-*p*-cresol (2,6-di-*tert*-butyl-4-methylphenol, butylatedhydroxytoluene, BHT or DBPC) *[128-37-0]* **$C_{15}H_{24}O$, M 220.4, m 71.5°, pK^{25} 12.23.** Dissolve BHT in *n*-hexane at room temperature, then cool with rapid stirring, to -60°. The precipitate is separated, redissolved in hexane, and the process is repeated until the mother liquor is no longer coloured. The final product is stored under N_2 at 0° [Blanchard *J Am Chem Soc* **82** 2014 *1960*, DOI: 10.1021/ja01493a041]. It has also been recrystallised from EtOH, MeOH, *benzene, *n*-hexane, methylcyclohexane or petroleum ether (b 60-80°), and is dried in a vacuum. [*Beilstein* **6** IV 3511.] It is a very effective antioxidant.

2,6-Di-*tert*-butyl-4-dimethylaminomethylphenol *[88-27-7]* **$C_{17}H_{29}NO$, M 263.4, m 93-94°, b 172°/30mm, pK_{Est} ~12.0.** Crystallise it from *n*-hexane. [*Beilstein* **13** IV 2014.]

Di-*tert*-butyldiperphthalate *[2155-71-7]* **$C_{16}H_{22}O_6$, M 310.3, m (48°) 57-57.5°, decomposes at 108°.** Crystallise the perphthalate from Et_2O or petroleum ether and dry it over H_2SO_4. The IR has ν_{max} at 1772cm^{-1} in CCl_4. [Milas & Surgenor *J Am Chem Soc* **68** 642 *1946*, DOI: 10.1021/ja01208a033; Klein & Milas *J Org Chem* **36** 2900 *1971*, DOI: 10.1021/jo00818a044; *Beilstein* **9** III 4190, **9** IV 3260.] **CARE**, potentially **EXPLOSIVE**.

2,6-Di-*tert*-butyl-4-ethylphenol *[4130-42-1]* **$C_{16}H_{26}O$, M 234.4, m 42-44°, pK_{Est} ~12.3.** Crystallise the phenol from aqueous EtOH or *n*-hexane. [*Beilstein* **6** IV 3529.]

2,5-Di-*tert*-butylhydroquinone *[88-58-4]* **$C_{14}H_{22}O_2$, M 222.3, m 222-223°.** Crystallise the hydroquinone from *C_6H_6 or AcOH. [*Beilstein* **6** III 4741.]

2,6-Di-*tert*-butyl-4-isopropylphenol *[5427-03-2]* **$C_{17}H_{28}O$, M 248.4, m 39-41°, 38-42°, b 105-106°/0.3mm, pK_{Est} ~12.3.** Crystallise from *n*-hexane or aqueous EtOH. It is used for making the respective *phenoxyl radical*. [Cook & Norcross *J Am Chem Soc* **78** 3797 *1956*, DOI: 10.1021/ja01596a064; *Beilstein* **6** III 3534.]

2,6-Di-*tert*-butylphenol *[128-39-2]* **$C_{14}H_{22}O$, M 206.3, m 37-38°, pK^{25} 11.70.** Crystallise the phenol from aqueous EtOH or *n*-hexane. [*Beilstein* **6** III 2061.]

Dibutyl phthalate (DBP, butyl phthalate) *[84-74-2]* **$C_{16}H_{22}O_4$, M 278.4, m -35°, b 44°/2.5x10^{-4}mm, 182°/5mm, 206°/20mm, 340°/760mm, d_4^{20} 1.4929, d^5 1.0426, n_D^{25} 1.490.** Wash DBP with H_2O (to free it from alcohol), then dilute NaOH (to remove any butyl hydrogen phthalate or acid), aqueous $NaHCO_3$ (charcoal), then distilled water. Dry it ($CaCl_2$), distil it at 10torr or less, and store it in a desiccator over P_2O_5. [*Beilstein* **9** II 586, **9** III 4102, **9** IV 3175.] It is an insect repellant.

2,4-Dichloroaniline *[554-00-7]* **$C_6H_5Cl_2N$, M 162.0, m 59°, 60°, 63°, b 245°/atm, pK^{25} 2.02.** Crystallise the aniline from EtOH/water. It also crystallises from EtOH and is dried *in vacuo* for 6 hours at 40° [Moore et al. *J Am Chem Soc* **108** 2257 *1986*, DOI: 10.1021/ja00269a022; Edidin et al. *J Am Chem Soc* **109** 3945 *1987*, DOI: 10.1021/ja00247a019]. [*Beilstein* **12** IV 1241.] ***3,4-Dichloroaniline*** *[95-76-1]* has **m 69°, 70°, 71.5°, b 272°/atm, pK^{25} 2.97.** Crystallise the aniline from MeOH, and/or distil it. [*Beilstein* **12** IV 1257.]

9,10-Dichloroanthracene *[605-48-1]* **$C_{14}H_8Cl_2$, M 247.1, m 214-215°.** Purify it by recrystallising it from

MeOH, EtOH, *C_6H_6 or Me_2CO (**m** 210-211°) followed by subliming *in vacuo*. [Masnori & Kochi *J Am Chem Soc* **107** 7880 *1985*, DOI: 10.1021/ja00312a014; *Beilstein* **5** H 664, **5** I 324, **5** II 575, **5** III 2134, **5** IV 2293.]

2,4-Dichlorobenzaldehyde *[874-42-0]* **$C_7H_4Cl_2O$, M 175.0, m 64°, 67°, 69°, b 233°/atm.** Crystallise the aldehyde from EtOH or ligroin. It has been distilled at atmospheric pressure. [*Beilstein* **7** IV 575.] ***2,6-Dichlorobenzaldehyde*** *[83-38-5]* has **m 69°, 70.5-71.5°.** Crystallise the aldehyde from EtOH/H_2O or petroleum ether (b 30-60°). [*Beilstein* **7** IV 576.]

1,2-Dichlorobenzene (ODCB) *[95-50-1]* **$C_6H_4Cl_2$, M 147.0, m -18° to -17°, b 81-82°/31-32mm, 180.5°/760mm, d_4^{20} 1.306, n_D^{20} 1.551, n_D^{25} 1.549.** Contaminants may include the *p*-isomer and trichlorobenzene [Suslick et al. *J Am Chem Soc* **106** 4522 *1984*, DOI: 10.1021/ja00328a036]. It should be shaken with concentrated or fuming H_2SO_4(CARE), washed with water, dried with $CaCl_2$, and distilled from CaH_2 or sodium in a glass-packed column. Low conductivity material (*ca* 10^{-10} mhos) has been obtained by refluxing with P_2O_5, fractionally distilling and passing it through a column packed with silica gel or activated alumina: it is stored in a dry-box under N_2 or with activated alumina. [*Beilstein* **5** IV 654.] ***1,3-Dichlorobenzene*** *[541-73-1]* has **m -25° to -22°, b 173.0°/atm, d_4^{20} 1.289, n_D^{20} 1.54586, n_D^{25} 1.54337.** Wash it with aqueous 10% NaOH, then with water until neutral, dry and distil it. Conductivity material (*ca* 10^{-10} mhos) has been prepared by refluxing over P_2O_5 for 8 hours, then fractionally distilling, and storing with activated alumina. *m*-Dichlorobenzene dissolves rubber stoppers. [*Beilstein* **5** IV 657.] ***1,4-Dichlorobenzene*** *[106-46-7]* has **m 52°, 53°, 54°, b 174.1°/atm, d_4^{20} 1.241, n_D^{60} 1.52849.** *o*-Dichlorobenzene is a common impurity. The *p*-isomer has been purified by steam distillation, crystallisation from EtOH or boiling MeOH, air-dried and dried in the dark under vacuum. It has also been purified by zone refining. [*Beilstein* **5** IV 658.]

2,2'-Dichlorobenzidine *[84-68-4]* **$C_{12}H_{10}Cl_2N_2$, M 253.1, m 165°, $pK_{Est(1)}$ ~3.0, $pK_{Est(2)}$~4.0.** Crystallise the benzidine from EtOH or H_2O. [*Beilstein* **13** H 234, **13** I 66, **13** II 106, **13** III 477, **13** IV 384.] ***3,3'-Dichlorobenzidine*** *[91-94-1]* has **m 132-133°, $pK_{Est(1)}$ ~4.8, $pK_{Est(2)}$~5.7.** Crystallise the benzidine from EtOH, petroleum ether (**m** 133°) or *benzene. [*Beilstein* **13** H 234, **13** I 67, **13** II 106, **13** III 477, **13** IV 384.] **CARCINOGEN.**

2,3-Dichlorobenzoic acid *[50-45-3]* **$C_7H_4Cl_2O_2$, M 191.0, m 168°, 168.3°, 169-170°, pK^{25} 2.67.** Aromatic acid impurities (to <0.05%) can be removed *via* the (±)-α-methylbenzylamine salt as described for 2,4-dichlorobenzoic acid [Ley & Yates *Organic Process Research & Development* **12** 120 *2008*, DOI: 10.1021/op7001547.] Crystallise the acid from H_2O, aqueous EtOH, or 30% aqueous AcOH and several times from *C_6H_6, then dry it *in vacuo* at 40° overnight. The ***methyl ester*** has **m 35-39°**. [Hope & Riley *J Chem Soc* **123** 2470 *1923*, DOI: 10.1021/op7001547; Lock *Monatsh Chem* **90** 683 *1959*, DOI: 10.1007/BF00902394; Mather & Shorter *J Chem Soc* 4744 *1961*, DOI: 10.1039/JR9610004744; *Beilstein* **9** II 228, **9** IV 998.] ***2,4-Dichlorobenzoic acid*** *[50-84-0]* has **m 160°, 163-164°, pK^{25} 2.68.** Crystallise the acid from aqueous EtOH (charcoal), then *benzene (charcoal). It can also be recrystallised from water. [*Beilstein* **9** IV 998.] It can be freed from isomeric acids (to <0.05%) *via* the (±)-α-methylbenzylamine salt as follows: dissolve the dichloro-acid (10g, 50.2mmol) in isopropanol (200ml), heat to 60° and add the (±)-benzylamine (5.49g, 45.3mmol), then stir it at 60° for 1 hour. Cool the mixture to room temperature, filter the slurry, wash it with isopropanol (25ml) and dry it *in vacuo* at 40° overnight to give 79% of the ***salt*** with **m 185.2°**. Dissolve the salt (5g) in H_2O (50ml) and MeOH (20ml), then heat to 60° and add concentrated HCl to pH <2.0. Cool the solution to room temperature add H_2O (12ml), filter it, wash it with H_2O (30ml) and dry it *in vacuo* at 40° overnight to give 94% of the ***acid*** with **m 162.0°**. [Ley & Yates *Organic Process Research & Development* **12** 120 *2008*, DOI: 10.1021/op7001547.] ***2,5-Dichlorobenzoic acid*** *[50-79-3]* has **m 152°, 154°, b 301°/760mm, pK^{25} 2.47.** Crystallise the acid from water. [*Beilstein* **9** IV 1005.] Aromatic acid impurities (to <0.05%) can be removed *via* the (±)-α-methylbenzylamine salt as described for 2,4-dichlorobenzoic acid [Ley & Yates *Organic Process Research & Development* **12** 120 *2008*, DOI: 10.1021/op7001547.] ***2,6-Dichlorobenzoic acid*** *[50-30-6]* has **m 139°, 140°, 141-142°, pK^{25} 1.59.** Crystallise the acid from EtOH and sublime it *in vacuo*. [*Beilstein* **9** IV 1005.] Aromatic acid impurities (to <0.05%) can be removed *via* the (±)-α-methylbenzylamine salt as described for 2,4-dichlorobenzoic acid [Ley & Yates *Organic Process Research & Development* **12** 120 *2008*, DOI: 10.1021/op7001547.] ***3,4-Dichlorobenzoic acid*** *[51-44-5]* has **m 204°, 205°, 206-207°, pK^{25} 3.64.** Recrystallise the acid from aqueous EtOH (charcoal) or acetic acid. [*Beilstein* **9** IV 1006.] Aromatic acid

impurities (to <0.05%) can be removed *via* the (±)-α-methylbenzylamine salt as described for 2,4-dichlorobenzoic acid [Ley & Yates *Organic Process Research & Development* **12** 120 *2008*, DOI: 10.1021/op7001547.] ***3,5-Dichlorobenzoic acid*** *[51-36-5]* has **m 185°, 187°, 188°, pK^{25} 3.54.** Crystallise the acid from EtOH and sublime it in a vacuum. [*Beilstein* **9** IV 1008.] Aromatic acid impurities (to <0.05%) can be removed *via* the (±)-α-methylbenzylamine salt as described for 2,4-dichlorobenzoic acid [Ley & Yates *Organic Process Research & Development* **12** 120 *2008*, DOI: 10.1021/op7001547.]

2,6-Dichlorobenzonitrile (Diclobenil) *[1194-65-6]* **$C_7H_3Cl_2N$, M 172.0, m 143°, 145°, 146°.** Crystallise the nitrile from acetone or petroleum ether. It is very poorly soluble in H_2O, being 18mg/L at 20°. [*Beilstein* **9** IV 1006.] It is used as a herbicide.

4,4'-Dichlorobenzophenone (4,4'-DBP) *[90-98-2]* **$C_{13}H_8Cl_2O$, M 251.1, m 144°, 145-146°, b 353°/atm.** Recrystallise it from EtOH [Wagner et al. *J Am Chem Soc* **108** 7727 *1986*, DOI: 10.1021/ja00284a041]. The ***oxime*** has **m 135.2-136.9°** (from MeOH, Sieger & Klein *J Org Chem* **22** 951 *1957*, DOI: 10.1021/jo01359a026). The ***semicarbazone*** has **m 192-193°** (from H_2O). [*Beilstein* **7** H 420, **7** I 228, **7** II 359, **7** III 2076, **7** IV 1376.]

2,5-Dichloro-1,4-benzoquinone *[615-93-0]* **$C_6H_2Cl_2O_2$, M 177.0, m 160°, 161-162°, 163°.** Recrystallise it twice from 95% EtOH to give yellow needles [Beck et al. *J Am Chem Soc* **108** 4018 *1986*, DOI: 10.1021/ja00274a027]. The ***dioxime*** has **m 278°(dec)**. [*Beilstein* **7** H 632, **7** I 346, **7** II 580, **7** III 3376, **7** IV 2081.] ***2,6-Dichloro-1,4-benzoquinone*** *[697-91-6]* has **m 122-124°.** Recrystallise the quinone from petroleum ether (b 60-70°). It sublimes at 41°/17.6μ. [Carlson & Miller *J Am Chem Soc* **107** 479 *1985*, DOI: 10.1021/ja00288a035; *Beilstein* **7** II 580. **7** III 3376.]

2,6-Dichlorobenzoyl chloride *[4659-45-4]* **$C_7H_3Cl_3O$, M 209.5, m 15-17°, b 122-124°/15mm, 142-143°/21mm, d_4^{20} 1.464. n_D^{20} 1.560.** Reflux the acid chloride for 2 hours with excess of acetyl chloride (3 volumes), distil off AcCl followed by the benzoyl chloride. Store it away from moisture. It is an **IRRITANT**. [*Beilstein* **9** III 1377.]

2,4-Dichlorobenzyl alcohol (Dybenal) *[1777-82-9]* **$C_7H_6Cl_2O$, M 177.0, m 55°, 57°, 58°, 59.5°.** Crystallise the alcohol from EtOH or water. [*Beilstein* **6** IV 2597.] It is an antiseptic. ***3,4-Dichlorobenzyl alcohol*** *[1805-32-8]* has **m 34°, 38°, 39°, 148-151°/760mm.** Crystallise the alcohol from EtOH (**m 32-34°**) or water (**m 38°**, needles). Its solubility at 20° is 1g in 1250ml of H_2O. [*Beilstein* **6** H 445, **6** III 1558, **6** IV 2598.]

2,3-Dichloro-5,6-dicyano-*p*-benzoquinone (DDQ) *[84-58-2]* **$C_8Cl_2N_2O_2$, M 227.0, m 203°(dec), 213-216°, (210-215°)(dec).** Crystallise DDQ from $CHCl_3$, $CHCl_3$/*benzene (4:1), or *benzene and store it at 0°. It is soluble in dioxane but decomposes in H_2O. [Pataki & Harvey *J Org Chem* **52** 2226 *1987*, DOI: 10.1021/jo00387a023; *Beilstein* **10** H 902, **10** II 635, **10** IV 3521.] It is a useful dehydrogenating and oxidising agent [Fieser **1** 128, **1** 215]. It was also used for the mild and efficient photochemical and thermal deprotection of thioacetals and thioketals in >90% yields [Mathew & Sankararaman *J Org Chem* **58** 7576 *1993*, DOI: 10.1021/jo00078a044], deprotection of acetals and ketals [McDonald et al. *Tetrahedron Lett* 35 57 *1994*, DOI: 10.1016/0040-4039(94)88161-8]. DDQ mediates carbon-carbon bonds in annulation reactions, as in the formation of quinolines [Bartolotti et al. *Tetrahedron* **49** 10157 *1993*. DOI: 10.1016/S0040-4020(01)80210-6], and the preparation of 1,2-benzisoxazoles from 2-hydroxyphenyl aldoximes and ketoximes in high yields [Iranpoor et al. *Tetrahedron Lett* **47** 8247 *2006*, DOI: 10.1016/j.tetlet.2006.09.120].

2,4-Dichloro-6-methylphenol (2,4-dichloro-*o*-cresol) *[1570-65-6]* **$C_7H_6Cl_2O$, M 177.0, m 55°, b 111-113°/16mm, 129-132°/40mm, 231.6-231.9°/760mm, pK^{20} 8.14.** Crystallise the cresol from Et_2O (**m 55°**) or water; it has **m 53-54°** after sublimation. [*Beilstein* **6** H 359, **6** II 332, **6** III 1267, **6** IV 2001.]

2,4-Dichloro-1-naphthol *[2050-76-2]* **$C_{10}H_6Cl_2O$, M 213.1, m 104°, 106-107°, pK_{Est} ~7.7.** Crystallise the naphthol from MeOH. The ***1-methyl ether*** has **m 58°** (from EtOH). [*Beilstein* **6** H 612, **6** I 308, **6** II 582, **6** III 2934, **6** IV 4233.]

2,3-Dichloro-1,4-naphthoquinone (Dichlone, Phygon) *[117-80-6]* **$C_{10}H_4Cl_2O_2$, M 227.1, m 193°.** Crystallise the quinone from EtOH (golden yellow needles), and sublime it *in vacuo*. [*Beilstein* **7** IV 2426.] It is a herbicide and fungicide.

2,5-Dichloro-4-nitroaniline *[6627-34-5]* **$C_6H_4Cl_2N_2O_2$, M 207.0, m 153-154°, 157-158°, pK^{25} -0.74 (aqueous H_2SO_4).** Recrystallise it from EtOH, then sublime it *in vacuo*. [*Beilstein* **12** H 735, **12** II 400.] ***2,6-Dichloro-4-nitroaniline* (Dichloran)** *[99-30-9]* has **m 190°, 192°, 193°.** Crystallise Dichloran from aqueous EtOH or *benzene/EtOH. [*Beilstein* **12** IV 1681.] It is a pesticide.

2,5-Dichloro-1-nitrobenzene (1,4-dichloro-4-nitrobenzene) *[89-61-2]* **$C_6H_3Cl_2NO_2$, M 192.0, m 52°, 54°, 56°, 266-269°/atm.** Crystallise the nitrobenzene from absolute EtOH. [*Beilstein* **5** IV 726.] ***3,4-Dichloro-1-nitrobenzene* (1,2-dichloro-4-nitrobenzene)** *[99-54-7]* has **m 43°.** Crystallise it from absolute EtOH. [*Beilstein* **5** IV 726.]

2,4-Dichloro-6-nitrophenol *[609-89-2]* **$C_6H_4Cl_2NO_3$, M 208.0, m 118°, 120°, 122-123°, pK_{Est} ~5.0.** Crystallise the chloronitrophenol from AcOH. Keep the solid moist with water. [*Beilstein* **6** IV 1358.] ***2,6-Dichloro-4-nitrophenol*** *[618-80-4]* has **m 125°(dec), pK^{25} 3.55.** Crystallise the chloronitrophenol from EtOH and dry it *in vacuo* over anhydrous $MgSO_4$. [*Beilstein* **6** IV 1361.]

Dichlorophen [2,2'-methylenebis(4-chlorophenol)] *[97-23-4]* **$C_{13}H_{10}Cl_2O_2$, M 269.1, b 168°, 172°, 177-178° pK_{Est} ~9.7.** Crystallise dichlorophen from toluene. It is quite soluble in 95% EtOH (1:1), but less so in Et_2O. It dissolves in aqueous alkaline solutions where some decomposition may occur. [*Beilstein* **6** III 5406.] It is a useful fungicide, germicide, antiprotozoan, anthelmintic, and because of its antibacterial properties it is used in shampoos and soaps.

2,3-Dichlorophenol *[576-24-9]* **$C_6H_4Cl_2O$, M 163.0, m 55 to 57°, 57°, 206°/atm, pK^{25} 7.70.** Crystallise it from ether, and/or distil it. [*Beilstein* **6** IV 883.] ***2,4-Dichlorophenol*** *[120-83-2]* has **m 42-43°, 45°, 209-211°/atm, pK^{25} 7.89.** Crystallise it from petroleum ether (b 30-40°). Purify it also by repeated zone melting, using a P_2O_5 guard tube to exclude moisture. It is steam volatile. It is very *hygroscopic* when dry. [*Beilstein* **6** IV 885.] ***2,5-Dichlorophenol*** *[583-78-8]* has **m 54° to 57°, 58°, b 211°/744mm, pK^{25} 7.51.** Crystallise it from ligroin and sublime it in a vacuum or distil it. [*Beilstein* **6** IV 942.] ***2,6-Dichlorophenol*** *[87-65-0]* has **m 64°, 64.5-65.5°, 66°, b 218-220°/atm, pK^{25} 6.786.** The white solid crystallises from petroleum ether. It is a sex pheromone of the lone star tick [Sonenshine et al *J Chem Ecology* **2** 201 *1976*, DOI: 10.1007/BF00987743]. [Tarbell et al. *Org Synth* Coll Vol **3** 267 *955*, DOI: 10.15227/orgsyn.029.0035; *Beilstein* **6** IV 949.] ***3,4-Dichlorophenol*** *[95-77-2]* has **m 64° to 67°, 68°, b 145-146°/767mm, pK^{25} 8.58.** Crystallise 3,4-dichlorophenol from petroleum ether/*benzene mixture and/or distil it. [*Beilstein* **6** IV 952.] ***3,5-Dichlorophenol*** *[591-35-5]* has **m 65° to 67°, 68°, b 122-124°/8mm, 233-234°/760mm, pK^{25} 8.81.** Crystallise 3,5-dichlorophenol from petroleum ether/*benzene mixture and/or distil it. [*Beilstein* **6** IV 957.]

2,4-Dichlorophenoxyacetic acid (2,4-D) *[94-75-7]* **$C_8H_6Cl_2O_3$, M 221.0, m 136°-138°, 140°, 146°, 160°/0.4mm, pK^{25} 2.90.** Crystallise 2,4-D from MeOH or *C_6H_6. It is a plant growth substance, a herbicide and is **TOXIC.** [*Beilstein* **6** IV 908.] Many salts and esters are available.

(±)-α-(2,4-Dichlorophenoxy)propionic acid (2,4-DP, Dichloroprop) *[120-36-5]* **$C_9H_8Cl_2O_3$, M 235.1, m 117°, 117-118°, pK^{20} 2,86,** Crystallise 2,4-DP from MeOH or *C_6H_6. The acid has low solubility in H_2O (350mg/L at 20°) but is soluble alkaline solution. The ***R(+)- and S(-)- enantiomers*** have **m 124°** (from *C_6H_6) and $[\alpha]_D^{25}$ +35.2 and -35.2 (c 1, Me_2CO), and $[\alpha]_D^{21}$ +26.2 (c 1.23, EtOH). [*Beilstein* **6** H 189, **6** III 708, **6** IV 922-923.] It is a plant growth substance, a herbicide and is **TOXIC.** Note that only the *dextro*-enantiomer is physiologically active.

2,4-Dichlorophenylacetic acid *[19719-28-9]* **$C_8H_6Cl_2O_2$, M 205.0, m 129°, 131°, 132-133°, pK_{Est} ~4.0.** Crystallise the acid from aqueous EtOH. [*Beilstein* **9** III 2271, **9** IV 1678.] ***2,6-Dichlorophenylacetic acid*** *[6575-24-2]* has **m 157-158°, 161°, pK_{Est} ~3.8.** Crystallise the acid from aqueous EtOH. [*Beilstein* **9** III 2272, **9** IV 2679.]

3-(3,4-Dichlorophenyl)-1,1-dimethyl urea (Diuron) *[330-54-1]* **$C_9H_{10}Cl_2N_2O$, M 233.1, m 153-154°, 155°, 158-159°.** Recrystallise it from 95% EtOH [Beck et al. *J Am Chem Soc* **108** 4018 *1986*, DOI: 10.1021/ja00274a027]. It is poorly soluble in H_2O (42mg/L at 25°). It is a herbicide. [*Beilstein* **12** IV 1263.]

4,5-Dichlorophthalic acid *[56962-08-4]* **$C_8H_4Cl_2O_4$, M 235.0, m 198°, 200° (dec to anhydride), $pK_{Est(1)}$ 2.2, pK $pK_{Est(2)}$ ~4.7.** Crystallise the acid from water. It has been purified by converting to the anhydride, reacting it with boiling EtOH to form **the *monoethyl ester*** (**m 133-134°**), and hydrolysing it back to the diacid (see next entry). [*Beilstein* **9** III 4205.] ***4,5-Dichlorophthalic anhydride*** *[942-06-3]* **$C_8H_2Cl_2O_3$, M 217.0,** has **m 185° to 187°** and is separated from the acid by extraction with $CHCl_3$. [*Beilstein* **17** H 483.] ***4,5-Dichlorophthalimide*** *[15997-89-4]* **$C_8H_3Cl_2NO_2$, M 216.0,** has **m 217°** to **219°.**

3,6-Dichlorophthalic anhydride *[4466-59-5]* **$C_8H_2Cl_2O_3$, M 188°, 190°, 191-191.5°, b 339°/atm.** Boil the anhydride in xylene (allowing any vapours which would contain H_2O to be removed, e.g. Dean and Stark trap), which causes any acid present to dehydrate to the anhydride, and cool. Recrystallise it from xylene [Villiger *Chem Ber* **42** 3529 *1909*, DOI: 10.1002/cber.19090420393; Fedoorow *Izv Akad Nauk SSSR Otd Khim Nauk* 397 *1948*, *Chem Abstr* **48** 1585 *1948*]. [*Beilstein* **17/11** V 260.]

2,6-Dichlorostyrene *[28469-92-3]* **$C_8H_6Cl_2$, M 173.0, m 8°, b 72-73°/2mm, 88-90°/8mm, d_4^{20} 1.4045, n_D^{20} 1.5798.** Purify the styrene by fractional crystallisation from the melt and by distillation *in vacuo*. [*Beilstein* **5** III 1174, *Beilstein* **5** IV 815.]

2,4-Dichlorotoluene *[95-73-8]* **$C_7H_6Cl_2$, M 161.1, m -13.5°, b 61-62°/3mm, 200°/atm, d_4^{20} 1.250, n_D^{20} 1.5513.** Recrystallise 2,4-dichlorotoluene from EtOH at low temperature or fractionally distil it. [*Beilstein* **5** IV 815.]

2,6-Dichlorotoluene *[118-69-4]* **$C_7H_6Cl_2$, M 161.1, b 196-203°/atm, 199-200°/atm, d_4^{20} 1.254, n_D^{20} 1.548.** Fractionally distil it and collect the middle fraction. [*Beilstein* **5** IV 815.] ***3,4-Dichlorotoluene*** *[95-75-0]* has **m -16°, b 205°/atm, d_4^{20} 1.2541, n_D^{20} 1.549.** Recrystallise it from EtOH at very low temperature or fractionally distil it. [*Beilstein* **5** IV 815.]

α,α'-Dichloro-*p*-xylene [1,4-bis(chloromethyl)benzene] *[623-25-6]* **$C_8H_8Cl_2$, M 175.1, m 98° to 101°, 100°, 254°/atm.** Crystallise the xylene from *benzene and dry it under vacuum. [*Beilstein* **5** IV 967.]

Dicinnamalacetone (1,9-diphenyl-1,3,6,8-nonatetraen-5-one) *[622-21-9]* **$C_{21}H_{18}O$, M 314.4, m 144°, 146°.** Crystallise the ketone from *benzene/isooctane (1:1). The ***1,3,5-trinitrobenzene complex***(1:1) has **m 113°** (from EtOH), and the ***1,3,5-trinitrobenzene complex***(1:2) has **m 110°** (from EtOH). [*Beilstein* **7** H 524, **7** I 293, **7** II 484, **7** III 2756, **7** IV 1834.] The ***2,4-dinitrophenylhydrazone*** has **m 199-200°**.

Dicumyl peroxide *[80-43-3]* **$C_{18}H_{22}O_2$, M 270.4, m 39° to 40°.** Crystallise the peroxide from 95% EtOH (charcoal). Store it at 0°. *Potentially* **EXPLOSIVE.** [*Beilstein* **6** IV 3220.]

9,10-Dicyanoanthracene *[1217-45-4]* **$C_{16}H_8N_2$, M 228.3, m 340°.** Recrystallise the dinitrile twice from pyridine [Mattes & Farid *J Am Chem Soc* **108** 7356 *1986*, DOI: 10.1021/ja00283a034]. [*Beilstein* **9** IV 3667.]

1,4-Dicyanobenzene (terephthalonitrile) *[623-26-7]* **$C_8H_4N_2$, M 128.1, m 221°, 222°, 225°.** Crystallise the dinitrile from EtOH or AcOH, and has **m 221.5-222.5°** after sublimation. [*Beilstein* **9** H 846, **9** I 376, **9** II 613, **9** III 4255, **9** IV 3328.]

1,4-Dicyanonaphthalene *[3029-30-9]* **$C_{12}H_6N_2$, M 178.2, m 206°.** Purify it by recrystallisation from EtOH (charcoal), **m 208°**, and sublime it *in vacuo*. [Bradbrook & Linstead *J Chem Soc* 1739 *1936*, DOI: 10.1039/JR9360001739; *Beilstein* **9** H 917, **9** II 651, **9** III 464.]

***trans*-4-(Diethylamino)azobenzene** *[3588-91-8]* **$C_{16}H_{19}N_3$, M 253.3, m 171°, pK^{26} 3.08 (50% aqueous EtOH)** Purify the azobenzene by column chromatography on alumina, elute with, and then recrystallise it from

toluene [Albini et al. *JCS Perkin Trans 2* 1393 *1982*, DOI: 10.1039/P29820001393; Flamigni & Monti *J Phys Chem* **89** 3702 *1985*, DOI: 10.1021/j100263a025]. The ***deoxycholate (1:4) complex*** has **m 194-194°** (from EtOH). [*Beilstein* **16** H 341, **16** I 311, **16** III 342, 16 IV 455.]

***N,N*-Diethylaniline (DEA)** *[91-66-7]* **$C_{10}H_{15}N$, M 149.2, m -38°, b 62-66°/3mm, 216.5°/atm, d_4^{20} 0.938, n_D^{20} 1.5409 pK^{25} 6.57.** Reflux the base for 4 hours with half its weight of acetic anhydride, then fractionally distil it under reduced pressure (**b** 92°/10mm). Its solubility in H_2O is ~1.4w/v% at 10°. [*Beilstein* **12** IV 252.]

Di-(2-ethylhexyl)phthalate (DEHP) ('di-iso-octyl' phthalate) *[117-81-7]* **$C_{24}H_{38}O_4$, M 390.6, m -47°, b 231°/5mm, 256-257°/1mm, 384°/atm, d_4^{20} 0.9803, n_D^{20} 1.4863.** Wash the ester with Na_2CO_3 solution, then shake it with water. After the resulting emulsion has been broken by adding ether, the ethereal solution is washed twice with water, dried ($CaCl_2$), and evaporated. The residual liquid is distilled several times under reduced pressure, then stored in a vacuum desiccator over P_2O_5 [French & Singer *J Chem Soc* 1424 *1956*, DOI: 10.1039/JR9560001424]. [*Beilstein* **9** IV 3184.] It is a useful plasticiser.

Diethyl phenyl orthoformate (diethoxy phenoxy ethane) *[14444-77-0]* **$C_{11}H_{16}O_3$, M 196.3, b 103-104°/10mm, 111°/11mm, 122°/13mm, d_4^{20} 1.0099, n_D^{20} 1.4799.** Fractionate the ortho-ester through an efficient column under vacuum [Smith *Acta Chem Scand* **10** 1006 *1956*, DOI: 10.3891/acta.chem.scand.10-1006.] A reagent for the diethoxymethylation of Grignard compounds [Stetter & Reske *Chem Ber* **103** 643 *1970*, DOI: 10.1002/cber.19701030236]. [*Beilstein* **6** IV 610.]

Diethyl phthalate (DEP) *[84-66-2]* **$C_{12}H_{14}O_4$, M 222.2, m -3°, b 172°/12mm, 295°/760mm, 298-299°/atm, d_4^{25} 1.1160, n_D^{20} 1.5022.** Wash the ester with aqueous Na_2CO_3, then distilled water, dry ($CaCl_2$), and distil it under reduced pressure. Store it in a vacuum desiccator over P_2O_5. [*Beilstein* **9** IV 3172.] It is used as an industrial solvent for varnishes and in the manufacture of varnishes.

Diethyl 2-phthalimidomalonate *[5680-61-5]* **$C_{15}H_{15}NO_6$, M 305.3, m 72-74°, 73-74°, 76°, pK^{25} 9.17.** Dissolve it in xylene and when the temperature is 30° add petroleum ether (b 40-60°) and cool to 20° whereby the malonate separates as a pale brown powder [Booth et al. *J Chem Soc* 666 *1944*, DOI: 10.1039/JR9440000666]. *Alternatively*, dissolve it in *C_6H_6, dry it over $CaCl_2$, filter, evaporate and the residual oil solidifies. Grind this with Et_2O, filter and wash it with Et_2O until white in colour, and dry it in a vacuum. It forms a yellow ***sodium salt*** **m 280°(dec)**. The anion has λ_{max} at 254nm (ε 18.5K) [Osterberg *Org Synth* Coll Vol **1** 271 *1941*, DOI: 10.15227/orgsyn.007.0078; UV of Na salt: Nnadi & Wang *J Am Chem Soc* **92** 4421 *1970*, DOI: 10.1021/ja00717a045]. [*Beilstein* **21** H 487, **21** I 379, **21** III/IV 5264.]

Diethylstilboesterol [DES, stilbesterol, stilboesterol, (*E*)-3,4-bis(4-hydroxyphenyl)-3-hexene] *[56-23-1]* **$C_{18}H_{20}O_2$, M 268.4, m 169°, 170°, 172°.** Crystallise stilbesterol from *benzene. [*Beilstein* **6** IV 6856.]

Diethyl terephthalate (diethyl 1,4-benzenedicarboxylic acid) *[636-09-0]* **$C_{12}H_{14}O_4$, M 222.2, m 44°, 142°/2mm, 302°/760mm.** Crystallise the ester from toluene and distil it under reduced pressure. [*Beilstein* **9** H 8, **9** I 374, **9** III 4250, **9** IV 3304.]

4,4'-Di-*n*-heptyloxyazoxybenzene *[2587-42-0, 2635-26-9]* **$C_{24}H_{34}N_2O_3$, M 426.6, m 75°, 95° (smectic ∅ nematic) and 127° (nematic ∅ liquid), pK_{Est} ~ -5.** Purify azoxybenzene by chromatography on Al_2O_3 (*benzene), recrystallise it from hexane or 95% EtOH and dry it by heating under vacuum. The liquid crystals can be sublimed *in vacuo*. [Mellifiori et al. *Spectrochim Acta Part A* **37(A)** 605 *1981*, DOI:10.1016/0584-8539(81)80057-8; Dewar & Schroeder *J Am Chem Soc* **86** 5235 *1964*, DOI: 10.1021/ja01077a039; Weygand & Glaber *J Prakt Chem* **155** 332 *1940*, *Beilstein* **16** III 600, **16** IV 5264.] It exhibits a negative low frequency dielectric anisotropy [McLemore & Carr *J Chem Phys* **57** 3245 *1972*, DOI:org/10.1063/1.1678746].

9,10-Dihydroanthracene *[613-31-0]* **$C_{14}H_{12}$, M 180.3, m 103° to 107°, 110-110.5°, b ~312°/atm, d_4^{20} 0.880.** Crystallise it from EtOH [Rabideau et al. *J Am Chem Soc* **108** 8130 *1986*, DOI: 10.1021/ja00286a002]. [*Beilstein* **5** H 641, **5** IV 2182.]

Dihydrochloranil (tetrachloro-1,4-hydroquinone) *[87-88-6]* **$C_6H_2Cl_4O_2$, M 247.9, m 240.5°.** Crystallise the hydroquinone from EtOH, AcOH/EtOH, AcOH (platelets), Me_2CO, *C_6H_6 or toluene (prisms). Sublime it at 77°/0.6x10^{-3}mm. The ***dibenzoyl*** derivative has **m 233°**. [Conant & Fieser *J Am Chem Soc* **45** 2194 *1923*, DOI: 10.1021/ja01662a027; Rabideau et al. *J Am Chem Soc* **108** 8130 *1986*, DOI: 10.1021/ja00286a002; *Beilstein* **6** H 851, **6** I 417, **6** II 846, **6** III 4436, **6** IV 5775.]

1,4-Dihydro-1,4-epoxynaphthalene *[573-57-9]* **$C_{10}H_8O$, M 144.2, m 53-54.5°, 54° to 56°, 55-56°.** Dissolve it in Et_2O, wash it with H_2O, dry it over K_2CO_3, filter, evaporate and dry the residue at 15mm, then recrystallise it from petroleum ether (b 40-60°), dry it at 25°/0.005mm and sublime it (sublimes slowly at room temperature)[Wittig & Pohmer *Chem Ber* **89** 1334 *1956*, DOI: 10.1002/cber.19560890539; Gilman & Gorsich *J Am Chem Soc* **79** 2625 *1957*, DOI: 10.1021/ja01567a072]. [*Beilstein* **17** III/IV 548.] It is an electron-rich dienophile for Diels-Alder and cycloaddition reactions [Hanson & Wren *JCS Perkin Trans 1* 2089 *1990*, DOI: 10.1039/P19900002089; Hisano et al. *Chem Pharm Bull Japan* **38** 605 *1990*, DOI: org/10.1248/cpb.38.605; Wegener & Mullen *Chem Ber* **124** 2101 *1991*, DOI: 10.1002/cber.19911240935].

1,8-Dihydroxyanthraquinone (Danthrone, Chrysazine) *[117-10-2]* **$C_{14}H_8O_4$, M 240.1, m 191° to 193°, 194-197°, pK_1^{25} 8.30, pK_2^{25} 12.46.** Crystallise Danthrone from EtOH and sublime it in a vacuum. It complexes with Ca, Ba and Pb to form 'lakes', and is used as a purgative for animals. POSSIBLE CARCINOGEN. [*Beilstein* **8** IV 3217.]

2,4-Dihydroxyazobenzene (Sudan orange G) *[2051-85-6]* **$C_{12}H_{10}N_2O_2$, M 214.2, m 143-146°, 228°, $pK_{Est(1)}$ <0, $pK_{Est(2)}$ ~7.3, $pK_{Est(3)}$ ~9.3.** Crystallise the dye from hot EtOH (charcoal). Has UV max at 350nm. [*Beilstein* **16** IV 264.]

2,3-Dihydroxybenzaldehyde *[24677-78-9]* **$C_7H_6O_3$, M 138.1, m 105-108°, 135-136°, b 120°/16mm, pK_1^{20} 7.73, pK_2^{20} 10.91.** Crystallise the aldehyde from water. It is air-sensitive, if possible store under N_2 in the dark. [*Beilstein* **8** III 1979.]

2,4-Dihydroxybenzoic acid (β-resorcylic acid) *[89-86-1]* **$C_7H_6O_4$, M 154.1, m 208 to 211°(dec), 226-227°(dec), pK_1^{25} 3.30, pK_2^{25} 9.12, pK_3^{25} 15.6.** Crystallise the acid from water which forms hydrated crystals. They dehydrate at 100° and melt with decomposition at 213° when heated rapidly. It is used as a spot test reagent for Fe. [Nierenstein & Clibbens *Org Synth* Coll Vol **2** 557 *1943*, DOI: 10.15227/orgsyn.010.0094; *Beilstein* **10** IV 1420.] ***2,5-Dihydroxybenzoic acid*** **(Gentisic acid, 5-hydroxysalicylic acid)** *[490-79-9]* has **m 204.5-205°, 204° to 208°, pK^{25} 2.95.** Crystallise gentisic acid from hot water or *benzene/acetone. Dry it in a vacuum desiccator over silica gel. It is dimorphic and its phase alters at ~200° before melting. It is soluble in hot H_2O and has low solubility in cold H_2O (~0.5% at 6°). The sodium salt, ***sodium gentisate*** *[4955-90-2]* **$C_7H_5NaO_4$, M 176.1 (anhydr),** crystallises with 5.5 H_2O which effloresces in air losing ~3 H_2O but holds on to the last 0.5 H_2O even at 100°. It is anti-inflammatory and an analgesic. [*Beilstein* **10** H 384, **10** IV 1441.] ***2,6-Dihydroxybenzoic acid*** **(γ-resorcylic acid)** *[303-07-1]* **$C_7H_6O_4$, M 154.1, m 167°(dec), pK^{25} 1.05.** Dissolve the acid in aqueous $NaHCO_3$ and the solution is washed with ether to remove non-acidic material. The acid is precipitated by adding H_2SO_4, and recrystallised from water. Dry it *in vacuo*, and store it in the dark [Lowe & Smith *JCS Faraday Trans 1* **69** 1934 *1973*, DOI: 10.1039/F19736901934]. [*Beilstein* **10** IV 1456.]

2,4-Dihydroxybenzophenone (DHB, benzoresorcinol) *[131-56-6]* **$C_{13}H_{10}O_3$, M 214.2, m 145.5°, 144-145°, 147°, $pK_{Est(1)}$ ~7.0, $pK_{Est(2)}$ ~12.0.** Recrystallise it from MeOH or H_2O. [*Beilstein* **8** IV 2442.]

4,4'-Dihydroxybenzophenone *[611-99-4]* **$C_{13}H_{10}O_3$, M 214.2, m 210°, 213-214°, 213-215°, 216.6-217.1°, pK_{Est} ~7.0.** The benzophenone was prepared by a Friedel-Crafts reaction between 4-methoxybenzoyl chloride and anisole with anhydrous $AlCl_3$ in anhydrous CS_2, followed by demethylation with $AlCl_3$ in boiling toluene. It could also be made directly from 4-hydroxybenzoic acid and an equivalent of phenol by heating with three parts of freshly fused anhydrous $ZnCl_2$ at 125-140° for 45 minutes; the cooled mass is treated with dilute HCl, the solid is filtered off, washed thoroughly with aqueous $NaHCO_3$ solution, H_2O, dried *in vacuo* and recrystallised from H_2O, aqueous EtOH, or dilute HCl. [Russell & Butler *J Am Chem Soc* **71** 3663 *1949*, DOI: 10.1021/ja01179a024.] The ***oxime*** has **m 266-267° (dec)** [Zigeuner & Ziegler *Monatsh Chem* **80** 359 *1949*,

DOI: 10.1007/BF00897769], and the ***2,4-dinitrophenylhydrazone*** has **m 190-192°** (from EtOH). [*Beilstein* **8** H 316, **8** I 641, **8** II 355, **8** III 2648, **8** IV 2452.] It is used in paints and plastics as absorber of UV light.

2,5-Dihydroxybenzyl alcohol (Gentisyl alcohol) *[495-08-9]* **$C_7H_8O_3$, M 140.1, m 47-48°, $pK_{Est(1)}$ ~9.3, $pK_{Est(2)}$ ~11.3.** Crystallise the alcohol from ligroin, $CHCl_3$, AcOH or H_2O. Sublime it at ~70° under high vacuum. It dissolves in aqueous NaOH solution and oxidises in air, as observed by the colour changing from yellow to red then brown. [*Beilstein* **6** II 1084, **6** III 6326.]

2,2'-Dihydroxybiphenyl *[1806-29-7]* **$C_{12}H_{10}O_2$, M 186.2, m 108.5-109.5°, 110°, b 315°/atm, pK_1^{25} 7.56, pK_2^{25} 11.80.** Crystallise the biphenyl repeatedly from toluene, then sublime it at 60°/10^{-4}mm. [*Beilstein* **6** IV 6645.] ***4.4'-Dihydroxybiphenyl*** **(4,4'-biphenol)** *[92-88-6]* has **m 280.5°, 280-285°, $pK_{Est(1)}$ ~3.6, $pK_{Est(2)}$ ~11.8.** Recrystallise the biphenol from aqueous EtOH preferably under N_2 to avoid oxidation to the extended qiunone. It is characterised as the ***dimethyl derivative (4,4'-dimethoxybiphenyl)*** from which it is prepared by demethylation. The dimethoxy derivative has **m 176.5-177°** (from AcOH, EtOH or hexane), and sublimes *in vacuo*. [Williamson & Rodebush *J Am Chem Soc* **63** 3018 *1941*, DOI: 10.1021/ja01856a044; *Beilstein* **6** I 485, **6** II 962, **6** III 6389, **6** IV 6651.]

1,8-Dihydroxy-3-methylanthraquinone (chrysophanic acid) *[481-74-3]* **$C_{15}H_{10}O_4$, M 245.3, m 196°, $pK_{Est(1)}$ ~8.2, $pK_{Est(2)}$ ~12.4.** Crystallise chrysophanic acid from EtOH or *benzene and has **m 195.6-196.2°**, after sublimation it in a vacuum. The yellow ***mono-acetate*** has **m 188-190°** (from MeOH or Me_2CO). It forms Ni^{2+}, Co^{2+} and Cu^{2+} complexes. [*Beilstein* **8** H 470, **8** I 725, **8** II 510, **8** III 3808, **8** IV 3277.]

1,2-Dihydroxynaphthalene *[574-00-5]* **$C_{10}H_8O_2$, M 160.2, m 101-103°, 108°(anhydrous).** It crystallises from CS_2 (needles), H_2O (leaflets, as hydrate) or aqueous EtOH (as hydrate). It is hygroscopic, air sensitive and oxidises readily in solution to the quinone. The ***diacetate*** *[6336-79-4]* has **m 109°** (**158-161°**), **$C_{14}H_{12}O_4$, M 244.2.** Methylation produces a mixture of 1-hydroxy-2-methoxy-, 1-methoxy-2-hydroxy and 1,2-dimethoxy naphthalenes which have to be separated [Bezdzik & Friedlaender *Monatsh Chem* **30** 271 *1909*, DOI: 10.1007/BF01519684]. ***1-methoxy-2-hydroxynaphthalene*** (colourless plates **m 92°** from light petroleum, Bell & Duewell *Aust J Chem* **16** 101 *1963*, DOI: 10.1071/CH9630101) was best prepared, in 44% yield, from 1-bromo-2-naphthol by conversion to the Grignard reagent followed by oxidation using the general procedure [Kharasch & Reynolds *J Am Chem Soc* **65** 501 *1943*, DOI: 10.1021/ja01244a005]. The ***dimethylether*** *[57189-64-7]* has **b 278-280°/atm, m 31°**, and its ***picrate*** forms red needles with **m 97°.** [*Beilstein* **6** H 975.] 1,2-Dihydroxynaphthalene is an **IRRITANT**, causing sneezing. For its use as a biomarker for naphthalene exposure in humans see Klotz et al. [*Int J Hyg Environ Health* **214** 110 *2011*, DOI: 10.1016/j.ijheh.2010.11.003, PMID: 21147027]. A useful GC-MS method for measuring 1,2-dihydroxynaphthalene and 1,4-dihydroxynaphthalene after enzymatic digestion of conjugates in urine was developed by Rapaport and coworkers [Wu et al. *J Chromatogr B*, **826** 206 *2005*, DOI: 10.1016/j.jchromb.2005.08.022].

1,3-Dihydroxynaphthalene (naphthoresorcinol) *[132-86-5]* **$C_{10}H_8O_2$, M 160.2, m 118-120°, 123-125°, 124-125°, pK_1^{25} 7.22, $pK_{Est(2)}$ ~10.0**. It crystallises from H_2O (leaflets), a H_2O/*C_6H_6 (80/20), Et_2O/petroleum ether, or $CHCl_3$. It was prepared by cyclisation of ethyl γ-phenylacetoacetate in concentrated H_2SO_4 and kept overnight before pouring onto ice and isolating the product by Et_2O extraction [Soliman & West *J Chem Soc* 53 *1944*, DOI: 10.1039/JR9440000053]. It gave a ***diacetate*** **m 56°** (prisms from aqueous AcOH). On a larger scale diethyl phenylacetylmalonate gave naphthoresorcinol in three steps in good yield. It was purified by dissolving in hot H_2O, decolorising with aqueous sodium hydrosulfite and norit, adding NaCl, and allowing to stand at 5° for 24hrs. The cold mixture should be shaken, after seeding, to avoid separation of the product as an oil and to form transparent plates. It is best purified by sublimation at 120-130°/5x10^{-4}mm. [Meyer & Bloch *Org Synth* **25** 73 *1945*, *Org Synth* Coll Vol **3** 637 *1955*, DOI: 10.15227/orgsyn.025.0073.]
The ***3-methoxy-1-naphthol*****,** single product obtained by methylation with 30 parts of MeOH/HCl at ~25°, forms colourless stout needles **m 99-100°** from hot petroleum ether, and has ^{13}C NMR ($CDCl_3$) with δ at 157.7 (CO), 152.9 (CO), 135.5, 132.2, 127.1, 123.0, 121.7, 101.4, 99.1, 55.3 (OCH_3). ***3-Methoxy-1-naphthyl acetate*** also crystallises from light petroleum in colourless needles with **m 74°**. [Bell & MCaffrey *Aust J Chem* **46** 731 *1993*, DOI: 10.1071/CH9930731.] ***1-methoxy-3-naphthol*** crystallises from light petroleum (b 40-60°, charcoal) in long fine needles **m 55-56°** and the derivative ***1-methoxy-4-phenylazo-3-naphthol*** has **m 145-146°** (orange-

red needles from MeOH) and is insoluble in alkali [Iskander et al. *J Chem Soc (C)* 1701 *1970*, DOI: 10.1039/J39700001701]. ***1,3-Dimethoxynaphthalene*** *[10076-61-3]* **$C_{12}H_{12}O_2$, M 188.2,** has **b 128-132°/1mm** and **b 145-150°/3mm**. [For IR spectra see van Gemert *Aust J Chem* **21** 2203 *1968*, DOI: 10.1071/CH9682203.] For the determination of glycolaldehyde in the presence of hydroxypyruvate and tartronate semialdehyde, whereby λ_{max} shifts from 660nm to 440nm, see Windt & van der Drift [*Analyt Biochem* **106** 342 *1980*, DOI: 10.1016/0003-2697(80)90530-8, PMID: 7447001], and for use as a colour test reagent for aldoses, ketoses, pentoses and glucuronic in urine see Forsyth [*Nature* **161** 239 *1948*, DOI:10.1038/161239a0].

1,4-Dihydroxynaphthalene *[571-60-8]* **$C_{10}H_8O_2$, M 160.2, m 191-192°(dec), pK_1^{25} 9.37, pK_2^{25} 10.93.** The diol obtained by reduction of 1,4-naphthaquinone with $SnCl_2$ is slightly pink and further recrystallisation from EtOH did not remove the colour. However, when dissolved in Et_2O, shaken with alumina and filtered, then addition of ligroin gives white crystals of 1,4-dihydroxynaphthalene. The UV (H_2O) has λ_{max} nm(ε_{max} $M^{-1}.cm^{-1}$) at 322(5350) for neutral species, 346(5700) for mono-anion and 363(6050) for di-anion. [Baxendale & Hardy *Trans Faraday Soc* **49** 1140 *1953*, DOI: 10.1039/TF9534901140]. It crystallises from hot EtOH in colourless needles where its solubility in EtOH is 50mg/ml at ~25°.
The ***monoacetate*** *[70662-30-5]* **$C_{12}H_{10}O_3$, M 202.2,** has **m 127°** (from cyclohexane), the ***diacetate*** *[5697-00-7]* **$C_{14}H_{12}O_4$, M 244.2,** has **m 128-130°** (plates from EtOH). ***4-Methoxy-1-naphthol*** *[84-85-5]* **$C_{11}H_{10}O_2$, M 174.2**, was isolated from *Galium mollugo* roots [by extraction with light petroleum (b 60-80°), *C_6H_6 then MeOH], purified by TLC (silica gel G/*C_6H_6-EtOAc 4:1; R_F 0.54), and recrystallised (needles) from light petroleum (b 60-80°). It had **m 124-126°**; the UV (EtOH) had λ_{max} nm(log ε) at 248(4.39), 317(3.78) and 331(3.77) and MS with *m/z* 174 [Burnett & Thomson *J Chem Soc (C)* 857 *1968*, DOI: 10.1039/J39680000854]. A useful GC-MS method for measuring 1,2-dihydroxynaphthalene and 1,4-dihydroxynaphthalene after enzymatic digestion of conjugates in urine was developed by Rapaport and coworkers [Wu et al. *J Chromatogr B*, **826** 206 *2005*, DOI: 10.1016/j.jchromb.2005.08.022].

1,5-Dihydroxynaphthalene (1,5-naphthalenediol) *[83-56-7]* **$C_{10}H_8O_2$, M 160.2, m 259°, 260°, 261°, 265°, $pK_{Est(1)}$ ~9.0, $pK_{Est(2)}$ ~11.0.** The diol (~30g) is purified by making into a thick paste with H_2O and suspendinthis in 3L of H_2O containing 200ml of EtOH, boiling under reflux for 3 hours, cooling to 30°, saturating with SO_2, digesting below the boiling point for 1 hour and filtering fast through a large hot filter paper. The hot filtrate is poured onto crushed ice whereby the diol (15-20g) separates as colourless needles (**m 258°**) [Wheeler & Ergle *J Am Chem Soc* **52** 4872 *1930*, DOI: 10.1021/ja01375a032]. Recrystallise it from H_2O or nitromethane under N_2 to avoid oxidation. The ***dibenzoyl*** derivative has **m 245°** (from EtOH). The ***1,5-naphthyl-bistriflate***, obtained from Tf_2O/pyridine in 76% yield (purified by column chromatography SiO_2/hexane) has **m 114-115°** and ^{1}H NMR ($CDCl_3$/TMS): 8.18 (2H, d *J* = 7.8Hz, C4 & 8-H's), 7.68 (4H, m, C-2, C3, C6 & C7-H's) [Takeuchi et al. *J Org Chem* **58** 7388 *1993*, DOI: 10.1021/jo00078a016]. The ***5-methoxy-1-naphthol*** derivative [prepared from the diol in MeOH/HCl (1:30 weight to volume ratio) and set aside at 25° for 9-10 days] crystallised from petroleum ether (**m 135-136°**) or from CH_2Cl_2/hexane (needles **m 140°**) [Bell & McCaffrey *Aust J Chem* **46** 731 *1993*, DOI:10.1071/CH9930731]. ***1,5-Dimethoxynaphthalene***, prepared by methylation (excess Me_2SO_4/aqueous KOH) has **b 179°/13mm** [Buu-Hoi & Lavit *J Org Chem* **20** 1191 *1955*, DOI: 10.1021/jo01126a007]. [IR spectra see van Gemert *Aust J Chem* **21** 2203 *1968*, DOI:10.1071/CH9682203; ^{13}C NMR see Ernst *Chem Ber* **108** 2030 *1975*, DOI: 10.1002/cber.19751080622; *Beilstein* **6** I 477, **6** II 950, **6** III 5265, **6** IV 6554.]

1,6-Dihydroxynaphthalene *[575-44-0]* **$C_{10}H_{18}O_2$, M 160.2, m 130°, 133°, 137-138°, 138-139° (with previous softening), $pK_{Est(1)}$ ~9.4, $pK_{Est(2)}$ ~11.** Crystallise it from *benzene or *benzene/EtOH after treatment with charcoal. [For fluorinated derivatives see Liu et al. *Bioorg Med Chem Lett* **11** 2903 *2001*, DOI: 10.1016/S0960-894X(01)00595-9]. [For IR spectra see van Gemert *Aust J Chem* **21** 2203 *1968*, DOI:10.1071/CH9682203; *Beilstein* **6** H 981, **6** I 480, **6** II 952, **6** III 5279, **6** IV 6557.] For catalytic reduction to 6-hydroxy-1-tetralone *[3470-50-6]* see below.

1,7-Dihydroxynaphthalene *[575-38-2]* **$C_{10}H_8O_2$, M 160.2, m 178-182°, 180-184°, $pK_{Est(1)}$ ~9.4, $pK_{Est(2)}$ ~11.** The diol is soluble in H_2O and crystallises as needles from $*C_6H_6$. The ***diacetate*** *[51850-49-8]* **$C_{14}H_{12}O_4$, M 244.2, m 108°**, forms plates from $*C_6H_6$. ***1-Methoxy-7-naphthol*** *[91344-50-2]* **$C_{11}H_{10}O_2$, M 174.1, m 71°**, crystallises in plates from hexane, the ***7-benzoate*** has **m 92°** (from aqueous EtOH) and the ***7-acetate*** has **m 152°** (from light petroleum, b 100-120°). ***7-Methoxy-1-naphthol*** *[67247-13-6]* **$C_{11}H_{10}O_2$, M 174.1,** prepared from ***7-methoxy-1-tetralone*** by reduction with elemental sulphur (heating with S at 240-250° until H_2S evolution ceased), has **b 145-148°**(bath temp)**/0.01mm,** and the solidified distillate has **m 104.5-105°** (**103-105°** also reported) after crystallising in plates from hexane. ***1,7-Dimethoxynaphthalene*** *[5309-18-2]* **$C_{12}H_{12}O_2$, M 188.2**, prepared from the 1,7-diol and Me_2SO_4, has **b 134-137°**(bath temp)**/0.01mm, b 123-130°/0.4mm, 170°/20mm,** and the solidified distillate has **m 68-68°** (**103-105°** also reported) after crystallising in plates from hexane. [Shand & Thomson *Tetrahedron* **19** 1919 *1963*, DOI: 10.1016/0040-4020(63)85007-3.] [For IR spectra see van Gemert *Aust J Chem* **21** 2203 *1968*, DOI: 10.1071/CH9682203; *Beilstein* **6** IV 6559.]

1,8-Dihydroxynaphthalene *[569-42-6]* **$C_{10}H_8O_2$, M 160.2, m 137-143°, 142-143°, 145-146°, pK_1^{20} 6.71, pK_2^{20} >13.** It crystallises from H_2O in leaflets. It was obtained by de-sulfonating 1,8-dihydroxynaphthalene-4-sulfonic acid (concentrated H_2SO_4 in an autoclave at 150°/1hr). It gives a golden-yellow solution in concentrated H_2SO_4 [Heller & Kretzschmann *Chem Ber* **54** 1098 *1921*, DOI: 10.1002/cber.19210540528]. *Alternatively*, it was prepared from 1-naphthol-8-sulfonic acid (50g), KOH (150g), NaOH (50g) and H_2O (75ml) which were fused slowly, with vigorous stirring, to 230° in a stainless steel beaker until the melt was encrusted with black tar. After cooling, the solid was crushed in portions and stirred vigorously with H_2O (2.5L) containing concentrated HCl (700ml), boiled for 10 minutes, filtered and cooled. This was extracted with Et_2O, the extract was dried, evaporated, and the residue was recrystallised from $*C_6H_6$/ligroin to give pure ***1,8-diol*** (4.3g) with **m 142-143°.** It crystallises in leaflets from H_2O. **[**Lurie et al. *J Am Chem Soc* **83** 5015 *1961*, DOI: 10.1021/ja01485a031]. The ***diacetate*** *[6566-25-2]* **$C_{14}H_{12}O_4$, M 244.2,** has **m 147-148°**. [For pKa see Musso & Matthies *Chem Ber* **94** 356 *1961*, DOI: 10.1002/cber.19610940211; and for IR spectra see van Gemert *Aust J Chem* **21** 2203 *1968*, DOI:10.1071/CH9682203]. ***1,8-Methoxynaphthalene*** *[10075-66-8]*, prepared by methylation (excess Me_2SO_4/KOH), has **b 167-168°/12mm**, and the solidified distillate was crystallised from Et_2O, EtOH or aqueous EtOH giving the less soluble leaflets **m 157°** (whose picrate has **m 172°,** brown-red needles from EtOH), and an equal amount of the more soluble ***8-methoxy-1-naphthol*** *[3588-75-6]* with **m 55-56°(57°)** (which is less soluble in the methylating solvent, and recrystallised from petroleum ether). On methylation in a large volume of EtOH the ratio of dimethoxy to monomethoxy changes from 8:7 to 15.5:3. [Buu-Hoï & Lavit *J Chem Soc 1956* 2412, DOI: 10.1039/JR9560002412]. Methylation with diazomethane apparently yields only the monmethyl ether. [Staudinger et al. *Helv Chim Acta* **4** 334 *1921*, DOI: 10.1002/hlca.19210040134.]

2,3-Dihydroxynaphthalene *[92-44-4]* **$C_{10}H_8O_2$, M 160.2, m 161-165°, 163°, 162-164°, 163-165°, b 353°/atm, d^{25} 1.81g/ml, pK_1^{25} 8.68, pK_2^{25} 12.5.** It is purified by recrystallisation from $*C_6H_6$, $CHCl_6$ or hot H_2O (leaflets). Also purified by sublimation. Useful for the photometric estimation of Fe^{3+}, V^{5+}, Ti and Mo [Patrovský *Coll Czech Chem Commun* **35** 1599 *1970*, DOI: 10.1135/cccc19701599], Th, U^{6+}, also for the extraction and estimation of boron with the 2,3-diol and crystal violet at 610nm [Sato & Uchikawa *Analyt Chim Acta* **143** 283 *1982*, DOI: 10.1016/S0003-2670(01)95513-8]; and Ti^{4+} interaction with serum albumin [Tinoco et al. *Inorg Chem* **47** 8380 *2008*, DOI: 10.1021/ic800529v].
2,3-Dibenzoyloxynaphthalene *[91201-70-6]* **$C_{24}H_{16}O_4$, M 368.3,** has **m 154-155°** (needles from CH_2Cl_2, or CH_2Cl_2/petroleum ether).
2,3-Dimethoxynaphthalene *[10103-06-7]* **$C_{12}H_{12}O_2$**, is obtained by methylation (excess Me_2SO_4/aq KOH) of the diol, has **b 182°/17mm**, **m 115-116°**, together with a small amount of ***2-hydroxy-3-methoxynaphthalene*** *[18515-11-2]* **m 108°** (colourless needles from $*C_6H_6$) [Buu-hoi & Lavit *J Org Chem* **21** 21 *1956*, DOI: 10.1021/jo01107a003]. [For the synthesis of 2,3-dimethoxynaphthalene from 2,5-diethoxy-tetrahydrofuran and veratrole in a Diels-Alder reaction (ice-cold 70% H_2SO_4/2.5hrs then steam distil) to form 1,4-dihydroxy-6.7-dimethoxy-1,2,3,4-tetrahydronaphthalene which dehydrates to 2,3-dimethoxy-naphthalene as driven by aromatization see Arcoleo et al. *Chem Ind (London)* 128 *1977*]. [For derivatives see Hewgill & Middleton *JCS (C)* 2316 *1967*, DOI: 10.1039/J39670002316; and Howell & Taylor *J Chem Soc* 4252 *1956*, DOI: 10.1039/JR9560004252; for the synthesis of butterflyshaped compounds from 2,3-dihydroxynaphthalene see Nakanishi et al. *J Org Chem* **79** 2625 *2014*, DOI: 10.1021/jo500085a; and for IR spectra see van Gemert

Aust J Chem **21** 2203 *1968*, DOI: 10.1071/CH9682203; *Beilstein* **6** III 5291, **6** IV 6564.]

2,6-Dihydroxynaphthalene *[581-43-1]* **$C_{10}H_8O_2$, M 160.2, m 211-217°($2H_2O$), 218°(ahydr), 223-225°** (also reported)**, $pK_{Est(1)}$ ~9.9, $pK_{Est(2)}$ ~11.** Purify it by recrystallisation from EtOH (plates) or aqueous EtOH or hot H_2O (with $2H_2O$), and sublime preferably *in vacuo*. Willstätter & Parnas [*Chem Ber* **40** 1406 *1907*; DOI: 10.1002/cber.19070400224] originally prepared the 2,6-diol by fusing disodium β-naphtholsulfonate (80g) with molten KOH (240g at 320°) at 320-350° for 15minutes, cooled *in vacuo*, poured into 1.5L of H_2O, acidified with concentrated HCl (charcoal) and filtered off the crude acid, which was then recrystallised from H_2O (10g of rhombic crystals). For a convenient synthesis from the readily available 6-bromo-2-naphthol in 52% overall yield and 95.7% purity *via* 6-methoxymethoxy-2-naphthol formate involving a Baeyer-Villiger oxidation-rearrangement see Cui & Li [*J Chem Res* **36** 675 *2012*, DOI: 10.3184/174751912X13497085947943].
The ***diacetate*** *[22426-47-7]* **$C_{14}H_{12}O_4$, M 244.2,** has **m 175°**, forms aqueous AcOH. The ***mono-methylether*** *[5111-66-0]* **$C_{11}H_{10}O_2$, M 174.2,** has **b 148-150°/0.15mm** and **m 149°**; and the ***di-methylether*** *[5486-55-5]* **$C_{12}H_{12}O_2$, M 188.2,** has **m 150°** (plates from EtOH and leaflets from *C_6H_6, with a fragrant odour). [For IR spectra see van Gemert *Aust J Chem* **21** 2203 *1968*, DOI: 10.1071/CH9682203; for ^{13}C NMR see Ernst *Chem Ber* **108** 2030 *1975*, DOI: 10.1002/cber.19751080622; and for ESR see Dixon et al. *Tetrahedron Lett* **17** 623 *1976*, DOI: 10.1016/S0040-4039(00)77929-9; *Beilstein* **6** IV 6566.] Reduction of the *di-methylether* with Na/isoamyl alcohol gave a demethylated-dihydrotetralone [Robinson & Weygand *J Chem Soc* 386 *1941*, DOI: 10.1039/JR9410000386] that was shown to be ***6-methoxy-2-tetralone*** *[2472-22-2]* **$C_{11}H_{12}O_2$, M 176.2, n_D^{20} 1.5645**, and had **m 36°** after recrystallisation from light petroleum (b 40-60°) [Cornforth et al. *J Chem Soc* 689 *1942*, DOI: 10.1039/JR9420000689]. ***6-Methoxy-2-tetralone 2,4-dinitrophenylhydrazone*** crystallised from EtOH in orange prisms and had **m 132°** [Crowley & Robinson *J Chem Soc* 2001 *1938*, DOI: 10.1039/JR9380002001].

2,7-Dihydroxynaphthalene *[582-17-2]* **$C_{10}H_8O_2$, M 160.2, m 188°, 185-190°, 190-194°, b 375.4°/760mm, d^{25} 1.33g/cm^3, $pK_{Est(1)}$ ~9.8, $pK_{Est(2)}$ ~11.** It is prepared commercially by fusing disodium 2,7-naphthalenedisulfonate with sodium hydroxide at high temperature. In a contiuous process an aqueous mixture of the disodium disulfonate and NaOH (2.5:10) is rolled as a film over a moving hot sheet at 290-300° during 5 hours where rapid evaporation occurs. Acidification provides 2,7-dihydroxynaphthaene in 92% yield. [Matsura et al. JP 02 11,530 (90 11,530) to Kawasaki steel, *Chem Abstr* **112** P197839t *1984*.] Purify it by recrystallisation from EtOH (plates) or aqueous EtOH(needles) or hot H_2O (with $2H_2O$, needles), and sublime preferably at high vacuum. ***2,7-Diacetoxynaphthalene*** *[22472-26-0]* has **m 136°** (from AcOH). ***2-Hydroxy-7-methoxy-naphthalene*** *[5060-82-2]* **$C_{11}H_{10}O_2$, M 174.2**, has **b 145-148°/0.01mm, m 122-124°** (needles fom EtOH or light petroleum), and ***2-acetoxy-7-methoxynaphthalene*** **$C_{13}H_{12}O_3$, M 216.2,** crystallises from MeOH with **m 124-124.5°.** ***2,7-Dimethoxynaphthalene*** *[3469-26-9]* **$C_{12}H_{12}O_2$, M 188.2**, prepared from reaction with Me_2SO_4/aqueous NaOH, has **b 319°/731mm, m 138°** (cream coloured needles from AcOH) [Wilson *Tetrahedron* **3** 236 *1958*, DOI: 10.1016/0040-4020(58)80019-8; Ullmann *Justus Liebigs Ann Chem* **327** 117 *1903*, DOI: 10.1002/ jlac.19033270105; *Beilstein* **6** H 986.] [For sulfonation see Ansink et al. *JCS Perkin Trans* 721 *1993*, DOI: 10.1039/P29930000721; for ^{13}C NMR see Ernst *Chem Ber* **108** 2030 *1975*, DOI: 10.1002/ cber.19751080622; and for IR spectra see van Gemert *Aust J Chem* **21** 2203 *1968*, DOI: 10.1071/CH9682203; *Beilstein* **6** IV 6570.]

2,5-Dihydroxyphenylacetic acid (homogentisic acid) *[451-13-8]* **$C_8H_8O_4$, M 168.2, m 152°, 154-152°, pK^{20} 4.14 (COOH).** Crystallise homogentisic acid from EtOH/$CHCl_3$ (anhydrous crystals) or H_2O (solubility is 85% at 25°) as monohydrate crystals. The ***dimethyl ether***, $C_{10}H_{12}O_4$, has **m 124.5°**, and the ***dimethyl ether methyl ester***, $C_{11}H_{14}O_4$, has **m 124.5°**. [*Beilstein* **10** IV 1506.]

3,4-Dihydroxytoluene (4-methylcatechol) *[452-86-8]* **$C_7H_8O_2$, M 124.1, m 65-66°, 68°, 69°, b 112°/3mm, 241°/760mm, 251°/760mm, pK_1^{25} 9.44 (9.7), pK_2^{25} 10.90 (11.9).** Crystallise the catechol from *C_6H_6. *Alternatively*, crystallise it from high-boiling petroleum ether and distil it in a vacuum. The purity can be checked by TLC. [*Beilstein* **6** IV 5878.]

1,4-Diiodobenzene *[624-38-4]* **$C_6H_4I_2$, M 329.9, m 131°, 132-133°, b 185°/atm.** Crystallise it from EtOH or boiling MeOH, then dry it in air. Store it in dark bottles away from light. [*Beilstein* **5** IV 700.]

***trans*-4,4'-Dimethoxyazobenzene** *[501-58-6]* **$C_{14}H_{14}N_2O_2$, M 242.3, m 162.7-164.7°, 165-166°, pK_{Est} ~0.** Chromatograph it on basic alumina and elute with *benzene. Then crystallise the residue from 2:2:1 (v/v) methanol/ethanol/*benzene or Me_2CO. [*Beilstein* **16** H 112, **16** I 237, **16** II 43, **16** III 93, **16** IV 172.]

3,5-Dimethoxybenzaldehyde *[7311-34-4]* **$C_9H_{10}O_3$, M 166.2, m 45.5°, 46-47°, 45-48°, b 115-118°/1mm, 151°/16mm.** The aldehyde was prepared by reduction of the corresponding acid chloride with 5%Pd/$CaCO_3$ in xylene, and was purified by distillation in a vacuum and by recrystallisation from hexane (**m 48°**), ligroin, petroleum ether (**m 45-46°**) or 70% aqueous EtOH. The ***oxime*** (**m 115°**) crystallises from *C_6H_6, the ***thiosemicarbazone*** (**m 211-212°**) crystallises from aqueous EtOH, and the ***2,4-dinitrophenylhydrazone*** (**m 260-261°**) forms orange needles from aqueous EtOH. [Mongolusk et al. *J Chem Soc* 2231 *1957*, DOI: 10.1039/JR9570002231; Lambooy *J Am Chem Soc* **76** 133 *1954*, DOI: 10.1021/ja01630a037; *Beilstein* **8** II 291, **8** III 2073, **8** IV 1786.]

1,2-Dimethoxybenzene (veratrole) *[91-16-7]* **$C_8H_{10}O_2$, M 137.2, m, 15°, 23°, b 208.5-208.7°atm, d_4^{20} 1.085, n_D^{25} 1.53232.** Steam distil veratrole, then fractionally distil it from BaO, CaH_2 or Na. Crystallise it from *benzene or low-boiling petroleum ether at 0°. Fractionally crystallise it from its melt. Store it over anhydrous Na_2SO_4. [*Beilstein* **6** IV 5564.] ***1,3-Dimethoxybenzene*** *[151-10-0]* has **m -52°, b 85-87°/7mm, 212-213°/atm, 217-218°/atm, d_4^{20} 1.056, n_D^{20} 1.5215.** Extract it with aqueous NaOH, and water, then dry it. Fractionally distil it from BaO or Na. [*Beilstein* **6** IV 5663.] ***1,4-Dimethoxybenzene*** *[150-78-7]* has **m 54°, 56°, 57.2-57.8°, 59°, 60°, b 213°/atm, d^{25} 1.053.** Steam distil 1,4-dimethoxybenzene, then crystallise it from hexane or *benzene, and from MeOH or EtOH, but these are wasteful due to high solubilities. Dry it under vacuum. It also sublimes under vacuum. [*Beilstein* **6** IV 5718.]

2,4-Dimethoxybenzoic acid *[91-52-1]* **$C_9H_{10}O_4$, M 182.2, m 107.3°, 109°, pK^{25} 4.36.** Crystallise the acid from water and dry it in a vacuum desiccator over H_2SO_4. The ***S-benzylisothiuronium salt*** has **m 158-159°** (from $CHCl_3$). [*Beilstein* **10** H 379, **10** I 177, **10** II 252, **10** III 1371, **10** IV 1422.] Aromatic acid impurities (to <0.05%) can be removed *via* the (±)-α-methylbenzylamine salt as described for 2,4-dichlorobenzoic acid [Ley & Yates *Organic Process Research & Development* **12** 120 *2008*, DOI: 10.1021/op7001547.] ***2,6-Dimethoxybenzoic acid*** *[1466-76-8]* has **m 185°, 186-187°, 188-191°, pK^{25} 3.44.** Crystallise the acid from water or 1,1-dichloroethane (**m** 187.5-188.5°). [*Beilstein* **10** H 388, **10** I 185, **10** II 259, **10** III 1401, **10** IV 1456.] ***3,4-Dimethoxybenzoic acid*** **(veratric acid)** *[93-07-2]* has **m 179°, 181-187°, 185-186°, pK^{25} 4.43.** Crystallise the acid from Et_2O, H_2O (solubility is 0.05w/v% at ~25°, and 0.6w/v% at ~100°) or aqueous acetic acid. It has **m 180-181°** after sublimation at 80°/1mm. [*Beilstein* **10** H 393, **10** I 188, **10** II 261, **10** III 1404, **10** IV 1406.] ***3,5-Dimethoxybenzoic acid*** *[1132-21-4]* has **m 178°, 180°, 185-186°, pK^{25} 3.97.** Crystallise the acid from water, EtOH or aqueous acetic acid and dry it in a vacuum. [*Beilstein* **10** H 405, **10** I 195, **10** III 1446, **10** IV 1501.]

4,4'-Dimethoxybenzophenone *[90-96-0]* **$C_{15}H_{14}O_3$, M 242.3, m 90-93°** (also reported)**, 141°, 143°, 144.5°, b 200°/17mm.** Crystallise the ketone from absolute EtOH, aqueous EtOH or EtOH/AcOH. The ***2,4-dinitrophenylhydrazone*** has **m 199-200°**. [*Beilstein* **8** H 317, **8** I 641, **8** II 355, **8** III 2649, **8** IV 2453.]

2,6-Dimethoxy-1,4-benzoquinone (DMBQ) *[530-55-2]* **$C_8H_8O_4$, M 168.1, m 253°, 255-256°, 257°(dec), 253°, 262-263°.** Crystallise the quinone from H_2O or acetic acid (golden-yellow prisms). It is soluble in aqueous alkaline solutions, is steam volatile and sublimes readily at 175-180°/1mm. It has UV with λ_{max} at 287 and 377nm ($CHCl_3$). [*Beilstein* **8** H 385, **8** I 683, **8** II 433, **8** III 3354, **8** IV 2710,]

5,6-Dimethoxy-1-indanone *[2107-69-9]* **$C_{11}H_{12}O_3$, M 192.2, m 118° to 120°.** Crystallise the indanone from MeOH, then sublime it in a vacuum. [*Beilstein* **8** IV 1985.]

1,4-Dimethoxynaphthalene *[10075-62-4]* **$C_{12}H_{12}O_2$, M 188.2, m 87-88°, 90°.** Crystallise the naphthalene from EtOH, MeOH (**m 85-86°**) or petroleum ether. [*Beilstein* **6** H 984, **6** III 5261, **6** IV 6546.] ***1,5-Dimethoxynaphthalene*** *[10075-63-5]* has **m 180°, 183-184°, b 179°/13mm.** Crystallise it from EtOH, AcOH (**m** 178-180°) or *C_6H_6. Also distil it in a vacuum. [*Beilstein* **6** III 5266, **6** IV 6554.]

3,4-Dimethoxy-6-nitrobenzaldehyde (6-nitroverataldehyde) *[20357-25-9]* **$C_9H_9NO_5$, M 211.2, m 131°, 132°, 133.5-134.5°.** The aldehyde is purified by dissolving 9g in 200ml of boiling 95% EtOH, and set aside overnight to crystallise. It is then dried *in vacuo* at 50° and recrystallised from 110ml of 95% EtOH to give 6-7g of aldehyde with **m 132-133°**. Crystallisation from aqueous EtOH provides light yellow needles. It is light sensitive and should be stored in the dark [Fetscher *Org Synth* Coll Vol **4** 735 *1963*, DOI: 10.15227/orgsyn.033.0065]. [*Beilstein* **8** H 262, **8** I 610, **8** II 290, **6** III 2065, **6** IV 1785.]

2,6-Dimethoxyphenol (pyrogallol-1,3-diethylether) *[91-10-1]* **$C_8H_{10}O_3$, M 154.2, m 50°, 54-56°, 57°, b 261°/atm, pK_{Est} ~9.6.** Purify the phenol by zone melting or sublimation in a vacuum. Its solubility in H_2O is 2w/v% at ~13°. [*Beilstein* **6** IV 7329.] It is a food-grade flavor ingredient. ***3,5-dimethoxyphenol* (phloroglucinol dimethylether)** *[500-99-2]* has **m 42-43°, 45-47°, b 115°/0.04mm, 172-175°/17mm, pK^{25} 9.35.** Purify the phenol by distillation followed by sublimation in a vacuum. [*Beilstein* **6** IV 7362.]

3,4-Dimethoxyphenyl acetic acid (homoveratric acid) *[93-40-3]* **$C_{10}H_{12}O_4$, M 196.2, m 96°, 97-99°, pK^{25} 4.33.** Recrystallise homoveratric acid from H_2O or $*C_6H_6$/ligroin. ***Homoveratryl chloride*** *[10131-60-7]* **$C_{10}H_{11}ClO_3$, M 214.7,** has **m 40-43°, b 119-119°/0.2mm, d_4^{24} 1.245, n_D^{20} 1.5489,** the ***amide*** has **m** 142° (from H_2O), and ***homoveratronitrile*** *[93-17-4]* **$C_{10}H_{11}NO_2$, M 177.2,** has **m 62-63.5°, b 171-178°/10mm,** which fluoresces at λ_{ex} 430nm, λ_{em} 511 (H_2O pH 7.1). [*Beilstein* **10** H 409, **10** I 197, **10** II 268, **10** III 1459, **10** IV 1509.]

3,5-Dimethoxyphenylacetonitrile *[13388-75-5]* **$C_{10}H_{11}NO_2$, M 177.2, m 54°, 53°, 57°.** Crystallise the nitrile from MeOH or petroleum ether (b 90-110°). [Adams et al. *J Am Chem Soc* **70** 664 *1948*, DOI: 10.1021/ja01182a068; Sankaraman et al. *J Am Chem Soc* **109** 5235 *1987*, DOI: 10.1021/ja00251a032; *Beilstein* **10** I 198, **10** II 269, **10** III 1470.]

2,6-Dimethoxytoluene *[5673-07-4]* **$C_9H_{12}O_2$, M 152.2, m 39-41°, b 97-99°/15mm, 219-220°/731mm.** Sublime 2,6-dimethoxytoluene *in vacuo*. Distil it (preferably under reduced pressure) and/or recrystallise it from pentane, EtOH or aqueous MeOH. [Sankaraman et al. *J Am Chem Soc* **109** 5235 *1987*, DOI: 10.1021/ja00251a032]. [*Beilstein* **6** H 872, **6** III 4513, **6** IV 5877.]

4,4'-Dimethoxytrityl chloride (DMT) *[40615-36-9]* **$C_{21}H_{19}ClO_2$, M 338.8, m 114°, 119-123°, 123-125°.** DMT crystallises from cyclohexane/acetyl chloride as the hydrochloride. Dry it over KOH pellets in a desiccator. When dissolved in $*C_6H_6$ and air is blown through, HCl is removed. It crystallises from Et_2O. [Baeyer & Villiger *Chem Ber* **36** 2774 *1903*, DOI: 10.1002/cber.19030360327; Smith et al. *J Am Chem Soc* **84** 430 *1962*, DOI: 10.1021/ja00862a023; Schaller et al. *J Am Chem Soc* **85** 3821 *1963*, DOI: 10.1021/ja00906a021.] If it has hydrolysed considerably (see OH in IR), then repeat the crystallisation from cyclohexane/acetyl chloride — excess of AcCl is removed in a vacuum over KOH, then recrystallise it from Et_2O. [*Beilstein* **6** IV 1042.] It is a useful protecting group [Amarnath & Broom *Chem Rev* **77** 183 *1977*, DOI: 10.1021/cr60306a002; Kohli et al. *Tetrahedron Lett* **21** 2683 *1980*, DOI: 10.1016/S0040-4039(00)78579-0; Reddy et al. *Tetrahedron Lett* **28** 23 *1987*, DOI: 10.1016/S0040-4039(00)95639-9] and is removed under mild detritylation conditions, using $ZnBr_2$ in $MeNO_2$ at 18° for ~1min. [Matteucci & Caruthers *Tetrahedron Lett* **21** 3243 *1980*, DOI: 10.1016/S0040-4039(00)78657-6].

4-Dimethylaminoazobenzene (DAB, Dimethyl Yellow, Butter yellow) *[60-11-7]* **$C_{14}H_{15}O_3$, M 225.3, m 111-116°, 118-119°(dec), pK_2^{15} -5.34 (aqueous H_2SO_4), pK_2^{15} 2.96.** Crystallise the dye from acetic acid or isooctane, or from 95% EtOH by adding hot water and cooling. Dry it over KOH under vacuum at 50°. [*Beilstein* **6** IV 448.] It has indicator properties, *viz*: it is red between pH 2.9 and 4 and turns yellow above pH 4.0 (cf. pK values). **CARCINOGEN, handle with care.**

4-Dimethylaminobenzaldehyde (Ehrlich's Reagent, DMAB) *[100-10-7]* **$C_9H_{11}NO$, M 149.2, m 73-75°, 73-75°, 74-75°, pK_{Est} ~2.6.** Crystallise DMAB from water, hexane, or from EtOH (2ml/g), after charcoal treatment, by adding excess of water. *Alternatively*, dissolve it in aqueous acetic acid, filter it, and precipitate it with ammonia. Finally recrystallise it from EtOH. It has been used for the detection of primary amino groups

[Gargiulo et al. *J Am Chem Soc* **116** 3760 *1944*, DOI: 10.1021/ja00088], pyrroles [Iyer et al. *J Org Chem* **59** 6038 *1994*, DOI: 10.1021/jo00099a039], and is also used for diagnostic purposes, e.g. differentiating between true scarlet fever and serum erruptions. [Campaigne & Archer *Org Synth* Coll Vol **4** 331 *1963*, DOI: 10.15227/orgsyn.033.0027 *Beilstein* **14** IV 51.] The ***hydrochloride*** has **m** 109° (from EtOH/HCl/Et_2O).

4-Dimethylaminobenzoic acid *[619-84-1]* **$C_9H_{11}NO_2$, M 165.2, m 241-243°(dec), 242.5-243.5°(dec), pK_1 2.51, pK_2 6.03.** Crystallise the acid from H_2O or EtOH/water. [*Beilstein* **14** IV 1164.]. ***4-Dimethylaminobenzoyl chloride*** *[4755-50-4]* **$C_9H_{10}ClNO$, M 183.6,** has **m 145-149°, b 180°/15mm,** is corrosive and moisture sensitive. The ***2-ethylhexyl ester*** **(Padimate O)** *[21245-02-3]* **$C_{17}H_{27}NO_2$, M 277.4,** has **b 325°/atm, d_4^{25} 0.995, n_D^{20} 1.552,** and is used as a sun screen.

4-Dimethylaminobenzophenone *[530-44-9]* **$C_{15}H_{15}NO$, M 225.3, m 89°, 90°, 92.5°, 92-93°, pK_{Est} ~2.7.** Crystallise the pale green *p*-dimethylaminobenzophenone from EtOH. Dissolve 100g in 600ml of boiling EtOH, add 5g of charcoal, cool, isolate the solid by centrifugation and similarly wash the pale crystals with ice-cold EtOH. When filtered by suction, EtOH solution remains on the crystals and turns deep green in air. Dry it in a vacuum and store it in the dark. The ***hydrazone*** has **m 128-130°** and forms a ketyl with potassium. [Hurd & Webb *Org Synth* Coll Vol **1** 217 *1941*, DOI: 10.15227/orgsyn.007.0024; *Beilstein* **14** H 82, **14** I 288, **14** III 218, **14** IV 248.]

N,N*-Dimethylamino-*p*-chlorobenzene (*p*-chloro-*N,N*-dimethylaniline)** *[698-69-1]* **$C_8H_{10}ClN$, M 155.6, m 32-33.5°, 35.5°, b 114-115°/12m, 231°/atm, 264.2-265.6°/760mm, pK^{25} 4.395.** Purify it by vacuum sublimation, or distillation preferably under vacuum. [Guarr et al. *J Am Chem Soc* **107** 5104 *1985*, DOI: 10.1021/ja00304a015]. The ***picrate has **m 126-128°** (from methanol).

4-Dimethylamino cinnamaldehyde *[6203-18-5]* **$C_{11}H_{13}NO$, M 175.2, m 138-140°, 141°.** The aldehyde crystallises from EtOH or ligroin and is dried *in vacuo*. Its solubility in $CHCl_3$/EtOH (1:1), and in dioxane is 5w/v%. Store below 0°. The ***oxime*** has **m 157°** (from ligroin). The ***phenylhydrazone*** has **m 169°** (from MeOH). It is used as a reagent for amines (with NH_3, UV has λ_{max} at 630nm). [König et al. *Chem Ber* **61** 2074 *1928,* DOI: 10.1002/cber.19280610903; Qureshi & Kahn *Anal Chim Acta* **86** 309 *1976*, DOI:10.1016/S0003-2670(01)83053-1; *Beilstein* **14** III 184, **14** IV 197.]

4-Dimethylamino *trans*-cinnamic acid *[1552-96-1]* **$C_{11}H_{13}NO_2$, M 191.2, m 218-220°(dec), 222°(dec), 225° (vigorous effervesces), 227-228°(dec), $pK_{Est(1)}$ ~2.2, $pK_{Est(2)}$ ~4.6.** Recrystallise the yellow acid from EtOH and sublime it at high vacuum. The ***methyl ester*** has **m 134-135°** (golden yellow plates from Me_2CO), and forms a colourless crystalline perchlorate salt [**$C_{12}H_{15}NO_2.HClO_4$**] with **m** 169-170° (from 70% aqueous $HClO_4$) [Pfeiffer & Haefelin *Chem Ber* **55** 1769 *1922*, DOI: 10.1002/cber.19220550632]. The ***ethyl ester*** has **m 77-78°** (from aqueous EtOH or $*C_6H_6$). [Shoppee *J Chem Soc* 982 *1930*, DOI: 10.1039/JR9300000968; Galat *J Am Chem Soc* **68** 376 *1946*, DOI: 10.1021/ja01207a009; for its photophysics in various solvents see Bangal & Chakravorti *J Photophys Photobiol* A: Chemistry **116** 191 *1998*, DOI:10.1016/S1010-6030(98)00303-7]. The high dipole moment of 4.6D (in$*C_6H_6$) for the ethyl ester is consistent with a zwiterionic-type *trans* structure [Weizmann *Trans Faraday Soc* **35** 329 *1940*, DOI: 10.1039/TF9403500329]. [*Beilstein* **14** H 522, **14** II 318, **14** III 1306, **14** IV 1766.]

2*S*,3*R*-(+)-4-Dimethylamino-1,2-diphenyl-3-methyl-2-butanol *[(+) 38345-66-3; (±) 4125-61-5]* **$C_{19}H_{25}NO$, M 283.4, m 54-55°, 55-57°, for free base, $[\alpha]_{546}^{20}$ +9.3 (c 9.6, EtOH), $[\alpha]_D^{20}$ +7.7 (c 9.6, EtOH), pK_{Est} ~10.0.** Purify the ***hydrochloride*** by dissolving 1.5g in 13.5 ml of 5N HCl, heat to boiling and evaporate in a vacuum. Recrystallise the ***hydrochloride*** three times from MeOH/EtOAc giving **m 189-190°**, $[\alpha]_D$ -33.7 (c 1, H_2O) {the enantiomer *[72541-03-8]* has +34.2°}. The ***hydrochloride*** in the minimum volume of water is basified with aqueous 5N NaOH and extracted with Et_2O. The extract is dried (K_2CO_3) and evaporated, leaving a residue which is stored in a desiccator over solid KOH, as a low melting solid. It can be recovered using these procedures from asymmetric reductions with LAH, and re-used. [Pohland & Sullivan *J Am Chem Soc* **77** 3400 *1955*, DOI: 10.1021/ja01617a081; Pohland et al. *J Org Chem* **28** 2483 *1963*, DOI: 10.1021/jo01044a530; *Beilstein* **13** IV 2221.] ;

***N,N*-Dimethylaniline** *[121-69-7]* **$C_8H_{11}N$, M 121.2, m 2°, b 84°/15mm, 192°/760mm, d_4^{20} 0.956, n_D^{25} 1.5556, pK^{25} 5.07.** Primary and secondary amines (including aniline and monomethylaniline) can be removed by refluxing for 4-5 hours with excess acetic anhydride, and then fractionally distilling. Crocker and Jones (*J Chem Soc* 1808 *1959*, DOI: 10.1039/JR9590001808) used four volumes of acetic anhydride, then distilled off the greater part of it, and dissolved the residue in ice-cold dilute HCl. Non-basic materials were removed by ether extraction, then the dimethylaniline was liberated with ammonia, extracted with ether, dried, and distilled under reduced pressure. Metzler and Tobolsky (*J Am Chem Soc* **76** 5178 *1954*, DOI: 10.1021/ja01649a072) refluxed it with only 10% (w/w) of acetic anhydride, then cooled and poured it into excess 20% HCl, which, after cooling, was extracted with diethyl ether. (The amine hydrochloride remains in the aqueous phase.) The HCl solution was cautiously made alkaline to phenolphthalein, and the amine layer was drawn off, dried over KOH and fractionally distilled under reduced pressure, under nitrogen. Suitable drying agents for dimethylaniline include NaOH, BaO, $CaSO_4$, and CaH_2.
Other purification procedures include the formation of the ***picrate*** (**m 163°** from Me_2CO or $EtOH/H_2O$), prepared in *benzene solution and recrystallised to constant melting point, then decomposed with warm 10% NaOH and extracted into ether: the extract was washed with water and distilled under reduced pressure. The *oxalate* salt has also been used for purification. The base has been fractionally crystallised by partial freezing and also from aqueous 80% EtOH then from absolute EtOH. It has been distilled from zinc dust, under nitrogen. Its solubility in H_2O is 2v/v% at 20°. [*Beilstein* **12** H 141, **12** I 151, **12** II 2, **12** III 245, **12** IV 243.] **TOXIC.**

2,3-Dimethylaniline [2,3-xylidine (*vic, o*)] *[87-59-2]* **$C_8H_{11}N$, M 121.2, m 2°, 2.5°, b 106°/15mm, 223°/760mm, d_4^{20} 1.570, n_D^{20} 0.991, pK^{25} 4.70.** Purify *vic*-xylidine by conversion into a derivative (see below), recrystallise the derivative, decompose the derivative with aqueous NaOH and fractionally distil the liquid base. The steam distillate is also extracted and evaporated to dryness. (The purification process depends on the much slower sulfonation of 3,4-dimethylphenol than most of its likely contaminants.) It can also be crystallised from water, hexane or petroleum ether, and sublimed in a vacuum. [Kester *Ind Eng Chem* **24** 770 *1932*, DOI: 10.1021/ie50271a010; Bernasconi & Paschalis *J Am Chem Soc* **108** 2969*1986*, DOI: 10.1021/ja00271a027; *Beilstein* **6** IV 3099.] ***3,5-Dimethylphenol*** *[108-68-9, 50356-23-5]* has **m 61-65°, 62.5°, 63.6°, 65.5°, 68°, b 219°/atm, 222°atm, pK^{25} 10.19.** Purify it as for 3,4-dimethylphenol. [*Beilstein* **6** IV 3141.]

2,6-Dimethylphenylisocyanide *[2769-71-3]* **C_9H_9N, M 131.2, m 72-76°, 72-75°.** Like most isocyanides (isonitriles, carbylamines), it reacts with transition metals to form aldimines [Malatesta & Bonati *Isonitrile Complexes of Metals* Wiley Interscience, NY *1969*, SBN 470 565551, Treichel in *Advances in Organometallic Chemistry* **Vol 11**, (Stone & West Eds) Academic Press NY *1973*], and because of the crowded area around the nitrogen atom it coordinates with the metal in metal catalysts to enhance their stereoselectivity. The isocyanide can function as a nucleophile, electrophile, carbene, radical acceptor or pseudohalogen [Ugi (ed.) *Isonitrile Chemistry Academic Press NY 1971*, Library of Congress No 73-84156]. Among the general methods for preparing isocyanides the one that uses the ***Vilsmeier reagent*** {(chloromethylene)dimethyliminium chloride, $[ClCH{=}NMe_2]^+ Cl^-$, **M 128.0, m 132°(dec)**, [3724-43-4]} has been commonly used, and in this case it is prepared *in situ*. Thus a solution of redistilled $SOCl_2$ (0.5mol) in DMF (150ml) is added slowly to a stirred solution of ***N-(2,6-dimethylphenyl)formamide*** (0.5mol, see below) {**M 149.2, m 165°**, see *[607-92-1]*} under N_2 and the temperature is kept below -50°. On completion, the cooling bath is momentarily removed to allow the temperature to rise to -45°, then the cooling bath is replaced while anhydrous Na_2CO_3 (1mol) is added very carefully with rapid stirring till evolution of CO_2 ceases. Stirring is continued while the mixture is heated to 35°, then kept at ~25° for 1 hour, diluted with ice-water and extracted into pentane. The extract is separated, dried (Na_2SO_4), and evaporated to give ***2,6-dimethylphenylisocyanide*** as a crystalline colourless solid in 74% yield. It can be recrystallised from pentane, and should be stored under N_2 between 2° to 8°. It is **toxic**. [Review: Periasamy and Walborsky *Org Prep Proc Int* **11** 295 *1979*, DOI:10.1080/00304947909355415.]
***N-(2,6-Dimethylphenyl)formamide**, *[607-92-1]* **M 149.2, m 164°** (**164-5°**, **168-170°** also reported, and **176-177°** on rapid heating) is prepared by heating 2,6-dimethylaniline (see *[87-62-7]*) with formic acid, pouring into

H_2O, filtering, drying and recrystallising from EtOH. [Hodgkinson & Limpach *J Chem Soc* **77** 65 (67) *1900*, DOI: 10.1039/CT9007700065; *Beilstein* 12 H 1109, 12 I 604.] It forms a 2:1 complex with gold.

Dimethyl phthalate *[131-11-3]* **$C_{10}H_{10}O_4$, M 194.2, m 2°, b 100°/1mm, 148°/10mm, 194°/60mm, 210°/100mm, 283°/760mm, d_4^{20} 1.190, d_4^{25} 1.1865, n_D^{20} 1.5149.** Wash the ester with aqueous Na_2CO_3, then distilled water, dry ($CaCl_2$) and distil it under reduced pressure (**b** 151-152°/0.1mm). It is used as a plasticiser, and an insect repellent. [*Beilstein* **7** IV 3170.] TOXIC.

2,4-Dimethylresorcinol *[634-65-1]* **$C_8H_{10}O_2$, M 138.1, m 111°, 112°, b 286.4°/760mm, d 1.2, n_D 1.582, $pK_{Est(1)}$ ~9.8, $pK_{Est(2)}$ ~11.7.** Crystallise the resorcinol from petroleum ether (b 60-80°), *C_6H_6/petroleum ether or toluene/BuOAc. It sublimes at 100-110°/1mm. [*Beilstein* **6** H 918, **6** II 891, **6** III 4588, **6** IV 5955.]

Dimethyl terephthalate (DMT) *[120-61-6]* **$C_{10}H_{10}O_4$, M 194.2, m 139-141°, 141.5-141.8°, 142°, b 288°/atm, pK_a -7.1, pK_b -6.6.** Purify it by recrystallisation from aqueous EtOH, MeOH or CCl_4; or by zone melting. [*Beilstein* **6** H 843, **6** III 4250, **6** IV 3303.] Plasticiser used for the preparation of polyesters, e.g. for plastic bottles.

N,N*-Dimethyl-*o*-toluidine** *[609-72-3]* **$C_9H_{13}N$, M 135.2, b 68°/10mm, 76°/18mm, 211-211.5°/760mm, d_4^{20} 0.937, n_D^{20} 1.53664, pK^{25} 6.11.** Isomers and other bases are removed by heating in a water bath for 100 hours with two equivalents of 20% HCl and two and a half volumes of 40% aqueous formaldehyde, then making the solution alkaline and separating the free base. After washing well with water, it is distilled at 10mm pressure and redistilled at ambient pressure [Braun & Aust *Chem Ber* **47** 260 *1914*, DOI: 10.1002/cber.19140470138]. Other procedures include drying with NaOH, distilling from zinc in an atmosphere of nitrogen under reduced pressure, and refluxing with excess of acetic anhydride in the presence of concentrated H_2SO_4 as catalyst, followed by fractional distillation in a vacuum. The ***picrate has **m 124-125°**. [*Beilstein* **12** H 857, **12** III 1843, **12** IV 1747.] ***N,N-Dimethyl-m-toluidine*** **(*m*-methyl-*N,N*-dimethylaniline)** *[121-72-2]* has **b 72-74°/5mm, 128°/57mm, 211.5-212.5°/760mm, 215°/atm, d_4^{20} 0.93, n_D^{20} 1.5500, pK^{25} 5.34.** Reflux it for 3 hours with 2 molar equivalents of Ac_2O, then fractionally distil it under reduced pressure. *Alternatively*, dry over BaO, distil and store it over KOH. The ***hydrochloride*** has **m 176°** (from EtOH) and the ***picrate*** has **m 131°**. Methods described for *N,N*-dimethylaniline are applicable. [*Beilstein* **12** H 857, **12** III 1953, **12** IV 1815.] ***N,N-Dimethyl-p-toluidine*** **(*p*-methyl-*N,N*-dimethylaniline)** *[99-97-8]* has **b 76.5-77.5°/4mm, 93-94°/11mm, b 211°/760mm, d_4^{20} 0.937, n_D^{20} 1.5469, $pK^{25.5}$ 5.56, pK^{25} 5.63.** Reflux for 3 hours with 2 molar equivalents of Ac_2O, then fractionally distil it under reduced pressure. *Alternatively*, dry it over BaO, distil and store it over KOH. The ***picrate*** has **m 128°** (from EtOH). Methods described for *N,N*-dimethylaniline are applicable here. [*Beilstein* **12** H 902, **12** III 2026, **12** IV 1874.]

2,4-Dinitroaniline *[97-02-9]* **$C_6H_5N_3O_4$, M 183.1, m 176-178°, 187.5-188°, 180°, ε_{348} 12,300 in dilute aqueous $HClO_4$, pK^{25} -4.27 (aqueous H_2SO_4).** Crystallise the nitroaniline from boiling EtOH by adding one-third volume of H_2O and cooling slowly. It also crystallises from EtOH (yellow needles) or Me_2CO (green-yellow plates). Dry it on a steam oven. The ***N-acetyl*** derivative has **m 180°**. [*Beilstein* **12** IV 1689.]
2,6-Dinitroaniline **(DNAN)** *[606-22-4]* has **m 134°(dec), 139-140°, pK^{25} -5.37 (aqueous H_2SO_4).** Purify the nitroaniline by chromatography on alumina, then crystallise it from *benzene or EtOH (pale orange needles). The ***N-acetyl*** derivative has **m 197°** (from EtOH). [Shultz *Org Synth* Coll Vol **4** 364 *1963*, DOI: 1.15227/orgsyn.031.0045; *Beilstein* **12** IV 1729.]

2,4-Dinitroanisole *[119-27-7]* **$C_7H_6N_2O_5$, M 198.1, m 87-88°(metastable), 94.5°, 94-95°, b 206-207°/12mm.** Crystallise the anisole from aqueous EtOH. The ***naphthalene complex*** has **m 50°** (from EtOH). [*Beilstein* **6** H 254, **6** III 858, **6** IV 1372.] It is a low sensitivity **explosive**. ***3,5-Dinitroanisole*** *[5327-44-6]* has **m 105-106°.** Purify the anisole by repeated crystallisation from EtOH, MeOH or H_2O and dry it in a vacuum desiccator over P_2O_5. The ***naphthalene complex*** has **m 69°** (from EtOH). [*Beilstein* **6** III 869, **6** IV 1385.]

1,2-Dinitrobenzene *[528-29-0]* **$C_6H_4N_2O_4$, M 168.1, m 114-117°, 116.5°, 118°, b 319°/773mm.** Steam distil it and then recrystallise it from EtOH. [*Beilstein* **5** IV 738.] ***1,3-Dinitrobenzene*** *[99-65-0]* has **m 84-86°, 90.5-91°, b 297°/atm, d^{25} 1.365.** Crystallise 1,3-dinitrobenzene from alkaline EtOH solution (20g in 750ml 95%

EtOH at 40°, plus 100ml of 2M NaOH) by cooling and adding 2.5L of H_2O. The precipitate, after filtering off, is washed with H_2O, sucked dry, and crystallised from 120ml, then 80ml of absolute EtOH [Callow et al. *Biochem J* **32** 1312 *1938,* DOI: 10.1042/bj0321312]. *Alternatively*, crystallise it from MeOH, CCl_4 or EtOAc. It can be sublimed in a vacuum. [Tanner et al. *J Org Chem* **52** 2142 *1987*, DOI: 10.1021/jo00387a005; *Beilstein* **5** IV 739.]

1,4-Dinitrobenzene *[100-25-4]* **$C_6H_4N_2O_4$, M 168.1, m 170-172°, 173°, b 183.4°/34m, d^{25} 1.625.** Crystallise 1,4-dinitrobenzene from EtOH or EtOAc. Dry it under vacuum over P_2O_5. It can be sublimed in a vacuum. [*Beilstein* **5** IV 741.]

2,4-Dinitrobenzoic acid *[610-30-3]* **$C_7H_4N_2O_6$, M 212.1, m 176° to 180°, 183°, pK^{25} 1.42.** Crystallise the acid from aqueous 20% EtOH (10ml/g) and let it dry at 100°. [*Beilstein* **9** II 279, **9** III 1776, **9** IV 1239.]
2,5-Dinitrobenzoic acid *[610-28-6]* has **m 178° to 182°, 179.5-180°, pK^{25} 1.62.** Crystallise the acid from distilled H_2O. Dry it in a vacuum desiccator. [*Beilstein* **9** II 279, **9** III 1778, **9** IV 1241.]
2,6-Dinitrobenzoic acid *[603-12-3]* has **m 202-203°, pK^{25} 1.14.** Crystallise the acid from water. [*Beilstein* **9** II 279, **9** III 1778, **9** IV 1242.]
3,4-Dinitrobenzoic acid *[528-45-0]* has **m 166°, 165.5-166.5°, pK^{25} 2.81.** Crystallise the acid from EtOH by addition of water. It is soluble in hot H_2O (solubility is 0.67w/v% at 25°). It sublimes *in vacuo*. [*Beilstein* **9** III 1778, **9** IV 1242.]
3,5-Dinitrobenzoic acid *[99-34-3]* has **m 204° to 206°, 205°, 206.5-207.2°, pK^{25} 2.73 (2.79).** Crystallise the acid from distilled H_2O (solubility is 2w/v% at 100°), or 50% EtOH (4ml/g). Dry it in a vacuum desiccator or at 70° over BaO under a vacuum for 6 hours. It sublimes *in vacuo*. It has been used for the derivatisation of modified polystyrene-divinylbenzene resins for HPLC [Bourque et al. *Anal Chem* **65** 2983 *1993*, DOI: 10.1021/ac00069a008]. [Brewster et al. *Org Synth* Coll Vol **3** 337 *1955*, DOI: 1.15227/orgsyn.022.0048; *Beilstein* **9** II 279, **9** III 1779, **9** IV 1242.] ***3,5-Dinitrobenzoyl chloride*** *[99-33-2]* **$C_7H_3ClN_2O_5$, M 230.6,** has **m 68-69°, 69.5°, b 196°/11mm.** Crystallise it from CCl_4 or petroleum ether (b 40-60°). It reacts readily with H_2O and should be kept in sealed ampoules. [*Beilstein* **9** IV 1350.] Used for characterisation and group protection of alcohol, amines and amino acids.

2,2'-Dinitrobiphenyl *[2436-96-6]* **$C_{12}H_8N_2O_4$, M 244.2, m 123-124°, 125°, 126°, b 194°/4mm, 305°/atm.** Crystallise the biphenyl from EtOH, AcOH (**m 124.5°**) or petroleum ether (**m 125.5-126°**). [*Beilstein* **5** H 538, **5** III 1759, **5** IV 1826.] ***2,4'-Dinitrobiphenyl*** *[606-81-5]* has **m 92.7-93.7°.** Crystallise the biphenyl from EtOH. [*Beilstein* **5** H 538, **5** I 274, **5** II 491, **5** III 1759, **5** IV 1827.] ***4,4'-Dinitrobiphenyl*** *[1528-74-1]* has **m 240.9-241.8°, 242°.** Crystallise the yellow biphenyl from $*C_6H_6$, EtOH (charcoal) or Me_2CO. Dry it under vacuum over P_2O_5. It is steam volatile. It sublimes at ~138°/2.9x10^{-3}mm, and has a musky odour. [*Beilstein* **5** H 584, **5** III 1760, **5** IV 1827.]

2,6-Dinitro-*p*-cresol (2,6-dinitro-4-methylphenol) *[609-93-8]* **$C_7H_6N_2O_5$, M 198.1, m 78-79°, 80.5°, 81-82°, 85°, pK_{Est}~3.7.** Recrystallise the cresol from EtOH. It is slightly soluble in H_2O, but is steam volatile. The ***piperidine salt*** has **m 195°**. [*Beilstein* **6** H 414, **6** II 391, **6** III 1390, **6** IV 2152.] **TOXIC IRRITANT.**
4,6-Dinitro-o-cresol **(4,6-dinitro-2-methylphenol)** *[534-52-1]* has **m 85-86°, 86-87°, 87°, pK^{25} 4.70.** The cresol crystallises from aqueous EtOH. [*Beilstein* **6** H 369, **6** III 1276.]

2,4-Dinitrodiphenylamine *[961-68-2]* **$C_{12}H_9N_3O_4$, M 259.2, m 157°, 159°, 160°, 161°, b 413.8°/760mm, pK_{Est} <0.** The amine forms red crystals from aqueous EtOH or $CHCl_3$/EtOH (**m** 158°). It dissolves in Me_2CO (25mg/ml) to give a clear orange to red solution. The UV has λ_{max} at 335nm (cyclohexane). [*Beilstein* **12** H 751, **12** III 1683, **12** IV 1692.] **IRRITANT.**

4,4'-Dinitrodiphenylurea [1,3-bis-(4-nitrophenyl)urea] *[587-90-6]* **$C_{13}H_{14}N_2O$, M 302.2, m 312°(dec).** Crystallise the urea from EtOH (**m 364°**, long heating), EtOH/Me_2CO (**m 301-303°, 300-304° dec, 318-319°**) or Me_2CO (**m 289° dec**). Its solubility in Me_2SO is 0.47w/v% at 25°. It sublimes *in vacuo*. [*Beilstein* **12** H 723, **12** II 393, **12** III 1619, **12** IV 1646.]

2,4-Dinitrofluorobenzene (FDNB, 1-fluoro-2,4-dinitrobenzene, Sanger's reagent) *[70-34-8]* **$C_6H_3FN_2O_4$,**

M 186.1, m 25-27°, b 133°/2mm, 137°/2mm, 140-141°/5mm, 178°/25mm, d_4^{20} 1.483, n_D^{20} 1.569. Crystallise the reagent from Et_2O or EtOH. Distil it in a vacuum through a Todd Column. If it is to be purified by distillation *in vacuo*, the distillation unit must be allowed to cool before air is allowed into the apparatus; otherwise the residue carbonises spontaneously and an **EXPLOSION** may occur. The material is a **skin irritant** and may cause serious dermatitis. It was developed for peptide analysis, characterisation of hydroxyl compounds, degradation of aldoses and replacement of a phenolic OH group by H. [Sanger *Biochem J* **39** 507 *1945*, DOI: 10.1042/bj0390507; **40** 261 *1946*, DOI: 10.1042/bj0400261; **45** 563 *1949*, DOI: 10.1042/bj0450563, Porter and Sanger *Biochem J* **42** 287 *1948*, DOI: 10.1042/bj0420287; Finger & Finnerty *Biochem Preparations* **3** 120 *1958*, See Fieser **1** 321, *Beilstein* **5** IV 742.]

1,8-Dinitronaphthalene *[602-38-0]* **$C_{10}H_6N_2O_4$, M 218.2, m 161°, 170-171°, 171-172°, 171.3°.** Crystallise the yellow crystalline powder from *benzene. The solubility in H_2O is 0.1w/v% at ~25°. It is a yellow colourant, and may react violently if heated or ground. [*Beilstein* **5** H 559, **5** II 455, **5** III 1608.]

2,4-Dinitro-1-naphthol (Martius Yellow) *[605-69-6]* **$C_{10}H_6N_2O_5$, M 234.2, m 127-133°, 130-133°, pK_{Est} ~3.7.** Crystallise the naphthol from *benzene or aqueous EtOH. Moisten with ~15% of H_2O as stabiliser. [*Beilstein* **6** IV 4240.] It is harmful if inhaled, if in contact with skin and irritates eyes, skin and respiratory system.

2,4-Dinitrophenetole *[610-54-8]* **$C_8H_8N_2O_5$, M 212.2, m 85-86°, 86°, b 210-211°/15mm, 359.1°/atm, d 1.381.** Crystallise it from aqueous EtOH. The 1:1 ***naphthalene complex*** has **m 41°** and is obtained by fusing the compound with naphthalene in various ratios, then crystallising the solidified mix from a little EtOH (Dermer & Smith *J Am Chem Soc* **61** 748 *1939*, DOI: 10.1021/ja01872a504). [*Beilstein* **6** H 254, **6** III 858, **6** IV 1373.] **TOXIC.**

2,4-Dinitrophenol *[51-28-5]* **$C_6H_4N_2O_5$, M 184.1, m 108°, 112°, 114°, pK^{25} 4.12.** Crystallise it from *benzene, EtOH, EtOH/H_2O or H_2O acidified with dilute HCl, dry it, then recrystallise it from CCl_4. Dry it in an oven and store it in a vacuum desiccator over $CaSO_4$. It is sparingly soluble in cold H_2O but more soluble at ~90° (1.2w/w%), and is much more soluble in organic solvents. An aqueous solution is colourless below pH 2.2 and yellow above pH 4.4 (see pKa, the anion is yellow in colour). It is **TOXIC** and has insecticidal properties. The ***benzoate*** has **m 132°** (from EtOH). [*Beilstein* **6** IV 1369.]

2,5-Dinitrophenol *[329-71-5]* has **m 103° to 106°, 108°, pK^{25} 5.20.** Crystallise 2,5-dinitrophenol from H_2O with a little EtOH. It is sparingly soluble in cold H_2O but more soluble in organic solvents. It is colourless in the acid form and the anion is yellow (cf. pKa). **EXPLOSIVE** when dry, store it with ~10% H_2O. [*Beilstein* **6** IV 1383.] **TOXIC.**

2,6-Dinitrophenol *[573-56-8]* has **m 63.0-63.7°, 63-64°, pK^{25} 3.73.** Crystallise it from H_2O, aqueous EtOH, *C_6H_6/cyclohexane, or *C_6H_6/petroleum ether (b 60-80°, 1:1). Like the preceding phenols, it is colourless in the acid form and the anion is yellow (cf. pKa). [*Beilstein* **6** III 867, **6** IV 1383.]

3,4-Dinitrophenol *[577-71-9]* has **m 130° to 135°, 138°, pK^{25} 5.42.** Steam distil and crystallise it from H_2O then dry it in air. **EXPLOSIVE** when dry, store it with ~10% H_2O. Like the preceding phenols, it is colourless in the acid form and the anion is yellow (cf. pKa). [*Beilstein* **6** III 868, **6** IV 1384.]

3,5-Dinitrophenol *[586-11-8]* has **m 125.1°, 126°, pK^{25} 6.68.** Crystallise it from *C_6H_6 or $CHCl_3$/petroleum ether. Store it with ~10% water as it is **EXPLOSIVE** when dry. Like the preceding phenols, it is colourless in the acid form and the anion is yellow (cf. pKa). [*Beilstein* **6** III 869, **6** IV 1383.]

2,4-Dinitrophenylacetic acid *[643-43-6]* **$C_8H_6N_2O_6$, M 226.2, m 19° to 175°, 179°(dec), b 430.2°/760mm, pK^{25} 3.50.** Crystallise the acid from H_2O. [*Beilstein* **9** IV 1691.]

2,4-Dinitrophenylhydrazine (DNPH) *[119-26-6]* **$C_6H_6N_4O_4$, M 198.1, m 194°, 197°, 200°(dec), 200-202°, pK_{Est} ~2.0.** Crystallise the red DNPH from butan-1-ol (30ml/g), dioxane (10ml/g), EtOH, *C_6H_6 or EtOAc. It is used for characterising carbonyl compounds and for dehydrohalogenation [Fieser **1** 321]. The ***hydrochloride*** has **m 186° (dec)**. [*Beilstein* **15** IV 380.] **DNPH reagent** is prepared by adding a solution of it (1g) in concentrated H_2SO_4 (7ml) to EtOH (75ml) and dilute with H_2O (250ml) and filter if necessary. *Alternatively*, dissolve DNPH (0.25g or its hydrochloride) in a mixture of concentrated HCl and H_2O (50ml) by warming (at ~95°)

then diluting with H_2O (250ml). This is useful with water-soluble aldehydes and ketones. Crystalline derivatives are prepared by adding a couple of drops (0.05—0.1g) of the carbonyl compound to the DNPH reagent (3ml) and shaking. If no precipitate separates then allow to stand for 15 minutes. A crystalline precipitate separates if an aldehyde or ketone is present, and if this separates as an oil then cool and scratch until crystals are formed. Collect and recrystallise from a suitable solvent. Usually the first crystals are quite pure.

2,4-Dinitroresorcinol *[519-44-8]* **$C_6H_4N_2O_6$, M 200.1, 146-148°, 147.5°, m 212.5-214.5°, b 280.9°/760mm, d^{25} 1.819, pK^{25} 3.05 (3.79).** Crystallise the resorcinol from aqueous EtOH (yellow crystals). Its solubility at 25° is 0.25% in EtOH and 0.08g/L in H_2O. It forms a monobasic Pb salt. Store < 10°. **EXPLOSIVE.** [*Beilstein* **6** II 824, **6** III 4352, **6** IV 5696.]

3,5-Dinitrosalicylic acid *[609-99-4]* **$C_7H_4N_2O_7$, M 228.1, m 169° to 172°, 173-174°, pK_1^{25} 0.70, pK_2^{25} 7.40.** Crystallise the acid from H_2O (yellow crystals). Used for quantifying carbohydrate levels in blood and reducing substances in urine to form 3-amino-5-nitrosalicyclic acid, which absorbs strongly at 540nm [Miller *Anal Chem*, **31** 426 *1959*, DOI: 10.1021/ac60147a030]. [*Beilstein* **10** IV 270.]

2,6-Dinitrothymol *[303-21-9]* **$C_{10}H_{12}N_2O_5$, M 240.2, m 54.5-55°, 80-81°, 81°.** Crystallise 2,4-dinitrothymol from aqueous EtOH or petroleum ether. [Ganguly & LeFévre *J Chem Soc* 848 *1934*, DOI: 10.1039/JR9340000848; *Beilstein* **6** H 543, **6** III 1911.]

2,3-Dinitrotoluene *[602-01-7]* **$C_7H_6N_2O_4$, M 182.1, m 59.2°, 61°, 63°.** Distil the toluene in steam and crystallise it from H_2O or *benzene/petroleum ether. Store it with 10% H_2O as it could be **EXPLOSIVE** when dry. [*Beilstein* **5** H 339, **5** III 758, **5** IV 865.]
2,4-Dinitrotoluene *[121-14-2]* has **m 67° to 70.0°, 70.5-71.0°, 71.8-72.2°, b 102.7°/1mm.** Crystallise it from Me_2CO, isopropanol or MeOH. Dry it in a vacuum over H_2SO_4. It has also been purified by zone melting. Store it with ~10% of H_2O. *It could be* **EXPLOSIVE** *when dry*. [*Beilstein* **5** H339, **5** III 759, **5** IV 865.]
2,5-Dinitrotoluene *[619-15-8]* has **m 50.3°, 51.2°, 52.5°, b 284°/atm** (reported, but may be dangerous to distil at atm pressure) Crystallise it from *benzene. Store it with ~10% of H_2O. It solubility in H_2O is very poor (0.03w/v% at 20°). EXPLOSIVE *when dry*. [*Beilstein* **5** III 760, **5** IV 866.] **TOXIC** to aquatic organisms, keep away from the environment.
2,6-Dinitrotoluene *[606-20-2]* has **m 56° to 61°, 64.3°, 66.1°.** Crystallise it from acetone. Store it with 10% of H_2O. **EXPLOSIVE** *when dry*. [*Beilstein* **5** III 761, **5** IV 866.]
3,4-Dinitrotoluene*[610-39-9]* has **m 54° to 57°, 58.5°, 60°, 61°.** Steam distil it and crystallise it from *C_6H_6/petroleum ether (pale yellow crystals). Store it with 10% of H_2O to avoid **EXPLOSION.** Used as standard in GS-MS. **[***Beilstein* **5** H 341, **5** III 761, **5** IV 866.]

3,5-Dinitro-*o*-toluic acid *[28169-46-2]* **$C_8H_6N_2O_6$, M 226.2, m 205°, 206°, 207.5-208°, pK_{Est} ~3.0.** Crystallise the acid from H_2O or aqueous EtOH. The ***ammonium salt*** forms yellow crystals from EtOH with **m 218-219°**, and the ***urea salt*** has **m 189-190°** (prisms from EtOH). [*Beilstein* **9** H 474, **9** II 323, **9** III 2316.]

2,4-Dinitro-*m*-xylene *[603-02-1]* **$C_8H_8N_2O_4$, M 196.2, m 83-84°.** Crystallise the yellow 2,4-dinitro-*m*-xylene from EtOH. [*Beilstein* **5** H 379, **5** II 295, **5** III 844.]

Dinonyl phthalate (mainly 3,5,5-trimethylhexyl phthalate isomer) *[84-76-4, 14103-61-8, 28553-12-0]* **$C_{26}H_{42}O_4$, M 418.6, m 26-29°, b 170°/2mm, 413°/atm, d_4^{20} 0.9640, n_D^{20} 1.4825.** Wash the colourless ester with aqueous Na_2CO_3 then shake it with water. Ether is added to break the emulsion, and the solution is washed twice with water, and dried ($CaCl_2$). After evaporating the ether, the residual liquid is distilled three times under reduced pressure. It is stored in a vacuum desiccator over P_2O_5. [*Beilstein* **9** IV 3183.] **IRRITANT.**

4,4'-Di-*n*-pentyloxyazoxybenzene *[64242-26-8]* **$C_{22}H_{30}N_2O_3$, M 370.6, m 124.5° (with phase change at 82°, becomes clear and remelts at 119°).** Crystallise it from Me_2CO, and dry it by heating under vacuum. [For Raman and mesogenic transition studies see Venugopalan & Rossabi *J Chem Phys* **85** 5273 *1986*, DOI: 10.163/1.1451669; *Beilstein* **16** III 599, **16** IV 175.]

Diphenic acid (diphenyl-2,2'-dicarboxylic acid) *[482-05-3]* **$C_{14}H_{10}O_4$, M 242.2, m 228-229°, pK ^{25} 3.46.** Crystallise diphenic acid from water. Hot Ac_2O provides the *anhydride* below. The ***dimethyl ester*** **m 74°** and **b 204-204°/14mm**, crystallises from MeOH as colourless prismatic plates, and the ***diethyl ester*** **m 74°**, crystallises as colourless cubes from EtOH. [*Beilstein* **9** H 922, **9** IV 3552.] ***Diphenic anhydride*** **(diphenyl-2,2'-dicarboxylic anhydride)** *[6050-13-1]* **$C_{14}H_8O_3$, M 466.3,** has **m 217°, 222-224°, 225-227°.** After removing free acid by extraction with cold aqueous Na_2CO_3, the residue is crystallised from acetic anhydride and dried at 100°. Acetic anhydride converts the acid to the anhydride. It also crystallises from *C_6H_6 (**m 219°**) or chlorobenzene (**m 224.5-225.5°**). [*Beilstein* **17** H 526, **17** II 495, **17** III/IV 6425.]

***N,N*-Diphenylacetamidine** *[621-09-0]* **$C_{14}H_{14}N_2$, M 210.3, m 131°, 131-133°, pK ^{25} 8.298.** Crystallise it from EtOH, then sublime it under vacuum at *ca* 96° onto a 'finger' cooled in solid CO_2/MeOH, with continuous pumping to free it from occluded solvent. Store in a sealed container <10°. [Schwarzenbach & Lutz *Helv Chim Acta* **23** 1162 *1940*, DOI: 10.1002/hlca.194002301141; *Beilstein* **12** H 248, **12** II 144, **12** III 471, **12** IV 384.]

Diphenylacetic acid *[117-34-0]* **$C_{14}H_{12}O_2$, M 212.3, m 147° to 149°, 147.4-148.4°, pK^{25} 3.94.** Crystallise the acid from *benzene, H_2O or aqueous 50% EtOH. [Marvel et al *Org Synth* Coll Vol **I** 224 *1941*, DOI: 10.15227/orgsyn.003.0045; Yost & Hauser *J Am Chem Soc* **69** 2325 *1947*, DOI: 10.1021/ja01202a023; *Beilstein* **9** H 673, **9** IV 2492.] ***Diphenylacetyl chloride*** *[1871-29-3]* $C_{14}H_{11}ClO$, M 230.7, has **m 49°** to **53°, 57°** (from petroleum ether), **178°/15mm**; ***methyl diphenylacetate*** *[3469-00-9]* $C_{15}H_{14}O_2$, M 226.3, has **m 59°** to **62°** (from aqueous MeOH); ***diphenylacetic anhydride*** *[1760-46-9]* $C_{28}H_{22}O_2$, M 406.5, has **m 98°** (**96°** to **100°**), **b 182°/3mm, 178°/15mm**, and is very reactive and sensitive to moisture, and ***diphenylacetamide*** *[519-87-9]* $C_{14}H_{13}NO$, M 211.3, has **m 167-168°**.

Diphenylacetonitrile *[86-29-3]* **$C_{14}H_{10}$, M 193.2, m 73-75°, 76°, b 181°/12mm.** Crystallise the nitrile from EtOH or petroleum ether (b 90-100°), and/or distil it in a vacuum. It is used as a herbicide. [*Beilstein* **9** IV 2505.]

Diphenylacetylene (tolan) *[501-65-5]* **$C_{14}H_{12}O_2$, M 178.2, m 59°, 61°, 62.5°, b 90-97°/0.3mm, 170°/19mm, 300°/atm.** Crystallise tolan from EtOH, and/or distil it in a vacuum. [*Beilstein* **5** H 656, **5** IV 2276.]

Diphenylamine *[122-39-4]* **$C_{12}H_{11}N$, M 169.2, m 50° to 53°, 62.0-62.5°, pK ^{25} 0.77 (aqueous H_2SO_4).** Crystallise diphenylamine from petroleum ether, MeOH or EtOH/water. Dry it under vacuum. [*Beilstein* **12** H 174, **12** IV 271.] Used for its reaction with oxidising substances, e.g. NO_3, ClO_3, which when used with H_2SO_4 gives a deep blue colour. The ***sulfate*** *[587-84-8]* $C_{12}H_{11}N.H_2SO_4$, M 267.3, has **m 144-146° (123-125°), b 302°/atm**, and is a yellow powder which is almost insoluble in H_2O, but soluble in EtOH/H_2SO_4.

Diphenylamine-2-carboxylic acid (DPC, *N*-phenylanthranilic acid) *[91-40-7]* **$C_{13}H_{11}NO_2$, M 213.2, m 182-183°, 184°, pK_1^{25} -1.28 (aqueous H_2SO_4), pK_2^{25} 3.86 (CO_2H).** Crystallise the acid from EtOH (5ml/g, leaflets) or AcOH (2ml/g) by adding hot water (1ml/g). It is an oxidation-reduction indicator for cerimetric titrations and detection of vanadium, and also serves as a source of non-steroidal anti-inflammatory drugs. [*Beilstein* **14** IV 1019.]

Diphenylamine-2,2'-dicarboxylic acid (2,2'-iminodibenzoic acid) *[579-92-0]* **$C_{14}H_{11}NO_4$, M 257.2, m 296-297°(dec), 298°(dec), 302°(dec), 320°(dec, long heating), pK_1^{35} 6.05, pK_2^{35} 7.02 (in 50% aqueous dioxane).** Crystallise the acid from EtOH (yellow crystals). It complexes with Cu^{2+}, Zn^{2+}, Cd^{2+}, Co^{2+} and Ni^{2+}, and is an oxidation-reduction indicator in acidic solutions, see previous entry. [*Beilstein* **14** H 354, **14** I 545, **14** III 942, **14** IV 1058.]

9,10-Diphenylanthracene *[1499-10-1]* **$C_{26}H_{18}$, M 330.4, m 245° to 247°. 248-249°.** Crystallise the anthracene from acetic acid or xylene [Baumstark et al. *J Org Chem* **52** 3308 *1987*, DOI: 10.1021/jo00391a024]. [*Beilstein* **5** IV 2807.]

***N,N'*-Diphenylbenzidine** *[531-91-9]* **$C_{24}H_{20}N_2$, M 336.4, m 242°, 245-247°, 248°, 251-252°, pK^{25} 0.30.** Crystallise the benzidine from toluene or ethyl acetate. Store it in the dark. [*Beilstein* **13** H 223, **13** IV 368.]

***trans-trans*-1,4-Diphenylbuta-1,3-diene (DPB, β,β'-bistyryl)** *[538-81-8]* **$C_{16}H_{14}$, M 206.3, m 150° to 152°. 153-153.5°, b 350°/atm.** Its solution in petroleum ether (b 60-70°) is chromatographed on an alumina-Celite column (4:1), and the column is washed with the same solvent. The main zone is cut out, eluted with ethanol and transferred to petroleum ether, which is then dried and evaporated [Pinckard et al. *J Am Chem Soc* **70** 1938 *1948*, DOI: 10.1021/ja01185a088]. Recrystallise it from hexane. Useful for Diels-Alder reactions. [McDonald & Campbell *Org Synth* Coll Vol 4 99 *1973*, DOI: 10.15227/orgsyn.040.0036; *Beilstein* **5** H 676, **9** IV 2319.]

***sym*-(1,5)-Diphenylcarbazide** *[140-22-7]* **$C_{13}H_{14}N_4O$, M 242.3, m 168-171° 170°, 172°, 175°.** A common impurity is phenyl-semicarbazide which can be removed by chromatography: ~8g in H_2O is placed on a column (polyamide 6 powder, Macherey-Nagel-GmbH-Germany, washed several times with MeOH), eluted with H_2O/MeOH/AcOH (1:3:0.04) at 7-8 drops/second, then eluted with the same solvent mixture but diluted 5 fold with H_2O. The purification is followed by UV light at 280nm. The effluent is evaporated to dryness *in vacuo* at ~28°. [For chromatography, IR & UV see Willems et al. *Anal Chim Acta* **51** 553 *1970*, DOI:10.1016/S0003-2670(01)95761-7]. Recrystallise it from EtOH by adding CCl_4 to induce crystallisation, or AcOH to give a white crystalline powder which turns pink in air. It is air and light sensitive and should be stored in the dark under N_2. [*Beilstein* **15** H 292, **15** IV 182.]

1,5-Diphenylcarbazone (phenyldiazinecarboxylic acid 2-phenylhydrazide) *[538-62-5]* **$C_{13}H_{12}N_4O$, M 240.3, m 119° to 123°, 124-127°, 156-159°(dec).** It crystallises from EtOH (*ca* 5ml/g), and dry the orange-red needles at 50°. A commercial sample, nominally *sym*-diphenylcarbazone (**m** 154-156°) was a mixture of diphenylcarbazide and diphenylcarbazone. The former was removed by dissolving 5g of the crude material in 75ml of warm EtOH, then adding 25g Na_2CO_3 dissolved in 400ml of distilled water. The alkaline solution was cooled and extracted six times with 50ml portions of diethyl ether (discarded). Diphenylcarbazone was then precipitated by acidifying the alkaline solution with 3M HNO_3 or glacial acetic acid. It was filtered off, air dried, and stored in the dark [Gerlach & Frazier *Anal Chem* **30** 1142 *1958*, DOI: 10.1021/ac60138a044]. Other impurities are phenylsemicarbazide and diphenylcarbodiazone. Impurities can be detected by chromatography [Willems et al. *Anal Chim Acta* **51** 544 *1970*, DOI:10.1016/S0003-2670(01)95761-7]. It is used for detection and estimation of Hg, Zn, Cd, Cr, Cu, Fe, Mg and Mo. [Cheng et al. *Handbook of Organic Analytical Reagents,* Boca Baton 277 *1982*, *Beilstein* **16** H 24, **16** IV 17.]

Diphenyl carbonate (phenyl carbonate) *[102-09-0]* **$C_{13}H_{10}O_3$, M 214.2, m 79°, 80°, 81-82°, 168°/15mm, 301-302°/760mm, 306°/760mm.** Purify it by distillation under reduced pressure, sublimation, or by gas chromatography with 20% Apiezon on Embacel, and crystallisation from EtOH. It is soluble in organic solvents. [*Beilstein* **6** H 158, **6** IV 629.]

Diphenylcyclopropenone (Diphencyprone) *[886-38-4]* **$C_{15}H_{10}O$, M 206.2, m 87-90°(hydrate), 118°, 119-121°, 122°(anhydrous).** Crystallise it from cyclohexane. Its UV (MeCN) has λ_{max} at 226, 282, 297nm. It is an anti-baldness substance. [*Beilstein* **17** IV 1736.]

1,1-Diphenylethanol (α-methylbenzhydrol) *[599-67-7]* **$C_{14}H_{14}O$, M 198.3, m 77° to 81°, 80-81°, 81-81.5°, 87°, 90°, b 144-145°/12mm, 260°/760mm (dec), d^{15} 1.1057.** Crystallise 1,1-diphenylethanol from *n*-heptane and/or distil it under vacuum. The ***benzoyl*** derivative has **m 115°** and the ***phenylurethane*** has **m 119°**. [Bromberg et al. *J Am Chem Soc* **107** 83 *1985*, DOI: 10.1021/ja00287a016; *Beilstein* **6** H 685, **6** I 330, **6** II 639, **6** III 3395, **6** IV 4713.] ***2,2-Diphenylethanol*** *[1883-32-5]* has **m 53° to 56°, 54.5°, 57-58°, 59.1-59.5°, 64-65°, b 150-151°/3mm, 160-162°/5mm, 192-194°/20mm (dec), d^{15} 1.1057.** If too impure, dissolve in Et_2O, wash with H_2O, dry ($MgSO_4$), evaporate and distil through a short column in a vacuum, whereby a clear colourless oil is obtained which solidifies on standing to give a solid with a sharp melting point. It can be recrystallised from petroleum ether. The ***tosylate***, **m 117-118°** (116° also reported) crystallises from Me_2CO as white needles, readily forms an anion which undergoes interesting rearrangements. [Hamrick & Hauser *J Org Chem* **26** 4199 *1961*, DOI: 10.1021/jo01069a005; Brown & Subba Rao *J Am Chem Soc* **78** 5694 *1956*, DOI: 10.1021/ja01602a063; Winstein et al. *J Am Chem Soc* **74** 1113 *1952*, DOI: 10.1021/ja01125a001; *Beilstein* **6** II 640.]

1,1-Diphenylethylene *[530-48-3]* **$C_{14}H_{12}$, M 180.3, m 6°, 8.2°, b 101°/2mm, 134°/10mm, 268-270°/760mm,**

d_4^{20} 1.024, n_D^{20} 1.6088. Distil it under reduced pressure from KOH. Dry it with CaH_2 and redistil it. [Allen & Converse *Org Synth* Coll Vol **1** 226 *1941*, DOI: 10.15227/orgsyn.006.0032; *Beilstein* **5** H 639, **5** III 1975, **5** IV 2173.]

(±)-*1RS,2RS-*, (+)-*1R,2R-*, (-)-*1S,2S-enantiomers of,* and *meso-* **1,2-Diphenylethylene-1,2-diamine** (DPEN) see *[16635-95-3]*, *[35132-20-8]*, *[29841-69-8]* and *[951-87-1]* respectively in Chapter 5, Catalysts—Part 2.

N,N'*-Diphenylethylenediamine (Wanzlick's Reagent, 1,2-dianilinoethane)** *[150-61-8]* **$C_{14}H_{16}N_2$, M 212.3, m 65-66°, 67.5°, b 178-182°/2mm, 228-230°/12mm, $pK_{Est(1)}$ ~0.5, $pK_{Est(2)}$ ~3.8.** Crystallise the reagent from aqueous EtOH or MeOH, and/or distil it in a vacuum. Store <10°. It is a reagent for aldehydes which react with it to form imidazolidines, and used to prepare crystallisable derivatives. Apart from using these imidazolines to characterise the aldehydes, they can also be hydrolysed to provide the pure recovered aldehydes almost quantitatively. [Wanzlick & Löchel *Chem Ber* **86** 1463 *1953*, DOI: 10.1002/cber.19530861116; Giannis et al. *Tetrahedron* **44** 7177 *1988*, DOI: 10.1016/S0040-4020(01)86086-5; Fieser **1** 187, **2** 98; *Beilstein* **12** H 543, **12** I 282, **12** II 287, **12** III 1042, **12** IV 986.] The ***dihydrochloride *[99590-70-2]* M 285.2 is commercially available. Useful as a resins stabiliser.

***N,N'*-Diphenylformamidine** *[622-15-1]* **$C_{13}H_{12}N_2$, M 196.2, m 142°, 137°, 136-139°, 141°.** Crystallise it from absolute EtOH. The *hydrate* is obtained from aqueous EtOH. [Kuhn & Staab *Chem Ber* 87 272 *1954*, DOI: 10.1002/cber.19540870223; *Beilstein* **12** H 236, **12** IV 372.]

1,3-Diphenylguanidine *[102-06-7]* **$C_{13}H_{13}N_3$, M 211.3, m 146-147°, 148°, 150°, pK^{25} 10.12.** Crystallise it from toluene, aqueous acetone, Et_2O or EtOH, and dry it in a vacuum. [*Beilstein* **12** H 369, **12** IV 769.]

1,6-Diphenyl-1,3,5-hexatriene (DPH, dicinnamyl) *[1720-32-7]* **$C_{18}H_{16}$, M 232.3, m 199°, 200-203°.** Crystallise the hexatriene from $CHCl_3$ or EtOH/$CHCl_3$ (1:1). [*Beilstein* **5** H 691, **5** IV 2425.]

1,1-Diphenylhydrazine *[530-50-7]* **$C_{12}H_{12}N_2$, M 184.2, m 34.5°, 44°, b 120°/1.1mm, 220°/40-50mm, pK_{Est} ~9.1.** Purify it *via* the ***hydrochloride*** *[530-47-2]* M 220.7, which has **m 165-170°(dec)** after crystallisation from aqueous EtOH (plus a few drops of HCl) and recover the free base with aqueous NaOH, extract it into Et_2O, dry it (KOH), filter, evaporate and distil the residue under a vacuum. The distillate crystallises on cooling. The ***benzoyl*** derivative has **m 194°** (from Me_2CO), and the ***4-nitrophenyl hydrazone*** (with the aldehyde) has **m 131-132°**. [Koga & Anselme *J Org Chem* **33** 3963 *1968*, DOI: 10.1021/jo01274a068; Prep: Beringer et al. *J Am Chem Soc* **75** 2705, DOI: 10.1021/ja01107a046; 7708 *1953*, DOI: 10.1021/ja01107a047; **84** 2819 *1962*, DOI: 10.1021/ja00873a035; *Beilstein* **15** IV 55.] ***1,2-Diphenylhydrazine*** **(hydrazobenzene)** *[122-66-7]* has **m 124-126°, b 175°/10mm, 222°/40mm, pK_{Est} ~1.7.** Crystallise hydrazobenzene from hot EtOH containing a little ammonium sulfide or H_2SO_3 (to prevent atmospheric oxidation), preferably under N_2. Dry it in a vacuum desiccator, and store it in the dark or under N_2. It has been distilled in a vacuum. *Alternatively*, crystallise it from petroleum ether (b 60-100°) to constant absorption spectrum. It is almost colourless but in air it turns yellow, then red with the formation of azobenzene. The ***hydrochloride*** crystallises from EtOH and has **m 163-164°(dec)**; however, hydrazobenzene readily rearranges to ***benzidine*** in the presence of acid. The ***picrate*** crystallises from $*C_6H_6$ and has **m 123°(dec)**. [*Beilstein* **15** H 123, **15** IV 56.]

Diphenylmethane *[101-81-5]* **$C_{13}H_{12}$, M 168.2, m 20° to 24°, 25.4°, b 74°/0.4mm, 157°/40mm, 129°/11mm, 260.5°/764.5mm, d_4^{25} 1.0008 (liq), n_D^{20} 1.57683,** Sublime it under vacuum, or distil it at 72-75°/0.4mm. Recrystallise it from cold EtOH. It has also been purified by fractional crystallisation from the melt. Freely soluble in organic solvents but insoluble in H_2O and liquid NH_3. [Armarego *Aust J Chem* **13** 95 *1960*, DOI: 10.1071/CH9600095.] ***Potassium diphenylmethide***, PhCHKPh, is prepared by dissolving K (e.g. 0.55 mole) in liquid NH_3 (800ml) until the blue colour is discharged (forming KNH_2), then adding to diphenylmethane (0.5 mole) in dry Et_2O (800ml), whereby the orange coloured diphenylmethide anion is formed. The NH_3 is evaporated off on a steam-bath (Et_2O being added to maintain the volume at 800ml) to provide a suspension of the methide in Et_2O. The methide can then be used in a variety of carbonylation reactions, e.g. with Dry-Ice (CO_2) it provides a 90% yield of ***diphenylacetic acid*** *[117-34-0]*. [Yost & Hauser *J Am Chem Soc* **69** 2325 *1947*, DOI: 10.1021/ja01202a023; Hamrick & Hauser *J Org Chem* **26** 4199 *1961*, DOI: 10.1021/jo01069a005.]

[Hartman & Phillips *Org Synth* Coll Vol **2** 232 *1943*, DOI: 10.15227/orgsyn.014.0034; *Beilstein* **5** II 498, **5** IV 1841.]

1,1-Diphenylmethylamine (benzhydrylamine, aminodiphenylmethane) *[91-00-9]* **$C_{13}H_{13}N$, M 183.2, m 12°, 34°, b 166°/12mm, 295°/atm, d_4^{25} 1.063, n_D^{20} 1.596, pK_{Est} ~9.1.** Crystallise the amine from H_2O. The *free base* absorbs CO_2 from the atmosphere; store it accordingly. The ***hydrochloride*** *[5267-34-5]* **M** 219.7 **m 293-295°**, crystallises from H_2O. [*Beilstein* **12** H 1323, **12** IV 3282.]
§A polymer bound ***benzhydrylamine hydrochloride*** is commercially available.

Diphenylmethyl chloride (benzhydryl chloride) *[90-99-3]* **$C_{13}H_{11}Cl$, M 202.7, m 15° to 17°, b 140°/3mm, 167°/17mm, n_D^{20} 1.5960.** Dry the chloride with Na_2SO_4 and fractionally distil it under reduced pressure. [*Beilstein* **5** H 590, **5** I 278, **5** II 500, **5** III 1790, **5** IV 1847.]

all-trans*-1,8-Diphenyl-1,3,5,7-octatetraene** *[3029-40-1]* **$C_{20}H_{18}$, M 258.4, m 232°, 235°, 235-237°.** Crystallise the yellow octatetraene from EtOH or $CHCl_3$/MeOH. It gives a red colour with concentrated H_2SO_4 and its ***1,3,5-trinitrobenzene complex, **m 55°**, crystallises in red-brown rhumbs [Kuhn & Winterstein *Helv Chim Acta* **11** 87 *1928*, DOI: 10.1002/hlca.19280110107.] Its UV (hexane) has one λ_{max} at 271-272nm (E_{cm}^{mol} **10.8 x 10^4**) [Zechmeister & Pinckard *J Am Chem Soc* **76** 4144 *1954*, DOI: 10.1021/ja01645a027]. [*Beilstein* **5** H 709, **5** II 620, **5** III 2328, **5** IV 2508.]

***N,N'*-Diphenyl-*p*-phenylenediamine** *[74-31-7]* **$C_{18}H_{16}N_2$, M 260.3, m 143° to 145°, 148-149°, b 219-224°/0.7mm, pK_{Est} <0.** Crystallise the diamine from EtOH, chlorobenzene/petroleum ether or *benzene. It has also been crystallised from aniline, then extracted three times with absolute EtOH. [*Beilstein* **13** H 80.]

1,1-Diphenyl-2-picrylhydrazine *[1707-75-1]* **$C_{18}H_{13}N_5O_6$, M 395.3, m 174°(dec), 178-179.5°(dec).** Crystallise the hydrazine from $CHCl_3$, or *benzene/petroleum ether (1:1), then degas it at 100° and <10^{-5}mm Hg for *ca* 50 hours to decompose the 1:1 molar complex formed with *benzene. [*Beilstein* **15** II 221, **15** IV 1210.] The respective ***hydrazyl free radical*** *[1898-66-4]* **$C_{18}H_{12}N_5O_6$, M 394.3,** crystallises from *C_6H_6/petroleum ether as dark violet prisms with **m 127-129°(dec),** [also ~135°(dec)], and is used as a reducing agent [Schenck et al. *Tetrahedron Lett* 193 *1967*, DOI: 10.1016/S0040-4039(00)90515-X].

2,2-Diphenylpropionic acid *[5558-66-7]* **$C_{15}H_{14}O_2$, M 226.3, m 172°, 173-174°, 175°, b 300°/atm, pK_{Est} ~3.8.** Crystallise the acid from EtOH. [*Beilstein* **9** II 474.] ***3,3-Diphenylpropionic acid*** *[606-83-7]* has **m 151° to 154°, 155°, pK_{Est} ~4.5.** Crystallise the acid from EtOH. [*Beilstein* **9** H 680, **9** IV 2532.]

1,1-Diphenylurea *[603-54-3]* **$C_{13}H_{12}N_2O$, M 212.3, m 238-239°.** Crystallise 1,1-diphenylurea from MeOH. [*Beilstein* for 1,3 **12** IV 741.]

2,6-Di-*iso*-propylaniline *[24544-04-5]* **$C_{12}H_{19}N$, M 177.3, m -45°, -54°, b 120-122°/10mm, 257°/atm, d_4^{25} 0.9367, n_D^{20} 1.5330, pK_{Est} ~0.** Nitration of 1,3-di-*iso*-propylbenzene in AcOH/Ac_2O (2:1 v/v) with 96% HNO_3 (1.24-2.05 equivalents) below 45-50°/24 hours gave, on fractionation through a 2.5 x 180cm column at 5-10mm, a mixture of lower boiling 4-nitro- (74%) and the higher boiling 2-nitro-1,3-di-*iso*-propylbenzene (24%). Reduction of the later in *iso*-propanol with H_2 (~1200psi, <100°) catalysed by Raney Ni (5-10% by weight), followed by filtration, evaporation of the solvent and fractionation through a 180cm column at 10mm, with a reflux ratio of 20:1 and a rate of 0.33ml/minute gave ***2,6-di-iso-propylaniline*** as a colourless oil in 94.9% yield. The ***benzoyl derivative*** separated as an oil which solidifies and provides a white crystalline powder, **m 106.0-106.7°**, on recrystallisation form *iso*-octane. [Newton *J Am Chem Soc* **65** 2434 *1943*, DOI: 10.1021/ja01252a059.] *Alternatively*, aniline (300g), $AlCl_3$ (18g), and Al powder (6g) are heated in a pressure vessel at 290°, and propylene is pumped into the vessel to a pressure of 250 atmospheres. From time to time more propylene is added to sustain the pressure. After *ca* 8 hours the pressure ceased to decrease, the vessel is opened and the product is shaken with dilute aqueous NaOH and fractionated under a vacuum. The three fractions that separate are *2,6-di-iso-propylaniline* (78%), 2-*iso*-propylaniline (15%), and a small amount of 2,4,6-tri-*iso*-propylaniline [Stroh et al. *Angew Chem* **69** 124 *1957*, DOI: 10.1002/ange.19570690403; also report **m 184.5-187°** for the ***acetyl*** derivative, and **m 254-256°** for the ***benzoyl*** derivative.] [*Beilstein* **12** III 2764.]

It is used for making NHCs for metal catalysed α-arylation of acyclic ketones, e.g. propiophenones, and amination of haloarenes [Matsubara et al. *J Org Chem* **72** 5069 *2007*, DOI: 10.1021/jo070313d]. It has been sulfonated for making sulfonated anilines, and consequently sulfonated NHCs, which provide water soluble Pd-NHCs used for Suzuki coupling of arylhalides with arylboronic acids in aqueous medium [Fleckenstein et al. *Chem Commun* 2870 *2007*, DOI: 10.1039/B703658B]. **N-*Trimethylsilyl 2,6-di-isopropylaniline*** *[78923-65-6]*, prepared by reaction of Me_3SiCl and the Li salt of the aniline in Et_2O, is purified by distillation in vacuum. It is used in preparing the key intermediate for the Schrock-Hoveyda molybdenum catalyst (see *[205815-80-1]*), and sometimes it is prepared *in situ* without isolating it while using Et_3N instead of Li as base. [Schrock et al. *J Am Chem Soc* **112** 3875 *1990*, DOI: 10.1021/ja00166a023; Alexander et al. *Organometallics* **19** 3700 *2000*, DOI: 10.1021/om000336h].

***N,N*-Di-*n*-propylaniline** *[2217-07-4]* **$C_{12}H_{19}N$, M 177.3, b 127°/10mm, 238-241°/760mm, pK^{23} 5.68.** Reflux the aniline for 3 hours with acetic anhydride, then fractionally distil under reduced pressure.

Di-*p*-tolyl carbonate *[621-02-3]* **$C_{15}H_{14}O_3$, M 242.3, m 115°.** Purify the carbonate by GLC with 20% Apiezon on Embacel followed by sublimation *in vacuo* and recrystallisation from EtOH (**m 114°**). [*Beilstein* **6** H 398, **6** I 201, **6** II 380, **6** III 1366.]

N,N'*-Di-*o*-tolylguanidine** *[97-39-2]* **$C_{15}H_{17}N_3$, M 239.3, m 179° (175-176°), pK^{18} 9.62.** The guanidine crystallises from aqueous EtOH. The ***sulfate has **m 253-254°**(dec, H_2O). [*Beilstein* **12** H 803, **12** II 445, **12** III 1871, **16** IV 1764.]

Di-*p*-tolylphenylamine (4,4'-dimethyltriphenylamine) *[20440-95-3]* **$C_{20}H_{19}N$, M 273.4, m 108.5°, 112°, b 250°/20-40mm, 417.5°/760mm, d 1.079, pK_{Est} ~ -5.0.** It is prepared from di-*p*-tolylamine, iodobenzene, K_2CO_3 and Cu bronze in nitrobenzene, boiled for 11 hours, nitrobenzene is steam distilled off, the residue is extracted with $*C_6H_6$, the extract is evaporated and the residue is distilled under reduced pressure. The distillate solidified and the solid is recrystallised once from EtOAc, then twice from EtOH to give pale yellow needles, **m 109°**(corr). [Marsden et al. *J Chem Soc* 627 *1937*, DOI: 10.1039/JR9370000627; *Beilstein* **12** III 2033.]

1,2-Divinylbenzene *[1321-74-0]* **$C_{10}H_{10}$, M 130.2, b 53°/3mm, 79.2-79.6°/15mm, 195°/760mm, d^{20} 0.919, n_4^{20} 1.573.** Purify divinylbenzene by dissolving in Et_2O, shaking with H_2O, drying over $CaCl_2$, filtering, evaporating and distilling *in vacuo*. It polymerises within 2-3 days unless 4-*tert*butylcatechol (0.05%) is added as stabiliser. [Fries & Bestian *Chem Ber* **69** 715 *1936*, DOI: 10.1002/cber.19360690416; *Beilstein* **5** III 1366.]

Duroquinone (tetramethylbenzoquinone) *[527-17-3]* **$C_{10}H_{12}O_2$, M 164.2, m 110-111°, 111-112°.** Crystallise duroquinone from 95% EtOH (yellow needles). Dry it *in vacuo*. It is poorly soluble in H_2O but is steam volatile, and is soluble in organic solvents. It can be sublimed unchanged. [*Beilstein* **7** H 669, **7** III 3417, **7** IV 2101.] ***Hydroduroquinone*** *[527-18-4]* **$C_{10}H_{14}O_2$, M 166.2, m 233°**(sintering at >200°), crystallises in almost colourless needles from EtOH, and is oxidised to duroquinone with $FeCl_3$. Its ***diacetyl derivative***, **m 207°**, also crystallises in colourless needles from EtOH. [Smith *Org Synth* Coll Vol **2** 254 *1943*, DOI: 10.15227/orgsyn.010.0040.]

Ellagic acid (4,4',5,5',6,6'-hexahydroxy-2,2'-diphenic acid dilactone) *[476-66-4]* **$C_{14}H_6O_8$, M 338.2, m >360°, $pK_{Est(1)}$~8, $pK_{Est(2)}$~11.** This antioxidant, isolated from the kino (exudate) of Australian *Eucalyptus* '*gum* tree' species, crystallises from pyridine. It forms a dark green solution in aqueous *N* NaOH, gives a blue $FeCl_3$ test, a cherry red colour with concentrated HNO_3, and under UV light it exhibits mauve fluoresces which turns yellow when fumed with NH_3. It is best purified by conversion into the ***tetra-actetate dilactone***, **$C_{22}H_{14}O_{12}$**, by refluxing with Ac_2O/AcONa/4 hours and recrystallising from Ac_2O which provides colourless needles with **m ~340°** depending on heating rate (343-346° also reported). The **tetra-acetyl** derivative (e.g. 0.3g) is then hydrolysed by refluxing with AcOH (5ml) and with H_2SO_4 (0.5ml) for 2 hours, diluted with H_2O, the solid ellagic acid is collected and recrystallised from pyridine to give cream coloured needles **m > 360°**. [Gell et al. *Aust J Chem* **11** 372 *1958*, DOI: 10.1071/CH9580372.] The UV (EtOH) has λ_{max} at 255nm (logε 4.60) and 366nm (logε 3.93). The ***tetra-carbethoxy derivative*** has **m 245-246°** [Hillis & Carle *Aust J Chem*

16 147 *1963*, DOI: 10.1071/CH9630147]. [*Beilstein* **19** H 261, **19** III/IV 3164, **19/7** V 108.] Possible anticarcinogen.

Emodine (1,3,8-trihydroxy-6-methyl-9,10-anthracenedione, archin) *[518-82-1]* **$C_{15}H_{10}O_5$, M 270.2, m 253-257°, 255-256°, 256-257°, 262°, 264° (phenolic pKs 7—10).** Archin forms orange needles from EtOH, Et_2O, *C_6H_6, toluene or pyridine. It sublimes above 200° at 12mm. [Tutin & Clewer *J Chem Soc* **99** 946 *1911*, DOI:10.1039/CT9119900946; IR: Bloom et al. *J Chem Soc* 178 *1959*, DOI: 10.1039/JR9590000178; UV: Birkinshaw *Biochem J* **59** 485 *1955*, DOI: 10.1042/bj0590485; Anslow et al. DOI: 10.1042/bj0340159; *Biochem J* **34** 159 *1940*, DOI: 10.1042/bj0340159; *Beilstein* **8** IV 3575.] It is a purgative.

3-Ethoxy-*N*,*N*-diethylaniline *[1846-92-2]* **$C_{12}H_{19}NO$, M 193.3, b 97-98°/0.6mm, 145°/14mm, 268-270°/760mm, n_D^{20} 1.5342, n_D^{25} 1.5325, pK_{Est} ~6.1.** Reflux it for 3 hours with Ac_2O, then fractionally distil it, preferably under reduced pressure. The ***picrate*** has **m 132-133°** (from EtOH). The ***N*,*N*-diethyl-*N*-methyl-*m*-phenetidinium iodide*** has **m 137-138°** (from MeOH/Et_2O) and its ***picrate*** has **m 101-102°** (from Me_2CO/H_2O) [Fahim & Fleifel *J Chem Soc* 2761 *1951*, DOI: 10.1039/JR9510002761]. [For 2-ethoxy-4-diethylaminobenzene 1-diazonium BF_4 see: Klaassens & Schoot *Recl Trav Chim Pays-Bas* **71** 1086 *1952,* DOI: 10.1002/recl.19520711106; Gilman & Kyle *J Am Chem Soc* **74** 3027 *1952,* DOI: 10.1021/ja01132a023; Brown & Mason *J Chem Soc* 1269 *1933*, DOI: 10.1039/JR9330001269; *Beilstein* **13** I 131, **13** III 942, **13** IV 970.]

1-Ethoxynaphthalene *[5328-01-8]* **$C_{12}H_{12}O$, M 172.2, b 136-138°/14mm, 282°/760mm, d_4^{20} 1.061, n_D^{20} 1.604.** Fractionally distil it (twice) under a vacuum, then dry it with, and distil it under a vacuum from sodium. The ***picrate*** has **m 118.5-119°** (from EtOH). [*Beilstein* **6** H 606, **6** II 578, **6** III 2924, **6** IV 4212.]
2-Ethoxynaphthalene *[93-18-5]* has **m 35.6-36.0°, 37-38°, b 142-143°/12mm, 280°/760mm,** Crystallise it from petroleum ether or EtOH (**m 37-38°**). Dry it *in vacuo*, or distil it in a vacuum. The ***picrate*** has **m 104.5°** (from EtOH or $CHCl_3$). [*Beilstein* **6** H 606, **6** II 578, **6** III 2972, **6** IV 4257.] It is used in perfumery.

Ethyl *p*-aminobenzoate (Benzocaine) *[94-09-7]* **$C_9H_{11}NO_2$, M 165.2, m 88° to 90°, 92°, pK^{25} 2.39.** Crystallise benzocaine from EtOH/H_2O or EtOH (**m 93-94°**), and dry it in air. [Adams & Cohen *Org Synth* Coll Vol **I** 240 *1941*, DOI: 10.15227/orgsyn.008.0066; *Beilstein* **14** H 422, **14** IV 1129.] Anaesthetic.

p*-Ethylaniline** *[589-16-2]* **$C_8H_{11}N$, M 121.2, m -5°, -4.8°, b 88°/8mm, 216°/atm, d_4^{20} 0.975, n_D^{20} 1.554, pK^{25} 5.00.** Dissolve *p*-ethylaniline in *benzene, then acetylate it. Recrystallise the ***acetyl derivative (**m 93-94°**, Hickinbottom & Waine *J Chem Soc* 1565 *1930*, DOI: 10.1039/JR9300001558) from *C_6H_6/petroleum ether or EOH, and hydrolyse by refluxing 50g with 500ml of H_2O and 115ml of concentrated H_2SO_4 until the solution becomes clear. The amine sulfate is isolated, suspended in H_2O and solid KOH is added to generate the free base, which separates. Dry it (KOH), and distil it from zinc dust in a vacuum [Berliner & Berliner *J Am Chem Soc* **76** *6179 1954*, DOI: 10.1021/ja01652a092]. The ***picrate*** has **m 171-172°** (from 1,2-dichloroethane). [*Beilstein* **12** H 1090, **12** III 2380, **12** IV 2419.]

***trans*-Ethyl cinnamate** *[103-36-6]* **$C_{11}H_{12}O_2$, M 176.2, m 6.7°, b 127°/6mm, 272.7°/768mm, d_4^{20} 1.040, n_D^{20} 1.55983.** Wash the ester with aqueous 10% Na_2CO_3, then water, dry ($MgSO_4$), and distil it. The purified ester is saponified with aqueous KOH, and, after acidifying the solution, cinnamic acid is isolated, washed and dried. The ester is reformed by refluxing for 15 hours the cinnamic acid (25g) with absolute EtOH (23g), conc H_2SO_4 (4g) and dry *benzene (100ml), after which it is isolated, washed, dried and distilled under reduced pressure [Jeffery & Vogel *J Chem Soc* 658 *1948*, DOI: 10.1039/JR9480000658]. [*Beilstein* **9** IV 2006.]

(±)-Ethyl α,β-dibromo-β-phenylpropionate *[5464-70-0, erythro 30983-70-1]* **$C_{11}H_{12}Br_2O_2$, M 336.0, m 74-75°, 75°.** Crystallise the propionate from petroleum ether (b 60-80° or 70-90°), EtOH or aqueous EtOH (**m 78°**, and an ***unstable*** form **m 65°**). [*Beilstein* **9** H 512, **9** I 202, **9** III 2406, **9** IV 1772.]

Ethyl gallate (ethyl 3,4,5-trihydroxybenzoate) *[831-61-8]* **$C_9H_{10}O_5$, M 198.2, m 149°, 150-151°, 153°, 163-165°.** Recrystallise the gallate from 1,2-dichloroethane. Its UV has λ_{max} (neutral species) at 275nm (ε 10,000), (anion) at 235nm (ε 10,300), 279nm (ε 11,400) and 324nm (ε 8 500) [Campbell & Coppinger *J Am Chem Soc* **73** 2708 *1951*, DOI: 10.1021/ja01150a079]. [*Beilstein* **10** IV 2002.] It is an antioxidant.

Ethyl *p*-nitrobenzoate *[99-77-4]* **$C_9H_9NO_4$, M 195.2, m 55°, 56°, 57°, 59°, b 314°/atm.** Dissolve it in Et_2O and wash it with aqueous alkali, then the ether is evaporated and the solid recrystallised from EtOH. Take all necessary precautions against explosion if it is to be distilled. [*Beilstein* **13** H 3787, **13** IV 1074.]

2-Ethylphenol *[90-00-6]* **$C_8H_{10}O$, M 122.2, m -28° and -3.4° (dimorphic), b 204.5°/760mm, 210-212°/atm, d_4^{20} 1.020, n_D^{20} 1.537, pK^{25} 10.20.** Purify as for *p*-ethylphenol below. [*Beilstein* **6** H 470, **6** IV 3011.]
4-Ethylphenol *[123-07-9]* has **m 41° to 44°, 47-48°, b 76°/1mm, 153°/100mm, 218.0°/762mm, n_D^{25} 1.5239, pK^{25} 10.21.** Non-acidic impurities are removed by passing steam through a boiling solution containing 1 mole of the phenol and 1.75 moles of NaOH (as an aqueous 10% solution). The residue is cooled and acidified with 30% (v/v) H_2SO_4, and the free phenol is extracted into diethyl ether. The extract is washed with water, dried with $CaSO_4$ and the ether is evaporated. The phenol is distilled at 100mm pressure through a Stedman gauze-packed column. It is further purified by fractional crystallisation by partial freezing, and by zone refining, under N_2 [Biddiscombe et al. *J Chem Soc* 5764 *1963*, DOI: 10.1039/JR9630005764]. *Alternatively*, purify it *via* the benzoate, as for phenol. The ***4-nitrophenylbenzoate*** has **m 80°** (from EtOH). [*Beilstein* **6** H 470, **6** III 1663, **5** IV 3020.]

Ethyl phenylacetate *[101-97-3]* **$C_{10}H_{12}O_2$, M 164.2, b 99-99.3°/14mm, 133°/30mm, 229°/atm, d_4^{20} 1.030, n_D^{20} 1.499.** Shake the ester with saturated aqueous Na_2CO_3 (three times), aqueous 50% $CaCl_2$ (twice) and saturated aqueous NaCl (twice). Dry with $CaCl_2$ and distil it under reduced pressure. [Adams & Thal *Org Synth* **2** 27 *1922*, DOI: 10.15227/orgsyn.002.0027; *Beilstein* **9** H 434, **9** IV 1618.] It has a pleasant odour and is used in perfumery.

Ethyl Red [2-(4-diethylaminophenylazo)benzoic acid] *[76058-33-8]* **$C_{17}H_{19}N_3O_2$, M 297.4, m 135°, 150-152°, pK_1 2.5, pK_2 9.5.** Crystallise the acid dye from EtOH/diethyl ether or toluene. It is an indicator: pH 4.4 (red) and 6.2 (yellow). Its UV has λ_{max} at 447nm. [*Beilstein* **16** I 316.]

Eugenol (4-allyl-2-methoxyphenol, 4-allylguaiacol) *[97-53-0]* **$C_{10}H_{12}O_2$, M 164.2, m -12° to -10°, b 253°/760mm, 255°/760mm, d_4^{20} 1.066, n_D^{20} 1.540, pK^{25} 10.19.** Fractional distillation of eugenol gives a pale yellow liquid which darkens and thickens on exposure to air. It should be stored under N_2 at -20°. [Waterman & Priedster *Recl Trav Chim Pays-Bas* **48** 1272 *1929*, DOI: 10.1002/recl.19290481210; *Beilstein* **6** H 961, **6** IV 6337.] It has a spicy odour like cloves, is used in perfumery and has some analgesic properties. It is also an insect attractant. Its ***benzoate*** has **m 60-70°**.
Eugenol methyl ether **(4-allyl-1,2-dimethoxybenzene)** *[93-15-2]* **$C_{11}H_{14}O_2$, M 178.2,** has **m -4°, b 127-129°/11mm, 146°/30mm, 154.7°/760mm, d_4^{20} 1.0354, n_D^{20} 11.53411.** Recrystallise the ether from hexane at low temperature and redistil it (preferably *in vacuo*). [Hillmer & Schorning *Z Phys Chem* [A] **167** 407 *1934*, Briner & Fliszár *Helv Chim Acta* **42** 2063 *1959*, DOI: 10.1002/hlca.19590420637; *Beilstein* **6** IV 6337.]

Fluoranthene **(benzo[*j*,*k*]fluorene)** *[206-44-0]* **$C_{16}H_{10}$, M 202.3, m 105° to 110°, 110-111°, b 384°/760mm.** Purify it by chromatography of CCl_4 solutions on alumina, with *benzene as eluent. Crystallise it from EtOH, MeOH or *benzene. Also purify it by zone melting. [Gorman et al. *J Am Chem Soc* **107** 4404 *1985*, DOI: 10.1021/ja00301a006; *Beilstein* **5** I 344, **5** IV 2463.]

Fluorene *[86-73-7]* **$C_{13}H_{10}$, M 166.2, m 111° to 114°, 114.7-115.1°, b 160°/15mm, 298°/atm.** Purify fluorene by chromatography of CCl_4 or petroleum ether (b 40-60°) solution on alumina, with *benzene as eluent. Crystallise it from 95% EtOH, 90% acetic acid and again from EtOH. Crystallisation using glacial acetic acid retains an impurity which is removed by partial mercuration and precipitation with LiBr [Brown et al. *J Am Chem Soc* **84** 1229 *1962*, DOI: 10.1021/ja00866a032]. It has also been crystallised from hexane, or *benzene/EtOH, distilled under vacuum and purified by zone refining. [Gorman et al. *J Am Chem Soc* **107** 4404 *1985*, DOI: 10.1021/ja00301a006; *Beilstein* **5** IV 2142.]

Fluorene-2,7-diamine *[525-64-4]* **$C_{13}H_{12}N_2$, M 196.3, m 160° to 162°, 165-166°.** Crystallise the diamine from hot H_2O or aqueous EtOH, dry it *in vacuo* and store it in the dark. [*Beilstein* **13** H 266, **13** II 123, **12** III 507, **13** IV 449.] It is a useful analytical reagent for metal dications, such as Cd, Cu, Co, Zn, as well as the

bromide, chloride, nitrite and persulfate anions.

9-Fluorenone *[486-25-9]* **$C_{13}H_8O_2$, M 180.2, m 82.5-83.0°, 85-86°, b 341°/760mm.** Crystallise 9-fluorenone from absolute EtOH, MeOH or *benzene/pentane. [Ikezawa *J Am Chem Soc* **108** 1589 *1986*, DOI: 10.1021/ja00267a032.] Also recrystallise it twice from toluene and sublime it in a vacuum [Saltiel *J Am Chem Soc* **108** 2674 *1986*, DOI: 10.1021/ja00270a028]. It can be distilled under high vacuum. The ***oxime*** *[2157-52-0]* **$C_{13}H_9NO$, M 195.2,** has **m 195.2°** (**194-195°**, **198°**) (yellow crystals from *C_6H_6 or xylene, Anet et al. *Can J Chem* **35** 180 *1957*, DOI: 10.1139/v57-027; Wislicenus & Waldmuller *Chem Ber* **41** 3334 *1908*, DOI: 10.1002/cber.19080410309.) [*Beilstein* **7** H 465, **7** III 2330, **7** IV 1629.] The ***hydrazone*** *[13629-22-6]* **$C_{13}H_{10}O_2$, M 194.2,** crystallises from *C_6H_6/petroleum ether (**m 148-150°**) or MeOH (**m 152°**). It is used for the photometric determination of ketosteroids. [*Beilstein* **7** I 251.]

9-Fluorenylmethyl chloroformate (FMOC-Cl) *[28920-43-6]* **$C_{15}H_{11}ClO_2$, M 258.7, m 61-63°, 61.4-63°, 62° to 64°.** If the IR contains no OH bands (at ~3000 cm^{-1}) due to the hydrolysis product 9-fluorenylmethanol, then purify it by recrystallisation from dry Et_2O. Its IR ($CHCl_3$) has a band at 1770 cm^{-1} (C=O), and the ^1H NMR ($CDCl_3$) has δ at 4-4.6 (m 2H, C*H*CH_2) and 7.1-7.8 (m, 8 aromatic *H*). The ***azide*** (*FMOC-N_3*) has **m 89-90°** (from hexane) and IR ($CHCl_3$) at 2135 (N_3) and 1730 (C=O) cm^{-1}, and the ***carbazate*** (*FMOC-$NHNH_2$*) has **m 171°(dec)** (from nitromethane) with IR (KBr) at 3310, 3202 (NH) and 1686 (CONH) cm^{-1}. [Caprino & Han *J Org Chem* **37**, 3404 *1972*, DOI: 10.1021/jo00795a005; *J Am Chem Soc* **92** 5748 *1970*, DOI: 10.1021/ja00722a043; Koole et al. *J Org Chem* **54** 1657 *1989*, DOI: 10.1021/jo00268a030; Fürst et al. *J Chromatogr* **499** 557 *1990*, DOI: 10.1016/S0021-9673(00)97000-6.] The reagent is used extensively for derivatising amino acids and in solid phase peptide synthesis. It is readily used for protection and de-protection of the N-terminal amino acid of peptides and proteins [Johnon et al. *JCS Chem Commun* 369 *1993*, DOI: 10.1039/C39930000369], as well as in oligonucleotide synthesis [Seela & Wenzel *Helv Chim Acta* **75** 1111 *1992*, DOI: 10.1002/hlca.19920750414].

9-Fluorenylmethyl succinimidyl carbonate *[82911-69-1]* **$C_{19}H_{15}NO_5$, M 337.3, m 147-151°(dec), 151° (dec), 153°(dec).** Recrystallise the carbonate from $CHCl_3$/Et_2O, or from petroleum ether (b 40-60°). [Paquet *Can J Chem* **60** 976 *1982*, DOI: 10.1139/v82-146; Lapatsanis et al. *Synthesis* 671 *1983*, DOI: 10.1055/s-1983-30468.] Efficient reagent for the selective *N*- protection.

Fluorobenzene *[462-06-6]* **C_6H_5F, M 96.1, m -42°, b 84.8°/760mm, d_4^{20} 1.025, n_D^{20} 1.46573, n_D^{30} 1.4610.** Dry fluorobenzene for several days with P_2O_5, then fractionally distil it. [*Beilstein* **5** H 198, **5** IV 632.]

2-Fluorobenzoic acid *[445-29-4]* **$C_7H_5FO_2$, M 140.1, m 122° to 125°, 126°, 127°, d^{25} 1.460, pK^{25} 3.27.** Crystallise the acid from 50% aqueous EtOH, dilute HCl or *C_6H_6, then purify it by zone melting or vacuum sublimation at 130-140°. [*Beilstein* **9** H 333. **9** III 1324, **9** IV 950.]
3-Fluorobenzoic acid *[445-38-9]* has **m 122-123°, 124°, 125°, d^{25} 1.474 pK^{25} 3.86.** Crystallise the acid from 50% aqueous EtOH or *C_6H_6, then sublime it *in vacuo* at 130-140°. [*Beilstein* **9** H 333, **9** IV 952.]

4-Fluorobenzoic acid *[456-22-4]* **$C_7H_5FO_2$, M 140.1, m 182°, 184°, b 253.7°/atm, d^{25} 1.479, pK^{25} 4.15.** Crystallise the acid from 50% aqueous EtOH, then purify it by zone melting or vacuum sublimation at 130-140°. [Schiemann & Winkelmüller *Org Synth* Coll Vol **2** 299 *1943*, DOI: 10.15227/orgsyn.013.0052; *Beilstein* **9** H 333, **9** III 1327, **9** IV 953.]

3-Fluoro-4-hydroxyphenylacetic acid *[458-09-3]* **$C_8H_7FO_3$, M 170.1, m 132° to 134°, $pK_{Est(1)}$ ~4.4, $pK_{Est(2)}$ ~9.4.** Crystallise the acid from water. [*Beilstein* **10** III 440.]

4-Fluoro-2-methylbenzaldehyde *[63082-45-1]* **C_8H_7FO, M 138.1, d_4^{25} 1.144, n_D^{25} 1.526.** The aldehyde has been purified by gas chromatography and should be kept under N_2 as it readily oxidises in air (flash point is 28°). [Burgess et al. *Aust J Chem* **30** 543 *1977*, DOI: 10.1071/CH9770543].

2-Fluoro-4-nitroaniline *[369-35-7]* **$C_6H_5FN_2O_2$, M 156.1, m 122° to 130°, 134-135°, 135-136°, pK^{25} -0.44 (aqueous $HClO_4$).** The aniline forms yellow crystals on recrystallisation from aqueous MeOH or EtOH. The

acetyl derivative has **m 203-204°** (from EtOH). [Wepster & Verkade *Recl Trav Chim Pays-Bas* **68** 77 *1949*, DOI: 10.1002/recl.19490680109; *Beilstein* **12** III 1647.]

1-Fluoro-4-nitrobenzene *[350-46-9]* **$C_6H_4FNO_2$, M 141.1, m 21.5°(unstable form), 27°(stable form), 22-24°, b 86.6°/14mm, 95-97.5°/22mm, 205.3°/735mm.** Crystallise it from EtOH or distil it in a vacuum. [*Beilstein* **5** H 241, **5** IV 719.]

1-Fluoro-4-nitronaphthalene *[341-92-4]* **$C_{10}H_6FNO_2$, M 191.2, m 80°, b 314.6°/760mm, d 1.369.** It crystallises from EtOH as yellow needles [Bunce et al. *J Org Chem* **52** 4214 *1987*, DOI: 10.1021/jo00228a012]. [*Beilstein* **5** III 1596, **5** IV 1675.]

4-Fluoro-3-nitrophenylazide *[28166-06-5]* **$C_6H_3FN_4O_2$, M 182.1, m 52-53°, 53-55°, 54-56°.** Dissolve the azide in Et_2O, dry it over $MgSO_4$, filter, evaporate and recrystallise the residue from petroleum ether (b 20-40°) to give orange needles. Store it in a stoppered container at ~0°. The ^1H NMR has δ at 7.75 (m 1H) and 7.35 (m 2H) in $CDCl_3$. [Hagedorn et al. *J Org Chem* **43** 2070 *1978,* DOI: 10.1021/jo00404a056.]

2-Fluorophenol *[367-12-4]* **C_6H_5FO, M 112.1, m 14° to 16°, 16.1°, b 53°/14mm, 171-172°/714mm, 172.06-173.06°/760mm, d_4^{20} 1.257, n_D^{20} 1.514, pK^{25} 8.70.** Pass *o*-fluorophenol at least twice through a gas chromatographic column for small quantities; otherwise fractionally distil it under reduced pressure. [*Beilstein* **6** I 97, **6** IV 770.]

4-Fluorophenoxyacetic acid *[405-79-8]* **$C_8H_7FO_3$, M 170.1, m 104.2-104.6°, 106°, pK^{25} 3.13.** Crystallise the acid from EtOH or H_2O. [Hayes & Branch *J Am Chem Soc* **65** 1555 *1943*, DOI: 10.1021/ja01248a031; *Beilstein* **6** III 971, **6** IV 776.]

4-Fluorophenylacetic acid *[405-50-5]* **$C_8H_7FO_2$, M 154.1, m 81° to 83°, 86°, 94°, b 164°/2mm, pK^{25} 4.22.** Crystallise it from heptane or $CHCl_3$, but it is best purified by distillation at high vacuum. [Bergmann et al. *J Am Chem Soc* **78** 6037 *1956*, DOI: 10.1021/ja01604a023; Olah et al. *J. Org Chem* **22** 879 *1957*, DOI: 10.1021/jo01359a005; *Beilstein* **9** III 2261, **9** IV 1672.]

4-Fluorophenyl isocyanate *[1195-45-5]* **C_7H_4FNO, M 137.1, b 55°/8mm, 166.9°/760mm, d 1.206, n_D^{20} 1.514.** Purify the isocyanate by repeated fractionation through an efficient column. If its IR indicates that there is too much urea (in the presence of moisture the symmetrical urea is formed), then dissolve it in dry EtOH-free $CHCl_3$, filter, evaporate and distil it. It hydrolyses in water. **It is a pungent LACHRYMATORY liquid, TOXIC.** [See Hardy *J Chem Soc* 2011 *1934*, DOI: 10.1039/JR9340002010, and Hickinbottom *Reactions of Organic Compounds* Longmans p 493 *1957*.]

4-Fluorophenyl *2*-nitrobenzyl ether *[448-37-3]* **$C_{13}H_{10}FNO_3$, M 247.2, m 62°.** Crystallise the ether from EtOH. [Jones *J Chem Soc* 1414 *1938*, DOI: 10.1039/JR9380001414; *Beilstein* **6** III 1564, **6** IV 2608.]

2-Fluorotoluene *[95-52-3]* **C_7H_7F, M 110.1, m -80°, -62°, b 114.4°/760mm, d_4^{20} 1.005, n_D^{20} 1.475.** Dry *o*-fluorotoluene with P_2O_5 or $CaSO_4$ and fractionally distil it through a silvered vacuum-jacketed glass column with 1/8th-in glass helices. A high reflux ratio is necessary because of the closeness of the boiling points of the *o*-, *m*- and *p*- isomers [Potter & Saylor *J Am Chem Soc* **73** 90 *1951*, DOI: 10.1021/ja01145a032]. [*Beilstein* **5** H 290, **5** III 676, **5** IV 799.] **TOXIC do not breath the vapours.** ***3-Fluorotoluene*** *[352-70-5]* has **m -111°, -87°, b 115°/atm, 116.5°/760mm, d_4^{20} 1.00, n_D^{27} 1.46524.** Purify it as for *o*-fluorotoluene. [*Beilstein* **5** H 290, **5** III 676, **5** IV 799.] **TOXIC do not breath the vapours.** ***4-Fluorotoluene*** *[352-32-9]* has **m -56°, 116.0°/760mm, d_4^{20} 1.00, n_D^{20} 1.46884.** Purify it as for *o*-fluorotoluene. [*Beilstein* **5** H 290, **5** III 677, **5** IV 799.] **TOXIC do not breath the vapours.**

Formanilide (N-phenylformamide) *[103-70-8]* **C_7H_7NO, M 121.1, m 46.6-47.5°, 48°, 50°, b 166°/14mm, 216°/120mm, 271°/atm, d_4^{20} 1.14.** Crystallise formanilide from Et_2O (**m** 45.3°), Et_2O/petroleum ether (**m** 46°), petroleum ether (**m** 47.6°), ligroin/xylene, or distil it preferably under reduced pressure. Its solubility in H_2O is 2.9w/v% at 25°. [*Beilstein* **12** H 230, **12** II 135, **12** III 453, **12** IV 368.]

Gallic acid (H_2O) (3,4,5-trihydroxybenzoic acid) *[5995-86-8 (H_2O), 149-91-7 (anhydrous)]* **$C_7H_6O_5$, M 188.1, m 251°(dec), 253°(dec), pK_1^{25} 4.27, pK_2^{25} 8.68.** Crystallise gallic from water, EtOH or $CHCl_3$. Its solubility in w/v is 1% in Et_2O, 1.2% in H_2O, 10% in glycerol, 20% in Me_2CO and 33% in EtOH. [*Beilstein* **10** H 470, **10** IV 1993.] The ***tri-O-acetyl*** derivative has **m 172°** (from MeOH), and the ***anilide*** has **m 207°**(from EtOH). The ***methyl ester*** *[99-24-1]* **$C_8H_8O_5$, M 184.1,** has **m 202°** (dry), and crystallises in prisms from MeOH. [*Beilstein* **10** IV 1998.] These have antioxidant, angiogenic and anticarcinogenic properties.

Galvinoxyl [2,6-di-*tert*-butyl-α-(3,5-di-*tert*-butyl-4-oxo-2,5-cyclohexadiene-1-ylidene)-*p*-tolyloxy] *[2370-18-5]* **$C_{29}H_{41}O_2$, M 421.65, m 153.2-153.6°, 158-159°.** It is a stable free radical inhibitor and a scavenger of short-lived free radicals with odd electrons on C or O. It is best prepared freshly by oxidation of 3,3',5,5'-tetra-*tert*-butyl-4,4'-dihydroxydiphenyl-methane [**m 154°**, 157.1-157.6°, obtained by gently heating for 10-15 minutes 2,6-di-*tert*-butylphenol, formaldehyde and NaOH in EtOH and recrystallised from EtOH (20g/100ml) as colourless plates [Karasch & Joshi *J Org Chem* **22** 1435 *1957*, DOI: 10.1021/jo01362a033; Bartlett et al. *J Am Chem Soc* **82** 1756 *1960* , DOI: 10.1021/ja01492a054; and **84** 2596 *1962*, DOI: 10.1021/ja00872a026.] Oxidation is carried out under N_2 with PbO_2 in Et_2O or isooctane [Coppinger *J Am Chem Soc* **79** 501 *1957*, DOI: 10.1021/ja01559a073; Bartlett et al. above] or with alkaline potassium ferricyanide [Karasch & Joshi, above], whereby Galvinoxyl separates as deep blue crystals and is recrystallised twice under N_2 from $*C_6H_6$ solution by suction evaporation at 30°. The VIS spectrum has λ_{max} at 407nm (ε 30,000), 431nm (ε 154,000) and weak absorption at 772.5nm, and its IR has ν_{max} at 1577 and 2967cm^{-1}, and is estimated by iodometric titration. It is sensitive to O_2 in the presence of OH^- ions and traces of strong acid in hydroxylic or hydrocarbon solvents. At 62.5° in a 0.62mM solution in $*C_6H_6$ the radical decays with a first order $k = 4 \times 10^{-8}$ sec^{-1} (half life 1.7×10^{17} sec, ~200 days) as observed by the change in OD at 550nm [see Greene & Adam *J Org Chem* **28** 3550 *1963*, DOI: 10.1021/jo01047a505].

R(-)*-Guaiaretic acid [4,4'-(2,3-dimethyl-1-butene-(1,4-diyl)-bis-(2-methoxyphenol)]** *[500-40-3]* **$C_{22}H_{24}O_4$,M 352.4, m 99-100.5°, $[\alpha]_D^{16}$ -91 (c 1.1, EtOH), pK_{Est} ~10.0.** Crystallise the acid once from petroleum ether (b 60-80°), twice from 60% aqueous MeOH and finally from EtOH (**m 100-101°**). Its UV has λ_{max} (EtOH) at 207 and 260nm (logε 4.64 and 4.28). The ***dimethyl ether, **$C_{24}H_{28}O_4$,** crystallises from MeOH in tiny needles with **m 94-94.5°**, **$[\alpha]_D^{16}$ -94 (c 0.6, EtOH),** and UV has λ_{max} (EtOH) at 211 and 259nm (logε 4.45 and 4.20). [King et al. *J Chem Soc* 4011 *1964*, DOI: 10.1039/JR9640004011; Schrecker & Hartwell *J Org Chem* **21** 381 *1956*, DOI: 10.1021/jo01109a617.]

Guaiacol (2-methoxyphenol) *[90-05-1]* **$C_7H_8O_2$, M 124.1, m 26° to 29°, 32°, b 53-55°/4mm, 106°/24mm, 205°/746mm, d^{25} 1.129g/ml, pK^{25} 9.90.** Crystallise guaiacol from *benzene/petroleum ether or distil it in a vacuum. It has some solubility in H_2O (1.5w/v%) but is much more soluble in glycerol (1g/ml). [*Beilstein* **6** H 768, **6** IV 5563.] ***Guaiacol carbonate*** *[553-17-3]* **$C_{15}H_{14}O_5$, M 274.3,** has **m 88.1°, 89°, b 392.6°/760mm, d^{25} 1.208g/ml,** Crystallise the carbonate from EtOH. It is estimated by bromination to the ***monobromo guaiacol carbonate*** **m 178°** (from EtOH) [Chernoff *J Am Chem Soc* **51** 3072 *1929*, DOI: 10.1021/ja01385a027]. Useful in bronchitis and pneumonia [Seifert *The Lancet* **154** 710 *1899*, DOI:10.1016/S0140-6736(01)58972-2]. [*Beilstein* **6** H 776, **6** I 386, **6** II 784, **6** III 4233.]

Guaiazulene (1,4-dimethyl-7-isopropylazulene, *see also Chamazulene above*) *[489-84-9]* **$C_{15}H_{18}$, M 198.3, m 29.5°, 30.5°, 31.5°, b 153°/7mm, d^{25} 0.976.** This hydrocarbon is present in and was isolated from chamomile oil and guaiac wood oil. [Sorm et al. *Coll Czech Chem Commun* **16** 168, DOI: org/10.1135/cccc19510168; Sorm et al. *Coll Czech Chem Commun* **16** 626 *1951*, DOI: org/10.1135/cccc19510626]. It forms blue-violet plates from EtOH. Also redistil it *in vacuo* until distillate solidifies. Its UV has λ_{max} at 284nm (log ε 4.6, heptane) and also maxima at 285, 351, 369, 605, 660, and 735 nm. Purification can also be achieved by chromatography over Al_2O_3 (Basic I) and eluting the blue band with petroleum ether. The ***trinitrobenzene complex*** *[4968-29-0]* **$C_{15}H_{18}.C_6H_3N_3O_6$, M 411.4**, crystallises as black needles from EtOH with **m 151°**. The ***picrate*** has **m 122°** (from EtOH). A water soluble form is obtained by sulfonation to give the ***sodium 3-sulfonate*** (sodium gualenate, **Azulon**) *[6223-35-4]* **$C_{15}H_{17}O_3S.Na$**, **M 300.3.** It has anti-inflammatory and antiulcerative activity. [cf. IR, UV: Plattner, Furst & Marti *Helv Chim Acta* **32** 2452 *1949*, DOI: 10.1002/hlca.19490320732; Mukherjee, Dunn and Houk *J Am Chem Soc* **101** 251 *1979*, DOI: 10.1021/ja00495a058; *Beilstein* **5** III 1677, **5** IV 1751.]

Guanabenz (1-[2,6-dichlorobenzylideneamino]guanidine, Wytensin, WY-8677) *[5051-62-7]* **$C_8H_8Cl_2N_4$, M 231.1, m 227-229°(dec), pK_{Est} ~9.** Crystallise the guanidine from MeCN and store it in a CO_2–free atmosphere. The ***monoHCl*** [23256-5-0] has **m 178°(dec)** [solubility w% at 25° is 1.1(H_2O), 5(EtOH), 0.1(EtOAc), 0.06($CHCl_3$)]. It is an antihypertensive drug. [Holmes et al. *Drugs* **26** 212 *1983*.]

Hexachlorobenzene *[118-74-1]* **C_6Cl_6, M 284.8, m 227° to 229°, 230.2-231.0°, b 323-326°/atm.** Crystallise hexachlorobenzene repeatedly from *benzene. Dry it under vacuum over P_2O_5. It can be sublimed. [*Beilstein* **5** H 205, **5** IV 670.] A former herbicide.

Hexachlorophene [2,2'-methylenebis(3,4,6-trichlorophenol)] *[70-30-4]* **$C_{13}H_6Cl_6O_2$, M 406.9, m 163-165°, 166-167°, b 471°/atm, d 1.71, pK_1^{20} 5.41, pK_2^{20} (30% aqueous MeOH).** It forms needles from MeOH, $C_2H_4Cl_2$, or toluene. The ***diacetate*** has **m 175-176°** (EtOH). This disinfectant is also available in MeOH (5mg/l). [*Beilstein* **6** III 5407, **6** IV 6659.]

Hexadecyl 3-hydroxynaphthalene-2-carboxylate *[531-84-0]* **$C_{27}H_{40}O_3$, M 412.6, m 72-73°, 73-74°, d^{135} 0.824.** Recrystallise the ester from hot EtOH (greenish-white flakes) and sublime it in a vacuum. It is soluble in *C_6H_6, petroleum ether and AcOH. [Oshima & Hayashi *J Soc Chem Ind Jpn* **44** 821 *1941*, *Chem Abs* **42** 2108 *1948*, *Beilstein* **5** H 471, **5** I 227, **5** II 358, **5** III 1106, **5** IV 1208.] Used for waterproofing synthetic cloth.

Hexaethylbenzene *[604-88-6]* **$C_{18}H_{30}$, M 246.3, m 128.7-129.5°.** Crystallise this hydrocarbon from *C_6H_6, or *C_6H_6/EtOH. The ***1,3,5-trinitrobenzene complex*** *(1:1)* has **m** 174°(EtOH). [*Beilstein* **5** III 3038, **5** IV 1137.]

Hexafluorobenzene *[392-56-3]* **C_6F_6, M 186.1, m -13° to -11°, 3.7° to 4.1°, 5.1°, b 79-80°/760mm, d_4^{20} 1.61, n_D^{20} 1.378.** Main impurities are incompletely fluorinated benzenes. Purify it by standing in contact with oleum for 4 hours at room temperature, repeating until the oleum does not become coloured. Wash with water several times, then dry with P_2O_5. Finally purify it by repeated fractional crystallisation. [*Beilstein* **5** III 523, **5** IV 640.]

Hexamethylbenzene *[87-85-4]* **$C_{12}H_{18}$, M 162.3, m 164°, 165-165.5°, 165.75°, 166°, b 264°/atm.** It is prepared, in an efficient fume cupboard, by passing a solution of phenol (100g, 1.06moles) in MeOH (1L) dropwise at a rate of 110ml/hour through a column (5.08cm diameter x 40.6cm long) packed with Al_2O_3 (300g, 4-8 or 8-14 mesh) as catalyst held at 370-380°, and arranged so that the effluent is connected to a receiver that allows the exit gasses (CO, CH_4 and H_2) into the fume cupboard. The yellow product (112-115g, 65-67%, m 134-145°) from the effluent which solidifies is washed with cold MeOH, and purified by recrystallisation from EtOH (50g/ 650ml) with 65-67% recovery, or from *C_6H_6 (50g/130ml) with 60% recovery to give pure colourless ***hexamethylbenzene*** **m 165-166°**. [Cullinane et al. *Org Synth* Coll Vol **4** 520 *1963*, DOI: 10.15227/orgsyn.035.0073.] It is also formed in >80% yields when ***hexamethyl-Dewar benzene*** [HMDB, 7641-77-2] comes into contact with anhydrous Al_2Cl_3 in hot *benzene (highly exothermic) [Schäfer & Hellmann *Angew Chem Int Ed* **6** 518 *1967*, DOI: 10.1002/anie.196705181]. It has been purified by sublimation, then recrystallisation from abolute EtOH, *benzene, EtOH/*benzene or EtOH/cyclohexane. It has also been purified by zone melting. Dry it in a low vacuum over P_2O_5. It forms 1:1 addition compounds with ***2.4.7-trinitrofluoren-one*** (**m 165-166.3°**), ***1,3,5-trinitrobenzene*** (**m 173°**), ***2,4,6-trinitrotoluene*** (**m 123°**), ***2-chloro-1,3,5-trinitrobenzene*** (**m 151°**), and 1:1 complexes with Ag^+, $Cr(CO)_3$ and $W(CO)_3$. Its FT-IR (Nujol) has ν_{max} at 1300.8, 1249.1, 1180.6, 1129.2, 1057.1, 994.9, 943.5, 794.7 and 772.0 cm^{-1}; the ^1H NMR (60MHz, $CDCl_3$, TMS) has δ at 2.22 (s, 18H, Me_6); and the ^{13}C NMR (15MHz, $CDCl_3$, TMS) has δ at 17.72 (6-Me C) and 132.89 (6-aromatic C). [*Beilstein* **5** H 450, **5** I 213, **5** II 341, **5** III 1038, **5** IV 1137.]

Homophthalic acid *[89-51-0]* **$C_9H_8O_4$, M 180.2, m 178° to 182°, 180-181°, 182-183°, 189-190°, (depends on heating rate) $pK_{Est(1)}$ ~3.5, $pK_{Est(2)}$ ~4.3.** Crystallise the acid from boiling H_2O (25ml/g; 63ml/g at 20°), aqueous AcOH (**m 180°**) Dry it at 100°. The ***S-benzylisothiuronium salt*** has **m 155-156°** (from EtOH). [Price *Org Synth* **22** 61*1942*, Grummitt et al. *Org Synth* Coll Vol **3** 449 *1955*, DOI: 10.15227/orgsyn.029.0049; *Beilstein* **9** H 857, **9** II 617, **9** III 4266, **9** IV 3343.] The ***anhydride*** *[703-59-3]* **M** 162.1 has **m 141-142°**. [*Beilstein* **17** IV 3343, **17/11** V 270.]

Homoveratronitrile (3,4-dimethoxybenzylnitrile) *[93-17-4]* **$C_{10}H_{11}NO_2$, M 177.2, m 62-64°, 68°, b 171-178°/10mm, 184°/20mm, 195-196°/2mm, 319.7°/760m, d^{25} 1.082g/ml.** Its solubility is 10% in MeOH, and it has been recrystallised from EtOH or MeOH. Purify it also by distillation followed by recrystallisation. [Niederl & Ziering *J Am Chem Soc* **64** 885 *1942*, DOI: 10.1021/ja01256a042; Julian & Sturgis *J Am Chem Soc* **57** 1126 *1935*, DOI: 10.1021/ja01309a053; *Beilstein* **10** I 198.]

Homoveratrylamine (2-[3,4-dimethoxyphenyl]ethylamine) *[120-20-7]* **$C_{10}H_{15}NO_2$, M 181.2, b 99.3-101.3°/0.5mm, 168-170°/15mm, d_4^{20} 1.091, n_D^{20} 1.5460, pK_{Est} ~9.8.** Purify the amine by fractionation through an efficient column in an inert atmosphere as it is a relatively strong base. [Horner & Sturm *Justus Liebigs Ann Chem* **608** 128 *1957*, DOI: 10.1002/jlac.19576080112; Jung et al. *J Am Chem Soc* **75** 4664 *1953*, DOI: 10.1021/ja01115a012.] The ***hydrochloride*** has **m 152°, 154°, 156°** (from EtOH, Me_2CO or EtOH/Et_2O), the ***picrate*** has **m 165-167°(dec)**, and the ***4-nitrobenzoyl*** derivative has **m 147°** [Buck *J Am Chem Soc* **55** 2593 *1933*, DOI: 10.1021/ja01333a060]. [*Beilstein* **13** H 800, **13** IV 2604.]

Hordenine {4-[(2-dimethylamino)ethyl]phenol} *[539-15-1]* **$C_{10}H_{15}NO_2$, M 165.2, m 116-118°, 117-118°, b 173-174°/11mm, pK^{25} 9.46 (OH).** Crystallise Hordenine from EtOH or H_2O and sublime it at 105°/5mm, or 140-150°/atm. The ***4,4'-dichlorodiphenyl disulfimide salt*** has **m 145-146°** (from Me_2CO/H_2O) [Runge et al. *Chem Ber* **88** 533 *1955*, DOI: 10.1002/cber.19550880414]. [*Beilstein* **13** H 626, **13** I 236, **13** II 356, **13** III 1640, **13** IV 1790.]

4-Hydrazinobenzoic acid *[619-67-0]* **$C_7H_8N_2O_2$, M 152.2, m 205°, 216-220°(dec), 217° (dec), pK^{25} 4.13.** The acid crystallises from water. [*Beilstein* **15** H 631, **15** IV 1372.] The ***hydrochloride*** [24589-37-3] **M 188.6**, has **m 253°(dec)** [*Beilstein* **15** III 837].

Hydrobenzamide [1-phenyl-*N,N*'-bis(phenylmethylene)-methanediamine] *[92-29-5]* **$C_{21}H_{18}N_2$, M 298.4, m 101-102°, 102-105°, 107-108°.** Crystallise hydrobenzamide from absolute EtOH, petroleum ether (**m** 107-108°), *C_6H_6 (**m 103°**), or cyclohexane/*benzene. Dry it under vacuum over P_2O_5. [Pirrone *Gazz Chim Ital* ***67*** 534 *1937*, *Beilstein* **7** H 215, **7** I 120, **7** II 166, **7** III 838.]

dl*-Hydrobenzoin (1,2-diphenyl-1,2-ethanediol, *iso*-hydrobenzoin)** *[492-70-6]* **$C_{14}H_{14}O_2$, M 214.3, m 120°, 123°.** Crystallise the diol from Et_2O /petroleum ether or H_2O (**m 121-122°**) [*Beilstein* **6** H 1004, **6** I 490, **6** II 969, **6** III 5431.] The ***R,R-(+)- *[52340-78-0]* and ***S,S-(-)-*** *[2325-10-2]* ***enantiomers*** have **m 148.5-149.5°(dec)**, $[\alpha]_D^{20}$ + and -94.0 (c 2, EtOH) [Eisenlohr & Hill *Chem Ber* **70** 942 *1937*, DOI: 10.1002/cber.19370700514].
meso-Hydrobenzoin *[579-43-1]* has **m 134-136°, 139°, 139-140°.** Crystallise it from EtOH or water. [*Beilstein* **6** H 1003, **6** I 490, **6** II 967. **6** III 5429, **6** IV 6682.]

Hydroquinone (1,4-dihydroxybenzene, quinol) *[123-31-9]* **$C_6H_6O_2$, M 110.1, m 170-171°, 172-175°, 175.4°, 176.6°, b 285°/atm, d^{25} 1.332, pK_1^{20} 9.91, p K_2^{20} 11.56.** Crystallise quinol from acetone, *benzene, EtOH, EtOH/*benzene, water or acetonitrile (25g in 30ml), preferably under nitrogen. Dry it under vacuum. [Wolfenden et al. *J Am Chem Soc* **109** 463 *1987*, DOI: 10.1021/ja00236a026; *Beilstein* **6** H 836, **6** IV 5712.] It has reducing properties and is used as a photographic developer, de-pigmentor and antioxidant.

4-Hydroxyacetophenone *[99-93-4]* **$C_8H_6O_2$, M 136.2, m 109°, 111°, 147-148°/3mm, pK^{25} 8.01.** Crystallise it from diethyl ether, aqueous EtOH or *benzene/petroleum ether. [*Beilstein* **8** H 87, **8** IV 339.]

3-Hydroxyanthranilic acid (2-amino-3-hydroxybenzoic acid) *[548-93-6]* **$C_7H_7NO_3$, M 153.1, m >240°(dec), 245-265°(dec), 253-154°, 252-255°, λ_{max} 298nm, log ε 3000 (0.1M HCl), pK_1^{20} 2.7, pK_2^{20} 5.19, pK_3^{20} 10.12.** Crystallise the acid from H_2O or EtOH (**m** 254-255°). Sublime it at 170°/0.1mm. The ***hydrochloride*** has **m** 227° (from dilute HCl). [*Beilstein* **14** H 587, **14** III 1463, **14** IV 2071.] **Possible carcinogen.**
5-Hydroxyanthranilic acid* (2-amino-5-hydroxybenzoic acid)** *[394-31-0]* has **m 233-234°, 235-236°, 247°(dec), 248°(dec), b 417.8°/760mm, d 1.491, pK_1^{25} 2.72, pK_2^{25} 5.37, pK_3^{20} 10.12.** Crystallise the acid from water. The ***benzamide has **m 240-242°** (fromAcOH). It is a hypoglycemic agent. [*Beilstein* **14** H 591, **14** II 357, **14** III 1468, **14** IV 2080.]

3-Hydroxybenzaldehyde *[100-83-4]* **$C_7H_6O_2$, M 122.1, m 100° to 103°, 108°, b 191°/50mm, pK_1^{25} 8.98, pK_2^{25} 15.81.** Crystallise the aldehyde from water. [*Beilstein* **8** H 58, **8** IV 240.]
4-Hydroxybenzaldehyde *[123-08-0]* has **m 112° to 115°, 115-116°, 117-119°, b 191°/50mm, 308.3°/atm, pK^{25} 7.61.** Crystallise it from water (containing some H_2SO_4). Dry it over P_2O_5 under vacuum. [*Beilstein* **8** IV 251.]

3-Hydroxybenzoic acid *[99-06-9]* **$C_7H_6O_3$, M 138.1, m 200° to 203°, 200° to 202°, 200.8°, b 346°/atm, pK_1^{25} 4.08, pK_2^{25} 9.98.** Crystallise the hydroxyacid from absolute EtOH. [*Beilstein* **10** IV 315.]
4-Hydroxybenzoic acid *[99-96-7]* has **m 213-214°, 214.5°, d 1.46, pK_1^{25} 4.50, pK_2^{25} 9.11.** Crystallise the hydroxyacid from water (solubility 0.5w.v%). [*Beilstein* **10** IV 345.]

2-Hydroxybenzyl alcohol (saligenine) *[90-01-7]* **$C_7H_8O_2$, M 124.1, m 83° to 85°, 86-87°, 87°, d 1.613, pK^{25} 9.92.** Crystallise saligenine from H_2O (6.7w/v% at 22°) or EtOH/*C_6H_6 (**m 89°**). [*Beilstein* **6** IV 5896.]
3-Hydroxybenzyl alcohol *[620-24-6]* has **m 69-70°, 71°, 72°, pK^{25} 9.83.** Crystallise the alcohol from *C_6H_6 or $CHCl_3$. [*Beilstein* **6** III 4545, **6** IV 5907.]
4-Hydroxybenzyl alcohol **(gastrodigenine)** *[623-05-2]* has **m 114° to 121°, 122°, 127°, 132°, pK^{25} 9.82.** Crystallise the alcohol from H_2O, *C_6H_6 (**m** 124°), *C_6H_6/EtOH or $ClCH_2CH_2Cl$ (**m** 122°). [*Beilstein* **6** III 4546, **6** IV 5909.] A food flavor ingredient. It is a pleiotropic agent inhibiting development of new blood vessels — tumour inhibitor.

2-Hydroxybiphenyl *[90-43-7]* **$C_{12}H_{10}O$, M 170.2, m 55.5° to 57.5°, 56°, 57° to 59°, b 145°/14mm, 282°/760mm, d 1.293, pK^{20} 10.01.** Crystallise it from petroleum ether. [*Beilstein* **6** IV 4579.] It forms a ***sodium tetrahydrate salt*** *[6152-33-6]* which is soluble in H_2O (1.2g/ml), in Me_2CO (1.4g/ml) and in MeOH (1.6/ml). [*Beilsein* **6** III 3281.] It is a disinfectant and a fungicide.
4-Hydroxybiphenyl **(4-phenylphenol)** *[92-69-3]* has **m 164-165°, 166°, b 305-308°/760mm, 321°/atm, pK^{23} 9.55.** Crystallise the phenol from aqueous EtOH, *C_6H_6, and dry it in a vacuum over $CaCl_2$ [Buchanan et al. *J Am Chem Soc* **108** 7703 *1986*, DOI: 10.1021/ja00284a039]. Also purified it by sublimation. [*Beilstein* **6** IV 4600.]

***trans*-4-Hydroxycinnamic acid** **(*p*-coumaric acid)** *[501-98-4]* **$C_9H_8O_3$, M 164.2, m 210-213°, 214-215°, 215°, pK_1^{25} 4.64, pK_2^{25} 9.45.** Crystallise *p*-coumaric acid from H_2O (charcoal). It forms needles from concentrated aqueous solutions as the *anhydrous acid*, but from hot dilute solutions the *monohydrate acid* separates on slow cooling. The acid (33g) has been crystallised from 2.5L of H_2O (1.5g charcoal) yielding 28.4g of recrystallised acid, **m 207°**. It is insoluble in *C_6H_6 or petroleum ether. The UV in 95% EtOH has λ_{max} at 223 and 286nm (ε 14,450 and 19000 $M^{-1}cm^{-1}$). [UV Wheeler & Covarrubias *J Org Chem* **28** 2015 *1963*, DOI: 10.1021/jo01043a016; Corti *Helv Chim Acta* **32** 681 *1949*, DOI: 10.1002/hlca.19490320309; *Beilstein* **10** IV 1005.]

3-(4-Hydroxy-3,5-dimethoxyphenyl)acrylic acid (sinapinic acid) *[530-59-6]* **$C_{11}H_{12}O_5$, M 224.2, m 195°(dec), 204-205°(dec), b 249.2°/atm, $pK_{Est(1)}$ ~4.6, $pK_{Est(2)}$ ~9.3.** Crystallise it from water. [*Beilstein* **10** H 508, **10** IV 2104.]

4-Hydroxydiphenylamine *[122-37-2]* **$C_{12}H_{11}NO$, M 185.2, m 72-73°, pK_{Est} ~10.0.** Crystallise the amine from chlorobenzene/petroleum ether, pentane (**m 72°**) or *C_6H_6/petroleum ether (**m 70°**). [*Beilstein* **13** III 1019, **13** IV 1052.] **Environmentally toxic.**

2-Hydroxy-4-(*n*-dodecyloxy)benzophenone *[2985-59-3]* **$C_{25}H_{34}O_3$, M 382.5, m 50-52°, b 506.3°/760mm, d 1.029, pK_{Est} ~7.1.** Recrystallise it from *n*-hexane and then 10% (v/v) EtOH in acetonitrile [Valenty et al. *J Am Chem Soc* **106** 6155 *1984*, DOI: 10.1021/ja00333a006].

4-Hydroxyindane *[1641-41-1]* **$C_9H_{10}O$, M 134.2, m 49-50°, b 120°/12mm, pK^{25} 10.32.** Crystallise 4-hydroxyindane from petroleum ether, pentane (**m 50-50.5°**) or *C_6H_6 (**m 39.5-40°**). It has UV with λ_{max} at 277nm (cyclohexane). The ***acetyl*** derivative has **m 30-32°** (from EtOH), **b** 127°/14mm and the ***3,5-dinitrobenzoyl*** derivative has **m 114°**. [Dallacker et al. *Chem Ber* **105** 2565 *1972*, DOI: 10.1002/cber.19721050818; *Beilstein* **6** III 2427, **6** IV 3827.] ***5-Hydroxyindane*** *[1470-94-6]* has **m 51° to 53°,**

55°, b 127°/14mm, 255°/760mm, pK^{23} 10.24. Crystallise 5-hydroxyindane from petroleum ether (**m 56°**) or pentane (**m 59-60°**). It has UV with λ_{max} at 283.5nm (cyclohexane). The ***3,5-dinitrobenzoyl*** derivative has **m 156°**. [*Beilstein* **6** III 2428, **6** IV 3829.]

4-Hydroxy-3-methoxyacetophenone (Apocynin, Acetovanilone) *[498-02-2]* **$C_9H_{10}O_3$, M 166.2, m 112° to 115°, b 263-265°/17mm, pK_{Est} ~7.9.** Crystallise apocynin from water, or EtOH/petroleum ether. [*Beilstein* **8** IV 1814.] It has the odour of vanilla. ***2-Hydroxy-4-methoxybenzophenone*** **(Oxybenzone)** *[131-57-7]* **$C_{14}H_{12}O_3$, M 228.2, m 65-66°, b 224-227°/atm, pK^{25} 7.6.** Recrystallise from *iso*PrOH. It is soluble in most organic solvents. Effective UV sunscreen. [Hardy & Forster USPat 2773903 *1956* to American Cyanamid Co.]

trans*-4-Hydroxy-3-methoxycinnamic acid (ferulic acid)** *[537-98-4; 1135-24-6]* **$C_{10}H_{10}O_4$, M 194.2, m 168° to 172°, 174°, pK_1^{25} 4.58, pK_2^{25} 9.39.** Crystallise ferulic acid from H_2O or EtOH/H_2O. UV has λ_{max} (EtOH) at 236nm (specific ε 6,000) and 322nm (specific ε 9,300). Its ***ethyl ester, $C_{12}H_{14}O_4$, provides *anhydrous* crystals **m 38°**, from petroleum ether (b 65-110°), and crystals of the ***monohydrate*** **m 75.5-76.5°**, from aqueous EtOH [Pearl & Beyer *J Org Chem* **16** 216 *1951*, DOI: 10.1021/jo01142a008]. [*Beilstein* **10** H 436, **10** IV 1776.] It is used in food preservation.

4-Hydroxy-2-methylazobenzene (3-methyl-4-phenylazophenol) *[1435-88-7]* **$C_{13}H_{12}N_2O$, M 212.2, m 100-101°, 112°, pK_{Est} ~9.5.** Crystallise the phenol from hexane. [*Beilstein* **16** II 61, **16** IV 195.]
4-Hydroxy-3-methylazobenzene **(2-methyl-4-phenylazophenol)** *[621-66-9]* has **m 125-126°.** Crystallise the phenol from hexane or petroleum ether (**m 130°**). [*Beilstein* **16** II 59, **16** III 104, **16** IV 193.]

3-Hydroxy-4-methylbenzaldehyde *[57295-30-4]* **$C_8H_8O_2$, M 136.1, m 73°, b 252.4°/760mm, pK_{Est} ~10.2.** Crystallise it from water or *C_6H_6 (**m 71-71°**). The ***O-methyl ether*** has **m 45-46°** (from Et_2O/hexane). [Sidgwick & Allott *J Chem Soc* 2819 1923, DOI: 10.1039/CT9232302819; Flitsch et al. *Justus Liebigs Ann Chem* 1413 *1985*, DOI: 10.1002/jlac.198519850712; *Beilstein* **8** H 100, **8** II 103, **8** IV 368.]

5-Hydroxy-2-methyl-1,4-naphthaquinone (plumbagin) *[481-42-5]* **$C_{11}H_8O_3$, M 188.2, m 78-79°, $pK_{Est(1)}$~9.5, $pK_{Est(2)}$~11.0.** Crystallise it from aqueous EtOH (yellow needles). It is steam volatile and sublimes on heating *in vacuo*. [Fieser & Dunn *J Am Chem Soc* **58** 572 *1936*, DOI: 10.1021/ja01295a010; *Beilstein* **8** III 2576, **8** IV 2376.] It inhibits UV-induced development of squamous carcinoma [Sand et al. *Carcinogenesis* **33** 184 *2012*, DOI: 10.1093/carcin/bgr249, PMID: 22072620].
6-Hydroxy-2-methyl-1,4-naphthaquinone *[633-71-6]* has **pK_{Est} ~10.0.** Crystallise the naphthaquinone from aqueous EtOH and sublime it in a vacuum.

2-Hydroxy-1-naphthaldehyde *[708-06-5]* **$C_{11}H_8O_2$, M 172.2, m 76° to 80°, 82°, b 139-142°/4mm, 192°/27mm, pK^{25} 8.27 (50% aqueous EtOH).** Crystallise the aldehyde from EtOH (1.5ml/g), aqueous EtOH, aqueous AcOH (**m 84°**), EtOAc or H_2O. It is air sensitive. [Russell & Lockhart *Org Synth* Coll Vol **3** 463 *1955*, DOI: 10.15227/orgsyn.022.0063; *Beilstein* **8** H 143, **8** I 564, **8** II 171, **8** III 1108, **8** IV 1160.]

2-Hydroxy-1-naphthaleneacetic acid *[10441-45-9]* **$C_{12}H_{10}O_3$, M 202.2, m 147-148°, $pK_{Est(1)}$ ~4.2, $pK_{Est(2)}$ ~8.3.** Crystallise the acid from EtOH/water (1:9, v/v, activated charcoal), H_2O (**m 157°**) or xylene (**m 147°**). Dry it under vacuum, over silica gel, in the dark. Store it in the dark at -20° [Gafni et al. *J Phys Chem* **80** 898 *1976*, DOI: 10.1021/j100549a027]. It readily forms a ***cyclic lactone*** (**m 107°**) [4352-63-0] **$C_{12}H_8O_2$**. [*Beilstein* **10** III 1102, **10** IV 1201.] ***6-Hydroxy-2-naphthalenepropionic acid*** *[553-39-9]* **$C_{13}H_{12}O_3$, M 216.2, m 180-181°, $pK_{Est(1)}$ ~4.6, $pK_{Est(2)}$~9.0** Crystallise the acid from aqueous EtOH or aqueous MeOH. [Ormancey & Horeau *Bull Soc Chim Fr* 962 *1955*, *Beilstein* **10** III 1113.]

3-Hydroxy-2-naphthalide (Naphthol AS) *[92-77-3]* **$C_{17}H_{13}NO_2$, M 263.3, m 246° to 248°, 248.0-248.5°, CI 37505.** Crystallise it from xylene or AcOH which forms plates **m 243-244°** [Schnopper et al. *Anal Chem* **31** 1542 *1959*, DOI: 10.1021/ac60153a035]. Its UV has λ_{max} (EtOH) at 394nm. [*Beilstein* **12** H 505.]

3-Hydroxy-2-naphtho-4'-chloro-*o*-toluidide *[92-76-2]* **$C_{18}H_{14}ClNO_2$, M 311.8, m 243.5-244.5°.** Crystallise it from xylene [Schnopper et al. *Anal Chem* **31** 1542 *1959*, DOI: 10.1021/ac60153a035].

3-Hydroxy-2-naphthoic-1'-naphthylamide *[123-68-3]* **$C_{21}H_{15}NO_2$, M 313.3, m 217-.5-218.0°, 222-223°, b 479.3°/760mm** Crystallise the amide from xylene [Schnopper et al. *Anal Chem* **31** 1542 *1959*, DOI: 10.1021/ac60153a035].
3-Hydroxy-2-naphthoic-2'-naphthylamide *[136-64-8]* has **m 243.5-244.5°, and other naphthol AS derivatives.** Crystallise it from xylene [see Schnopper et al. *Anal Chem* above DOI: 10.1021/ ac60153a035].

2-Hydroxy-1,4-naphthoquinone (Lawsone B, Neutral Orange 6, hennotanic acid, tautomeric with 4-hydroxy-1,2-naphthoquinone) *[83-72-7]* **$C_{10}H_6O_3$, M 174.2, m 191° to 193°(dec), 192° to 195°(dec), CI 75480 pK_1^{25} -5.6 (C=O protonation), pK_2^{25} 2.38, pK_3^{25} 4.00 (phenolic OH).** Crystallise Lawsone B from *C_6H_6 or AcOH (**m** 192.5°, 195-196°). Its solubility in $CHCl_3$ is 0.1g/ml. It sublimes in a vacuum (**m** 194°). It has UV with λ_{max} at 455nm (aqueous NaOH). [*Beilstein* **8** H 300, **8** I 635, **8** II 344, **8** III 2543, **8** IV 2360.] It is an antimicrobial antioxidant dye isolated from hemp and used to dye hair and skin.
5-Hydroxy-1,4-naphthoquinone **(Juglone)** *[481-39-0]* has **m 155°, 161° to 163°, 164-165°, pK^{25} 8.7.** Crystallise Juglone from *benzene/petroleum ether or petetroleum ether. It is steam volatile and can be sublimed. Its UV has λ_{max} (MeOH) at 420nm (ε 7482). It dissolves in alkalies to give a purple-red solution. [*Beilstein* **8** III 2558, **8** IV 2368.]

2-Hydroxy-5-nitrobenzyl bromide (Koshland's reagent) *[772-33-8]* **$C_7H_6BrN_3$, M 232.0, m 144-146°, 147°, 148-149°, pK_{Est} ~8.0.** Crystallise the bromide from * C_6H_6 or * C_6H_6/ligroin. It is slightly soluble in EtOH, soluble in *C_6H_6 and AcOH, and very soluble in ligroin. Store at 2-8°. [*Beilstein* **6** H 367.] Enzyme inhibitor.

2-Hydroxyphenylacetic acid *[614-75-5]* **$C_8H_8O_3$, M 152.2, m 145-147°, 148-149°, 152-153°, b 240-243°/760mm, $pK_{Est(1)}$~4.3, $pK_{Est(2)}$~10.1.** Crystallise the acid from ether or chloroform (**m 147°**, m from latter solvent is always lower). [*Beilstein* **10** H 187, **10** I 81, **10** II 112, **10** III 422, **10** IV 536.]
3-Hydroxyphenylacetic acid *[621-37-4]* has **m 128°, 129° to 133°, 130°, $pK_{Ext(1)}$~4.3, $pK_{Ext(2)}$~10.** Crystallise the acid from *C_6H_6/ligroin or EtOAc/cyclohexane (**m** 131-132°). [*Beilstein* **10** II 112, **10** III 428, **10** IV 541.]
4-Hydroxyphenylacetic acid *[156-38-7]* has **m 148-150°, 150-151°, 152°, pK_1 4.28, pK_2 10.1.** Crystallise the acid from water or Et_2O/petroleum ether. The ***p-bromophenacyl ester*** has **m 117°** (from EtOH). [*Beilstein* **10** II 112, **10** III 430, **10** IV 543.]

***N*-(4-Hydroxyphenyl)-3-phenylsalicylamide** *[550-57-2]* **$C_{19}H_{15}NO_3$, M 305.3, m 183-184°, pK_{Est} ~9.5.** Crystallise the amide from aqueous MeOH. [*Beilstein* **13** IV 224.]

***R*(+)-2-Hydroxy-3-phenylpropionic acid (3-phenyl lactic acid)** *[7326-19-4] and* ***S*(-)-2-Hydroxy-3-phenylpropionic acid** *[20312-36-1]* **$C_9H_{10}O_3$, M 166.2, m 122° to 124°, 125-126°, $[\alpha]_D^{12}$ (+)** and **(-) 18.7 (EtOH), $[\alpha]_D^{20}$ (+)** and **(-) 22 (c 1, H_2O),** for **pK** see below**.** Crystallise the acid from water, MeOH, EtOH or *benzene. [*Beilstein* **10** IV 653.]
dl-2-Hydroxy-3-phenylpropionic acid *[828-01-3]* has **m 97-98°, b 148-150°/15mm, pK_{Est} ~3.7.** Crystallise the propionic acid from *benzene or chloroform. [*Beilstein* **10** IV 653.]
3-p-Hydroxyphenylpropionic acid **(phloretic acid)** *[501-97-3]* has **m 129-130°, 131°, 131-133°, $pK_{Est(1)}$~4.7, $pK_{Est(2)}$~10.1.** Crystallise phloretic acid from ether or H_2O. [*Beilstein* **10** IV 631.] It is a fluorogenic reagent for amine oxidase assays [Matsumoto et al. *Anal Biochem* **138** 133 *1984*, DOI: 10.1016/0003-2697(84)90780-2].

4-Hydroxyphenylpyruvic acid *[156-39-8]* **$C_9H_8O_4$, M 180.2, m 199-220°(dec), pK_{Est} ~2.3.** Crystallise it three times from 0.1M HCl/EtOH (4:1, v/v) immediately before use [Rose & Powell *Biochem J* **87** 541 *1963*, DOI: 10.1042/bj0870541], or from Et_2O. The ***3,4-dinitrophenylhydrazone*** has **m 178°**. [*Beilstein* **10** IV 3630.]

N*-Hydroxyphthalimide** *[524-38-9]* **$C_8H_5NO_3$, M 163.1, m 230°, ~235°(dec), 237-240°, pK^{30} 7.0.** Dissolve the imide in H_2O by adding Et_3N to form the salt and while hot, acidify, cool and pour into a large volume of H_2O. Filter off the solid, wash it with H_2O and dry it over P_2O_5 in a vacuum. [Nefkens & Tesser *J Am Chem Soc* **83** 1263 *1961*, DOI: 10.1021/ja01466a068; Fieser **1** 485, Nefkens et al. *Recl Trav Chim Pays-Bas* **81** 683 *1962*, DOI: 10.1002/recl.19620810807.] It crystallises from H_2O in yellow needles. The ***O-acetyl derivative has **m 178-180°** (from EtOH). [*Beilstein* **21/11** V 100.] Activates terminal carboxy groups in peptide synthesis.

4'-Hydroxypropiophenone *[70-70-2]* **$C_9H_{10}NO_2$, M 150.2, m 147.5-148.5°, 149°, b 140-145°/0.5mm, pK^{25} 8.05.** Crystallise the phenone from H_2O (**m** 149.8-150.2°) (with solubilities of 0.03w/v% at 15° and 3.3w/v% at 100°) or EtOH (**m 147°**). It is an inhibitor of pituitary gonadotrophin. The ***benzoyl derivative*** has **m 117°**, and the ***semicarbazone*** has **m 183°** (EtOH). [Miller & Hartung *Org Synth* Coll Vol **2** 543 *1943*, DOI: 10.15227/orgsyn.013.0090; *Beilstein* **8** H 102, **8** II 104, **8** III 379.]

***trans*-4-Hydroxystilbene** *[6554-98-9]* **$C_{14}H_{12}O$, M 196.3, m 185° to 188°, 189°.** Crystallise it from *C_6H_6, MeOH (**m** 186-187°) or acetic acid. [*Beilstein* **6** H 693, **6** II 657, **6** III 3497, **6** 4855.]

6-Hydroxy-1-tetralone *[3470-50-6]* **$C_{10}H_{10}O_2$, M 162.2, m 154-157°.** It has been prepared by catalytic reduction with Pd/$SrCO_3$ in EtOAc [Cornforth et al. *J Chem Soc* 3348 *1955*, DOI: 10.1039/JR9550003348], RaNi in aqueous NaOH [Papa et al. *J Org Chem* **71** 3241 *1949*, DOI: 10.1021/jo01155a005] or Pt_2O/AcOH [Papa *J Am Chem Soc* **71** 3241 *1949*, DOI: 10.1021/ja01177a515] of 1,6-dihydroxynaphthalene *[see 575-44-0 above]* and purified by recrystallisation from 20% aqueous MeOH or H_2O. ***NOTE*:** *two hydrogen atoms are introduced into the ring containing the 1-hydroxygroup of* 1,6-dihydroxynaphthalene *which produces* 3,4-dihydro-1,6-dihydroxynaphthalene *(the enol) which ketonises to* 6-hydroxy-1-tetralone. The ***semicarbazone***, prepared in the usual way, has **m 216.5-217.5°** after crystallisation from EtOH. Acetylation gave ***6-acetoxy-1-tetralone*** with **m 61-62°** (from aqueous MeOH). Methylation with Me_2SO_4/alkali produced ***6-methoxy-1-tetralone*** *[1078-19-9]* **$C_{11}H_{12}O_2$, M 176.2,** with **b 135-139°/1mm(171°/11mm), m 75-77°(77-79°)** [*Beilstein* **8** IV 904.] The isomeric ***5-methoxy-2-tetralone*** *[32940-15-1]* **$C_{11}H_{12}O_2$, M 176.2,** has **b 120-122°/0.4mm, m 32-**36°, and was prepared by reduction of ***1,6-dimethoxynaphthalene*** with Na/EtOH, isolation as the bisulfite which was hydrolysed with aqueous Na_2CO_3 and extracted into EtOH [Cornforth et al. *J Chem Soc* 689 *1942*, DOI: 10.1039/JR9420000689].

2R*(+) *2*-Hydroxy-1,2,2-triphenylacetate [(*R*-HYTRA, 1,2-ethanediol, 1,1,2-triphenylacetate)** *[95061-47-5]* **and *2S*(-) *2*-Hydroxy-1,2,2-triphenylacetate** *[95061-51-1, 89559-96-6]* **$C_{22}H_{20}O_3$, M 332.4, m 237° to 240°, 249-251°, $[\alpha]_D^{20}$ (+) or (–) 212 to 218 (c 1, pyridine).** The ester is prepared by adding, under N_2 with stirring, a solution of $Sc(OTf)_3$ (1.23g 2.5mmol) in dry MeCN (125ml) slowly (~35min) to a solution of *R*(+)-1,1,2-triphenylethane-1,2-diol (35g, 0.121mol, *[9506-46-4]* see below) and Ac_2O (17.1ml, 0.181mol) and stirring is continued for 3 hours. The white solid, which started to separate after ~8 minutes, is filtered off washed with dry MeCN (2 x 25ml) and dried *in vacuo* at 40 overnight to give the pale yellow ester (35.4g 88% yield). The melting point varied with solvent of recrystallisation; and was **m 213-221°** from *C_6H_6 [Macor et al. *Org Synth* **77** 45 *2000*, *Org Synth* Coll Vol **10** 464 *2000*, DOI: 10.15227/orgsyn.077.0045], **m 249-251°** from toluene [Braun et al. *Org Synth* Coll Vol **9** 507 *1998*, *Org Synth* **72** 32 *1995*, DOI: 10.15227/orgsyn.072.0032, from CH_3COCl/ pyridine/CH_2Cl_2/0° then ~25°/4hr in 92.3% yield], **m 220-221°** from Et_2O [Polansky et al. *Monatsh Chem* **87** 24 *1956*, DOI: 10.1007/BF00903587], **m 220-220.5°** from Et_2O/CH_2Cl_2 [Corey & Casanova *J Am Chem Soc* **85** 165 *1963* DOI: DOI: 10.1021/ja00885a013] and **m 224.5-225.5°** from *C_6H_6 [Ito, Nishino & Kurosawa *Bull Chem Soc Jpn* **56** 3527 *1983*, DOI: 10.1246/bcsj.56.3527], and **m 239° (*R*) and 237° (*S*) after sublimation at 180/0.001mm** [Devant, Mahler and Braun *Chem Ber* **121** 397 *1988*, DOI: 10.1002/cber.19881210303]. **Note** that acetylation takes place with *retention* of configuration. It has IR ($CHCl_3$) with ν_{max} at 3064, 3024, 1737, 1495, 1372, 1239, 1168, 779 cm^{-1} and the ^1H NMR (300MHz, $CDCl_3$ TMS) has δ at 1.96 (3H, s, CH_3CO), 2.78 (1H, s, OH), 6.68 (1H, s, PhC*H*OAc), 7.05-7.40 (13H, m, ArH) and 7.54-7.57 (2H, m, Ar-H); ^{13}C NMR (125MHz, $CDCl_3$, TMS) has δ at 21.1 (CH_3), 78.5 (*C*HOAc), 80.3 (Ph_2COH), 126.2, 126.3, 127.0, 127.3, 125.5, 127.8, 127.9, 128.4, 128.5 (Ar-*C*), 135.9, 142.7, 144.8 (*ipso*-Ar) and 169.7 (C=O). Similar reactions with the same consequences have been performed with the ***S*(-)-*enantiomers [Devant, Mahler and Braun *Chem Ber* **121** 397 *1988*, DOI: 10.1002/cber.19881210303]. This ester undergoes stereospecific aldol condensations *via* a doubly deprotonated acetate methyl group; e.g. the *R*(+)-ester with 2-methylpropanal in the presence of lithium diisopropylamide/THF at -126° followed by hydrolysis with KOH/H_2O/MeOH/reflux provides ***R(+)-3-hydroxy-4-methylpentanoic acid*** *[77981-87-4]* $[\alpha]_D^{20}$ +32 to +37 (c 1.22, $CHCl_3$; 86-92% optical purity) in 61-78% yield. [Braun & Gräf *Org Synth* Coll Vol **9** 497 *1998*, DOI: 10.15227/orgsyn.072.0038; Devant et al. *Chem Ber* **121** 397 *1988*, DOI: 10.1002/cber.19881210303; Fieser **16** 180.]

9-Hydroxytriptycene *[73597-16-7]* **$C_{20}H_{14}O$, M 270.3, m 242-243°, 245-246.5°.** Prepared by hydrolysis of 9-acetoxytriptycene. It was recrystallised from *benzene/petroleum ether (colourless leaves). Dried it at 100° in

a vacuum (turning into white leaves). [Bartlett & Greene *J Am Chem Soc* **76** 1088 *1954*, DOI: 10.1021/ja01633a047.] The ^{1}H NMR (400MHz, $CDCl_3$, and TMS) has δ at 7.53 (1-H, 8-H, 13-H), 7.06 (2-H, 7-H, 14-H), 7.01 (3-H, 6-H, 15-H), 7.37 (4-H, 5-H, 16-H), 5.39 (10-H, bridgehead) and 3.34 (OH) with $J_{1,2}$ = 7.7Hz, $J_{1,3}$ = 0.9Hz, $J_{1,4}$ = 0.1Hz, $J_{2,3}$ = 7.4Hz, $J_{2,4}$ = 0.8Hz and $J_{3,4}$ = 7.5Hz; the ^{13}C NMR (100MHz, $CDCl_3$, and TMS) has δ at 118.8 (1-C, 8-C, 13-C), 124.9 (2-C, 7-C, 14-C), 125.3 (3-C, 6-C, 15-C), 123.1 (4-C, 5-C, 16-C), 143.5 (4a-C, 10a-C, 11-C), 145.7 (9a-C, 8a-C, 12-C), 80.6 (9-C) and 52.6 (10-C); and the ^{13}C NMR for the solid state has been recorded but is only slightly different from the solution spectrum [Imashiro et al. *J Am Chem Soc* **109** 729 *1987*, DOI: 10.1021/ja00237a016].

Hypericin (hypericum, 4,5,7,4',5',7'-hexahydroxy-2',2'-dimethylnaphthodianthrone) *[548-04-9]* **$C_{30}H_{16}O_6$, M 504.4, m 320°(dec).** Crystallise hypericin from pyridine by addition of methanolic HCl to give a bluish-black solid. [*Beilstein* **8** IV 3761.] This active ingredient of the plant called St John's Wort is an antibiotic, an antiviral and a non-specific kinase inhibitor. It is used also to treat depression, cancer and AIDS.

Ibuprofen [*(S+)* and *(R-)* 4-*iso*butyl-α-methylphenylacetic acid, α-methyl-4-(2-methylpropyl)phenyl acetic acid, Brufen, Nurofen, Motrui] *[(S +) 51146-56-6, (R —) 51146-57-7, (RS —) 15687-27-1]* **$C_{13}H_{18}O_2$, M 206.3, m 52-53°, $[\alpha]_D^{20}$ +59 (c 2, EtOH).** Crystallise the (+) and (-) acids from EtOH or aqueous EtOH. The ***racemate***, which crystallises from petroleum ether with **m 75-77°**, is sparingly soluble in H_2O and has IR (film) with ν_{max} at 1705 (C=O), 2300—3700 (OH broad) cm^{-1}. [Shiori et al. *J Org Chem* **43** 2936 *1978*, DOI: 10.1021/jo00408a049; Kaiser et al. *J Pharm Sci* **65** 269 *1976*, DOI: 10.1002/jps.2600650222; *J Pharm Sci* **81** 221 *1992*, DOI: 10.1002/jps.2600810306; Freer *Acta Cryst* (C) **49** 1378 *1993*, DOI: 10.1107/S0108270193000629 for the *(S+)-enantiomer*; for a new synthesis using the reaction of *p-iso*butylphenylPb(OAc)$_3$ and the 5-methyl-Meldrum acid derivative (2,2,5-trimethyl-1,3-dioxan-4,6-dione) to give 2,2-dimethyl-5-methyl-5-*iso*butylphenyl-1,3-dioxan-4,6-dione quantitatively followed by hydrolysis and decarboxylation to ***ibuprofen*** see Pinhey & Rowe [*Tetrahedron Lett* **21** 965 *1980*, DOI: 10.1016/S0040-4039(00)77752-5.] It is a cyclooxygenase (COX) inhibitor, and a non-steroidal anti-inflammatory (NSAID) drug. Used with codeine as an analgesic. The physiological activity resides mainly in the *S-enantiomer*.
The ***S(+)-Ibuprofen-S-lysine salt (Dexibuprofen lysine,* MK-223)** *[141505-32-0]* **$C_{13}H_{18}O_2 \cdot C_6H_{14}N_2O_2 \cdot H_2O$, M 370.5,** is prepared by adding *S*(+)-ibuprofen (52.6g, 0.25mole) in EtOH (250ml) with stirring over 5 minutes to a solution of *S*-lysine (37.5, 0.25mole) in H_2O (42ml) at ≤ 35°, filtered through a medium frit glass funnel, diluted with EtOH (575ml) over 5 minutes at 20-25°, seeded with the salt (50mg), diluted further with EtOH (400ml) over 10 minutes and the suspension is stirred at 20-25° for 1 hour then cooled to 0-5° for 1 hour. The salt is filtered off, washed with cold EtOH (2 x 5ml) and dried at 50° *in vacuo* to give *pure salt* (74g, 84%) with **$[\alpha]_{405}^{25}$ +14.9 (c 1, MeOH)**. [King C. Kwan US Pat 5200558A to Merck & Co, Aug 9, *1991*.]

1,3-Indandione *[606-23-5]* **$C_9H_7O_2$, M 146.2, m 129-132°, pK^{18} 7.2 (1% aqueous EtOH).** Recrystallise it from EtOH or *C_6H_6. In dilute alkali it gives a deep yellow solution of the enol. [Bernasconi & Paschalis *J Am Chem Soc* **108** 2969 *1986*, DOI: 10.1021/ja00271a027]. [*Beilstein* **7** IV 2344.] Its mono-oxime ***2-oximino-1-indanone*** *[15028-10-1]* **$C_9H_7NO_2$, M 161.2,** has **m 209°(dec)** (from EtOH).

Indane (indan, hydrindene, 1,2-trimethyenebenzene) *[496-11-7]* **C_9H_{10}, M 118.1, m –51.4°, b 79°/29mm, 177-179.5°/760mm, d_4^{20} 0.960, n_D^{20} 1.536.** Shake indane with concentrated H_2SO_4, then water, dry (Na_2SO_4) and fractionally distil it. [*Beilstein* **5** H 486, **5** I 234, **5** II 376, **5** III 1200, **5** IV 1371.]

Indene *[95-13-6]* **C_9H_8, M 116.2, f -1.5°, m -5° to -3°, b 114.5°/100mm, 181-182°/atm, d_4^{20} 0.994, n_D^{20} 1.5763.** Shake indene with 6M HCl for 24 hours (to remove basic nitrogenous material), then reflux it with 40% NaOH for 2 hours (to remove benzonitrile). Fractionally distil, then fractionally crystallise it by partial freezing. The higher-melting portion is converted into its sodium salt by adding a quarter of its weight of sodamide under nitrogen and stirring for 3 hours at 120°. Unreacted organic material is distilled off at 120°/1mm. The sodium salts are hydrolysed with water, and the organic fraction is separated by steam disillation, followed by fractional distillation. Before use, the distillate is passed, under nitrogen, through a column of activated silica gel. It turns yellow in air as it readily oxidises and polymerises. Store it in the presence of *tert*-butylcatechol (50-100ppm) as antioxidant. [Russell *J Am Chem Soc* **78** 1041 *1956*, DOI: 10.1021/ja01586a045; *Beilstein* **5** IV 1532.]

2-Iodoaniline *[615-43-0]* **C_6H_6IN, M 219.0, m 55-58°, 60-61°, pK^{25} 2.54.** Distil 2-iodoaniline with steam and crystallise it from *benzene/petroleum ether. The ***N-acetyl*** derivative has **m 110°.** [*Beilstein* **12** IV 1542.]
4-Iodoaniline *[540-37-4]* has **m 62-63°, pK^{25} 3.81.** Crystallise it from petroleum ether (b 60-80°) by refluxing, then cool it in an ice-salt bath freezing mixture. Dry it in air. *Alternatively*, crystallise it from EtOH and dry it *in vacuo* for 6 hours at 40° [Edidin et al. *J Am Chem Soc* **109** 3945 *1987*, DOI: 10.1021/ja00247a019]. The ***N-acetyl*** derivative has **m 184°** (from MeOH). [*Beilstein* **12** IV 1544.]

4-Iodoanisole *[696-62-8]* **C_7H_7IO, M 234.0, m 48° to 51°, 51-52°, b 133-133.3°/25mm, 139°/35mm, 237°/726mm.** Crystallise 4-iodoanisole from aqueous EtOH and/or distil it under vacuum. [*Beilstein* **6** H 208, **6** I 109, **6** II 199, **6** III 744, **6** IV 1075.]

Iodobenzene *[591-50-4]* **C_6H_5I, M 204.0, m -29°, b 63-65°/10mm, 188°/atm, d $^{20}_4$ 1.829, n $^{25}_D$ 1.6169.** Wash it with dilute aqueous $Na_2S_2O_3$, then water. Dry it with $CaCl_2$ or $CaSO_4$, decolourise with charcoal and distil it under reduced pressure then store it in the dark with Hg or silver powder to stabilise it. [*Beilstein* **5** IV 688.]

2-Iodobenzoic acid *[88-67-5]* **$C_7H_5IO_2$, M 248.4, m 160-161°, 161-162°, 161.6-162°, 162°, 162.7-163.5°, 164°, d 2.25, pK^{20} 2.93, pK^{25} 2.84 (H_2O), pK^{20} 2.93 (1% EtOH), pK −7.78 (H_2SO_4).** Crystallise the acid repeatedly from water (charcoal), EtOH, aqueous EtOH, aqueous Me_2CO, Me_2CO/Et_2O or $*C_6H_6$. Sublime it under vacuum at 100°. o-Iodobenzoic acid is prepared by the following procedure: anthranilic acid (31.9g, 233mmol, see [118-92-3]) is dissolved in dilute H_2SO_4 (50g, 27ml, 98% acid, 500mmol, in 250ml of H_2O), cooled to 0°; and while stirring $NaNO_2$ (20g, 290mmol) in H_2O (40ml) is added dropwise keeping the temperature below 10° (add crushed ice to the mixture if necessary). Diazotisation is complete when starch-iodide paper wetted with a drop of the mixture turns blue or brown due to the presence of excess of HNO_2. A solution of KI (60g, 360mmol) in H_2O (100ml) is gradually added with stirring, the mixture is set aside for 1 hour then heated at ~100° until effervescence (N_2 liberated) ceases. The mixture is cooled in ice, the brown iodo-acid (~92%) is filtered off, washed well with H_2O and dried *in vacuo*. The brown colour is not easily removed by recrystallisation so the acid is converted into the ethyl ester e.g. by Fischer and Speier's method [Fischer & Speier *Chem Ber* **28** 3252 *1895*, DOI: 10.1002/cber.189502803176]. Dry HCl gas is bubbled through EtOH (~200ml) cooled in ice-water until the increase in weight is ~4g. The crude iodobenzoic acid is added to it and the mixture is boiled under reflux for 2 hours, or until an aliquot poured into H_2O does not deposit a solid. The mixture is poured into cold H_2O, the heavy oil that separated is extracted into Et_2O, the extract is washed with H_2O, saturated aqueous $NaHCO_3$ (care-effervescence), brine, dried ($CaCl_2$), filtered, evaporated and the residual oil is distilled to give a 73% yield of pure ***ethyl* o-*iodobenzoate*** **M 276.0** *[1829-28-3]*, **b 151-152°/12-13mm (163-165°/23mm, 275°/atm).** This ester is dissolved in 0.5 *N* alcoholic KOH (from 7g of KOH dissolved in 7ml of H_2O and diluted to 250ml with EtOH) in the ratio of 1g:25ml, and refluxed for 30 minutes (or until a drop added to H_2O dissolves completely), poured it into H_2O, and the clear solution of the potassium salt is acidified to pH <0 when pure iodobenzoic acid (theoretical yield) separates. It is collected, washed with cold H_2O, and dried *in vacuo*. [Baker et al. *J Chem Soc* 3721 *1965*, DOI: 10.1039/JR9650003721; Cohen & Raper *J Chem Soc* 1271 *1904*, DOI: 10.1039/CT9048501271.] The FT-IR (Nujol) has ν_{max} at 3061.7, 2646.1, 1683.9, 1582.4, 1405.0, 1269.8, 1015.8, 739.0 and 679.7 cm^{-1}; the ^{1}H NMR (DMSOd_6, TMS) has δ at 7.25 (t of d, 1H, *J* = 7 Hz and 1.5 Hz, H-5), 4.85 (t, 1H, *J* = 7 Hz, H-4), 7.72 (d of d, 1H, *J* = 7 and 1.5 Hz, H-6) and 8.01 (d, 1H, *J* = 7 Hz, H-3); and the ^{13}C NMR (DMSOd_6, TMS) has δ at 167.93, 140.32, 136.72, 132.25, 129.88 127.97 and 93.92.
The ***acid chloride*** *[609-67-6]* **M 266.4**, has **m 35-40°, b 135°/19mm (159°/27mm)**, and the ***amide*** *[3930-83-4]* **M 247.0**, has **m 183°** (needles from H_2O). The ***4-bromobenzylisothiuronium salt*** has **m 154°** (from EtOH), and the ***4-chlorobenzylisothiuronium salt*** has **m 162°** (from dioxane). 4-Iodobiphenyl *[1591-31-7]* **$C_{12}H_9I$, M 280.1, m 110° to 113°, 113.7-114.3°, b 207°/28mm.** Crystallise 4-iodobiphenyl from EtOH/*C_6H_6, and dry it *in vacuo* over P_2O_5. [*Beilstein* **5** H 581, **5** I 273, **5** II 486, **5** III 1748, **5** IV 1821.]

1-Iodo-2,4-dinitrobenzene *[709-49-9]* **$C_6H_3IN_2O_4$, M 294.0, m 87°, 88°, 89-90°.** Crystallise it from EtOAc. [*Beilstein* **5** H 270.]

1-Iodo-4-nitrobenzene *[636-98-6]* **$C_6H_4INO_2$, M 249.0, m 171-172°, 173°, b 289°/772mm.** Precipitate it from acetone by addition of water, followed by recrystallisation from EtOH. [*Beilstein* **8** H 523, **8** H 523, **8** II 191, **8** III 623, **8** IV 743.]

2-Iodophenol *[533-58-4]* **C_6H_5IO, M 280.0, m 37° to 43°, b 186-187°/160mm, d^{25} 1.947, pK^{25} 8.51.** Crystallise 2-iodophenol from $CHCl_3$ or diethyl ether. The ***acetate*** has **m 65-66°** (from MeOH). [*Beilstein* **6** H 208, **6** II 198, **6** III 774, **6** IV 1074.]
4-Iodophenol *[540-38-5]* has **m 92°** to **94°, b 138-140°/5mm, pK^{25} 9.30.** Crystallise 4-iodophenol from petroleum ether (b 80-100°) or distil it *in vacuo*. If the material has a brown or violet color, then dissolve it in $CHCl_3$, shake it with 5% sodium thiosulfate solution until colourless. Dry (Na_2SO_4) the organic layer, filter, evaporate and disil the residue *in vacuo*. [Dains & Eberly *Org Synth* Coll Vol **2** 355 *1943*, DOI: 10.15227/orgsyn.015.0039; *Beilstein* **6** IV 1074.]

5-Iodosalicylic acid (2-hydroxy-5-iodobenzoic acid) *[119-30-2]* **$C_7H_5IO_3$, M 264.0, m 189° to 191°, 194°, 197°, 196-200°, pK_1^{25} 2.65, pK_2^{25} 13.05.** Crystallise the acid from water. [*Beilstein* **10** H 112.]

2-Iodosobenzoic acid *[304-91-6]* **$C_7H_5IO_3$, M 264.0, m >200°, 230°(dec), pK_{Est} ~2.6.** Crystallise the acid from EtOH and dry it *in vacuo*. Store at -0°. [*Beilstein* **9** H 363.]

4-Iodotoluene *[624-31-7]* **C_7H_7I, M 218.0, m 33-34°, 35°, b 211-212°/atm.** Crystallise 4-iodotoluene from EtOH and/or distil it. [*Beilstein* **5** IV 840.]

Isonitrosoacetophenone (phenylglyoxaldoxime) *[532-54-7]* **$C_8H_7NO_2$, M 149.2, m 126-128°.** Crystallise it from water. It is used for detecting Fe^{2+} which gives a blue $CHCl_3$ soluble complex. [*Beilstein* **7** IV 2132.]

Isophthalic acid (benzene-1,3-dicarboxylic acid) *[121-91-5]* **$C_8H_6O_4$, M 166.1, m 341° to 343°, 345-348°, pK_1^{25} 3.70, pK_2^{25} 4.60.** Crystallise the acid from aqueous EtOH, or H_2O (with solubilities of 0.013w/v% at ~20° and 0.22w/v% at 100°). It sublimes undecomposed. [*Beilstein* **9** IV 3292.]

4,4'-Isopropylidenediphenol (Bisphenol A, 2,2-bis[4-hydroxyphenol]propane) *[80-05-7]* **$C_{15}H_{16}O_2$, M 228.3, m 158-159°, b 220°/4mm, pK_{Est} ~10.3.** Crystallise bisphenol from acetic acid/water (1:1). It decomposes above 220° even in a vacuum. It is used for making polycarbonate bottles and leaches out slowly on heating. It is a known 'estrogenic chemical' shown to disrupt chemical signaling in the complex network of glands, hormones and cell receptors which make up the endocrine system. It causes low sperm count and damages the ecosystem by the feminisation of fish, reptiles and birds. [See **Bisphenol A** in SOURCES OF IMPURITIES in Chapter 1; *Beilstein* **6** IV 6717.]

Isopropyl *p*-nitrobenzoate *[13756-40-6]* **$C_{10}H_{11}NO_4$, M 209.2, m 105-106°, 108-110°.** Dissolve it in Et_2O,

wash it with aqueous alkali, then H_2O and dry it. Evaporate the ether and recrystallise it from EtOH to give pure material. It gives yellow crystals from petroleum ether (**m 109°, 110°**). [*Beilstein* **9** H 391, **9** II 258, **9** III 1543, **9** IV 1075.]

Isovanillin (3-hydroxy-4-methoxybenzaldehyde) *[621-59-0]* **$C_8H_8O_3$, M 152.2, m 113-114°, 116°, 117°, b 175°/14mm, 342.9°/760mm, pK^{25} 8.89.** Crystallise isovaniline from H_2O or *C_6H_6. The ***oxime*** has **m 147°**. [*Beilstein* **8** IV 1764.] It is a selective inhibitor of aldehyde oxidase.

Isoviolanthrone *[128-64-3]* **$C_{34}H_{14}O_2$, M 456.5, m 510-511°(uncorrected).** Dissolve isoviolanthrone in 98% H_2SO_4 and precipitate it by adding water to reduce the acid concentration to about 90%. It sublimes *in vacuo* to give dark green-violet needles [Parkyns & Ubblehode *J Chem Soc* 4188 *1960*, DOI: 10.1039/JR9600004188]. [*Beilstein* **7** I 465, **7** II 815, **7** III 4538, **7** IV 2747.]

Janus Red B {3-[(2-hydroxy-1-naphtholenyl)azo-2-methylphenylazo]*N,N,N*-trimethyl-benzenaminium chloride} *[2636-31-9]* **$C_{26}H_{26}ClN_5O$, M 460.0.** Crystallise the dye from EtOH/H_2O (1:1 v/v) and dry in vacuum. Store it in a dark bottle. [*Beilstein* **16** II 149.]

Ketone moschus (4-*tert*-butyl-2,6-dimethyl-3,5-dinitroacetophenone, Musk ketone) *[81-14-1]* **$C_{14}H_{18}N_2O_5$, M 294.3, m 134-137°, 137-138°.** Purify the ketone by recrystallisation from MeOH. It has a strong odour of musk and is used in perfumery. [Fuson et al. *J Org Chem* **12** 587 *1947*, DOI: 10.1021/jo01168a016; *Beilstein* **7** IV 808.]

Lapachol [2-hydroxy-3-(3-methyl-2-butenyl)-1,4-naphthalenedione, Neutral Yellow 16] *[84-79-7]* **$C_{15}H_{14}O_3$, M 242.3, CI 7549, m 141-143°, 140°.** Crystallise Lapachol from petroleum ether/EtOH, EtOH or Et_2O. [*Beilstein* **8** H 326, **8** I 644, **8** II 365, **8** III 2720.]

Leucomalachite Green $C_{23}H_{26}N_2$, *[129-73-7]* **M 330.5, m 92-93°, 100-102°, pK^{25} 6.90 (several pK's).** Crystallise it from 95% EtOH (10ml/g), then from *benzene/EtOH, and finally from petroleum ether. Its UV-VIS has λ_{max} at 623nm. [*Beilstein* **13** H 275, **13** II 89, **13** II 135, **13** III 529, **13** IV 481.]

Malachite Green (carbinol) *[510-13-4]* **$C_{23}H_{26}N_2O$, M 346.4, m 112-114°, CI 42000, pK^{24} 6.84.** The ***oxalate*** *[2437-29-8]* [*Beilstein* **8** H 326, **13** IV 2279.] is recrystallised from hot water and dried in air. The carbinol is precipitated from the oxalate (1g) in distilled water (100ml) by adding M NaOH (10ml). The precipitate is filtered off, recrystallised from 95% EtOH containing a little dissolved KOH, then washed with ether, and crystallised from petroleum ether. Dry it in a vacuum at 40°. An acid, almost colourless, solution (2 x 10^{-5}M in 6 x 10^{-5}M H_2SO_4) rapidly reverts to the coloured dye. [Swain & Hedberg *J Am Chem Soc* **72** 3373 *1950*, DOI: 10.1021/ja01164a015; *Beilstein* **13** H 243, 744.]

Mandelic acid (α-hydroxyphenylacetic acid) *[S-(+)- 17199-29-0, R-(-)- 611-71-2]* **$C_8H_8O_3$, M 152.2, m 130-133°, 133°, 133.1° (evacuated capillary), 133-133.5°, $[\alpha]_{546}^{20}$ (+) and (-) 188 (c 5, H_2O), $[\alpha]_D^{20}$ (+) and (-) 155 (c 5, H_2O) and (+) and (-) 158 (c 5, Me_2CO), pK^{25} 3.41.** Purify the mandelic acids by recrystallisation from H_2O, *C_6H_6 or $CHCl_3$. [Roger *J Chem Soc* 2168 *1932*, DOI: 10.1039/JR9320002168; Jamison & Turner *J Chem Soc* 611 *1942*, DOI: 10.1039/JR9420000611.] They have solubilities in H_2O of *ca* 11% at 25°. [Banks & Davies *J Chem Soc* 73 *1938*, DOI: 10.1039/JR9420000611.] The ***S-benzylisothiuronium salt*** has **m 180°** (from H_2O) and $[\alpha]_D^{25}$ (+) and (-) 57 (c 20, EtOH) [El Masri et al. *Biochem J* **68** 199 *1958*, DOI: 10.1042/bj0680199]. [*Beilstein* **10** IV 564.] ***Methyl R-(-)-mandelate*** *[20698-91-3]* **$C_9H_{10}O_3$, M 166.2, b 85°/1.5mm, m 56-58°, 57-58°**, is prepared by dissolving *R-(-)-mandelic acid* (10g, 0.066mol) and excess MeOH (5.3ml, 132mol) in *C_6H_6 (50ml) containing concentrated H_2SO_4 (0.1ml) and refluxed under a Dean-Stark trap while H_2O is removed azeotropically (~3 hours). The mixture is cooled, washed with aqueous saturated $NaHCO_3$ (3 x 50ml) and the

aqueous phase is extracted with Et_2O (3 x 50ml), the organic layers are combined, dried ($MgSO_4$), filtered, evaporated to dryness and the residual yellow oil is distilled in a vacuum. The distillate solidified and is reacrystallised from low boiling petroleum ether to give white crystalline ***(-)-ester*** (9.3g, 85%) with the above physical properties. [Toniolo et al. *J Org Chem* 35 6 *1970*, DOI: 10.1021/jo00826a002]
RS*-(±)-Mandelic acid** *[61-72-3]* has **m 118°, 120-121°.** Purify mandelic acid by Soxhlet extraction with *C_6H_6 (about 6ml/g) and allow the extract to crystallise. It can also be recrystallised from $CHCl_3$. The ***S*-*benzylisothiuronium salt has **m 169°** (**166°**) (from H_2O). Dry it at room temperature *in vacuo*
[*Beilstein* **10** IV 565.]

Mescaline sulfate [2-(3,4,5-trimethoxyphenyl)ethylamine sulfate] *[642-73-9, 1152-765967-42-0]* **$C_{11}H_{19}NO_7S$, M 309.3, m 181-184°, 183-184°, 186-189°, pK_{Est} ~9.7.** The salt crystallises from water with $2H_2O$ or from hot MeOH. The ***acid sulfate*** has **m 158°**. [Salomon & Bina *J Am Chem Soc* **68** 2403 *1946*, DOI: 10.1021/ja01215a509; *Beilstein* **13** I 338, **13** II 521, **13** III 2375, **13** IV 2919.] It is a halucinogen

Mesitylene (1,3,5-trimethylbenzene) *[108-67-8]* **C_9H_{12}, M 120.2, m -44.7°, b 61°/20mm, 99.0-99.8°/100mm, 166.5-167°/760mm, d_4^{20} 0.865, n_D^{25} 1.4967.** Dry it with $CaCl_2$ and distil it from Na in a glass helices-packed column. Treat it with silica gel and redistil it. *Alternative* purifications include vapour-phase chromatography, or fractional distillation followed by azeotropic distillation with 2-methoxyethanol (which is subsequently washed out with H_2O), drying and fractional distilling. More exhaustive purification uses sulfonation by dissolving in two volumes of concentrated H_2SO_4, precipitating with four volumes of concentrated HCl at 0°, washing with concentrated HCl and recrystallising from $CHCl_3$. The mesitylene sulfonic acid is hydrolysed with boiling 20% HCl and steam distilled. The separated mesitylene is dried ($MgSO_4$ or $CaSO_4$) and distilled. It can also be fractionally crystallised from the melt at low temperatures. [Adams & Hufferd *Org Synth* Coll Vol **1** 341 *1941,* DOI: 10.15227/orgsyn.002.0041; *Beilstein* **5** IV 1016.] **IRRITANT and TOXIC.**

4'-Methoxyacetophenone *[100-06-1]* **$C_9H_{10}O_2$, M 150.2, m 36° to 38°, 39°, b 139°/15mm, 152-154°/26mm, 264°/736mm.** Crystallise the ketone from diethyl ether/petroleum ether, and/or distil it under reduced pressure. The ***oxime*** has **m 86°, 87°** (from petroleum ether, v. Auwers et al. *Chem Ber* **58** 36 *1925*, DOI: 10.1002/cber.19250580109). [*Beilstein* **8** H 87, **8** I 536, **8** II 84, **8** III 277, **8** IV 340.]

4-Methoxyazobenzene *[2396-60-3]* **$C_{13}H_{12}N_2O$, M 212.3, m 54-56°, 340°/atm.** Crystallise 4-methoxyazobenzene from EtOH. [*Beilstein* **16** IV 162.]

3-Methoxybenzanthrone *[3688-79-7]* **$C_{18}H_{12}O_2$, M 274.3, m 173°.** Crystallise it from *benzene, EtOH or Me_2CO to give yellow needles. It has light fastening, photo tendering and fluorescence properties [Allen et al. *J Appl Chem & Biotechnology* **27** 269 *1977*, DOI: 10.1002/jctb.5020270140]. [*Beilstein* **8** II 239, **8** III 1629, **8** IV 1476.]

3-Methoxybenzoic acid (*m*-anisic acid) *[586-38-9]* **$C_8H_8O_3$, M 152.2, m 105° to 107°, 110°, b 170-172°/10mm, pK^{25} 4.09.** Crystallise *m*-anisic acid from H_2O (**m 109°, 110.5°**) or EtOH/water. The ***S*-*benzylisothiuronium salt*** has **m 176°** (from EtOH). [*Beilstein* **10** II 80, **10** III 244, **10** IV 316.]
4-Methoxybenzoic acid* (*p*-anisic acid)** *[100-09-4]* has **m 182° to 185°, 184.0-184.5°, b 276-280°/atm, pK^{25} 4.51.** Crystallise *p*-anisic acid from EtOH, water, EtOH/water or toluene. It sublimes above its melting point. The ***S*-*benzylisothiuronium salt has **m 189°** (from EtOH). [*Beilstein* **10** II 91, **10** III 280, **10** IV 346.] It is a tyrosinase inhibitor.

4-Methoxybenzyl chloride (anisyl chloride) *[824-94-2]* **$C_8H_9Cl_3O$, M 156.6, m -1°, b 76°/0.1mm, 95°/5mm, 110°/10mm, 117-117.5°/14mm, 117°/18mm, d_4^{20} 1.15491, n_D^{20} 1.55478.** Purify 4-anisyl chloride by fractional distillation under vacuum, and the middle fraction is redistilled at 10^{-6} mm at room temperature by intermittent cooling of the receiver in liquid N_2, and the middle fraction is collected. [Kosower & Mohammed *J Am Chem Soc* **93** 2709 *1971*, DOI: 10.1021/ja00740a021; *Beilstein* **6** IV 2137.] Useful O- and N- protective group reagent, may contain some K_2CO_3 as stabiliser. **LACHRYMATORY.**

'Methoxychlor' (1,1-bis[*p*-methoxyphenyl]-2,2,2-trichloroethane, DMDT) *[72-43-5]* **$C_{16}H_{15}Cl_3O_2$, M**

345.7, m 78-78.2°, or 86-88°. Free the insecticide from 1,1-bis(*p*-chlorophenyl)-2,2,2-trichloroethane by crystallising from EtOH. It is dimorphic and also crystallises from Et_2O/EtOH (**m 92°**). [Fritsch & Feldmann *Justus Liebigs Ann Chem* **306** 72 *1899*, DOI: 10.1002/jlac.18993060106; Smith et al. *Aust J Chem* **29** 743 *1976*, DOI: 10.1071/CH9760743; *Beilstein* **6** H 1007.]

***trans*-*p*-Methoxycinnamic acid** *[830-09-1, 943-89-5 (trans)]* **$C_{10}H_{10}O_3$, M 178.2, m 170° to 173°, 173.4-174.8°, pK^{25} 4.54.** Crystallise the acid from MeOH to constant melting point and UV spectrum. It forms liquid crystals with a crystalline to nematic phase change at 173.5°, and a nematic to isotropic phase at 190°. [*Beilstein* **10** H 928, **10** IV 1005.]

6-Methoxy-1-indanone *[13623-25-1]* **$C_{10}H_{10}O_2$, M 162.2, m 103°, 104°, 105-109°, 107-111°, b 291.7°/760mm, d 1.166.** Crystallise the yellow powder from MeOH, then sublime it at high vacuum. [*Beilstein* **8** IV 894.]

1-Methoxy-4-nitronaphthalene *[4900-63-4]* **$C_{11}H_9NO_3$, M 203.2, m 83-84°, 85°.** Purify it by chromatography on silica gel, then recrystallise it from MeOH or EtOH (yellow needles). [Hodgson & Habeshaw *J Chem Soc* 47 *1942*, DOI: 10.1039/JR9420000045; Bunce et al. *J Org Chem* **52** 4214 *1987*, DOI: 10.1021/jo00228a012; *Beilstein* **6** H 616, **6** III 2938.]

4-Methoxyphenol *[150-76-5]* **$C_7H_8O_2$, M 124.1, m 54-55°, 55-57°, b 243°/atm, pK^{25} 10.21.** Crystallise 4-methoxyphenol from *benzene, petroleum ether or H_2O, and dry it under vacuum over P_2O_5 at room temperature. Sublime it *in vacuo*. [Wolfenden et al. *J Am Chem Soc* **109** 463 *1987*, DOI: 10.1021/ja00236a026; *Beilstein* **6** IV 5717.]

α-Methoxyphenylacetic acid (*O*-methyl mandelic acid) *[*R*-(-)- 3966-32-3, *S*-(+)- 26164-26-1]* **$C_9H_{10}O_3$, M 166.2, m 62.9°, 62-65°, 65-66°, $[\alpha]_{546}^{20}$ (-) and (+) 179 (169.8°), $[\alpha]_D^{20}$ (-) and (+) 150.7 (148) (c 0.5, EtOH), pK_{Est} ~3.1.** Purify the acids by recrystallising from *C_6H_6/petroleum ether (**b** 80-100°). [Neilson & Peters *J Chem Soc* 1519 *1962*, Weizmann et al. *J Am Chem Soc* **70** 1153 *1948*, DOI: 10.1021/ja01183a082; Pirie & Smith *J Chem Soc* 338 *1932*, DOI: 10.1039/JR9320000337; NMR: Dale & Mosher *J Am Chem Soc* **95** 512 *1973*, DOI: 10.1021/ja01183a082; for resolution see Roy & Deslongchamps *Can J Chem* **63** 651 *1985*, DOI: 10.1139/v85-106; Trost et al. *J Am Chem Soc* **108** 4974 *1986*, DOI: 10.1021/ja00276a044.] The ***racemic mixture*** *[7021-09-2]* has **m 72°, b 121-122°/0.4mm, 165°/18mm** (from petroleum ether) [Braun et al. *Chem Ber* **63** 2847 *1930*, DOI: 10.1002/cber.19300631027]. [*Beilstein* **10** IV 566.]

2-Methoxyphenylacetic acid *[93-25-4]* **$C_9H_{10}O_3$, M 166.2, m 124-125°, pK_{Est} ~4.4.** Crystallise the acid from H_2O, EtOH or aqueous EtOH, petroleum ether/Et_2O and dry it in a vacuum desiccator over Sicapent. The ***amide*** has **m 131°** (from EtOH). [*Beilstein* **10** H 188, **10** III 422, **10** IV 536.]

3-Methoxyphenylacetic acid *[1798-09-0]* has **m 66-67°, 68-69°, 71.0-71.2°, pK_{Est} ~4.3.** Crystallise the acid from H_2O, or aqueous EtOH. The ***S-benzylisothiuronium salt*** has **m 160-161°** (from EtOH). [*Beilstein* **10** I 82, **10** III 428, **10** IV 541.]

4-Methoxyphenylacetic acid* (homoanisic acid)** *[104-01-8]* has **m 85-87°, b 138-140°/2-3mm, pK^{25} 4.36.** Crystallise the acid from EtOH/water, EtOAc/petroleum ether (**m 87°**) or *C_6H_6/petroleum ether (**m 84-86°**). [*Beilstein* **10** III 431, **10** IV 544.] The ***acid chloride *[4693-91-8]* has **M 184.6, b 143°/10mm, d_4^{25} 1.208.** [*Beilstein* **10** III 434.]

N*-(*p*-Methoxyphenyl)-*p*-phenylenediamine** *[101-64-4]* **$C_{13}H_{14}N_2O$, M 214.3, m 102°, b 200°/2mm, 238°/12mm, pK^{25} 6.6 (5.9).** Crystallise the diamine from ligroin or *C_6H_6/petroleum ether (**m 99-100°**). The ***picrate has **m 164°** (from EtOH). [*Beilstein* **13** III 1161, **13** IV 1243.]

α-Methoxy-α-trifluoromethylphenylacetic acid (MTPA, Mosher's acid) *[*R*-(+)- 20445-31-2, *S*-(-)- 17257-71-5]* **$C_{10}H_9F_3O_3$, M 234.2, m 43-45°, 95-97°/0.05mm, 90°/0.1mm, 105-107°/1mm, $[\alpha]_{546}^{20}$ (+) and (-) 87, $[\alpha]_D^{20}$ (+) and (-) 73 (c 2, MeOH), pK_{Est} ~2.5.** A likely impurity is phenylethylamine from the resolution. Dissolve the acid in Et_2O/*benzene (3:1), wash with 0.5N H_2SO_4, then water, dry over magnesium sulfate, filter, evaporate and distil it. Store in a sealed container under Ar or N_2 in a cool place. [Dale et al. *J Org Chem*

34 2543 *1969*, DOI: 10.1021/jo01261a013, *J Am Chem Soc* **95** 512 *1973*, DOI: 10.1021/ja00783a034.] The acid, by conversion to the acid chloride, see below) is a useful derivatising reagent for determination of enantiomeric excess of chiral alcohols and amines by NMR [George & Sudalai *Tetrahedron Asymmetry* **18** 975 *2007*, DOI: 10.1016/j.tetasy.2007.04.008; De Luca et al. *J Org Chem* **72** 3955 *2007*, DOI: 10.1021/jo070142c]. The ***(±)-acid*** *[81655-41-6]* **$C_{10}H_9F_3O_3$, M 234.2,** has **m 41-46°** (from aquous MeOH) and **b 95-98°/0.05mm**.

α-Methoxy-α-trifluoromethylphenylacetyl chloride *[R-(-)- 39637-99-5, S-(+)- 20445-33-4]* **$C_{10}H_8ClF_3O_2$, M 252.6, b 54-56°/1mm, 213-214°/760mm, d $_4^{20}$ 1.353, n $_D^{20}$ 1.468, [α] $_{546}^{20}$ (-) and (+) 167, [α] $_D^{20}$ (-) and (+) 137 (c 4, CCl_4), [α] $_D^{24}$ (-) and (+) 10.0 (neat).** The most likely impurity is the free acid due to hydrolysis and should be checked by IR. If free from acid, then distil, taking care to keep moisture out of the apparatus. Otherwise add $SOCl_2$ and reflux for 5 hours then distil it. ***Note*** that shorter reflux times result in a higher boiling fraction (**b 130-155°/1mm**) which has been identified as the anhydride. Store under argon or N_2 in a sealed container (in aliquots) at –20°. [Dale et al. *J Org Chem* **34** 2543 *1969*, DOI: 10.1021/jo01261a013 for enantiomeric purity see Dale & Mosher *J Am Chem Soc* **95** 512 *1973*, DOI: 10.1021/ja00783a034.] See previous entry for use in determining enantiomeric excess of chiral alcohols, thiols and amines.

N*-Methylacetanilide** *[579-10-2]* **$C_9H_{11}NO$, M 149.2, m 101°, 102-104°, b 145-146°/30mm, 225°/760mm.** Crystallise the anilide from water, ether, petroleum ether (b 80-100°) or *C_6H_6 (**m 105°**). The ***BF_3 salt has **m 114°** (from Me_2CO/diisopropyl ether). [*Beilstein* **12** III 465, **12** IV 378.]

4-Methylacetophenone *[122-00-9]* **$C_9H_{10}O$, M 134.2, m 22-24°, b 93.5°/7mm, 110°/14mm, d $_4^{20}$ 1.000, n $_4^{20}$ 1.5335.** Impurities, including the *o*- and *m*-isomers, are removed by forming the ***semicarbazone*** (**m 212-213.5°**) which, after repeated crystallisation, is hydrolysed to the ketone. [Brown & Marino *J Am Chem Soc* **84** 1236 *1962*, DOI: 10.1021/ja00866a034.] It can also be purified by distillation under reduced pressure, followed by low temperature crystallisation from isopentane. The ***oxime*** has **m 87-88°** (from MeOH then cyclohexane Pearson & Ball *J Org Chem* **14** 125 *1949*, DOI: 10.1021/jo01153a018). [*Beilstein* **7** H 307, **7** I 154, **7** II 238, **7** III 1060, **7** IV 701.]

[Cosulich & Smith *J Am Chem Soc* **70** 1923 *1948*, DOI: 10.1021/ja01185a081; *Beilstein* **14** H 323, **14** III 895, **14** IV 1015.]

3-(Methylamino)benzoic acid *[51524-84-6]* **$C_8H_9NO_2$, M 151.1, m 129°, pK $_1^{25}$ 3.08, pK $_2^{25}$ 5.10.** Crystallise the acid from H_2O (needles), petroleum ether (plates) or $CHCl_3$ (**m** 127°). The ***hydrochloride*** has **m 244°** (plates from EtOH). [*Beilstein* **14** H 391, **14** I 559.]

4-Methylaminophenol hemisulfate (Photol, Metol) *[55-55-0]* **$C_7H_{11}NO_5S$, M 344.4, m 260°(dec), 261-263°(dec), pK^{25} 5.9.** Crystallise this photographic developer from H_2O (needles **m 250-260°**) (its solubility is 5% at 20° and 17% at 100°) or MeOH. It is used for determining Ag. [Palit et al. *Indian J Chem, Sect B* **28** 64 *1989*.]

N*-Methylaniline** *[100-61-8]* **C_7H_9N, M 107.2, b 57°/4mm, 81-82°/14mm, d $_4^{20}$ 0.985, n $_D^{20}$ 1.570, pK^{25} 4.56.** Dry it with KOH pellets and fractionally distil it under vacuum. Acetylate, and the ***acetyl derivative is recrystallised to constant melting point (**m 101-102°**), then hydrolysed with aqueous HCl and distilled from zinc dust under reduced pressure. [Hammond & Parks *J Am Chem Soc* **77** 340 *1955*, DOI: 10.1021/ja01607a029; *Beilstein* **12** IV 241.] ***N-Methylaniline hydrochloride*** *[2739-12-0]* **$C_7H_9N.HCl$, M 143.7,** has **m 123.0-123.1°.** Crystallise the salt from dry *benzene/$CHCl_3$ and dry under vacuum. [*Beilstein* **12** IV 241.]

Methyl *p*-anisate *[121-98-2]* **$C_9H_{10}O_3$, M 166.2, m 48°, 49° to 51°, b 123.8°/12mm, 244-245°/760mm.** Distil the ester and/or crystallise it from EtOH. [*Beilstein* **10** H 159, **10** III 297, **10** IV 360.]

4-Methyl anisole *[104-93-8, 3494-45-9]* **$C_8H_{10}O$, M 122.2, b 56.2°/9mm, 67°/20mm, 175-176°/760mm, d_{15}^{15} 0.9757, n_D^{20} 1.512.** Dissolve 4-methyl anisole in diethyl ether, wash it with M NaOH, water, dry (Na_2CO_3), evaporate and distil it under vacuum. The ***picrate*** has **m 103°** (from aqueous EtOH). [*Beilstein* **6** IV 2098.]

2-Methylanthracene *[613-12-7]* **$C_{15}H_{12}$, M 192.3, m 204-206°.** Chromatograph it on silica gel with cyclohexane as eluent and then recrystallise it from EtOH [Werst et al. *J Am Chem Soc* **109** 32 *1987*, DOI: 10.1021/ja00235a005]. [*Beilstein* **5** IV 2311.]
9-Methylanthracene *[779-02-2]* has **m 77-79°, b 196-197°/12mm, d_4^{24} 1.066.** Chromatograph it on silica gel with cyclohexane as eluent and recrystallise it from EtOH [Werst et al. *J Am Chem Soc* **109** 32 *1987*, DOI: 10.1021/ja00235a005]. [*Beilstein* **5** IV 2312.]

2-Methylanthraquinone *[84-54-8]* **$C_{15}H_{10}O_2$, M 222.3, m 170° to 173°, 176°, b 236-238°/10mm.** Crystallise the quinone from EtOH, then sublime it. It has λ_{max} at 257, 275 and 330nm (EtOH). [Hersberg & Fieser *J Am Chem Soc* **63** 2562 *1941*, DOI: 10.1021/ja01855a005; *Beilstein* **7** H 809, **7** III 4104, **7** IV 2574.]

Methylarenes (see also pentamethyl- and hexamethyl- benzenes). Recrystallise them from EtOH and sublime them in a vacuum [Schlesener et al. *J Am Chem Soc* **106** 7472 *1984*, DOI: 10.1021/ja00336a029].

Methyl benzoate *[93-58-3]* **$C_8H_8O_2$, M 136.2, m -12°, b 104-105°/39mm, 199.5°/760mm, d_4^{20} 1.087, n^{15} 1.52049, n_D^{24} 1.51701, pK^{20} -8.11, -6.51 (H_o scale, aqueous H_2SO_4).** Wash the ester with dilute aqueous $NaHCO_3$, then water, dry with Na_2SO_4 and fractionally distil it in a vacuum. [*Beilstein* **9** IV 283.]

4-Methylbenzophenone *[134-84-9]* **$C_{14}H_{12}O$, M 196.3, m 56.-57°, 57°, b 154-155°/3mm, 183-184°/15mm, 277-281°/3mm, d^{20} 0.9926.** Crystallise the ketone from MeOH, Et_2O (**m 58-59°**) or petroleum ether. The ***cis-oxime*** has **m 154°(153-156°)** (from EtOH), and the ***trans-oxime*** has **m 114-116°** (from petroleum ether). [*Beilstein* **7** H 440, **7** III 2127, **7** IV 1403.]

Methyl-1,4-benzoquinone (*p*-toluoquinone) *[553-97-9]* **$C_7H_6O_2$, M 122.1, m 66-67°, 68-69°.** Crystallise *p*-toluoquinone from heptane or EtOH, dry rapidly (vacuum/P_2O_5) and store it in a vacuum. [*Beilstein* **7** IV 2088.]

Methyl benzoylformate (methyl phenylglyoxalate) *[15206-55-0]* **$C_9H_8O_3$, M 164.2, m 246-248°, d_D^{25} 1.155, n_D^{20} 1.526.** Purify the ester by radial chromatography (diethyl ether/hexane, 1:1), and dry it at 110-112°/6mm. [Meyers & Oppenlaender *J Am Chem Soc* **108** 1989 *1986*, DOI: 10.1021/ja00268a043; *Beilstein* **10** IV 2738.]

2-Methyl-3,4-benzphenanthrene (2-methylbenzo[*c*]phenanthrene) *[652-04-0]* **$C_{19}H_{14}$, M 242.3, m 70°, 80.6-81.4°, b 200°/0.4mm.** Crystallise it from EtOH (**m 81-82.5°**). The ***picrate*** has **m 118-118.5°** (yellow needles from MeOH). [Mukerji & Rao *Nature* **168** 1041 *1951*, DOI:10.1038/1681041a0; *Beilstein* **5** III 2394, **5** IV 2570.] **POTENT CARCINOGEN.**

R*-(+)-α-Methylbenzylamine** *[R(+) 3886-69-9, RS(±) 618-36-0]* **$C_8H_{11}N$, M 121.2, b 187-188°/atm, $[\alpha]_{546}^{20}$ +35 (c 10, EtOH), $[\alpha]_D^{25}$ +39.7 (neat), pK 9.08 (for *RS*).** Dissolve the amine in toluene, dry over NaOH and distil; fraction boiling at 187-188°/atm is collected. Store it under N_2 to avoid forming the carbamate and urea. Similarly for the ***S*-(-) *enantiomer *[2627-86-3]*. [For the optical resolution of phenethylamine see: Ingersoll *Org Synth* Coll Vol **2** 506 *1943*, DOI: 10.15227/orgsyn.017.0080; *Beilstein* **12** IV 2424, 2425.] The **(±)-*racemic base*** purified in the same manner has **b 185°/756mm**; and can be fractionated under reduced pressure, **b 80-81°/18mm, d_4^{25} 0.94, n_D^{20} 1.526.** [Synthesis of *dl*-: Ingersoll *Org Synth* Coll Vol **2** 503 *1943*, DOI: 10.15227/ orgsyn.017.0076; Robinson & Snyder *Org Synth* Coll Vol **3** 717 *1955*, DOI: 10.15227/orgsyn.023.0068]. [*Beilstein* **12** IV 2452.]

4-Methylbenzyl chloride *[104-82-5]* **C_8H_9Cl, M 140.6, m 4-6°, b 80°/2mm, 98-101°/27mm, 199-201°/atm, d_4^{20} 1.085, n_D^{20} 1.543.** Dry the chloride with $CaSO_4$ and fractionally distil it under vacuum. [*Beilstein* **5** H 384, **5** III 854, **5** IV 966.] **Lachrymatory**, handle with care.

Methyl 2-bromobenzoate *[610-94-6]* **$C_8H_7BrO_2$, M 215.1, b 131.4-132°/16mm, 234-244°/760mm, 252°/**

atm, d_4^{24} 1.532, n_D^{20} 1.559. A solution of the ester in ether is washed with 10% aqueous Na_2CO_3, water, then dried and distilled. [*Beilstein* **9** H 348, **9** III 1385, **9** IV 1012.]

Methyl 4-bromobenzoate *[619-42-1]* **$C_8H_7BrO_2$, M 215.1, m 77° to 81°, 79.5-80.5°, d 1.689.** Crystallise the ester from MeOH. EtOH (**m 81°**, also 80.5°, 79.5°) or *C_6H_6/petroleum ether (**m 78-79°**). [*Beilstein* **9** H 352, **9** III 1405, **9** IV 1017.]

(±)-3'-Methyl-1,2-cyclopentenophenanthrene (16,17-dihydro-17-methyl-15*H*-cyclopenta-[*a*]–phenanthrene *[549-38-2]* **$C_{18}H_{16}$, M 232.3, m 126-127°.** Crystallise it from AcOH or EtOH (plates, **m 125.5-126°**). The ***picrate*** has **m 130-131°** (orange-red needles from EtOH). [Tatta & Bardhan *J Chem Soc (C)* 893 *1968*, DOI: 10.1039/J39680000893; *Beilstein* **5** IV 2433.]

Methyl 2,4-dichlorophenoxyacetate *[1928-38-7]* **$C_9H_8Cl_2O_3$, M 235.1, m 43°, b 119°/11mm.** Crystallise the herbicide ester from MeOH. [Branch & Jones *J Chem Soc* 2921 *1955*, DOI: 10.1039/JR9550002921; *Beilstein* **6** III 705, **6** IV 909.]

3,4-Methylenedioxyaniline *[14268-66-7]* **$C_7H_7NO_2$, M 137.1, m 39° to 41°, 44.5-45.5°, 45-46°, b 108°/1mm, 144°/14mm, 156°/30mm, pK_{Est} ~3.8.** Crystallise the base from petroleum ether and/or distil it in a vacuum. The ***hydrochloride*** has **m 198°(dec)**. [Sonn & Benirschke *Chem Ber* **54** 1730 *1921*, DOI: 10.1002/cber.19210540808; *Beilstein* **19** H 328, **19** II 341, **19** III/IV 4056.]

***trans*-3,4-Methylenedioxycinnamic acid** *[2373-80-0]* **$C_{10}H_8O_4$, M 192.2, m 243-244°(dec), pK_{Est} ~4.6.** Crystallise the acid from glacial AcOH, EtOH (**m 247°**) or aqueous EtOH (**m 240-242°**), and it has **m 242°** after sublimation. [*Beilstein* **19** H 278, **19** II 299, **19** III/IV 3548.]

5,5'-Methylenedisalicylic acid *[122-25-8; 27496-82-2]* **$C_{15}H_{12}O_6$, M 288.2, m 238°(dec), 242°, 243.5°, b 569.6°/atm.** Crystallise the acid from Me_2CO, *C_6H_6 or $CHCl_3$/MeOH (**m 268-268°**). It has λ_{max} at 312nm (ε 7530)in EtOH. [Cushman & Kanamathareddy *Tetrahedron* **46** 1491 *1990*, DOI: 10.1016/S0040-4020(01)81957-8.]

N*-Methylephedrine (2-dimethylamino-1-phenylpropanol)** *[1*S*,2*R*-(+)- 42151-56-4, 1*R*,2*S*-(-)- 552-79-4]* **$C_{10}H_{15}NO_3$, M 179.3, m 85-86°, 87-87.5°, 90°, b 115°/2mm, $[\alpha]_{546}^{20}$ (+) and (-) 35, $[\alpha]_D^{20}$ (+) and (-) 30 (c 4.5, MeOH), pK^{26} 9.22.** *N*-Methylephedrine has been recrystallised from Et_2O, petroleum ether, of aqueous EtOH or aqueous MeOH and has been distilled under reduced pressure. [Smith *J Chem Soc* 2056 *1927*, DOI: 10.1039/JR9270002056; Tanaka & Sugawa *Yakugaku Zasshi (J Pharm Soc Japan)* ***72 1548 *1952* (*Chem Abstr* **47** 8682 *1953*), Takamatsu *Yakugaku Zasshi (J Pharm Soc Japan)* **76** 1227 *1956*, *Chem Abstr* **51** 4304 *1957*.] The ***hydrochloride*** has **m 192-193°** and $[\alpha]_D^{20}$ +30° (c 5,H_2O) [Prelog & Häfliger *Chim Acta* **33** 2021 *1950*, DOI: 10.1002/hlca.19500330708]. [*Beilstein* **13** IV 1884.]

Methyl gallate *[99-24-1]* **$C_8H_8O_5$, M 184.2, m 201°, 202°, 203°, 198-203°, b 450°/atm.** Crystallise the gallate ester from MeOH, or aqueous MeOH, usually solvated but can be readily de-solvated. [*Beilstein* **10** IV 1998.]

Methyl Green *[82-94-0, 7114-03-6 ($ZnCl_2$ salt)]* **$C_{27}H_{35}BrClN_3$. $ZnCl_2$, M 517.0 (without Zn), 653.2, m >200°(dec), >300°(dec).** Crystallise the dye (violet or green crystals) from hot water. [*Beilstein* **13** IV 2286.] It is an indicator which is yellow at pH 0.2 and blue at 1.8. It is a biological stain, e.g. for DNA and amyloid.

Methyl 4-hydroxybenzoate (methyl paraben) *[99-76-3]* **$C_8H_8O_3$, M 152.2, m 125°, 127.5°, 185°, b 270°/atm with dec, pK_{Est} ~9.3.** Fractionally crystallise the ester from its melt, and recrystallise it from *benzene, then from *benzene/MeOH and dry it over $CaCl_2$ in a vacuum desiccator. Its solubility in H_2O at 25° is ~0.3w/v%. It is a food additive. [*Beilstein* **10** IV 360.]

Methyl 3-hydroxy-2-naphthoate *[883-99-8]* **$C_{12}H_{10}O_3$, M 202.2, m 73-74°, 76° to 78°, b 205-207°/atm, pK_{Est} ~9.0.** Crystallise the ester from MeOH (charcoal) containing a little water. [*Beilstein* **10** IV 1186.]

3-Methylmercaptoaniline *[1783-81-9]* **C_7H_9NS, M 139.2, b 101.5-102.5°/0.3mm, 163-165°/16mm, d_4^{20} 1.147, n_D^{20} 1.641, pK^{25} 4.05.** Purify the aniline by fractional distillation in an inert atmostphere. It has UV max at 226 and 300nm. [Bordwell & Cooper *J Am Chem Soc* **74** 1058 *1952*, DOI: 10.1021/ja01124a057.] The *N-**acetyl*** derivative has **m 78-78.5°** (from aqueous EtOH). The ***hydrochloride*** has **m 260-261°** (aqueous EtOH/HCl) or **m** 225-227° (EtOH/Et_2O). [*Beilstein* **13** H 533, **13** III 1221, **13** IV 1289.]
4-Methylmercaptoaniline *[104-96-1]* has **b 140°/15mm, 151°/25mm, 155°/23mm, d_4^{20} 1.137, n_D^{20} 1.639, pK^{25} 4.40.** Purify the aniline by fractional distillation in an inert atmosphere. The ***hydrochloride*** has **m 242-246°** (from aqueous EtOH/HCl). The ***sulfone*** has **m 137°** (from H_2O), pK^{25} 1.48, and the ***sulfone hydrochloride*** has **m 260-261°** (from aqueous EtOH/HCl). [Lumbroso & Passerini *Bull Soc Chim Fr* 311 *1957*, Mangini & Passerini *J Chem Soc* 4954 *1956*, DOI: 10.1039/JR9560004954; *Beilstein* **13** H 533, **13** II 297, **13** IV 1221.]

1-Methylnaphthalene *[90-12-0]* **$C_{11}H_{10}$, M 142.2, m -22°, -30°, b 244.6°/atm. d_4^{20} 1.021, n_D^{20} 1.6108.** Dry 1-methylnaphthalene for several days with $CaCl_2$ or by prolonged refluxing with BaO. Fractionally distil it through a glass helices-packed column from sodium. Purify it further by solution in MeOH and precipitation of its ***picrate complex*** by adding to a saturated solution of picric acid in MeOH. The picrate, after crystallisation to constant melting point (**m 140-141°**) from MeOH, is dissolved in *benzene and extracted with aqueous 10% LiOH until the extract is colourless. Evaporation of the *benzene solution under vacuum gives 1-methylnaphthalene [Kloetzel & Herzog *J Am Chem Soc* **72** 1991 *1950*, DOI: 10.1021/ja01161a032]. However, neither the picrate nor the styphnate complexes satisfactorily separate 1- and 2- methylnaphthalenes. To achieve this, 2-methylnaphthalene (10.7g) in 95% EtOH (50ml) has been precipitated with 1,3,5-trinitrobenzene (7.8g) and this complex has been crystallised from MeOH to **m 153-153.5°** (**m** of the 2-methyl isomer is **124°**). [*Alternatively*, 2,4,7-trinitrofluorenone in hot glacial acetic acid could be used, and the derivative (**m 163-164°**) is recrystallised from glacial acetic acid]. The 1-methylnaphthalene is regenerated by passing a solution of the complex in dry *benzene through a 15-in column of activated alumina and washing with *benzene/petroleum ether (b 35-60°) until the coloured band of the nitro compound had moved down near the end of the column. The complex can also be decomposed using tin and acetic-hydrochloric acids, followed by extraction with diethyl ether and *benzene; the extracts are washed successively with dilute HCl, strongly alkaline sodium hypophosphite, water, dilute HCl and water. [Soffer & Stewart *J Am Chem Soc* **74** 567 *1952*, DOI: 10.1021/ja01122a518.] It can be freed from anthracene by zone melting [*Beilstein* **5** IV 1687.]
2-Methylnaphthalene *[91-57-6]* has **m 34.7-34.9°, 34° to 36°, b 129-130°/25mm, 141-142°/atm, d^{25} 1.00.** Fractionally crystallise repeatedly from its melt, then fractionally distil under reduced pressure. It has been crystallised from *benzene and dried under vacuum in an Abderhalden pistol. It can be purified *via* its ***picrate*** (**m 114-115°**) or better *via* the ***1,3,5-trinitrobenzene complex*** as for 1-methylnaphthalene (above). [*Beilstein* **5** IV 1693.]

6-Methyl-2-naphthol *[17579-79-2]* **$C_{11}H_{10}O$, M 158.2, m 128-129°, b 177.5-178°/15mm, pK_{Est} ~9.8.** Crystallise the naphthol from EtOH or ligroin. Sublime it *in vacuo*. [*Beilstein* **6** II 618, **6** III 3028.]
7-Methyl-2-naphthol *[26593-50-0]* has **m 118°, b 312°/760mm, d 1.1, pK_{Est} ~9.7.** Crystallise the naphthol from EtOH or ligroin. It has **m 118°** after sublimation *in vacuo*. [Halsall & Thomas *J Chem Soc* 2431 *1956*, DOI: 10.1039/JR9560002431; *Beilstein* **6** IV 3029.]

Methyl 1-naphthyl ether (1-methoxynaphthalene) *[2216-69-5]* **$C_{11}H_{10}O$, M 158.2, b 90-91°/2mm, 135-137°/12mm, d_4^{20} 1.095, n_D^{20} 1.6210.** Steam distil the ether from alkaline solution. The distillate is extracted with Et_2O. After drying ($MgSO_4$) the extract and evaporating Et_2O, the methyl naphthyl ether is fractionated under reduced pressure from CaH_2. The ***picrate*** has **m 129.5-130.5°** (from EtOH). [*Beilstein* **6** IV 4211.]
Methyl 2-naphthyl ether **(2-methoxynaphthalene, Nerolin)** *[93-04-9]* has **m 70-72°, 73.0- 73.6°, b 138°/10mm 273°/760mm.** Fractionally distil the ether under vacuum. Crystallise it from absolute EtOH, aqueous EtOH, *C_6H_6, petroleum ether or *n*-heptane, and dry it under vacuum in an Abderhalden pistol or distil it *in vacuo*. The ***picrate*** has **m 118°** (from EtOH or $CHCl_3$). [Kikuchi et al. *J Phys Chem* **91** 574 *1987*, DOI: 10.1021/j100287a017; Hiers & Hager *Org Synth* Coll Vol **I** 58 *1941*, DOI: 10.15227/orgsyn.009.0012; *Beilstein* **6** III 2969, **6** IV 4257.]

2-Methyl-3-nitroaniline *[603-83-8]* **$C_7H_8N_2O_2$, M 152.2 m 88° to 90°, 92°, b 305°/760mm, pK_{Est} ~ 2.3.**

Crystallise the yellow nitrotoluidine from EtOH or *C_6H_6. It is steam volatile. The ***acetyl*** derivative crystallises from aqueous EtOH and has **m 164°**. [*Beilstein* **12** I 395, **12** II 460, **12** III 1944, **2** IV 1811.]
2-Methyl-4-nitroaniline *[99-52-5]* has **m 129°, 130° to 132°, pK_{25} 0.93.** Crystallise the nitrotoluidine from EtOH. The ***acetyl*** and ***benzoyl*** derivatives have **m 200°** and **174°** (EtOH) respectively. [*Beilstein* **12** IV 1809.]
2-Methyl-5-nitroaniline *[99-55-8]* has **m 103° to 106°, 109°, pK^{25} 2.35.** Acetylate the aniline, and the acetyl derivative is crystallised to constant melting point; then hydrolyse it with 70% H_2SO_4 and the free base is regenerated by treatment with NH_3 [Bevan et al. *J Chem Soc* 4284 *1956*, DOI: 10.1039/JR9560004284]. [*Beilstein* **12** H 844. **12** IV 1807.]
4-Methyl-3-nitroaniline *[119-32-4]* has **m 74° to 77°, 81.5°, d 1.312, pK^{25} 3.02.** Crystallise the aniline from hot water (charcoal), then ethanol and dry it in a vacuum desiccator. [*Beilstein* **12** H 966.]
N-Methyl-4-nitroaniline *[100-15-2]* has **m 149° to 151°, 152.2°, 152-154°, pK^{25} 0.55.** Crystallise the aniline from aqueous EtOH. [*Beilstein* **12** H 714.]

2-Methyl-3-nitroanisole *[4837-88-1]* **$C_8H_9N_2O_3$, M 176.2, m 54-56°.** 2-Methyl-5-nitroanisole crystallises from MeOH (yellow needles) and sublimes *in vacuo*. [Kuffner et al. *Monatsh Chem* **91** 1152 *1960*, DOI: 10.1007/BF00899842; *Beilstein* **6** I 178.]

Methyl 3-nitrobenzoate *[618-95-1]* **$C_8H_7NO_4$, M 181.2, m 76°, 78°, 79-80°, b 279°/atm.** Crystallise the benzoate from MeOH (1g/ml). [*Beilstein* **9** H 378, **9** I 153, **9** II 248, **9** III 1493, **9** IV 1056.]
Methyl 4-nitrobenzoate *[619-50-1]* has **m 95-95.5°, 96°, 95-97°.** Dissolve the benzoate in diethyl ether, then wash it with aqueous alkali; the ether is evaporated and the ester is recrystallised from EtOH. [*Beilstein* **9** H 390, **9** IV 1074.]

3-Methyl-2-nitrobenzoic acid *[5437-38-7]* **$C_8H_7NO_4$, M 181.2, m 219-222°, 220-222.5°, 223°, b 340°/atm, d^{25} 1.393g/ml, pK^{20} 2.91 (1% aqueous EtOH).** Recrystallise it from EtOH or hot H_2O (solubility at 22° is 0.1w/v%). The ***methyl ester*** has **m 74°** (from MeOH), and the ***amide*** [60310-07-8] **M 180.1,** has **m 192°** (needles from H_2O, prisms from EtOH). [*Beilstein* **9** H 480, **9** IV 1722.]
4-Methyl-3-nitrobenzoic acid **(3-nitro-*p*-toluic acid)** *[96-98-0]* has **m 187-190°, 190-191°, pK^{20} 3.62 (1% aqueous EtOH).** Recrystallise the acid from EtOH. The ***S-benzylisothiuronium salt*** has **m 167-168°** (EtOH). The ***acid chloride*** *[10397-30-5]* has **m 20-21°, b 185°/36mm**, and the ***methyl ester*** *[7356-11-8]* crystallises as pale yellow needles from MeOH with **m 51°**. [*Beilstein* **9** H 502, **9** II 334, **9** III 2359, **9** IV 1746.]

N*-Methyl-4-nitrosoaniline** *[10595-51-4]* **$C_7H_8N_2O$, M 136.2, m 114-115°, 118°, pK_{Est} ~1.0.** Crystallise it from *C_6H_6. The ***picrate has **m 166°(dec)** (from MeOH or $CHCl_3$). [*Beilstein* **7** III 3370, **12** IV 1228.]

4-Methylphenylacetic acid (*p*-tolylacetic acid) *[622-47-9]* **$C_9H_{10}O_2$, M 150.2, m 88° to 92°, 90-93°, 94°, b 265-267°/atm, pK^{25} 4.37.** Crystallise the acid from heptane or water. [*Beilstein* **9** IV 1795.]

1-Methyl-1-phenylhydrazine sulfate *[33008-18-3]* **$C_7H_{12}N_2O_4S$, M 218.2, pK^{25} 4.98 (free base).** Crystallise the sulfate from hot H_2O by addition of hot EtOH. [*Beilstein* **15** IV 53 for free base.]

***N*-Methylphthalimide** *[550-44-7]* **$C_9H_7NO_2$, M 161.1, m 129° to 132°, 133.8°.** Recrystallise the imide from absolute EtOH or AcOH (**m 134°**). The IR has ν_{max} at 1780 and 1380cm^{-1}. [*Beilstein* **21** III/IV 5030.]

Methyl Red (4-dimethylaminoazobenzene-2'-carboxylic acid) *[493-52-7]* **$C_{15}H_{15}N_3O_2$, M 269.3, m 179-180°, 181-182°, CI 13020, pK_1^{25} 2.30, pK_2^{25} 4.82, pK_3^{25} 9.5.** The acid is extracted with boiling toluene using a Soxhlet apparatus. The crystals which separate on slow cooling to room temperature are filtered off, washed with a little toluene and recrystallised from glacial acetic acid, *benzene or toluene followed by pyridine/water. *Alternatively*, dissolve it in aqueous 5% $NaHCO_3$ solution, and precipitate it from a hot solution by dropwise addition of aqueous HCl. Repeat this until the extinction coefficients do not increase at λ_{max} at 410nm (H_2O). It is a titration indicator which is red at pH 4.4 an below, and yellow at pH at 6.2 and above (see pKa values). It is easily reduced to a colourless product. [Clarke & Kirner *Org Synth* Coll Vol **1** 374 *1941*, DOI: 10.15227/orgsyn.002.0047; *Beilstein* **16** IV 504.]

Methyl salicylate (methyl 2-hydroxybenzoate, oil of winter green) *[119-36-8]* **$C_8H_8O_3$, M 152.2, m -8.6°, b 79°/6mm, 104-105°/14mm, 223.3°/atm, d_4^{20} 1.1149, n_D^{20} 1.5380, pK^{25} 10.19.** Dilute the ester with Et_2O, wash with saturated $NaHCO_3$ (it may effervesce due to the presence of free acid), brine, dry $MgSO_4$, filter, evaporate and distil it. Its solubility is 1g/1.5L of H_2O. The ***benzoyl*** derivative has **m 92°** (**b 270-280°/120mm**), and the ***3,5-dinitrobenzoate*** has **m 107.5°**, and the ***3,5-dinitrocarbamoyl*** derivative has **m 180-181°**. [Hallas *J Chem Soc* 5737 p5770 *1965*, DOI: 10.1039/JR9650005737; *Beilstein* **10** IV 143.] It has a fragrant odour and is used in foods and beverages, and in liniments.

α-Methylstyrene (monomer, 2-phenylpropene) *[98-83-9]* **C_9H_{10}, M 118.2, m -24°, b 57°/15mm, 165-169°/atm, 172-173°/atm, d_4^{20} 0.910, n_D^{20} 1.5368.** Wash the monomer three times with aqueous 10% NaOH (to remove inhibitors such as quinol), then six times with distilled water, dry with $CaCl_2$ and distil it under vacuum. The distillate is kept under nitrogen, in the cold, and redistilled if kept for more than 48 hours before use. It can also be dried with CaH_2. Add stabiliser (e.g. 4-*tert*-butylcatechol) if it is to be stored for long periods. [*Beilstein* **5** IV 1364.]

***trans*-β-Methylstyrene (1-phenylpropene)** *[873-66-5]* **C_9H_{10}, M 118.2, b 64-65°/10mm, 176°/760mm, d_4^{20} 0.910, n_D^{20} 1.5496.** Distil it under N_2 from powdered NaOH through a Vigreux column, and pass it through activated neutral alumina before use [Wong et al. *J Am Chem Soc* **109** 3428 *1987*, DOI: 10.1021/ja00245a039]. Store at ~2-8°. [*Beilstein* **5** III 1184, **5** IV 1359.]

4-Methylstyrene *[622-97-9]* **C_9H_{10}, M 118.2, b 60°/12mm, 106°/10mm, d_4^{20} 0.9173, n_D^{20} 1.542.** Purify it as the above styrenes and add a small amount of antioxidant if it is to be stored. It has UV in EtOH at λ_{max} at 285nm (log ε 3.07), and in EtOH + HCl 295nm (log ε 2.84) and 252nm (log ε 4.23). [Schwartzman & Corson *J Am Chem Soc* **78** 322 *1956*, DOI: 10.1021/ja01583a020; Joy & Orchin *J Am Chem Soc* **81** 305 *1959*, DOI: 10.1021/ja01511a012; Buck et al. *J Chem Soc* 2377 *1949*, DOI: 10.1039/JR9490002377; *Beilstein* **5** IV 1369.]

Methyl Violet 2B [4,4'-bis-(diethylamino)-4"-methyliminotriphenylmethyl hydrochloride) *[8004-87-3]* **$C_{24}H_{28}ClN_3$, M 394.0, m 137°(dec), CI 42535, λ_{max} ~580nm.** Crystallise the dye from EtOH by precipitation with Et_2O during cooling in an ice-bath. Filter it off and dry it at 105°. [*Beilstein* **13** H 755, **13** IV 2283.] It is a biological stain which, with iodine, is used for identifying chromosomes, chromatin, nucleoli and amyloid.

Michler's ketone [4,4'-bis(dimethylamino)benzophenone] *[90-94-8]* **$C_{17}H_{20}N_2O$, M 268.4, m 173°, 174-176°, 179°, pK^{25} 9.84.** Dissolve the ketone in dilute HCl, filter and precipitate it by adding ammonia (to remove water-insoluble impurities such as benzophenone). Then crystallise it from EtOH or petroleum ether. [Suppan *JCS Faraday Trans 1* **71** 539 *1975*, DOI: 10.1039/F19757100539.] It is also purified by dissolving in *benzene, then washing with water until the aqueous phase is colourless. The *benzene is evaporated off, and the residue is recrystallised three times from *benzene and EtOH [Hoshino & Kogure *J Phys Chem* **92** 417 *1988*, DOI: 10.1021/j100313a035]. [*Beilstein* **14** IV 255.]

Naphthacene (benz[b]anthracene, 2,3-benzanthracene, rubene) *[92-24-0]* $C_{18}H_{12}$, M 228.3, m >300°, 341° (open capillary), 349°, 357°.

Naphthacene crystallises in orange needles from EtOH, $*C_6H_6$ or toluene. Dissolve it in sodium-dried *benzene and pass it through a column of alumina. The eluent is evaporated under vacuum, and the chromatography is repeated using fresh *benzene. Finally, the naphthacene is sublimed *in vacuo* at 186°. [Martin & Ubblehode *J Chem Soc* 4948 *1961*, DOI: 10.1039/JR9610004948; UV: Clar *Chem Ber* **65** 503 *1932*, DOI: 10.1002/cber.19320650402; Clar *Chem Ber* **69** 607 *1936*, DOI: 10.1002/cber.19360690327; IR: Cannon & Sutherland *Spectrochim Acta* **4** 373 *1951*, *Beilstein* **5** IV 2545.]

1-Naphthaldehyde *[66-77-3]* **$C_{11}H_8O$, M 156.2, m 1-2°, b 160-161°/15mm, 292°/760mm, d 1.155, pK^{20} -7.04 (aqueous H_2SO_4).** Distil 1-naphthaldehyde with steam, extract the distillate into Et_2O, dry (Na_2SO_4), filter, evaporate the filtrate and distil the residue in a vacuum. [*Beilstein* **7** IV 1286.]
2-Naphthaldehyde *[66-99-9]* has **m 59°, 60°, 61°, 59-62°, b 160°/19mm, 308.4°/760mm, d^{25} 1.6211g/ml, pK^{20} -7.04 (aqueous H_2SO_4).** Distil 2-naphthaldehyde with steam, then crystallise it from water or EtOH. [*Beilstein* **7** IV 1288.]

Naphthalene *[91-20-3]* **$C_{10}H_8$, M 128.2, m 80.3°, 80° to 82°, b 87.5°/10mm, 218.0°/atm, d_4^{20} 1.0253, d_4^{100} 0.9625, n^{85} 1.5590.** Crystallise naphthalene once or more times from the following solvents: EtOH, MeOH, CCl_4, *C_6H_6, glacial acetic acid, acetone or diethyl ether, followed by drying at 60° in an Abderhalden drying apparatus. It has also been purified by vacuum sublimation and by fractional crystallisation from its melt. Other purification procedures include refluxing in EtOH over Raney Ni and chromatography of a CCl_4 solution on alumina with *benzene as eluting solvent. Baly and Tuck [*J Chem Soc* 1902 *1908*, DOI: 10.1039/CT9089301902,] purified naphthalene for spectroscopy by heating with concentrate H_2SO_4 and MnO_2, followed by steam distillation (repeating the process), and formation of the ***picrate*** which, after recrystallisation (**m 150°**) is decomposed with base and the naphthalene is steam distilled. It is then crystallised from dilute EtOH. It can be dried over P_2O_5 under vacuum (take care not to make it sublime). Also purify it by sublimation and subsequent crystallisation from cyclohexane. *Alternatively*, it has been washed at 85° with 10% NaOH to remove phenols, with 50% NaOH to remove nitriles, with 10% H_2SO_4 to remove organic bases, and with 0.8g $AlCl_3$ to remove thianaphthalenes and various alkyl derivatives. Then it is treated with 20% H_2SO_4, 15% Na_2CO_3 and finally distilled. [Gorman et al. *J Am Chem Soc* **107** 4404 *1985*, DOI: 10.1021/ja00301a006.]
Zone refining purified naphthalene from anthracene, 2,4-dinitrophenylhydrazine, methyl violet, benzoic acid, methyl red, chrysene, pentacene and indoline. [*Beilstein* **5** IV 1640.]

1,8-Naphthalic acid (naphthalene-1,8-dicarboxylic acid) *[518-05-8]* **$C_{12}H_8O_4$, M 216.9, m 270°, $pK_{Est(1)}$~ 2.1, $pK_{Est(2)}$~ 4.5.** Crystallise the acid from EtOH or aqueous EtOH. [Raecke & Schrip *Org Synth* **40** 71 *1960*, DOI: 10.15227/orgsyn.040.0071; *Beilstein* **9** II 651, **9** III 4466.] ***1,8-Naphthalic anhydride*** *[81-84-5]* **$C_{12}H_6O_3$, M 198.2, m 267° to 296°, 274°, 274-275°.** Extract it with cold aqueous Na_2CO_3 to remove free acid, then crystallise from acetic anhydride. [*Beilstein* **17** III/IV 6392, **17/11** V 492.]

2-Naphthamide (2-naphthoic acid amide) *[2243-82-5]* **$C_{11}H_9NO_2$, M 171.2, m 195°, pK^{20} -2.30 (H_o scale, aqueous H_2SO_4).** Crystallise it from EtOH (197°). [Clemo & Spence *J Chem Soc* 2818 *1928*, DOI: 10.1039/JR9280002811; *Beilstein* **9** H 657, **9** II 45, **9** IV 2417.] Useful for preparing antiallergic agents [Ikawa et al. US Patent 5,714,613, February 3, *1998*].

Naphthazarin (5,8-dihydroxy-1,4-naphthoquinone) *[475-38-7]* **$C_{10}H_6O_4$, M 190.2, m ~ 220-230°(dec), m 225-230°, pK_1^{20} 8.2, p K_2^{20} 10.2.** It crystallises in red-brown needles with a green shine from EtOH or dioxane (m 228-232°). It also crystallises from hexane and is further purified by sublimation at 2-10mm. [Huppert et al. *J Phys Chem* **89** 5811 *1985*, DOI: 10.1021/j100272a047.] It is sparingly soluble in H_2O but soluble in alkalies. The ***diacetate*** forms golden yellow prisms from $CHCl_3$, **m 192-193°** and the ***5,8-dimethoxy*** derivative has **m 157°** (**155°**) (from petroleum ether) [Bruce & Thompson *J Chem Soc* 1089 *1955*, DOI: 10.1039/JR9550001089; IR: Schmand & Boldt *J Am Chem Soc* **97** 447 *1975*, DOI: 10.1021/ja00835a052; NMR: Brockmann & Zeeck *Chem Ber* **101** 4221 *1968*, DOI: 10.1002/cber.19681011222]. The ***monothiosemicarbazone*** has **m 168°(dec)** from EtOH [Gardner et al. *J Am Chem Soc* 74 2106 *1952*, DOI: 10.1021/ja01128a509]. [*Beilstein* **8** H 412, **8** III 3600.]

1-Naphthoic acid *[86-55-5]* **$C_{11}H_8O_2$, M 172.2, m 157° to 160°, 160.5-162.0°, 162.5-163.0°, >300°/atm, pK^{25} 3.60.** Crystallise the acid from toluene (3ml/g) (charcoal), petroleum ether (b 80-100°), or aqueous 50% EtOH. The ***amide*** has **m 202°** (from EtOH). [Gilman et al. *Org Synth* Coll Vol **2** 425 *1943*, DOI: 10.15227/orgsyn.011.0080; *Beilstein* **9** IV 2402.] Mild irritant.
2-Naphthoic acid *[93-09-4]* has **m 180-184°, 184-185°, 186-187°, >300°/atm, d 1.08, pK^{25} 4.14.** Crystallise the acid from 95% EtOH (4ml/g), aqueous 50% EtOH or Me_2CO (**m** 185-186°). Dry it at 100°. The ***acid chloride*** *[2243-83-6]* has **m 52-52°** (from *C_6H_6/petroleum ether) and **b 160-162°/11mm** [Hersberg & Carson *Org Synth* Coll Vol **3** 629 *1955*], the ***amide*** has **m 192°** (from EtOH), and the ***N-Methyl amide*** has **m 109-109.5°** (form *C_6H_6). [Newman & Holmes *Org Synth* Coll Vol **2** 428 *1943*, DOI: 10.15227/orgsyn.017.0065; *Beilstein* **9** H 656, **9** III 3174, **9** IV 2414.] Mild irritant.

1–Naphthol *[90-15-3]* **$C_{10}H_8O$, M 144.2, m 94-96°, 95.5-96°, 278-280°/atm, $d_4^{98.7}$ 1.0954, pK^{25} 9.34.** Sublime 1-naphthol, then crystallise it from aqueous MeOH (charcoal), aqueous 25% or 50% EtOH, *C_6H_6, cyclohexane, heptane, CCl_4 or H_2O. Dry it over P_2O_5 *in vacuo*. The ***4-nitrobenzoate*** has **m 143°** (from EtOH). [Shizuka et al. *J Am Chem Soc* **107** 7816 *1985*, DOI: 10.1021/ja00312a003; *Beilstein* **8** H 596, **6** IV 4208.]

2-Naphthol *[135-19-3]* **$C_{10}H_8O$, M 144.2, m 121°, 122.5-123.5°, b 285-286°/atm, d 1.22, pK^{25} 9.57.** Crystallise 2-naphthol from aqueous 25% EtOH (charcoal), H_2O (solubility is 0.1 w/v% at ~20° and ~1.3w.v% at 100°), *benzene, toluene or CCl_4. *Alternatively*, extract it repeatedly with small amounts of EtOH (solubility is 125w/v% at ~20°), followed by dissolution in a minimum volume of EtOH and precipitation with distilled water, then drying over P_2O_5 under vacuum. It has also been dissolved in aqueous NaOH and precipitated by adding acid (repeat several times), then precipitated from *benzene by addition of heptane. Final purification can be by zone melting or sublimation *in vacuo*. Its solubility at ~20° in $CHCl_3$ is 5.9w/v%, and in Et_2O it is 77w.v%. The ***4-nitrobenzoate*** has **m 104°** (from EtOH). [Bardez et al. *J Phys Chem* **89** 5031 *1985*, DOI: 10.1021/j100269a029; Kikuchi et al. *J Phys Chem* **91** 574 *1987*, DOI: 10.1021/j100287a017; *Beilstein* **6** IV 4253.] Used in making antioxidants, is an antiseptic and an anthelmintic.

Naphthol AS-D (3-hydroxy-2-naphthoic-*o*-toluide) *[135-61-5]* **$C_{18}H_{15}NO_2$, M 277.3, m 196-198°, CI 37520, pK_{Est} ~8.5.** Purify it by recrystallisation from xylene. This gives yellow-green fluorescent solutions at pH 8.2-9.5. [IR: Schnopper et al. *Anal Chem* **31** 1542 *1959*, DOI:10.1021/ac60153a035.] The ***naphthol AS-D acetate*** is obtained with AcCl, **m 168-169°**, and with chloroacetyl chloride ***naphthol AS-D-chloroacetate*** is obtained [Moloney et al. *J Histochem Cytochem* **8** 200 *1960*, DOI:10.1177/8.3.200; Burstone *Arch Pathology* **63** 164 *1957*, PMID: 13393921]. [*Beilstein* **12** H 505.]

α-Naphtholbenzein [bis-(α-{4-hydroxynaphth-1-yl})-benzyl alcohol] *[145-50-6 (anhydrous), 6948-88-5 (covalent hydrate)]* **$C_{27}H_{18}O_2$, $C_{27}H_{18}O_2.H_2O$, M 374.5 (anhydrous), 392.5 (covalent hydrate), m 122-125°, 230-235°, pK_{Est} ~ 9.3.** Crystallise the alcohol from EtOH, aqueous EtOH or glacial acetic acid. It is an indicator in titrations of weak bases and amino acids, also in non-aqueous media, e.g. glacial AcOH, for the pH range (pH 0.0-0.8/pH 8,2-10.0) 8.2 to 10 with a visual transition from yellow to blue. It is soluble in EtOH, Me_2CO and AcOH, and almost insoluble in H_2O. [Nabeau & Branchen *J Am Chem Soc* **57** 1363 *1935*, DOI: 10.1021/ja01310a056; *Beilstein* **6** H 1150.]

1-Naphthol-2-carboxylic acid (1-hydroxy-2-naphthoic acid) *[86-48-6]* **$C_{11}H_8O_3$, M 188.2, m 191-192°, 195° to 200°, 203-204°, $pK_{Est(1)}$~2.5, $pK_{Est(2)}$~12.** Successively crystallise the acid (red crystals) from EtOH/water, diethyl ether and acetonitrile, with filtration through a column of charcoal and Celite. Its solubility in H_2O is low but it is soluble in organic solvents and aqueous alkalies where it forms salts. [Tong & Glesmann *J Am Chem Soc* **79** 583 *1957*, DOI: 10.1021/ja01560a023; *Beilstein* **10** H 331, **10** IV 1194.]
3-Naphthol-2-carboxylic acid* (3-hydroxy-2-naphthoic acid)** *[92-70-6]* has **m 218-221°, 222-223°, pK_1^{25} 2.79, pK_2^{25} 12.84.** Crystallise it from water or acetic acid. It is soluble in organic solvents and aqueous alkalies. The ***S-benzyisothiuronium salt has **m 216-217°** (from EtOH). It forms many metal complex salts. [*Beilstein* **10** H 333, **10** III 1084.]

1,2-Naphthaquinone (*o-* , β-naphthoquinone) *[524-42-5]* **$C_{10}H_6O_2$, M 158.2, m 115-120°(dec), 139-140°(dec), 140-142°(dec), 145-147°(softening at ~140° dec).** Crystallise the quinone from ether (red needles) or *benzene (orange leaflets). [Note the variations in **m**.] Unlike the α–isomer below it is non-steam volatile. It has been prepared by the oxidation of 1-amino-2-naphthol hydrochloride of reasonably high purity in H_2O, to which $FeCl_3$ $6H_2O$ in concentrated HCl and diluted with H_2O was added all at once with stirring, whereby the golden yellow microcrystalline quinone separated. This was filtered off then washed well with H_2O; the solid was sliced and dried on a filter paper at ~25° in an acid-free atmosphere. Recrystallisation from the above stated solvents provides nice crystals but is wasteful and the solid does not keep well. The crude dry quinone [145-147°(softening at ~140° dec)] is essentially pure and will store, as it is, indefinitely without serious deterioration, preferably in the absence of light. It can become very *electrified* if pulversised, and it is advised not to do so. [Fieser *Org Synth* Coll Vol **2** 430 *1943*, *Org Synth* **17** 68 *1937*, DOI: 10.15227/orgsyn.017.0068.] [*Beilstein* **7** IV 2417.] The ***dioxime*** *[1Z,2E: 6436-72-1]* crystallises in yellow needles from EtOH with **m 169°** (also reported m 142-144°, 149°, isomers?). The oxime complexes with Ni, Co and Fe^{2+} [Kuse et al. *Anal Chim Acta* **70** 75 *1974*, DOI :10.1016/S0003-2670(01)82911-1] and its derivatives can be used as analytical reagents for the spectrophotometric determination of Ni [Tôel et al. *Anal Chim Acta* **75** 323 *1975*, DOI:10.1016/S0003-2670(01)85357-5]. The ***2-semicarbazone*** (Haemostop, Naftazone) *[31853-38-0]* **$C_{11}H_9N_3O_2$, M** 215.2 is haemostatic.

1,4-Naphthaquinone (*p*-naphthoquinone, α-naphthoquinone) *[130-15-4]* **$C_{10}H_6O_2$, M 158.2, m 119-122°, 125-125.5°, pKa -7.5 (in H_2SO_4).** Crystallise the quinone from diethyl ether (charcoal). It distils in steam. It also crystallises from *benzene, petroleum ether or aqueous EtOH (yellow needles) and sublimes in a vacuum. It has been prepared by the oxidation of 1-amino-4-naphthol hydrochloride with $K_2Cr_2O_7/H_2SO_4/H_2O$ in 78-81% yield [Fieser *Org Synth* Coll Vol **1** 383 *1941*, DOI: 10.15227/orgsyn/.005.0079], or by direct oxidation of naphthalene with CrO_3/AcOH/H_2O (2-3 hours during naphthalene/AcOH addition to oxidant at 10-15°, warmed overnight, then the dark green solution is set aside with occasional stirring for 3 days at ~25°) in consistent 32-35% yields (50% yields have also been reported [Chawla et al. *Tetrahedron* **51** 2709 *1995*, DOI: 10.1016/0040-4020(95)00019-5]). Purification by crystallisation from petroleum ether (b 80-100°) is more convenient than by steam distillation, and one crystallisation gives a product of high purity. Its IR (KBr) has a band at ν_{max} 1644cm^{-1}. [Braude & Fawcett *Org Synth* Coll Vol **4** 698 *1963*, DOI: 10.15227/orgsyn.033.0050.] The quinone is an **IRRITANT** and a **VESICANT**. [For the fluorescence detection of cyanide by quinone derivatives see Guilbault & Kramer *Anal Chem* **37** 1395 *1965*, DOI: 10.1021/ac60230a027; for UV spectra of naphthoquinones see Singh et al. *Tetrahedron* **24** 6053 *1968*, DOI:10.1016/S0040-4020(01)90989-5; *Beilstein* **7** IV 2422.] The ***dioxime*** *[14140-02-4]* **$C_{10}H_8N_2O_2$, M 188.2,** crystallises in needles with **m 207°(dec)** from EtOH.

1,5-Naphthaquinone (1,5-naphthoquinone) *[51583-62-1]* **$C_{10}H_6O_2$, M 158.2.** Theoretical studies by Boldt and coworkers [Schmand & Boldt *J Am Chem Soc* **97** 447 *1975*, DOI: 10.1021/ja00835a052; and Schmand et al. *Justus Liebigs Ann Chem* **1976** 1560 *1976*, DOI: 10.1002/jlac.197619760905; see also 1,7- and 2,3-naphthaquinone below] showed that this quinone should not be *isolable* unless stabilised by inserting shielding alkyl groups. Attempted synthesis of 2,3,4,6,7,8-tetramethyl-1,5-naphthoquinone failed. However, they succeeded in preparing ***3,5-di*-tert-*butyl-1,5-naphthoquinone*** by oxidation of the respective 1,5-diol, with 2,3-dichloro-5,6-dicyanobenzoquinone (DDQ) in $CHCl_3$ under N_2, as red crystals in nearly quantitative yield. The quinone was fully charcterised and was stable under N_2; thus the TLC (silica gel, CH_2Cl_2) under N_2 and absence of moisture gave a spot with $R_F = 0.2$. However, on exposure to H_2O it was slowly converted to ***5-hydroxy-3,5-di*-tert-*butyl-1,4-naphthoquinone*** which crystallised from MeOH with **m 113°**, and was characterised fully (IR, NMR and MS). They also showed from SCF-LCAO-MO calculations and spectral comparisons that **naphthazarin** (5,8-dihydroxy-1,4-naphthoquinone, see *[475-38-7]*) is a 1,4- and not a 1,5-naphthoquinone.

1,7-Naphthaquinone (1,7-naphthoquinone) *[46001-16-5]* **$C_{10}H_6O_2$, M 158.2.** Theoretical calculations by Bolt and coworkers [Menting et al. *J Org Chem* **48** 2814 *1983*, DOI: 10.1021/jo00165a006] on the naphthaquinones showed the reasons why some quinones are unstable; 1,7-naphthaquinone being one of them (the 1,5-naphthaquinone above was another unstable isomer as was the 2,3-isomer below). Their instability at room temperature being possibly due to their reactivity with H_2O and polymerisation which they argued could be avoided by heavy substitution with alkyl groups. In an attempt to improve their stability, they synthesised ***3,6-di-tert-butyl-8-methyl-1,7-naphthoquinone*** *[83021-64-1]* (in 13 steps), successfully by final DDQ oxidation of ***3,6-di-tert-butyl-8-methyl-naphthalene 1,7-diol*** (*[83021-63-0*], sublimes at 160-200/vacuum; **m 167°**, ^{1}HNMR, MS and analyses) as a bright red residue which they characterised fully (IR, UV/vis. NMR and MS) as well as reductive acetylation to ***1,7-diacetoxy-3,6-di-tert-butyl-8-methyl-naphthalene*** (*[86392-51-0]*, **m 60-61°**, ^{1}HNMR, MS and analyses). However, it proved to be unexpectedly unstable and the authors concluded from MNDO calculations that the alkyl groups caused high steric strain, making it non-planar and thus unstable.

2,3-Naphthaquinone (2,3-naphthoquinone) *[4939-92-8]* **$C_{10}H_6O_2$, M 158.2.** All attempts to prepare this quinone by oxidation of 2,3-dihydroxynaphthalene failed because of the expected instability of the quinone. Apparently it possibly reacts readily with H_2O and polymerises. However, its transient existence was demonstrated by Horak and coworkers by oxidation of 2,3-dihydroxynaphthalene with aqueous KIO_3 in the presence of a large excess of cyclopentadiene, used also as solvent, that provided a 56% yield of the ***1,4-(1:1)-Diels-Alder adduct*, m 170°,** which crystallised from cyclohexane and sublimed *in vacuo*. Its IR, ^{1}H NMR and MS are consistent with its structure, and on reduction with $NaBH_4$ it yielded 1,2-dihydroxynaphthalene, m 160° (from cyclohexane) see *[92-44-4]* above. [Horak et al. *Tetrahedron Lett* **22** 3577 *1981*, DOI:10.1016/S0040-4039(01)81962-6.]

2,6-Naphthaquinone (*amphi*-naphthaquinone, 2,6-naphthoquinone) *[613-20-7]* **$C_{10}H_6O_2$, M 158.2, m 130-**

135°, 135°(dec). It is formed by the oxidation of 2,6-dihydroxynaphthalene in *C_6H_6 with suspended active lead dioxide (prepared from lead tetraacetate) by shaking for 1-2 minutes, filtering and evaporating [Kuhn & Hammer *Chem Ber* **83** 413 *1950*, DOI: 10.1002/cber.19500830415; Willstätter & Parnas *Chem Ber* **40** 1406 *1907,* DOI: 10.1002/cber.19070400224]. *Alternatively*, 2,6-naphthaquinone was prepared by dissolving 2-aminonaphthalene (0.1g) in a mixture of $CHCl_3$ and MeOH (1:1 v/v, 100ml) and a dye sensitiser (5mg, methylene blue) and illuminated with a tungsten lamp (2 x 200Watt) through a $K_2Cr_2O_7$ screen as O_2 was bubbled through the solution for 18 hours, and the 2,6-naphthaquinone, **m 132-134°**, was isolated after filtration and evaporation [Chawla et al. *Tetrahedron* **51** 2709 *1995*, DOI: 0.1016/0040-4020(95)00019-5; Chawla et al. *Indian J Chem* **32B** 733 *1993*.] The quinone crystallises from *C_6H_6, *C_6H_6/light petroleum or petroleum ether in yellowish-red to brick-red prisms, and forms yellow needles from ligroin. It is odourless, non-volatile and stable, and unchanged for a long time. It is soluble in EtOH and MeOH but not in H_2O. When heated to 130-135°, it turns grey and the product then dissolves in alkali. It turns a solution of hematoxylin red in colour, and a solution of $K_3[Fe(CN_6)]$ blue in colour. It shows the characteristic oxidising power of quinones and is a better oxidant than 1,2- and 1,4-naphthaquinone. [*Beilstein* **7** 733, **7** II 656, **7** III 3706, **7** IV 2417.]

β-Naphthoxyacetic acid (BNOA) *[120-23-0]* **$C_{12}H_{10}O_3$, M 202.2, m 151° to 154°, 155°, 156°, pK_{Est} ~3.0.** Crystallise the acid from hot water or *benzene. The ***ethyl ester***, **m 49°**, crystallises from EtOH. [*Beilstein* **6** IV 4274.] It has herbicide activity.

β-Naphthoyltrifluoroacetone (4,4,4-trifluoro-2-naphthylbutan-1,3-dione) *[893-33-4]* **$C_{14}H_9F_3O_2$, M 266.2, m 70-71°, 72°, 74-76°, pK^{20} 6.35.** Crystallise the dione from EtOH. It forms complexes with metals, and the lanthanide complexes are particularly useful. The ***mono-oxime*** crystallises from H_2O or aqueous EtOH and has **m 137-138°**. [Reid & Calvin *J Am Chem Soc* **72** 2948 *1950*, DOI: 10.1021/ja01163a038; *Beilstein* **7** IV 2478.]

Naphthvalene (2,3-dihydro-1,2,3-metheno-1*H*-indene) *[34305-47-0]* **$C_{10}H_8$, M 128.1, m dec at 175° to benzvalene.** Purify it by chromatography on alumina and eluting with pentane, also by reverse phase (ODS) HPLC using MeCN as solvent. It is stable at room temperature [Kjell et al. *J Am Chem Soc* **108** 4111 *1986*, DOI: 10.1021/ja00274a042; Abelt et al. *J Am Chem Soc* **107** 4148 *1985*, DOI: 10.1021/ja00300a010]. The ^1H NMR in CCl_4 has τ 3.18 (4H), 6.17 (t *J* 1.5Hz, 2H), 7.60 (t *J* 1.5Hz 2H).

1-Naphthyl acetate *[830-81-9]* **$C_{12}H_{10}O_2$, M 186.2, m 43° to 46°, 45-46°, 48-49°, b 114-115°/1mm.** Chromatograph the acetate on silica gel and crystallise as the 2-isomer below. The ***2,4,7-trinitrofluoren-9-one complex*** has **m 120°** (from EtOH). [*Beilstein* **6** H 608, **6** III 2928, **6** IV 4217.]
2-Naphthyl acetate *[1523-11-1]* has **m 68° to 70°, 71°, 71-72°, b 133-134°/2mm.** Distil the acetate in a high vaccum and/or crystallise it from petroleum ether (b 60-80°) or dilute aqueous EtOH. The ***picrate*** has **m 80°** (from EtOH). [*Beilstein* **6** H 644, **6** I 313, **6** II 600, **5** III 2982, **6** IV 4267.]

2-Naphthyl urea *[13114-62-0]* has **m 212°, 219-220°.** Crystallise the urea from EtOH. [*Beilstein* **12** H 1292, **12** III 3029, **12** IV 3149.]

Narcein {6-[6-(2-dimethylaminoethyl)]-2-methoxy-3,4-(methylenedioxy)phenylacetyl]-2,3-dimethoxy-benzoic acid} *[131-28-2]* **$C_{23}H_{27}NO_8$, M 445.4, m 176-177° (145° anhydrous), pK_1^{15} 3.5, pK_2^{15} 9.3.** Recrystallise this alkaloid, which is present in opium and used as a morphine substitute from water (as fine white crystals of the trihydrate). The ***styphnate*** has **m 185-189°** (from EtOH), and the ***picrate*** has **m 200°** (from EtOH). [*Beilstein* **19** H 370, **19** I 797, **19** II 386, **19** IV 4382.]

Neostigmine [(3-dimethylcarbamoylphenyl)trimethylammonium] bromide *[114-80-7]* **$C_{12}H_{19}BrN_2O_2$, M 303.2, m 176°(dec), 181°(dec).** Crystallise neostigmine bromide from EtOH/diethyl ether. Its solubility in H_2O is ~50%. [*Beilstein* **13** III 939.] (It is cholinergic and parasympathomimetic, and *highly* **TOXIC**.) The starting material **3-dimethylcarbamoyl-*N,N*-dimethylaniline** *[59-99-4]* has **b 195°/20mm** [*Beilstein* **13** III 936], and its

picrate has **m 138°** (from EtOH).

Neostigmine methyl sulfate (Prostigmine B) *[51-60-5]]* **$C_{13}H_{22}N_2O_6S$ M 334.4, m 142-145°.** Crystallise the sulfate from EtOH or Me_2CO (**m** 143-144°). Its solubility in H_2O is ~10%. [*Beilstein* **13** III 939.] (It is cholinergic and parasympathomimetic, and *highly* **TOXIC**.)

Ninhydrin (1,2,3-triketohydrindene hydrate) *[485-47-2]* **$C_9H_6O_4$ (hydrate), M 178.1, m 241-243°(dec), 250°(dec), d 0.86, pK^{30} 8.82.** Crystallise ninhydrin from hot water (charcoal). Dry it under vacuum and store it in sealed brown containers. It becomes red on heating above 100°. It is a yellow toxic powder, soluble in EtOH, and a useful reagent for amines, amino acids and related compounds giving a deep blue or purple colour (Ruhemann's purple) and used in detection and analysis.[*Beilstein* **7** IV 2786.]

2-Nitroacetanilide *[552-32-9]* **$C_8H_8N_2O_3$, M 180.2, m 90-92°, 93-94°, pK_{Est} <0.** Crystallise the anilide from H_2O, aqueous EtOH (**m 92-93°**) or EtOH (**m 92.5-93.5°**). [*Beilstein* **12** II 371, **12** III 1523, **12** IV 1574.]
4-Nitroacetanilide *[104-04-1]* has **m 213-215°, 217°, pK_{Est} <0.** Precipitate the anilide from 80% H_2SO_4 by adding ice, then wash with water, and crystallise from aqueous EtOH. Dry it in air. [*Beilstein* **12** IV 1632.]

3-Nitroacetophenone *[121-89-1]* **$C_8H_7NO_3$, M 165.2, m 76-80°, 79°, 81°, b 167°/18mm, 202°/760mm.** Distil the ketone in steam and crystallise it from EtOH. [*Beilstein* **7** IV 656.]
4-Nitroacetophenone *[100-19-6]* has **m 77-81°, 79°, 80-81°, 81.8°, b 202°/760mm.** Crystallise the ketone from EtOH or aqueous EtOH. [*Beilstein* **7** IV 657.]

3-Nitroalizarin (1,2-dihydroxy-3-nitro-9,10-anthraquinone, Alizarin Orange) *[568-93-4]* **$C_{14}H_7NO_6$, M 285.2, m 244° (dec), $pK_{Est(1)}$~4.6, $pK_{Est(2)}$~9.6.** Crystallise the dye from AcOH (**m** 244-245°). It has λ_{max} at 494nm (H_2SO_4) and forms Cu salts. [*Beilstein* **8** H 447, **8** II 491, **8** III 3774, **8** IV 2359.]

2-Nitroaniline *[88-74-4]* **$C_6H_6N_2O_2$, M 138.1, m 70-73°, 72.5-73.0°, b 284°/atm, pK^{25} -0.25 (-0.31).** Crystallise the aniline from hot water (charcoal), then from aqueous 50% EtOH, or EtOH, and dry it in a vacuum desiccator. It has also been chromatographed on alumina, then recrystallised from *benzene. [Ehrenfeld & Puterbaugh *Org Synth* Coll Vol **I** 388 *1941*, DOI: 10.15227/orgsyn.009.0064; *Beilstein* **12** IV 1563.]
3-Nitroaniline *[99-09-2]* has **m 114°, pK^{25} 2.46.** Purify it as for 2-nitroaniline. **Warning: it is absorbed through the skin. [***Beilstein* **12** IV 1589.]
4-Nitroaniline *[100-01-6]* has **m 148-148.5°, pK^{25} 1.02.** Purify it as for *2*-nitroaniline. It also crystallises from acetone. It is freed from *o*- and *m*-isomers by zone melting and sublimation. [*Beilstein* **12** IV 1613.]

2-Nitroanisole (2-methoxynitrobenzene) *[91-23-6]* **$C_7H_7NO_2$, M 153.1, m 9.4°, 11-12°, b 265°/737mm, 273°/atm, d_4^{20} 1.251, n_D^{20} 1.563.** Purify it by repeated vacuum distillation in the absence of oxygen. It is volatile in steam. [*Beilstein* **6** IV 1249.] Possible carcinogen.
4-Nitroanisole **(4-methoxynitrobenzene)** *[100-17-4]* has **m 54°, b 260°/atm, b 274°/atm, d_4^{25} 1.233.** Crystallise it from petroleum ether or hexane and dry it *in vacuo*. [*Beilstein* **6** IV 1282.]

9-Nitroanthracene *[602-60-8]* **$C_{14}H_9NO_2$, M 223.2, m 141° to 144°, 142-143°.** Purify it by recrystallisation from EtOH or MeOH. Further purify it also by sublimation or TLC. [*Beilstein* **5** H 666, **5** II 578, **5** III 2136, **5** IV 2296.]

2-Nitrobenzaldehyde *[552-89-6]* **$C_7H_5NO_3$, M 151.1, m 42-43°, 44-45°, b 120-144°/3-6mm, 153°/23mm.** Crystallise the aldehyde from toluene (2-2.5ml/g) by addition of 7ml petroleum ether (b 40-60°) for 1ml of solution. It can also be distilled under reduced pressures. It is steam volatile. [*Beilstein* **7** IV 584.]
3-Nitrobenzaldehyde *[99-61-6]* has **m 55-56°, 58°, b 164°/23mm.** Crystallise the aldehyde from water or EtOH/water, then sublime it twice at 2mm pressure at a temperature slightly above its melting point. It is steam volatile. [*Beilstein* **7** IV 591.]
4-Nitrobenzaldehyde *[555-16-8]* has **m 106°, 106-107°.** Purify it as for 3-nitrobenzaldehyde above. It is steam volatile and can be sublimed. [*Beilstein* **7** H 256, **7** I 141, **7** II 196, **7** III 907, **7** IV 589.]

Nitrobenzene *[98-95-3]* **$C_6H_5NO_2$, M 123.1, m 5.8°, 6°, b 84-86.5°/6.5-8mm, 210.8°/760mm, d_4^{20} 1.206, n^{15} 1.55457, n_D^{20} 1.55257, pK^{18} -11.26 (aqueous H_2SO_4).** Common impurities include nitrotoluene, dinitrothiophene, dinitrobenzene and aniline. Most impurities can be removed by steam distillation in the presence of dilute H_2SO_4, followed by drying with $CaCl_2$, and shaking with, then distilling at low pressure from BaO, P_2O_5, $AlCl_3$ or activated alumina. It can also be purified by fractional crystallisation from absolute EtOH (by refrigeration). Another purification process includes extraction with aqueous 2M NaOH, then water, dilute HCl, and water, followed by drying ($CaCl_2$, $MgSO_4$ or $CaSO_4$) and fractional distillation under reduced pressure. The pure material is stored in a brown bottle, in contact with silica gel or CaH_2. It is very *hygroscopic*. [*Beilstein* **5** H 233, **5** I 124, **5** II 171, **5** III 591, **5** IV 708.]

4-Nitrobenzene-azo-resorcinol (magneson-I) *[74-39-5]* **$C_{12}H_9N_3O_4$, M 259.2, m 185°(dec), 195-198°(dec), 199-200°(dec).** Crystallise the dye from EtOH. It has λ_{max} at 432nm. It is insoluble in H_2O but soluble in aqueous alkalies and gives a red-violet complex with molybdenum. [*Beilstein* **16** H 181, **16** IV 1266.]

4-Nitrobenzenediazonium fluoroborate *[456-27-9]* **$C_6H_4BF_4N_3O_2$, M 236.9, m 144-148°(dec).** It crystallises from water. Drain it well and use it as soon as possible. Store at 2-8°. [Whetsel et al. *J Am Chem Soc* **78** 3360 *1956*, DOI: 10.1021/ja01595a027; *Beilstein* **16** IV 816.] **It can be EXPLOSIVE when dry.**

4-Nitrobenzhydrazide (4-Nitrobenzoic hydrazide) *[636-97-5]* **$C_7H_7N_3O_3$, M 181.1, m 124°, 124°, 210-214°, 216-218°, 218°(dec).** Crystallise the hydrazide from EtOH or EtOAc (**m** 120°). [*Beilstein* **9** H 375, **9** I 152, **9** II 246, **9** III 1481, **9** IV 1052.]

2-Nitrobenzoic acid *[552-16-9]* **$C_7H_5NO_4$, M 167.1, m 141° to 148°, 147.5°, 146-148°, 146-149°, pK^{25} 2.21.** Crystallise the acid from *benzene (twice), *n*-butyl ether (twice), then water (twice). Dry and store it in a vacuum desiccator. [Le Noble & Wheland *J Am Chem Soc* **80** 5397 *1958*, DOI: 10.1021/ja01553a020.] It has also been crystallised from EtOH/H_2O. The ***amide*** *[610-15-1]* **$C_7H_6N_2O_3$, M 166.1,** has **m 176.5°** (from H_2O, also **m 174-178°**). [*Beilstein* **9** III 1466, **9** IV 1046.] It is used as an NH protecting group.
3-Nitrobenzoic acid *[121-92-6]* has **m 139-141°, 143-143.5°, pK^{25} 3.46.** Crystallise the acid from *benzene, H_2O, EtOH (charcoal), glacial acetic acid or MeOH/H_2O. Dry and store it in a vacuum desiccator. The ***amide*** *[645-09-0]* **$C_7H_6N_2O_3$, M 166.1,** has **m 143°** (from H_2O or $*C_6H_6$, also **m** 143° and 140-143°). [*Beilstein* **9** III 1489, **9** IV 1055.]
4-Nitrobenzoic acid *[62-23-7]* has **m 137-240°, 241-242°, pK^{25} 3.43.** Purify it as for 3-nitrobenzoic acid above. The ***amide*** *[619-80-7]* **$C_7H_6N_2O_3$, M 166.1,** has **m 201.6°** (from H_2O, also **m 202.5°** and **201-204°**). [*Beilstein* **9** III 1537, **9** IV 1072.] ***4-Nitrobenzoic anhydride*** *[902-47-6]* **$C_{14}H_8N_2O_7$, M 316.2,** has **m 192°, 195-195.5°.** Crystallise the anhydride from Me_2CO, toluene, $*C_6H_6$/EtOAc or EtOAc. [*Beilstein* **9** II 268, **9** III 1684.]

4-Nitrobenzoyl chloride *[122-04-3]* **$C_7H_4ClNO_3$, M 185.6, m 71° to 74°, 75°, b 155°/20mm, 202-205°/105mm.** Crystallise the acid chloride from dry petroleum ether (b 60-80°), $*C_6H_6$ or CCl_4 (yellow crystals). Distil it under vacuum. **IRRITANT**. [Adams & Jenkins *Org Synth* Coll Vol **1** 394 *1941*, DOI: 10.15227/orgsyn.003.0075; *Beilstein* **9** III 1709, **9** IV 1191.]

3-Nitrobenzyl alcohol (3-NBA, NOBA) *[619-25-0]* **$C_7H_7NO_3$, M 153.1, m 30° to 32°, 94°, b 178-180°/3mm, d_4^{20} 1.29.** If the IR contains OH bands, then heat with oxalyl chloride until evolution of gasses ceases and then evaporate excess of oxalyl chloride and distil the residue in a vacuum. [*Beilstein* **6** IV 2609.] It is a very useful material as a matrix in mass spectrometry [Meili & Seibl *Org Mass Spectrom* **19** 581 *1984*, DOI: 10.1002/oms.1210191111; Zhao et al. *Anal Chem* **63** 450 *1991*, DOI: 10.1021/ac00005a012; Chan et al. *Org Mass Spectrom* **27** 53 *1992*, DOI: 10.1002/oms.1210270114; Iavarone & Williams *J Am Chem Soc* **125** 2319 *2003*, DOI: 10.1021/ja021202t].
4-Nitrobenzyl alcohol *[619-73-8]* has **m 92°, 93°, 94°, b 185°/12mm.** Crystallise the alcohol from EtOH and sublime it *in vacuo*. Purity should be at least 99.5%. Sublimed samples should be stored in the dark over anhydrous $CaSO_4$ (Drierite). If the IR contains OH bands, then the sample should be resublimed before use. [Kosower & Mohammed *J Am Chem Soc* **93** 2709 *1971*, DOI: 10.1021/ja00740a021; *Beilstein* **6** IV 2611.]

4-Nitrobenzyl bromide *[100-11-8]* **$C_7H_6BrNO_2$, M 216.0, m 96-98°, 98.5-99.0°, 99-101°.** Recrystallise the

bromide four times from absolute EtOH, then twice from cyclohexane/hexane/*benzene (1:1:1), followed by sublimation at 0.1mm and final recrystallisation from the same solvent mixture. [Lichtin & Rao *J Am Chem Soc* **83** 2417 *1961*, DOI: 10.1021/ja01472a002.] It has also been crystallised from petroleum ether (b 80-100°, 10ml/g, charcoal). It slowly decomposes even when stored in a desiccator in the dark. **IRRITANT. [***Beilstein* **5** IV 861.]

3-Nitrobenzyl chloride *[619-23-8]* **$C_7H_6ClNO_2$, M 171.6, m 41-44°, 45°, 46°, b 85-87°/5mm.** Crystallise the chloride from petroleum ether (b 90-120°), and/or distil in a vacuum. **IRRITANT**. [*Beilstein* **5** IV 855.]
4-Nitrobenzyl chloride *[100-14-1]* has **m 70-73°, 72.5-73°, 70-74°, b 112°/0.6mm.** Crystallise the chloride from CCl_4, dry diethyl ether, or *n*-heptane, and dry it under vacuum. **IRRITANT**. [*Beilstein* **5** IV 856.]

4-Nitrobenzyl cyanide *[555-21-5]* **$C_8H_6N_2O_2$, M 162.2, m 117°, 115-118°, b 197°/12mm, 336.2°/760mm, d 1.272.** Crystallise the nitrile from EtOH, and/or distil it under vacuum. **TOXIC**, can liberate HCN. [*Beilstein* **9** H 456, **9** I 183, **9** II 313, **9** III 2291.]

2-Nitrobiphenyl *[86-00-0]* **$C_{12}H_9NO_2$, M 199.2, m 36.7°, 37°, 37.5°, 36-38°, b 165-170°/13mm, 185-195°/20-30mm.** *o*-Nitrobiphenyl has been prepared by a Gomberg reaction between diazotised 2-nitroaniline and *C_6H_6 [Elks et al. *J Chem Soc* 1284 *1940*, DOI: 10.1039/JR9400001284] or by the nitration of biphenyl [Morgan & Walls , **49** 15T *1930*]. Although the respective yields are ~45% and ~25%, the latter method is by far more convenient to perform experimentally. Crystallise it from EtOH (seeding required) or petroleum ether (b 40-60°). Sublime it under vacuum. [*Beilstein* **5** H 582, **5** I 273, **5** II 487, **5** III 1750.]

trans*-3-Nitrocinnamic acid** *[555-68-0]* **$C_9H_7NO_4$, M 193.2, m 200-201°, 200-202°, pK^{25} 2.58 (*trans*).** Crystallise the acid from *C_6H_6 or EtOH. The ***p-bromophenacyl ester has **m** 178° (from AcOH). [Thayer *Org Synth* Coll Vol **1** 398 *1941*, DOI: 10.15227/orgsyn.005.0083; *Beilstein* **9** III 271, **9** IV 2043.]
trans-4-Nitrocinnamic acid *[882-06-4]* has **m 143° (*cis*), 286°(*trans*), pK_{Est} ~2.6 (*trans*).** Crystallise the acid from H_2O. The ***p-bromophenacyl ester*** has **m 191°** (from AcOH). [*Beilstein* **9** H 606, **9** III 2744, **9** IV 2045.]

4-Nitrodiphenylamine *[836-30-6]* **$C_{12}H_{10}N_2O_2$, M 214.2, m 132-135°, 133-134°, 135.3°, b 211°/30mm, 355.2°/760mm, pK^{25} -2.5.** Crystallise the amine from EtOH or aqueous EtOH (**m 135-136°**) and has **m 131.5-132°** after sublimation *in vacuo*. [*Beilstein* **12** H 715, **12** III 1586.]

2-Nitrodiphenyl ether *[2216-12-8]* **$C_{12}H_9NO_3$, M 215.2, b 106-108°/0.01mm, 137-138°/0.5mm, 161-162°/4mm, 188-189°/12mm, 195-200°/25mm, d_4^{20} 1.241, n_D^{25} 1.600.** Purify the ether by fractional disillation. Its UV (EtOH) has λ_{max} at: 255, 315mm (ε 6200 and 2800), and the IR (CS_2) has bands at 1350 (NO_2) and 1245, 1265 (COC) cm^{-1} [UV, IR: Dahlgard & Brewster *J Am Chem Soc* **80** 5861 *1958*, DOI: 10.1021/ja01554a070; Tomita & Takase *Yakugaku Zasshi (J Pharm Soc Japan)* **75** 1077 *1955*, Fox & Turner *J Chem Soc* 1115 *1930*, DOI: 10.1039/JR9300001115; Henley *J Chem Soc* 1222 *1930*, DOI: 10.1039/JR9300001222]. [*Beilstein* **6** H 218, **6** II 210, **6** III 801.]

Nitrodurene (1,2,4.5-tetramethyl-3-nitrobenzene) *[3463-36-3]* **$C_{10}H_{13}NO_2$, M 179.2, m 113-114°, b 143-144°/10mm.** Distil nitrodurene in a vacuum and/or crystallise it from EtOH (yellow prisms, **m** 113-113.5°), MeOH, acetic acid, petroleum ether or chloroform. It has been crystallised by dissolving in hexane and kept at -20° for crystals to form (**m 111-112°**). Its UV has λ_{max} at 238 and 400nm (iso-octane). [Masnovi et al. *J Am Chem Soc* **111** 2263 *1989*, DOI: 10.1021/ja00188a048; cf. Powell & Johnson *Org Synth* Coll Vol **2** 449 *1943*, DOI: 10.15227/orgsyn.014.0068; *Beilstein* **5** H 432, **5** III 982, **5** IV 1080.]

3-Nitrofluoranthene *[892-21-7]* **$C_{16}H_9NO_2$, M 247.3, m 157-159°, 159-160°.** Recrystallise it from AcOH or EtOAc (yellow crystals) and/or sublime it at high vacuum. It is soluble in CH_2Cl_2, Me_2CO or *C_6H_6, soluble in warm EtOH and very soluble in Et_2O. [Kloetzel et al. *J Am Chem Soc* **78** 1165 *1956*, DOI: 10.1021/ja01587a020; *Beilstein* **5** III 2279.] It elicits apoptosis and necrosis [Asare et al. *Toxicology* **255** 140 *2009*, DOI: 10.1016/j.tox.2008.10.021].

2-Nitrofluorene *[607-57-8]* **$C_{13}H_9NO_2$, M 211.2, m 156°, 156-158°.** Crystallise 2-nitrofluorene from aqueous

acetic acid or Me_2CO (**m** 158-158.5º, also 160-160.5º). [*Beilstein* **5** H 628, **5** III 1948.] Possible carcinogen.

Nitromesitylene (2-nitro-1,3,5-trimethylbenzene) *[603-71-4]* **$C_9H_{11}NO_2$, M 165.2, m 41-43º, 44º, b 255º/760mm.** Crystallise it from EtOH, or a small volume of MeOH and cool in an ice-salt bath (**m 43.5º**). [Powell & Johnson *Org Synth* Coll Vol **2** 449 *1943*, DOI: 10.15227/orgsyn.014.0068; *Beilstein* **5** H 410, **5** III 923, **5** IV 1028.]

Nitromethylphenylsulfone *[21272-85-5]* **$C_7H_7NO_4S$, M 201.2, m 78-79º.** Recrystallise the sulfone from $CHCl_3$, or 95% EtOH, then sublime it at 100-120º/0.1 Torr and recrystallise again. It is an acidic analogue of nitromethane [Wade et al. *J Org Chem* **46** 765 *1981*, DOI: 10.1021/jo00317a023], used making phenylsulfonyl ntrile oxide for syn-cyanohydroxylations of olefins for the general synthesis of aliphatic acids and nitriles [Wade & Pillay *J Org Chem* **46** 5425 *1981*, DOI: 10.1021/jo00339a041; Dubey & Knaus *J Org Chem* **49** 123 *1984*, DOI: 10.1021/jo00175a025], and in cycloaddition reactions with olefins to form heterocycles [Wade et al. *J Org Chem* **49** 4595 *1984*, DOI: 10.1021/jo00198a005]. [*Beilstein* 6 II 292.]

1-Nitronaphthalene *[86-57-7]* **$C_{10}H_7NO_2$, M 173.2, m 53-57º, 57.3-58.3º, b 30-40º/0.01mm, 304º/atm, d_4^{25} 1.223,** Fractionally distil 1-nitronaphthalene under reduced pressure, then crystallise it from EtOH, aqueous EtOH or heptane. Chromatograph it on alumina with *benzene/petroleum ether as eluent. It sublimes *in vacuo*. The ***1:1 picrate complex*** has **m 72º** (from EtOH). [*Beilstein* **5** H 553, **5** III 1593, **5** IV 1673.]
2-Nitronaphthalene *[581-89-5]* has **m 79º, b 165º/15mm.** Distil it in a vacuum and/or crystallise it from aqueous EtOH and sublime in a vacuum. The **1:1** ***1,3,5-trinitrobenzene complex*** has **m 75.5º** (from EtOH). [*Beilstein* **5** H 555, **5** III 1596, **5** IV 1675.]

1-Nitro-2-naphthol *[550-60-7]* **$C_{10}H_7NO_3$, M 189.2, m 103º, b 115º/0.05mm, pK^{25} 5.93.** Distil it under high vacuum and/or crystallise the naphthol (repeatedly) from *benzene/petroleum ether (b 60-80º)(1:1), or aqueous EtOH (yellow needles or plates). It forms an insoluble complex with Co. [*Beilstein* **6** III 3002, **6** IV 4370.]
2-Nitro-1-naphthol *[607-24-9]* has **m 123-125º, 127-128º, pK^{25} 5.89.** Crystallise the naphthol (repeatedly) from EtOH. [*Beilstein* **6** H 615, **6** III 2938, **6** IV 4236.]

2-Nitrophenol *[88-75-5]* **$C_6H_5NO_3$, M 139.1, m 44.8º, 44.5-45.5º, 46º, 44-48º, b 214-215º/760mm, pK^{25} 7.23.** Crystallise 2-nitrophenol from EtOH/water, water, EtOH, *benzene or MeOH/petroleum ether (b 70-90º). It can be steam distilled. Petrucci and Weygandt [*Anal Chem* **33** 275 *1961*, DOI: 10.1021/ac60170a038] crystallised it from hot water (twice), then EtOH (twice), followed by fractional crystallisation from the melt (twice), drying over $CaCl_2$ in a vacuum desiccator and then in a drying pistol. The ***4-nitrobenzoate*** had **m 141º** (from EtOH). [*Beilstein* **6** IV 1246.]
3-Nitrophenol *[554-84-7]* has **m 96º, b 160-165º/12mm, 214-216º(dec)/atm, pK^{25} 8.36.** Crystallise 3-nitrophenol from water, $CHCl_3$, CS_2, EtOH or petroleum ether (b 80-100º), and dry it under vacuum over P_2O_5 at room temperature. It can also be distilled at low pressure (it decomposes at its bp at 760mm). The ***4-nitrobenzoate*** has **m 174º** (from EtOH). [*Beilstein* **6** IV 1269.]
4-Nitrophenol *[100-02-7]* has **m 110-115º, 113-114º, b 279º/atm, pK^{25} 7.16.** Crystallise 4-nitrophenol from water (which may be acidified, e.g. with *N* H_2SO_4 or 0.5*N* HCl), EtOH, aqueous MeOH, $CHCl_3$, *benzene or petroleum ether, then dry it *in vacuo* over P_2O_5 at 25º. It can be sublimed at 60º/10^{-4}mm. A 0.1% aqueous EtOH has been used as an indicator giving a colourless solution of the neutral species below pH 5.6, and a yellow solution of the anionic species at pH values above 7.6 (see pKa). The ***4-nitrobenzoate*** has **m 159º** (from EtOH). [*Beilstein* **6** IV 1279.]

2-Nitrophenoxyacetic acid *[1878-87-1]* **$C_8H_7NO_5$, M 197.2, m 150-159º, 156-159º, 158.2-158.5º, pK^{25} 2.90.** Crystallise the acid from water, and dry it over P_2O_5 *in vacuo*. The ***S-benzylisothiuronium salt*** has **m 155-156º** (from EtOH). [Hayes & Branch *J Am Chem Soc* **65** 1555 *1943*, DOI: 10.1021/ja01248a031; *Beilstein* **6** H 220, **6** II 211, **6** III 804, **6** IV 1261.]

4-Nitrophenyl acetate *[830-03-5]* **$C_8H_7NO_4$, M 181.2, m 75-77º, 77-79º, 78-79º.** Recrystallise the ester from absolute EtOH [Moss et al. *J Am Chem Soc* **108** 5520 *1986*, DOI: 10.1021/ja00278a025]. [*Beilstein* **6** IV 1298.] It is a chromogenic esterase substrate since the released 4-nitrophenol formed provides a solution of the

yellow anion.

2-Nitrophenylacetic acid *[3740-52-1]* **$C_8H_7NO_4$, M 181.2, m 137-140°, 141-142.5°, pK^{25} 3.95.** The acid crystallises as yellow needles from EtOH, EtOH/water and dry it over P_2O_5 under vacuum. The ***amide*** has **m 160-161°** (from *C_6H_6 plates or EtOH, needles). [*Beilstein* **9** III 2282, **9** IV 1687.]
4-Nitrophenylacetic acid *[104-03-0]* has **m 150-155°, 153.4-154.6°, pK^{25} 3.92.** Crystallise the acid from EtOH/water (1:1), then from sodium-dried diethyl ether and dry it over P_2O_5 *in vacuo*. The ***styphnate*** has **m 196.5-197°** (prisms from EtOH). The ***amide*** has **m** 191° (from EtOH). [*Beilstein* **9** III 2284, **9** IV 1698.]

4-Nitro-1,2-phenylenediamine (1,2-diamino-4-nitrobenzene) *[99-56-9]* **$C_6H_7N_3O_2$, M 153.1, m 199-201°, 201°, pK$_1^{25}$ 1.39 (1-NH_2), pK$_2^{25}$ 2.61 (2-NH_2).** Crystallise the diamine from water (solubility is 1.2g/L at 20°). [*Beilstein* **13** IV 75.]

1-(4-Nitrophenyl)ethylamine hydrochloride *[R-(+)- 57233-86-0, S-(-)- 132873-57-5]* **$C_8H_{11}ClN_2O_2$, M 202.6, m 225°, 240-242°(dec), 243-245°(dec), 248-250°, [α]$_D^{20}$ (+) and (-) 72 (c 1, 0.05 M NaOH), (+) and (-) 0.3 (H_2O), pK_{Est} ~8.6.** To ensure dryness, the hydrochloride (*ca* 175 g) is extracted with EtOH (3x100ml) and evaporated to dryness (any residual H_2O increases the solubility in EtOH and lowers the yield). The hydrochloride residue is triturated with absolute EtOH and dried *in vacuo*. The product is further purified by refluxing with absolute EtOH (200 ml for 83g) for 1 hour, and cooling to 10° to give 76.6g of the hydrochloride **m 243-245°(dec)**. The ***free base*** *[R, 22038-87-5; S, 4187-53-5]* $C_8H_{10}N_2O_2$, M 166.2, is prepared by dissolving in N NaOH, extracting with CH_2Cl_2 (3 x 500ml), drying (Na_2CO_3), filtering, evaporating and distilling it. It has **m 27°, b 119-120°/0.5mm** [105-107°/0.5mm, 157-159°/9mm, d$_4^{20}$ 1.1764, n$_D^{20}$ 1.5688, [α]$_D^{24}$ (+) and (-) 17.7 (neat)] [Perry et al. *Synthesis* 492 *1977*, DOI: 10.1055/s-1977-24459; ORD: Nerdel & Liebig *Justus Liebigs Ann Chem* **621** 42 *1959*, DOI: 10.1002/jlac.19596210107]. [*Beilstein* **12** IV 2451.]

4-Nitrophenylhydrazine *[100-16-3]* **$C_6H_7N_3O_2$, M 153.1, m 156°(dec), 158°(dec), pK$_1^{25}$ -9.2 (aqueous H_2SO_4), pK$_2^{25}$ 3.70.** Crystallise the hydrazine from EtOH. Add water to stabilise it The ***hydrochloride*** has **m 212°(dec)** (from EtOH, also **m 202-203° dec**). [*Beilstein* **15** III 331, **15** IV 317.] Reagent for making hydrazones for characterisation of carbonyl compounds.

3-Nitrophenyl isocyanate *[3320-87-4]* **$C_7H_4N_2O_3$, M 164.1, m 51-52°, 52-54°, b 130-131°/11mm.** Distil the isocyanate in a vacuum, and/or recrystallise it from petroleum ether (b 28-38°) or toluene/petroleum ether (**m 52°**). Store at 2-8°. [*Beilstein* **12** H 708, **12** III 1573.]
4-Nitrophenyl isocyanate *[100-28-7]* has **m 56-59°, b 137-138°/11mm, 162-164°/20mm.** Distil the isocyanate in a vacuum, and/or recrystallise it from petroleum ether (b 28-38°), *C_6H_6/petroleum ether (**m 58°**) or CCl_4 (**m 56-57°**). Store at 2-8°. [*Beilstein* **12** H 725, **12** III 1630.]

2-Nitrophenylpropiolic acid *[530-85-8, 92358-21-4]* **$C_9H_5NO_4$, M 191.1, m 157°(dec), 160.5-161°, 166-167°(dec), pK^{25} 2.83 (50% aqueous dioxane), 3.39 (50% aqueous EtOH).** Digest the acid with boiling $CHCl_3$, then crystallise it from H_2O. It can explode (store cold). The ***amide*** has **m 159°** (plates, from H_2O). [Schofield & Simpson *J Chem Soc* 512 *1945*, DOI: 10.1039/JR9450000512; *Beilstein* **9** H 636, **9** I 267, **9** II 438, **9** III 3067, **9** IV 2330.]

4-Nitrophenyl trifluoroacetate *[658-78-6]* **$C_8H_4F_3NO_4$, M 235.1, m 35-37°, 37-39°, b 120°/12mm.** Recrystallise the ester from $CHCl_3$/hexane [Margolis et al. *J Biol Chem* **253** 7891 *1978*, http://www.jbc.org/content/253/21/7891.full.html#ref-list-1]. It sublimes *in vacuo* (**m** 36-38°). It is *moisture sensitive*. Store at 2-8°. [Sakakibara & Inukai *Bull Chem Soc Jpn* **37** 1231 *1964*, DOI: 10.1246/bcsj.37.1231.]

4-Nitrophenyl urea *[556-10-5]* **$C_7H_7N_3O_3$, M 181.2, m 232°(dec), 238°, 242°.** Crystallise the urea from EtOH or hot water. Its UV has λ_{max} at 322nm (EtOH). [*Beilstein* **12** II 392, **12** III 1617, **12** IV 1645.]

3-Nitrophthalic acid *[603-11-2]* **$C_8H_5NO_6$, M 211.1, m 210°, 216-218°, b 441.3°/atm, d 1.671, pK^{25} 3.93.** Crystallise 3-nitrophthalic acid from hot water (1.5ml/g). Dry it in air. The ***amide*** has **m 201°** (from EtOH). [*Beilstein* **9** H 823, **9** IV 3275.]

4-Nitrophthalic acid *[610-27-5]* **$C_8H_5NO_6$, M 211.1, m 165°, pK^{25} 4.12.** Crystallise 4-nitrophthalic acid from Et_2O, EtOAc or *C_6H_6 (**m** 166°). The ***amide*** has **m 200°** (from EtOH). [Huntress et al. *Org Synth* Coll Vol **2** 457 *1943*, DOI: 10.15227/orgsyn.016.0056; *Beilstein* **9** H 828, **9** IV 4234.]

3-Nitrophthalic anhydride *[641-70-3]* **$C_8H_3NO_5$, M 193.1, m 163°, 164°, 165°.** Crystallise it from *C_6H_6, *C_6H_6/petroleum ether, Me_2CO, AcOH, or Ac_2O (**m 164-165°**). Dry it at 100°. [*Beilstein* **17/11** V 266.]
4-Nitrophthalic anhydride *[5466-84-2]* has **m 116-120°, 120-121.5°, b 196-197°/8mm.** Distil the anhydride in a vacuum and/or recrystallise it from *C_6H_6 or Et_2O/petroleum ether. Dry it *in vacuo*. It forms addition compounds with anthracene (**m 118°**), and phenanthrene (**m 96°**). [*Beilstein* **17** III/IV 6150, **17/11** V 267.]

5-Nitro-2-*n*-propoxyaniline *[553-79-7]* **$C_9H_{12}N_2O_3$, M 196.2, m 47.5-48.5°, 48°, 49°. pK_{Est} ~2.32.** Crystallise the aniline from *n*-propyl alcohol/petroleum ether or H_2O (136mg/L at 20°). It is an orange solid that is 4,000 the sweetness of sucose, but was banned in the US due to its possible toxicity.[*Beilstein* **13** III 878, **13** IV 897.]

2-Nitroresorcinol *[601-89-8]* **$C_6H_5NO_4$, M 155.1, m 81-82°, 83°, 84-85°, pK_1^{20} 6.37, pK_2^{20} 9.46.** Recrystallise 2-nitroresorcinol from aqueous EtOH. [*Beilstein* **6** H 823.]

4-Nitrosalicylic acid *[619-19-2]* **$C_7H_5NO_5$, M 183.1, m 234°, 235-238°(dec), 237-240°, pK^{25} 2.23.** Crystallise the acid from H_2O (**m 236-238°**) or aqueous EtOH (**m 235-236° dec**). [*Beilstein* **10** III 194, **10** IV 231.]
5-Nitrosalicylic acid *[96-97-9]* has **m 233°, b 1.730, pK_1^{25} 2.32, pK_2^{25} 10.34.** Crystallise the acid from Me_2CO (charcoal), then twice more from Me_2CO alone, aqueous EtOH (**m 234-236°**) or H_2O (**m 232-233°**). [*Beilstein* **10** III 197, **10** IV 255.]

Nitrosobenzene (NOB) *[586-96-9]* **C_6H_5NO, M 107.1, m 67.5-68°, 65-69°, b 57-59°/18mm.** Steam distil nitrosobenzene, then crystallise it from a small volume of EtOH with cooling below 0°, dry it over $CaCl_2$ in a dessicator at atmospheric pressure, and store it under N_2 at 0°. *Alternatively*, it can be distilled onto a cold finger cooled with brine at ~-10° in a vacuum at 17mm (water pump), while heating in a water bath at 65-70° [Robertson & Vaughan *J Chem Educ* **27** 605 *1950*, DOI: 10.1021/ed027p605]. [*Beilstein* **5** IV 702.] It is a spin trap reagent and used in the study of oxidative DNA damage [Ohkuma & Kawanishi *Biochem Biophys Res Commun* 257 555 *1999*, http://www.idealibrary.com/bbrc.1999.0525], and nitroso-induced repiratory burst in neutrophils [Nakata *J Biochem (Tokyo)* **122** 188 *1997*, PMID: 9276687].

4-Nitrosodiphenylamine (tautomer of benzoquinone-1,4-phenylimine oxime) *[156-10-5]* **$C_{12}H_{10}N_2O$, M 198.2, m 144°(dec), 144-145°(dec), 145.4-146.6°, 144-148°.** The amine forms dark green crystals from EtOH or *C_6H_6 (**m** 143°). It has UV with λ_{max} at 421nm (EtOH), and it is used for detecting Pd and Rh. *It is highly toxic and a possible carcinogen*. [*Beilstein* **12** H 207, **12** II 122, **12** III 347, **12** IV 1860ß.]

1-Nitroso-2-naphthol *[131-91-9]* **$C_{10}H_7NO_2$, M 173.2, m 106-108°, 110.4-110.8°, pK^{25} 7.63.** Crystallise the naphthol from petroleum ether (b 60-80°, 7.5ml/g). Its solubility in cold H_2O is 0.1w/w%, and in cold EtOH it is 2.9w/w%, but more soluble on heating. It forms a Cobalt complex and is used to separate it from Ni. [Marvel & Porter *Org Synth* Coll Vol **1** 411 *1941*, DOI: 10.15227/orgsyn.002.0061; *Beilstein* **7** H 712, **7** IV 2419.]
2-Nitroso-1-naphthol *[132-53-6]* has **m 150-155°, 162-164°, pK^{25} 7.24.** Purify the naphthol by recrystallisation from petroleum ether (b 60-80°) or by dissolving it in hot EtOH, followed by successive addition of small volumes of water (**m 158° dec**). It also crystallises from *C_6H_6 or H_2O. Crystallisation from *C_6H_6/petroleum ether gives **m** (**106-109 °**, also **109.5°**). It has λ_{max} at 274.5 and 382nm ($CHCl_3$). It complexes with metals. [*Beilstein* **7** H 712, **7** I 385, **7** II 647, **7** III 3688, **7** IV 2419.]
4-Nitroso-1-naphthol *[605-60-7]* has **m 198°(dec), pK^{25} 8.18.** Crystallise the naphthol from *C_6H_6 or H_2O (**m** 197°, dec). and sublime it at 75-80°/0.2mm. It has λ_{max} at 336nm (EtOH). [*Beilstein* **7** H 715, **7** II 653, **7** III 3700, **7** IV 2424.]

4-Nitrosophenol (benzoquinone mono oxime) *[104-91-6]* **$C_6H_5NO_2$, M 123.1, m >124°(dec), 132-144°(dec), pK^{25} 6.36.** 4-Nitrosophenol forms yellow crystals from xylene, *C_6H_6 (**m ~144°**) or Et_2O (**m 128-129°, dec**). The solubility in H_2O is ~0.01w.v% at 21°. [*Beilstein* **7** H 622, **7** II 574, **7** III 3367.]

***N*-Nitroso-*N*-phenylbenzylamine** *[612-98-6]* **$C_{13}H_{12}N_2O$, M 212.2, m 58°.** Crystallise the amine from absolute EtOH (yellow needles) and dry it in air. It is slightly soluble in organic solvents. [*Beilstein* **12** H 1071, **12** II 335, **12** III 2335.]

***trans*-β-Nitrostyrene** *[5153-67-3]* **$C_8H_7NO_2$, M 149.2, m 55-58°, 58°, 60°, b 250-260°/atm.** Crystallise the styrene from absolute EtOH, or three times from *benzene/petroleum ether (b 60-80°) (1:1). [*Beilstein* **5** III 1180, **5** IV 1352.]

4-Nitrostyrene *[100-13-0]* **$C_8H_7NO_2$, M 149.2, m 20.5-21°, 25-28°, 29°, b 93-96°/3mm, 120°/10mm** Crystallise it from $CHCl_3$/hexane. Purify it by addition of MeOH to precipitate the polymer, then crystallise it at -40° from MeOH. It has also been crystallised from EtOH. [Bernasconi et al. *J Am Chem Soc* **108** 4541 *1986* DOI: 10.1021/ja00275a047; *Beilstein* **5** H 478, **5** III 1180, **5** IV 1351.]

2-Nitrotoluene *[88-72-2]* **$C_7H_7NO_2$, M 137.1, m -9.55° (α-form), -3.85° (β-form), b 118°/16mm, 222.3°/760mm, d_4^{20} 1.163, n_D^{20} 1.545.** Crystallise 2-nitrotoluene (repeatedly) from absolute EtOH by cooling in a Dry-ice/alcohol mixture. Further purify it by passing an alcoholic solution through a column of alumina. [*Beilstein* **5** IV 845.]
3-Nitrotoluene *[99-08-1]* has **m 14°, 16°, b 113-114°/15mm, 232.6°/atm, d_4^{20} 1.156, n_D^{20} 1.544.** Dry 3-nitrotoluene over P_2O_5 for 24 hours, then fractionally distil it under reduced pressure. [Clarke & Taylor *Org Synth* Coll Vol **1** 415 *1941*, DOI: 10.15227/orgsyn.003.0091; *Beilstein* **5** IV 847.]
4-Nitrotoluene *[99-99-0]* has **m 51°, 51.6°, 52°, 54°, b 238°/atm, d_4^{25} 1.392.** Crystallise 4-nitrotoluene from EtOH, MeOH/water, EtOH/water (1:1) or MeOH. Dry it in air, then dry it in a vacuum desiccator over H_2SO_4. [Wright & Gilliom *J Am Chem Soc* **108** 2340 *1986*, DOI: 10.1021/ja00269a033; *Beilstein* **5** IV 848.]

5-Nitrovanillin (nitroveratric aldehyde) *[6635-20-7]* **$C_8H_7NO_5$, M 197.2, m 172-175°, 176°, 178°.** It forms yellow plates from AcOH and needles from EtOH [Slotta & Szyszka *Chem Ber* **68** 184 *1935*, DOI: 10.1002/cber.19350680140]. With diazomethane, 5-nitro-3,4-dimethoxyacetophenone is formed [Brady & Manjunath *J Chem Soc* **125** 1060 *1924*, DOI: 10.1039/CT9242501060]. The ***methyl ether*** crystallises from EtOAc or AcOH, **m 88°, 90-91°**, and the ***phenylhydrazone*** has **m 108-110°** (from aqueous EtOH). [Finger & Schott *J Prakt Chem* [2] **115** 281 *1927*, DOI: 10.1002/prac.19271150122.] The ***oxime*** has **m 216°** (from EtOH or AcOH), and the ***oxime acetate*** has **m 147°** (from aqueous EtOH) [Vogl *Monatsh Chem* **20** 383 *1899*, DOI: 10.1007/BF01524832; Brady & Dunn *J Chem Soc* **107** 1858 *1915*, DOI: 10.1039/CT9150701858]. [*Beilstein* **8** III 2064.]

Nordihydroguaiaretic [1,4-bis(3,4-dihydroxyphenyl)-2,3-dimethylbutane] acid *[500-38-9]* **$C_{18}H_{22}O_4$, M 302.4, m 184-185°, $pK_{Est(1)}$~9.7, $pK_{Est(2)}$~12.** Crystallise the acid from dilute acetic acid. It is an antioxidant and was banned as a nutritional supplement because it has renal and hepato toxicity. [*Beilstein* **6** IV 7771.]

1,2,3,4,6,7,8-Octahydroanthracene *[1079-71-6]* **$C_{14}H_{18}$, M 186.3, m 73°, 73.5°, 78°, d_4^{80} 0.9703, n_D^{80} 1.5372.** Crystallise the compound from EtOH, then purify it by zone melting. [*Beilstein* **5** III 1400.]

***n*-Octylammonium 9-anthranilate** *[88020-99-9]* **M 351.5, m 134-135°, pK^{25} 10.65 (for octylamine).** Recrystallise the ester several times from ethyl acetate.

4-Octylbenzoic acid *[3575-31-3]* **$C_{15}H_{22}O_2$, M 234.3, m 97-98°, 98°, 99-100°, pK^{25} 6.5 (80% aqueous EtOH), pK_{Est} ~4.5 (H_2O).** When crystallised from EtOH it has **m 139°**, but when crystallised from aqueous EtOH it has **m 99-100°**. It forms liquid crystals. [*Beilstein* **9** H 571, **9** III 2611.]

4-(*tert*-Octyl)phenol *[140-66-9]* **$C_{14}H_{22}O$, M 206.3, m 79-82°, 85-86°, b 166°/20mm, 175°/30mm, pK_{Est} ~ 10.4.** Crystallise the phenol from *n*-hexane and/or distil it in a vacuum. [*Beilstein* **6** III 2051, **6** IV 3484.]

Opianic acid (2-formyl-4,5-dimethylbenzoic acid) *[519-05-1]* **$C_{10}H_{10}O_5$, M 210.2, m 145-147°, 148°, 150°,**

pK^{25} 3.07. Crystallise the acid from water. [*Beilstein* **10** H 990, **10** I 484, **10** II 719, **10** III 4511, **10** IV 3863.]

Orcine moohydrate (orcinol hydrate, 3,5-dihydroxytoluene) *[6153-39-5]* **$C_7H_{10}O_3$, M 142.2, m 56°, 56-58°, 58°, 56-61°, b 147°/5 mm, 290°/atm, pK$_1^{20}$ 9.48 (9.26), pK$_2^{20}$ 11.20 (11.66).** Purify orcine by recrystallisation from H_2O as the ***monohydrate***. It sublimes *in vacuo*, and the ***anhydrous*** compound has **m 106.5-108° (110°, 108°)**. It can be recrystallised from $CHCl_3$ (plates) or *C_6H_6 (needles or prisms). [UV: Kiss et al. *Bull Soc Chim Fr* 275 *1949*, Adams et al. *J Am Chem Soc* **62** 732 *1940*, DOI: 10.1021/ja01861a010.]

Orcinol (5-methylresorcinol) *[504-15-4; 6153-39-5 H_2O]* **$C_7H_8O_2$, M 124.2, m 107.5°, 106-108°, 110°, 106-13138112°, m 59-61° (hydrate cf. orcine), pK$_1^{20}$ 9.36 (9.48), pK$_2^{20}$ 11.6 (11.20).** Crystallise orcinol from $CHCl_3$/*benzene (2:3). See *hydrate* in previous entry. [*Beilstein* **6** H 882, **6** IV 5892.]

[2.2]-Paracyclophane (tricyclo[8.2.2.2^{4,7}]hexadeca-4,6,10,12,13,15-hexaene)*[1633-22-3]* **$C_{16}H_{16}$, M 208.3, m 284°, 285-287°, 286-288°, 288-290°.** Purify it by recrystallisation from AcOH. ^{1}H-NMR δ: 1.62 (Ar-H) and 1.71 (CH_2) [Waugh & Fessenden *J Am Chem Soc* **79** 846 *1957*, DOI: 10.1021/ja01561a017; IR and UV: Cram et al. *J Am Chem Soc* **76** 6132 *1954*, DOI: 10.1021/ja01652a081; Cram & Steinberg *J Am Chem Soc* **73** 5691 *1951,* DOI: 10.1021/ja01156a059. It complexes with unsaturated compounds: Cram & Bauer *J Am Chem Soc* **81** 5971 *1959*, DOI: 10.1021/ja01531a031; Syntheses: Brink DOI: 10.1055/s-1975-23940; 807 *1975*, Givens et al. *J Org Chem* **44** 1608 *1979*, DOI: 10.1021/jo01324a005; Kaplan & Truesdale *Tetrahedron Lett* 3665 *1976*, DOI: 10.1016/S0040-4039(00)93075-2]. [*Beilstein* **5** IV 2223.]

Para Red [1-(4-nitrophenylazo)-2-naphthol] *[6410-10-2]* **$C_{16}H_{11}N_3O_3$, M 293.3, m 250-251°, 248-252°, CI 12070, pK$_{est}$ ~ 9.3.** Crystallise this red dye from AcOH or xylene and dry it *in vacuo*. It has λ_{max} at 488nm. [*Beilstein* **16** II 70.]

Pargyline hydrochloride (Eutonyl, *N*-methyl-*n*-propargylbenzylamine hydrochloride) *[306-07-0]* **$C_{11}H_{14}ClN$, M 195.7, m 154-155°, 155°, pK^{25} 6.9.** Recrystallise the salt from EtOH/Et_2O and dry it *in vacuo*. It is very soluble in H_2O, in which it is unstable. The ***free base*** has **b 101-103°/11mm**. It is a glucuronyl transferase inducer and a monoamine oxidase inhibitor. [von Braun et al. *Justus Liebigs Ann Chem* **445** 201 *1925*, DOI: 10.1002/jlac.19254450114; Langston et al. *Science* **225** 1480 *1984*, DOI: 10.1126/science.6332378; *Beilstein* **12** II 548.] It is an irreversible MAO inhibitor and an antihypertensive drug.

Pavatrine hydrochloride [fluorine-9-carboxylic acid, 2-(diethylamino)ethyl ester hydrochloride] *[548-65-2]* **$C_{20}H_{24}ClNO_2$, M 333.7, m 143-144°, pK$_{Est}$ ~9.0** Recrystallise the salt from isopropanol, EtOAc/isoPrOH and dry it over P_2O_5 *in vacuo*. 1-(Pentafluorophenyl)ethanol *[R-(+)- 104371-21-3, S-(-)- 104371-20-2]* **$C_8H_5F_5O$, M 212.1, m 41-42°, 42°, 42.5-43°, $[\alpha]_{546}^{20}$ (+) and (-) 9, $[\alpha]_D^{20}$ (+) and (-) 7.5 (c 1, *n*-pentane).** Recrystallise the ethanol from *n*-pentane at -40° and sublime it at 25°/0.3mm (use ice-cooled cold finger). It has also been purified by column chromatography through Kieselgel 60 (0.063-0.2mm mesh, Merck) and eluted with EtOAc/*n*-hexane (1:5), then recrystallised from *n*-pentane and sublimed in a vacuum. It has R_F 0.28, on Kieselgel 60 F_{254} TLC foil and eluting with EtOAc/*n*-hexane (1:5). [Meese *Justus Liebigs Ann Chem* 2004 *1986*, DOI: 10.1002/jlac.198619861120.]
The ***racemate*** *[75853-08-6]* has **m 32-34°, b 77-79°/8mm, 80-82°/37mm, n_D^{20} 1.4426**; the ***3,4-dinitrobenzoate*** has **m 83°** [Nield et al. *J Chem Soc* 166 *1959*, DOI: 10.1039/JR9590000166]. [*Beilstein* **6** IV 3044.]

Pentamethylbenzene *[700-12-9]* **$C_{11}H_{16}$, M 148.3, m 50-51°, 53°, 54.5°, 53.5-55.1°, b 231-232°/atm, d_4^{25} 0.917.** Successively crystallise it from absolute EtOH, aqueous EtOH, MeOH, toluene *C_6H_6, and dry it under vacuum. [Rader & Smith *J Am Chem Soc* **84** 1443 *1962*, DOI: 10.1021/ja00867a021.] It has also been sublimed. The ***1,3,5-trinitrobenzene complex (1:1)*** has **m 121°** (EtOH). Its FT-IR (neat) has ν_{max} at 2939.4, 2728.0, 1568.1, 1475.5, 1381.8, 1067.6, 1013.9, 860.7 and 524.6 cm^{-1}; [*Beilstein* **5** H 443, **5** III 1010, **5** IV 1109.] It is a very electron rich hydrocarbon which readily undergoes electrophilic reactions.

Perbenzoic acid *[93-59-4]* **$C_7H_6O_3$, M 138.1, m 42°, 41-43°, b 97-110°/13-15mm, pK_{Est} ~7.7.** Crystallise the peracid from *C_6H_6, or petroleum ether. It sublimes readily and is steam volatile. It is soluble in $CHCl_3$, CCl_4

and Et_2O. It is advisable **NOT** to distil it unless extreme precautions are taken. [Braun *Org Synth* Coll Vol **1** 431 *1941*, DOI: 10.15227/orgsyn.008.0030.] **EXPLOSIVE.**

Perylene *[198-55-0]* **$C_{20}H_{12}$, M 252.3, m 273-274°, 276-279°.** Purify perylene by silica-gel chromatography of its recrystallised picrate. [Ware *J Am Chem Soc* **83** 4374 *1961*, DOI: 10.1021/ja01482a019.] Crystallise it from *benzene, toluene or EtOH and sublime it at 142° in a flow of oxygen-free nitrogen. It forms a **1:1 *benzene-complex*** (**m 223-224.5°** needles from $*C_6H_6$), and a **1:2 *benzene-complex*** (**m 154-155°** from $*C_6H_6$ or H_2O). The ***2,4,7-trinitrofluoren-9-one*** has **m 270-271°** (from EtOH/$*C_6H_6$). [Gorman et al. *J Am Chem Soc* **107** 4404 *1985,* DOI: 10.1021/ja00301a006; Johansson et al. *J Am Chem Soc* **109** 7374 *1987*, DOI: 10.1021/ja00258a021; *Beilstein* **5** III 2521, **5** IV 2689.]

Phenanthrene *[85-01-8]* **$C_{14}H_{10}$, M 178.2, m 98°, 98.7-99°, 99.15°, 100.8-101.3°, b 148-149°/1mm, b 340°/760mm, d^{25} 1.175.** Likely contaminants include anthracene, carbazole, fluorene and other polycyclic hydrocarbons. Purify it by distillation from sodium under vacuum, boiling with maleic anhydride in xylene, crystallisation from acetic acid, sublimation and zone melting. It has also been recrystallised repeatedly from EtOH, *benzene or petroleum ether (b 60-70°), with subsequent drying under vacuum over P_2O_5 in an Abderhalden pistol. Feldman, Pantages and Orchin [*J Am Chem Soc* **73** 4341 *1951*, DOI: 10.1021/ja01153a091] separated most of the anthracene impurity by refluxing phenanthrene (671g) with maleic anhydride (194g) in xylene (1.25L) under nitrogen for 22 hours, then filtered. The filtrate was extracted with aqueous 10% NaOH, the organic phase was separated, and the solvent was evaporated. The residue, after stirring for 2 hours with 7g of sodium, was distilled in a vacuum, then recrystallised twice from 30% *benzene in EtOH. It was then dissolved in hot acetic acid (2.2ml/g), and to it was slowly added an aqueous solution of CrO_3 (60g in 72ml H_2O plus 2.2L of acetic acid), followed by slow addition of concentrated H_2SO_4 (30ml). The mixture was refluxed for 15 minutes, diluted with an equal volume of water and cooled. The precipitate was filtered off, washed with water, dried and distilled, then recrystallised twice from EtOH. Further purification is possible by chromatography from a $CHCl_3$ solution on activated alumina, with *benzene as eluent, and by zone refining. The ***picrate (1:1)*** forms golden yellow needles with **m 146°**, and the ***styphnate (1:1)*** has **m 138-139°** (plates or needles from EtOH or EtOH/H_2O respectively). [Dornfeld et al. *Org Synth* Coll Vol **3** 134 *1955*, DOI: 10.15227/orgsyn.028.0019; *Beilstein* **5** H 667, **5** I 327, **5** II 579, **5** III 2136, **5** IV 2297.]

Phenanthrene-9-aldehyde *[4707-71-5]* **$C_{15}H_{10}O$, M 206.3, m 102-103°, pK^{25} -6.39 (aqueous H_2SO_4).** Recrystallise the aldehyde from EtOH and sublime it at 95-98°/0.07mm. It is a white powder with blue fluorescence, and its solubility in $CHCl_3$ is 0.04M. The ***2,4-dinitrophenylhydrazone*** has **m 272-273°**. [*Beilstein* **7** III 2532, **7** IV 1740.]

9,10-Phenanthrenequinone *[84-11-7]* **$C_{14}H_8O_2$, M 208.2, m 206°, 208°, 210°, 209-212°, b 360°/760mm, d 1.405, pK^{25} -7.1 (aqueous H_2SO_4).** Crystallise the quinone from dioxane or 95% EtOH and dry it under vacuum. It gives a green colour in H_2SO_4. [*Beilstein* **7** IV 2565.]

Phenethylamine *[64-04-0]* **$C_8H_{11}N$, M 121.2, m -60°, b 87°/13mm, 194-195°/atm, 200-202°/atm, d_4^{20} 0.962, n_D^{20} 1.535, pK^{25} 9.88.** Distil the amine from CaH_2, under reduced pressure, just before use. It is a strong base, store under N_2. [*Beilstein* **12** H 1096, **12** IV 2453.]

Phenethyl bromide *[103-63-9]* **C_8H_9Br, M 185.1, m -65.7°, -56°, b 92°/11mm, 220-221°/atm, d_4^{20} 1.368, n_4^{20} 1.557**. Wash the bromide with concentrated H_2SO_4, water, aqueous 10% Na_2CO_3 and water again, then dry it with $CaCl_2$ and fractionally distil it just before use. [*Beilstein* **5** IV 907.]

(±)-*N*-1-Phenethyl urea (*N*-α-phenethyl urea) *[60295-51-4]* **$C_9H_{12}N_2O$, M 164.2, m 137°.** Crystallise the urea from H_2O, EtOAc or $*C_6H_6$. [Buck *J Am Chem Soc* **56** 1607 *1934*, DOI: 10.1021/ja01322a047; *Beilstein* **12** I 1096, **12** IV 1440.]

***N*-2-Phenethyl urea** *[2158-04-5]* **$C_9H_{12}N_2O$, M 164.2, m 112°.** Crystallise the (±)-urea from H_2O (**m 112-113°**) or EtOH. The *picrate* has **m 113-115°** (from H_2O) [Spica *Gazzetta* **9** 567 *1879*, Shapiro et al. *J Am Chem Soc* **81** 2220 *1959*, DOI: 10.1021/ja01518a052]. [*Beilstein* **12** 1099, **12** III 2423, **12** IV 2470.]

Phenetole *[103-73-1]* **$C_8H_{10}O$, M 122.2, m -30°, b 60°/9mm, 77.5°/31mm, 170.0°/760mm, d_4^{20} 0.967, n_D^{20} 1.50735, n^{25} 1.50485.** Small quantities of phenol can be removed by shaking with NaOH, but this is not a very likely contaminant of commercial material. Fractional distillation from sodium, at low pressures, probably gives adequate purification. It can be dissolved in diethyl ether and washed with 10% NaOH (to remove phenols), then water. The ethereal solution is evaporated, and phenetole is fractionally distilled under vacuum. [*Beilstein* **6** H 140, **6** I 80, **6** II 142, **6** III 545.]

Phenocoll hydrochloride (4-ethoxyaniline HCl, *p*-phenetidine HCl) *[637-56-9]* **$C_8H_{11}NO.HCl$, M 230.7, m 234°, pK^{28} 5.20.** Crystallise the salt from water then sublime it *in vacuo*. [*Beilstein* **13** IV 1017.]

Phenol (carbolic acid) *[108-95-2]* **C_6H_6O, M 94.1, m 40.5°, 40.9°, b 85.5-86.0°/20mm, 180.8°/760mm, 181.70°/760mm, d_4^{20} 1.06, n_D^{41} 1.54178, n_D^{40} 1.53957, pK^{25} 9.86** (in H_2O, **9.95, 10.02** also reported)**, 29.1** (in MeCN). Steam is passed through a boiling solution containing 1mole of phenol and 1.5-2.0moles of NaOH in 5L of H_2O until all non-acidic material has distilled. The residue is cooled, acidified with 20% (v/v) H_2SO_4, and the phenol is separated, dried with $CaSO_4$ and fractionally distilled under reduced pressure. It is then fractionally crystallised several times from its melt [Andon et al. *J Chem Soc* 5246 *1960*, DOI: 10.1039/JR9600005246]. Purification *via* the benzoate has been used by Berliner, Berliner and Nelidow [*J Am Chem Soc* **76** 507 *1954*, DOI: 10.1021/ja01631a052]. The ***benzoate***, (**m 70°, b 314°/760mm**), is crystallised from 95% EtOH, then hydrolysed to the free phenol by refluxing with two equivalents of KOH in aqueous EtOH until the solution becomes homogeneous. It is acidified with HCl and extracted with diethyl ether. The ether layer is freed from benzoic acid by thorough extraction with aqueous $NaHCO_3$, and, after drying and removing the ether, the phenol is distilled. Phenol has also been crystallised from a 75% w/w solution in water by cooling to 11° and seeding with a crystal of the hydrate. The crystals are centrifuged off, rinsed with cold water (0-2°), saturated with phenol, and dried. It can be crystallised from petroleum ether [Bernasconi & Paschalis *J Am Chem Soc* **108** 2969 *1986*, DOI: 10.1021/ja00271a027]. Its solubility in H_2O is 8.3w/v% at 20°.
Draper and Pollard [*Science* **109** 448 *1949*, DOI: 10.1126/science.109.2835.448] added 12% water, 0.1% aluminium (can also use zinc) and 0.05% $NaHCO_3$ to phenol, and distilled it at atmospheric pressure until the azeotrope was removed. The phenol was then distilled at 25mm. Phenol has also been dried by distillation from the *benzene solution to remove the water/*benzene azeotrope and the excess *benzene, followed by distillation of the phenol at reduced pressure under nitrogen. Processes such as this are probably adequate for analytical grade phenol which has as its main impurity water. Phenol has also been crystallised from petroleum ether/*benzene or petroleum ether (b 40-60°). The purified material is stored in a vacuum desiccator over P_2O_5 or $CaSO_4$. [*Beilstein* **6** IV 531.] *It has a sweet tarry odour. An aqueous solution is used as an antiseptic, should be used with gloves as it causes severe skin burns and can be lethal if ingested.*

Phenolphthalein *[77-09-8]* **$C_{20}H_{14}O_4$, M 318.2, m 252-°, 263°, d_4^{25} 0.918, $pK_{Est(1)}$~ 4.2, $pK_{Est(2)}$~ 9.8.** Dissolve it in EtOH (7ml/g), then dilute it with eight volumes of cold water, filter and heat on a water-bath to remove most of the alcohol and the phenolphthalein that precipitates is filtered off and dried *in vacuo* to give white or pale yellow microcrystals. A 0.5% solution in EtOH/H_2O (1:1) is used as a titration indicator in which it is colourless below pH 8.0 and red at pH values above 10 (see pKa ~9.8). [*Beilstein* **18** II 119, **18** III/1V 1945, **18/4** V 188.] It has laxative properties and is used as a purgative.

Phenolphthalol {2-[bis(4-hydroxyphenyl)methyl]benzyl alcohol, Normolax, Egmol, Velaxin} *[81-92-5]*

$C_{20}H_{18}O_3$, M 306.3, m 201-202°, pK_{Est} ~ 9.8. Crystallise it from aqueous EtOH. [*Beilstein* **6** H 1146, **6** II 1110, **6** IV 7623.] Laxative.

Phenoxyacetic acid *[122-59-8]* **$C_8H_8O_3$, M 152.2, m 98-99°, 98-100°, 285°/atm (dec), pK^{25} 3.18.** Crystallise the acid from water (solubility at ~20° is 1.33w/v%), or aqueous EtOH. [*Beilstein* **6** IV 634.] It is an irritant fungicide which can soften hard callus skin. ***Phenoxyacetyl chloride*** *[701-99-5]* **$C_8H_7ClO_2$, M 170.6,** has **b 112°/10mm, 102°/16mm, 225-226°/atm, d_4^{20} 1.235, n_D^{20} 1.534.** If it has no OH band in the IR then distil it in a vacuum, taking precautions for the moisture-sensitive compound. If it contains free acid (due to hydrolysis, OH bands in the IR), then add an equal volume of redistilled $SOCl_2$, reflux for 2-3 hours, evaporate and distil the residue in a vacuum as before. It is a useful reagent for generating phenyloxyketene that undergoes cycloaddition reactions to imines leading to β-lactams [Shaikh et al. *Tetrahedron* **63** 3380 *2007*, DOI: 10.1016/j.tet.2007.02.022; Huang & Calter *Tetrahedron Lett* **48** 1657 *2007*, DOI: 10.1016/j.tetlet.2006.12.091]. The ***amide*** *[621-88-5]* has **m 101°**. [McElvain & Carney *J Am Chem Soc* **68** 2592 *1946*, DOI: 10.1021/ja01216a051; *Beilstein* **6** III 613.]

4-Phenoxyaniline *[139-59-3, 73166-61-7]* **$C_{12}H_{11}NO$, M 185.2, m 82-84°, 95°, b 140°/2.3mm, pK^{20} 4.44 (50% aqueous EtOH).** Crystallise 4-phenoxyaniline from water (solubility at 20° is 0.1w/v%). [*Beilstein* **13** IV 1020.]

Phenoxybenzamine [*N*-(2-chloroethyl)-*N*-(1-methyl-2-phenoxyethyl)benzylamine] *[59-96-1]* **M 303.5, m 38-40°, hydrochloride** *[63-92-3]* **$C_{18}H_{22}ClNO$, M 340.0, m 137.5-140°, pK_{Est} ~4.2.** The free base is crystallised from petroleum ether, and the ***hydrochloride*** is recrystallised from EtOH/diethyl ether. [*Beilstein* **12** IV 2204.] Antihypertensive.

2-Phenoxybenzoic acid *[2243-42-7, 36361-03-2]* **$C_{13}H_{10}O_3$, M 214.2, m 110-112°, 113°, b 355°/760mm, $pK^{15/25}$ 3.53.** Crystallise the acid from aqueous EtOH or H_2O (**m** 114°). [*Beilstein* **10** H 65, **10** I 28, **10** II 40, **10** III 99, **10** IV 132.]
3-Phenoxybenzoic acid *[61-72-3, 3739-38-6]* has **m 145°, 147-149°, 147-150°, pK^{25} 3.95.** Crystallise the acid from aqueous EtOH. [*Beilstein* **10** H 138, **10** III 247, **10** IV 316.]
4-Phenoxybutyric acid *[6303-58-8]* has **m 64°, 63-65°, 65-66°, b 170°/7mm, 180-185°/12mm, pK 3.17.** It has been purified by recrystallisation from petroleum ether, *C_6H_6, Et_2O/petroleum ether, EtOH and from H_2O. It can be steam distilled or distilled in a good vacuum. [UV: Ramart-Lucas & Hoch *Bull Soc Chim Fr* [4] **51** 824 *1932*, Dann & Arndt *Justus Liebigs Ann Chem* **587** 38 *1954*, DOI: 10.1002/jlac.19545870104.] The ***acid chloride*** has **b 154-156°/20mm** [Hanford & Adams *J Am Chem Soc* **57** 921 *1935*, DOI: 10.1021/ja01308a044], and the ***amide*** crystallises from *C_6H_6 as needles with **m 113°**. [*Beilstein* **6** IV 645.]

2-Phenoxypropionic acid (lactic acid *O*-phenylether) *[940-31-8]* **$C_9H_{10}O_3$, M 166.2, m 112-115°, 115-116°, 116-119°, b 105-106°/5mm, 265-266°/758mm, pK^{25} 3.11.** Crystallise the acid from water. [*Beilstein* **6** H 163, **6** II 158, **6** III 614.]

Phensuximide (*N*-methyl-2-phenylsuccinimide) *[86-34-0]* **$C_{11}H_{11}NO_2$, M 189.2, m 71-73°.** Crystallise phensuximide from hot 95% EtOH (**m** 72-73°). At 25° 1g of the imide dissolves in 1g of *C_6H_6, 18g of Et_2O, 9.5g of EtOH, 5.1g of MeOH and 235g of H_2O. [*Beilstein* **21** II 300, **21** III/IV 5465.] It is an anticonvulsant and an antiepileptic drug.

Phenylacetic acid *[103-82-2]* **$C_8H_8O_2$, M 136.2, m 76-77°, 77.5°, 76-79°, b 140-150°/20mm, 265.5°/760mm, d 1.1, pK_1 -7.59 (aqueous H_2SO_4), pK_2 4.31.** Crystallise the acid from petroleum ether (b 40-60°), isopropyl alcohol, 50% aqueous EtOH or hot water (**m 77.8-78.2°**). Dry it *in vacuo*. It can be distilled under a vacuum. [*Beilstein* **9** II 294, **9** III 2169.] Present in faint odour of flowers as well as horse urine. ***Phenyl acetate*** *[122-79-2]* **$C_8H_8O_2$, M 136.2,** has **m -30°, b 78°/10mm, 195-196°/atm, d_4^{20} 1.079, n_D^{22} 1.5039.** Phenyl acetate acid is freed from phenol and acetic acid by washing (either directly or as a solution in pentane) with aqueous 5% Na_2CO_3, then with saturated aqueous $CaCl_2$, drying with $CaSO_4$ or Na_2SO_4, and fractionally distilling under reduced pressure. [*Beilstein* **6** II 153, **6** III 595, **6** IV 611.] ***Phenylacetamide*** *[103-81-1]* **$C_{18}H_9NO$, M 135.2,** has **m 155°, 156°, 157°, 158.5°.** Crystallise the acetamide repeatedly from absolute EtOH, EtOAc (**m 160-161°**)

or H_2O (**m 159-160°**). Dry it *in vacuo* over P_2O_5. [*Beilstein* **9** H 347, **9** III 2193, **9** IV 1632.]

Phenylacetone (1-phenylpropan-2-one) *[103-79-9, 136675-26-8]* **$C_9H_{10}O$, M 134.2, m -15°, b 69-71°/3mm, 214-216°/760mm, d_4^{20} 1.006, n_D^{20} 1.516.** Convert the ketone to the ***semicarbazone*** and crystallise it three times from EtOH (**m 186-187°**). The semicarbazone is then hydrolysed with 10% phosphoric acid, and the ketone is recovered by distillation. [Kumler et al. *J Am Chem Soc* **72** 1463 *1950*, DOI: 10.1021/ja01160a010; *Beilstein* **7** H 303, **7** I 161, **7** II 223, **7** III 1037, **7** IV 687.]

4'-Phenylacetophenone (4-acetylbiphenyl) *[92-91-1]* **$C_{14}H_{12}O$, M 196.3, m 117-123°, 118-121°, 120.3-121.2°, b 168°/8mm, 196-210°/18mm, 325-327°/760mm.** Crystallise it from EtOH or acetone. It can also be distilled under reduced or atmospheric pressure. The ***semicarbazone*** has **m 131-132°** (aqueous EtOH). [*Beilstein* **7** H 443, **7** III 2134, **7** IV 1407.]

Phenylacetylene *[536-74-3]* **C_8H_6, M 102.1, m -45°, -44.8°, b 75°/80mm, 142-144°/760mm, d_4^{20} 0.930, n_D^{25} 1.5463, pK ~19.** Distil phenylacetylene through a spinning band column. It should be filtered through a short column of alumina before use [Campbell & Campbell *Org Synth* Coll Vol **4** 763 *1963*, DOI: 10.15227/orgsyn.030.0072; for pK see Brandsma *Preparative Acetylenic Chemistry,* 1st Edn Elsevier 1971, p. 15, ISBN 0444409475]. [*Beilstein* **5** IV 1525.]

Phenylalaninol (2-amino-3-phenylpropan-1-ol) *[R-(+)- 5267-64-1, S-(-)- 3182-95-4]* **$C_9H_{13}NO$, M 151.2, m 91-92°, 91.5°, 92-94°, b 80°/11mm (Kügelrohr), $[\alpha]_{546}^{20}$ (+) and (-) 28, $[\alpha]_D^{20\text{-}25}$ (+) and (-) 23-28.7 (c 1-5, EtOH), pK_{Est} ~9.3.** It has been recrystallised from Et_2O, *C_6H_6/petroleum ether (b 40-60°) or toluene and distilled in a vacuum. It has been purified by dissolving in Et_2O, drying over K_2CO_3, filtering, evaporating to a small volume, cooling in ice and collecting the plates. Store them in the presence of KOH (i.e. CO_2—free atm). [Karrer & Ehrhardt *Helv Chim Acta* **34** 2202 *1951*, DOI: 10.1002/hlca.19510340714; Oeda *Bull Chem Soc Jpn* **13** 465 *1938*, DOI:10.1246/bcsj.13.465.] The ***picrate*** has **m 141-141.5°** (from EtOH/petroleum ether). The ***hydrogen oxalate*** has **m 177°, 161-162°** [Hunt & McHale *J Chem Soc* 2073 *1957*, DOI: 10.1039/JR9570002073]. The ***racemate*** has **m 87-88°** from *C_6H_6/petroleum ether (**75-77°** from Et_2O), and the ***hydrochloride*** has **m 139-141°** [Fodor et al. *J Chem Soc* 1858 *1951*, DOI: 10.1039/JR9510001858]. [*Beilstein* **13** IV 1920.]

3-Phenylallyl chloride (cinnamyl chloride) *[E: 18685-01-3, Z: 39199-93-4]* **C_9H_9Cl, M 152.6, *trans*: m -19° 7-8°, b 92-93°/3mm, 108°/12mm, d_4^{25} 1.086, n_D^{25} 1.5802, *cis*: 85°/3mm, d_4^{25} 1.0891, n_D^{25} 1.5746.** Distil the chloride under vacuum three times from K_2CO_3.
